Lexicon of Geologic Names Of the United States For 1936-1960

Part 2, G–O

GEOLOGICAL SURVEY BULLETIN 1200

Lexicon of Geologic Names Of the United States For 1936-1960

By GRACE C. KEROHER *and others*

Part 2, G–O

GEOLOGICAL SURVEY BULLETIN 1200

A compilation of the geologic names of the United States, its possessions, the Trust Territory of the Pacific Islands, and the Panama Canal Zone

UNITED STATES GOVERNMENT PRINTING OFFICE, WASHINGTON : 1966

UNITED STATES DEPARTMENT OF THE INTERIOR

STEWART L. UDALL, *Secretary*

GEOLOGICAL SURVEY

William T. Pecora, *Director*

Library of Congress catalog-card No. GS 66–170

For sale by the Superintendent of Documents, U.S. Government Printing Office
Washington, D.C. - Price $13 (paper cover) per set of 3 Volumes

Gabbs Formation[1]

Upper Triassic: Southwestern Nevada.

Original reference: S. W. Muller and H. G. Ferguson, 1936, Geol. Soc. America Bull., v. 47, p. 241–252.

H. G. Ferguson, S. W. Muller, and S. H. Cathcart, 1954, U.S. Geol. Survey (geol.) Quad. Map GQ–45. Described in Mina quadrangle where it consists of sandy shale and limestone in upper part, brown shaly limestone in middle, and black carbonaceous shale with a few beds of black impure limestone, weathering purple, in lower part. Thickness at type locality 420 feet. Overlies Luning formation; underlies Sunrise formation.

Named for Gabbs Valley Range, where it is well exposed in New York area.

Gabilan Limestone[1]

Pre-Franciscan: Western California.

Original reference: G. F. Becker, 1888, U.S. Geol. Survey Mon. 13, p. 128, 181.

I. F. Wilson, 1943, California Jour. Mines and Geology, v. 39, no. 2, p. 193, 224 (fig. 3). Described as a white to bluish-gray, thoroughly recrystallized marble, commonly exhibiting faint banding. Occurs as isolated roof pendants in Santa Lucia granite and as fault breccia along San Andreas fault zone.

Occurs in San Francisco Bay region.

Gabilan Mesa Quartz Diorite

[Cretaceous]: Central western California.

G. H. Curtis, J. F. Evernden, and J. Lipson, 1958, California Div. Mines Spec. Rept. 54, p. 9. Discussed in paper dealing with potassium-argon age determinations. Age given as 83.8 million years.

Occurs in Gabilan Mesa, which covers an area of approximately 250 square miles east of Salinas Valley. Oldest sedimentary rock resting in depositional contact on flanks of mesa is Miocene in age. Dated specimen collected in sec. 29, T. 17 S., R. 7 E., on road to Pinnacles National Monument, 3.2 miles east of its junction with Metz Road.

Gaddes Basalt (in Ash Creek Group)

Precambrian (Yavapai Series): Central Arizona.

C. A. Anderson and S. C. Creasey, 1958, U.S. Geol. Survey Prof. Paper 308, p. 10–11, pl. 1. Forms black to dark-green outcrops. On unweathered surfaces basalt is dark green. Chiefly pillow lavas; local intercalated rhyolitic flows. Pyroclastic rocks of highly vesicular or amygdaloidal, irregular-shaped basaltic fragments resembling lapilli and small bombs appear in bodies of small size east of Mingus Mountain. Pillow structures range from 1 to 5 feet in length and average 1½ to 2 feet. Estimated thickness in Black Canyon, 2,000 to 2,500 feet. Underlies Buzzard rhyolite (new).

Good exposures in Gaddes Canyon, south of Mingus Mountain, and in Black Canyon, Jerome area, Yavapai County.

Gadsden Limestone (in Ocala Group)

Eocene, upper: Northwestern Florida (subsurface).

W. E. Moore, 1955, Florida Geol. Survey Bull. 37, p. 21 (table 1), 30, 42–44. Introduced for some limestones of Jackson age that occur in subsurface sections of southeastern Jackson County. Consists of those limestones that have no, or few, specimens of the larger Foraminifera such as *Lepidocyclina*, *Asterocyclina*, or *Operculinoides*. Underlain in Jackson County by Marianna limestone. Stratigraphic equivalent of Crystal River formation which includes the Bumpnose member. Grades laterally into Crystal River formation, and youngest Gadsden beds extend farthest to northwest. Depending upon where the Gadsden is encountered, it is underlain by the Crystal River formation or by older Eocene formations. Overlies Tallahassee limestone in well W–4 in Gadsden County. Thickness 0 to 180 feet in Jackson County. Gadsden is confined to area southeast of Cypress fault, and from fault it thickens to southeast at expense of Crystal River.

H. S. Puri, 1957, Florida Geol. Survey Bull. 38, p. 34–35. Appears to be a faunal facies of the Crystal River. Suggested that name be abandoned.

Named for occurrence in City of Quincy water well W–4, Gadsden County.

Gaffney Marble[1]

Gaffney Formation

Mississippian: Northwestern South Carolina and southern North Carolina.

Original reference: A. Keith and D. B. Sterrett, 1921, Limestones and marls of North Carolina, by G. F. Loughlin and others: North Carolina Geol. and Econ. Survey Bull. 28, p. 28, 72–75.

T. L. Kessler, 1944, Geol. Soc. America Bull., v. 55, no. 6, p. 756, 764, 776, 780. The quartzite, carbonate-silicate rocks, and crystalline limestone have been mapped as Cambrian (the Kings Mountain, Blacksburg, and Gaffney formations). Near Kings Mountain, mica schist and gneisses previously mapped as Carolina gneiss, and hornblende gneisses previously mapped as Roan gneiss actually constitute the metamorphosed upper part of the Gaffney; names Carolina and Roan, therefore, have lithologic but not stratigraphic significance.

U.S. Geological Survey currently designates the age of the Gaffney Marble as Mississippian on the basis of a study now in progress.

Named for exposures at Gaffney, Cherokee County, S.C.

Gage Shale Member (of Doyle Shale)

Gage Shale (in Chase Group)[1]

Permian: Southeastern Nebraska and eastern Kansas.

Original reference: G. E. Condra and J. E. Upp, 1931, Nebraska Geol. Survey Bull. 6, 2d ser., p. 45.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 44. As currently defined, consists mostly of clayey shale with calcareous fossiliferous shale and a minor amount of limestone in upper part; lower and middle parts are chiefly varicolored noncalcareous shale consisting of red, green, purple, and chocolate-colored zones interbedded with gray and yellow layers. Thickness approximately 45 feet. Overlies Towanda limestone member; underlies Stovall limestone member of Winfield limestone.

Type locality: Between 1 and 2 miles south of west side of Wymore, Gage County, Nebr.

Gaikema Sandstone (in Tuxedni Group)

Gaikema Sandstone Member (of Kialagvik Formation)

Gaikema Sandstone Member (of Tuxedni Formation)

Middle Jurassic: Central southern Alaska.

C. E. Kirschner and D. L. Minard, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 95 [1949]. Member of Kialagvik formation. Predominantly of resistant cliff-forming sandstone beds 1 to 10 feet thick; usually separated by thin laminae of siltstone. Pebble lenses common and several conglomerate beds present. Thickest conglomerate bed approximately 50 feet. Rocks are dark green in fresh exposure and dark brown in weathered exposures. Thickness ranges from 500 feet in southern part of outcrop area to about 970 feet in northern part. Overlies unnamed siltstone member; underlies Tuxedni formation. Lower Jurassic. Name credited to Kellum and Wedow (rept. in preparation).

R. W. Imlay, 1953, U.S. Geol. Survey Prof. Paper 249-B, table 5 facing p. 60. Assigned to Tuxedni formation. Lies between two unnamed siltstone members. Middle Jurassic.

U.S. Geological Survey currently classifies the Gaikema Sandstone as a formation in Tuxedni Group on the basis of a study now in progress.

Well exposed on Gaikema Creek, in northern part of Iniskin Peninsula.

Gailor Dolomite

Lower Ordovician: East-central New York.

D. W. Fisher and G. F. Hanson, 1951, Am. Jour. Sci., v. 249, no. 11, p. 797, 803 (fig. 3), 807–808, 811–812, 813. Because *Ophileta*, *Helicotoma*(?) *uniangulata*, and *Ectenoceras* are exclusive Canadian index fossils, the latter two indicative of the Lower Canadian, the age of the cherty dolomite above Mosherville sandstone (new) is established as lowermost Ordovician. Name Little Falls dolomite for these beds is in error, and name Skene dolomite (Wheeler, 1942) is not applicable because it was defined as Upper Cambrian. Hence, name Gailor dolomite is proposed for these beds. Thickness varies from about 80 feet in northern part of Amsterdam quadrangle to about 150 feet in Saratoga region. West of Petrified Sea Gardens, formation is capped by massive 6-foot gray chert bed which locally contains *Cryptozoon*. Underlies Tribes Hill limestone in western part of area and Amsterdam limestone in eastern part of area. Section at Rock City Falls shows 12 feet of Gailor dolomite below thin Lowville limestone. Mosherville sandstone also referred to as basal member of Gailor.

D. W. Fisher, 1954, Geol. Soc. America Bull., v. 65, no. 1, p. 85. Traced into Fort Johnson member (new) of Tribes Hill formation in Mohawk Valley. Debatable whether some of dolomite beneath the Fort Johnson in that area should be assigned to the Gailor.

Type locality: Gailor quarry at northern edge of city of Saratoga Springs, one-eighth mile west of U.S. Highway 9, Saratoga County.

Gaines Group

Gaines Stage

Upper Cretaceous (Chico): Northern California.

F. M. Anderson, 1937, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 21, no. 12, p. 1612. Group in lower part of Chico series; embraces late Albian to Turonian. Thickness 5,300 feet. Underlies Panoche group.

F. M. Anderson, 1943, California Div. Mines Bull. 118, pt. 2, p. 185 (fig. 69) [preprint 1941]. Shown as a stage, based on a faunal assemblage, in Pioneer group.

Group present in western Shasta County.

†Gainesville[1]

Lower Cretaceous (Comanche Series): Northeastern Texas and southwestern Arkansas.

Original reference: F. W. Cragin, 1895, Am. Geologist, v. 16, p. 384–385.

Named for Gainesville, Cooke County, Tex.

Gainesville Sandstone Bed (in Blackjack Knob Member of Theodosia Formation)

Lower Ordovician: Southern Missouri and northern Arkansas.

J. S. Cullison, 1944, Missouri Univ. School Mines and Metallurgy Bull., Tech. Ser., v. 15, no. 2, p. 31, pl. 2. Fossiliferous sandstone at least 8 feet thick that occurs near the base of the Blackjack Knob.

Well exposed on Missouri Highway 80 just east of county seat [Gainesville] of Ozark County, Mo.

Gakona Formation[1]

Eocene, upper: Southeastern Alaska.

Original reference: W. C. Mendenhall, 1905, U.S. Geol. Survey Prof. Paper 41, p. 52, map.

Occurs east of Gakona Glacier, central Copper River district.

Galap Sub-Member (of Ngarsul Member of Aimeliik Formation)

Eocene: Caroline Islands (Palau).

U.S. Army Corps of Engineers, 1956, Military geology of Palau Islands, Caroline Islands: U.S. Army Corps of Engineers, Far East, p. 44, pl. 8. Andesitic-basaltic tuff intercalated with tuff breccia in lower part of Ngarsul member (new).

Occurs only in north part of Babelthuap Island on Arekalong Peninsula. Well exposed along coast north of village of Galap.

Galata Ash

[Recent]: Northwestern Montana, and Alberta, Canada.

Leland Horberg and R. A. Robie, 1955, Geol. Soc. America Bull., v. 66, p. 949–955. Volcanic ash layer that occurs in postglacial alluvium and colluvium at several localities. Stratigraphic relations and physical properties indicate a single episode of volcanic activity and possible correlation with an ash layer in southeastern Glacier Park assigned on basis of pollen analyses to postglacial Xerothermic period. If correlation with postglacial ash from Glacier Peak, Wash., is established by later studies, this name should be dropped and term Glacier Peak ash adopted.

Galatia Sandstone (in McLeansboro Formation)[1]

Pennsylvanian: Southeastern Illinois.

Original reference: G. H. Cady, 1926, Illinois State Acad. Sci. Trans., v. 19, p. 256–258.

Crops out about one-half mile north of Galatia, Saline County.

Galdog Beds

See Ngardok (Galdog) Beds.

Various spellings—Galdock, Goldock, Goldog, Garudokku.

Gale Sand[1]

Pleistocene (Wisconsin): Western Washington.

Original reference: B. Willis and G. O. Smith, 1899, U.S. Geol. Survey, Geol. Atlas, Folio 54.

Named for creek in Tacoma quadrangle, which flows across part of area covered by Gale sands, Puget Sound region.

Galena Dolomite[1]

Galena Group or Formation

Middle Ordovician: Northern Illinois, eastern Iowa, southern Minnesota, and southwestern Wisconsin.

Original reference: J. Hall, 1851, Rept. on geology of Lake Superior land district, by J. W. Foster and J. D. Whitney, pt. 2, p. 146–148.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 81, 82–90, measured sections. Formation, in southeastern Minnesota, comprises (ascending) Decorah shale, with Guttenberg and Ion submembers, Prosser, and Stewartville members. Overlies Spechts Ferry member of Platteville formation; underlies Dubuque member of Maquoketa formation. Mohawkian.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., p. 6, fig. 3. Group, in Dixon-Oregon area, Illinois, comprises (ascending) Spechts Ferry (missing in some places), Guttenberg, Dunleith (new), Wise Lake (new), and Dubuque formations. Overlies Platteville group.

M. P. Weiss, 1955, Jour. Paleontology, v. 29, no. 5, p. 763–766. Formation, in southeastern Minnesota, comprises carbonate rocks that overlie Decorah shales and underlie limestones and shales of Dubuque formation. Thickness about 93 feet. Includes (ascending) Cummingsville (new), Prosser, and Stewartville members.

A. F. Agnew and others, 1956, U.S. Geol. Survey Prof. Paper 274–K, p. 255, 257, 259, 261–269, 296–300. In zinc-lead district, Galena dolomite is commonly coarsely crystalline massive vuggy dolomite or limestone divisible regionally into two units: a cherty lower unit 105 feet thick and a noncherty upper unit 120 feet thick. Cherty unit is divisible into four zones based primarily upon relative chert content and presence of *Receptaculites*. Noncherty unity unit is divided on basis of thinness of bedding and amount of interbedded shale into Dubuque, at top, and the more massive, less shaly Stewartville and zone P of the Prosser below; latter is divided less precisely on basis of *Receptaculites* which are abundant in the Stewartville but not in zone P below. Name Dubuque is applied much as it has been in past; name Stewartville is applied more or less as it has been in past; name Prosser includes the cherty unit and probably all of zone P overlying noncherty unit. Because of paleontologic deficiencies and because of distinct lithologic difference, the Galena in this report is subdivided into cherty and noncherty units rather than into Prosser, Stewartville, and Dubuque members of common, although not precise, usage. Overlies Decorah formation; underlies Maquoketa shale.

Named for exposures in bluffs of Mississippi River in vicinity of Galena, Jo Daviess County, Ill.

†Galena Series[1]

Middle Ordovician: Upper Mississippi Valley region.

Original reference: F. W. Sardeson, 1896, Am. Geologist, v. 18, p. 356–368.

Galesburg Shale (in Kansas City Group)[1]

Original reference: G. I. Adams, 1903, U.S. Geol. Survey, Bull. 211, p. 36.

Pennsylvanian (Missouri Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 11–12. Redefined to exclude Canville limestone and Stark shale formerly included in it by Missouri Geological Survey.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 87. Thickness 3 to 75 feet. In southern Kansas, includes Dodds Creek sandstone member. Overlies Swope limestone; underlies Dennis limestone. Southward from point where Swope limestone disappears, a few miles north of Oklahoma line, Galesburg is not separable as a unit and forms upper part of Coffeyville formation. In Bronson subgroup of Kansas City group.

T. L. Welp, L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 65, p. 421. Thickness about 8 feet in Madison County, Iowa. Separates Swope formation below from Dennis formation above. Kansas City group.

Named for Galesburg, Neosho County, Kans.

Galesville Sandstone (in Dresbach Group)

Galesville Member[1] (of Dresbach Formation)

Upper Cambrian: Wisconsin, Iowa, and southern Minnesota.

Original reference: A. C. Trowbridge and G. I. Atwater, 1934, Geol. Soc. America Bull., v. 45, p. 45, 79.

W. H. Twenhofel, G. O. Raasch, and F. T. Thwaites, 1935, Geol. Soc. America Bull., v. 46, no. 11, p. 1696–1697. Uppermost member of Dresbach formation; overlies Eau Claire member; underlies Ironton member of Franconia formation.

R. R. Berg, 1954, Geol. Soc. America Bull., v. 65, no. 9, p. 861–862. Underlies Woodhill member of Franconia formation. Name Woodhill replaces term Ironton. Measured sections show thickness 13 to 60 feet.

U.S. Geological Survey currently classifies the Galesville as a formation in Dresbach Group on the basis of a study now in progress.

Named for exposures on bluff of Beaver Creek at mill dam at Galesville, Trempealeau County, Wis.

Galice Formation[1]

Upper urassic: Southwestern Oregon and northern California.

Original reference: J. S. Diller, 1907, Am. Jour. Sci., 4th, v. 23, p. 401–421.

N. L. Taliaferro, 1942, Geol. Soc. America Bull., v. 53, no. 1, p. 74, 81–83. Diller (1907) concluded that the Dothan was younger than the Galice and believed entire section, Galice, volcanics, and Dothan, was overturned. Present study indicates that Dothan sediments in type section are not overturned, except locally on drag folds; Dothan is older than Galice and, at type section at least, is separated from it by volcanics which grade downward into former and upward into latter; Dillard series lies unconformably on and overlaps Dothan and Galice.

F. G. Wells, P. E. Hotz, and F. W. Cater, Jr., 1949, Oregon Dept. Geology and Mineral Industries Bull. 40, p. 4–9. Described in Kerby quadrangle. Galice, as defined by Diller, included only slates and sandstones in type area; present mapping shows that volcanic rocks are intercalated with slates and sandstones and form part of a continuous cycle of deposition; they are here included in the formation. Consists of volcanic member and sedimentary member. Estimated thickness of sedimentary member 15,000 feet; volcanic member 10,000 feet. Unconformably overlies gneiss in northeastern part of quadrangle; in fault contact with similar gneiss in southwestern part of quadrangle; not in contact with Dothan.

F. G. Wells and F. W. Cater, Jr., 1950, California Div. Mines Bull. 134, pt. 1, chap. 2, p. 81. Geographically extended into northern California.

F. G. Wells and G. W. Walker, 1953, Geology of the Galice quadrangle, Oregon; U.S. Geol. Survey Geol. Quad. Map [GQ-25]. In Galice quadrangle, lies to east of Rogue formation (new).

F. W. Cater, Jr., and F. G. Wells, 1953, U.S. Geol. Survey Bull. 995-C, p. 79, 84 (chart), 86-92, pl. 11. Geographically extended into Gasquet quadrangle, California, where it includes a lower metavolcanic rock unit at least 7,000 feet thick, consisting of andesitic flows, breccias, and tuffs, and an upper sedimentary unit consisting of not less than 3,000 feet of slate and phyllite with interbedded tuffaceous sandstone. Contacts between Dothan and Galice have been destroyed by plutonic intrusions.

Well exposed at Galice, on Rogue River, and on Galice Creek, Josephine County, Oreg.

Galisteo Formation

Galisteo Sandstone[1]

Eocene-Oligocene(?): Central northern New Mexico.

Original reference: F. V. Hayden, 1869, U.S. Geol. and Geog. Survey Terr. 3d Ann. Rept., p. 40, 67, 90.

C. E. Stearns, 1943, Jour. Geology, v. 51, no. 5, p. 301-319. Referred to as formation. Consists of from 900 to at least 4,000 feet of sandstone, sand, and clay, variegated in color, together with minor amounts of conglomerate, fresh-water limestone, and water-laid tuff. Succeeded without interruption by deposition of Espinaso volcanics (new). Unconformably overlies Upper Cretaceous Mancos or Mesaverde. Fossil evidence indicates Duchesnean (late Eocene or early Oligocene).

Peter Robinson, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 4, p. 757. Molar of *Coryphodon*, collected from red mudstone bed approximately 700 feet above base of formation in Santa Fe County, indicates lower Eocene (Wasatchian) age for lower part of formation.

A. E. Disbrow and W. C. Stoll, 1957, New Mexico Bur. Mines Mineral Resources Bull. 48, p. 5 (table 1), 10-11, pl. 1. Formation described in Cerrillos area where it is 1,200 to 3,000 feet thick and consists of sandstone, clay, conglomerate, with silicified wood. Includes strata lying between erosion surface that cuts Upper Cretaceous and top of first massive sandstone beneath Espinaso volcanics. Fossil evidence indicates deposition of Galisteo terminated in late Eocene or possibly early Oligocene.

Named for occurrence in valley of Galisteo Creek.

Galiuro Limestone[1]

Pennsylvanian: Southeastern Arizona.

Original reference: A. A. Stoyanow, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 517-521.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 facing p. 706 (column 52b). Galiuro formation used on Pennsylvanian correlation chart.

Type section: In Galiuro Mountains at junction of Gila and San Pedro Rivers, about 45 miles northeast of Tucson and 6 miles east of Winkelman, south of Deer Creek coal field and Ash Creek, and at foot of Saddle Mountain, Gila Basin.

Galiuro Rhyolite[1]

Tertiary: Southeastern Arizona.

Original reference: W. P. Blake, 1902, Eng. and Mining Jour., v. 73, p. 546.

Galiuro Mountains.

Galkyoku Limestone

See Ngarekeukl Limestone.

Gallatin Limestone[1] or Formation

Gallatin Group

Upper Cambrian: Southern Montana and northwestern Wyoming.

Original references: A. C. Peale, 1893, U.S. Geol. Survey Bull. 110; 1896, U.S. Geol. Survey Geol. Atlas, Folio 24.

B. M. Miller, 1936, Jour. Geology, v. 44, no. 2, p. 124–127. In Wind River Mountains and Owl Creek-Bridger uplift, formation is subdivided to include Du Noir member (new).

Erling Dorf and Christina Lochman, 1938, Geol. Soc. America Proc. 1937, p. 275–276; 1940, Geol. Soc. America Bull., v. 51, no. 4, p. 541–555. Term Gallatin eliminated; its use in any sense other than original definition of Peale is invalid and confusing. Replaced by (ascending) Maurice, Snowy Range, and Grove Creek formations (all new).

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1091–1105. Terms Du Noir and Gallatin not applicable to Wind River Canyon section which is herein divided into Depass formation and Boysen formation (new).

H. A. Tourtelot and R. M. Thompson, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 91. Formation, in Boysen area, Wyoming, consists of 455 feet of limestone and limestone-pebble conglomerate with lesser amounts of limy siltstone and shale. Contact between Gallatin and overlying Gros Ventre is placed at base of prominent cliff-forming limestone about 87 feet thick; the contact thus placed is approximately at base of Gallatin as used by Miller (1936) and is about 60 feet above contact between DePass and Boysen formations of Deiss (1938). Underlies Bighorn dolomite. In southern Big Horn Mountains, Gallatin underlies Madison formation.

A. B. Shaw and P. O. McGrew, 1954, Wyoming Geol. Assoc. Guidebook 9th Ann. Field Conf., chart 2. Rank raised to group. Includes (ascending) Du Noir limestone, Dry Creek shale, and Sage limestone. It should be noted that Dry Creek shale in most exposures is thin and rarely mappable and should be most commonly regarded as member of Sage limestone.

C. R. DeLand, 1954, (abs.) Geol. Soc. America Bull., v. 65, no. 12, pt. 2, p. 1374. Formation comprises three subdivisions (ascending): Du Noir limestone, Dry Creek shale, and Sage limestone:

A. B. Shaw and C. R. DeLand, 1955, Wyoming Geol. Assoc. Guidebook 10th Ann. Field Conf., p. 38, 39 (fig. 1), 40 (fig. 2), 41. Group in southwestern Wyoming, comprises (ascending) Du Noir limestone and Open Door limestone (new).

Named for typical occurrence in Gallatin Range, the southern extension of which is in northwestern corner of Yellowstone Park.

Gallatinian series[1]

Precambrian: Montana.

Original reference: C. R. Keyes, 1926, Pan-Am. Geologist, v. 46.

Gallaway Beds or Formation

Miocene: Northern California.

C. E. Weaver, 1943, California Div. Mines Bull., 118, p. 630–632. Alternating units of dark-gray and brown argillaceous shale, mudstones, and medium-grained sandstone interstratified with thick units of massive and bedded brownish-gray sandy shales. Beds strongly folded. Thickness 2,075 feet. Underlies Point Arena beds (new); overlies Skooner Gulch basalt (new).

C. E. Weaver, 1944, Washington [State] Univ. Pubs. in Geology, v. 6, no. 1, p. 4, 19, 20, 21, pl. 2. Described as a formation; overlies Skooner Gulch formation (redescribed); type section designated.

Type section: In sea cliffs from north side of Skooner Gulch northward to Abalone Cove for a distance of about 3,800 feet. Point Arena-Fort Ross area, Mendocino County.

Gallego Sandstone Member (of Gallup Sandstone)

Gallego Sandstone Member (of Miguel Formation)[1]

Upper Cretaceous: Southwestern New Mexico.

Original reference: D. E. Winchester, 1920, U.S. Geol. Survey Bull. 716–A.

C. A. Dane, A. A. Wanek, and J. B. Reeside, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 2, p. 187, 188 (fig. 2). Cretaceous section in Alamosa Creek valley area, Catron and Socorro Counties, reinterpreted and stratigraphic names used in San Juan basin extended into valley. Name Gallego sandstone member retained but applied to upper sandstone member of Gallup standstone, and name Miguel formation abandoned. Underlies Dilco coal member of Crevasse Canyon formation; overlies D–Cross tongue (new) of Mancos shale.

Named for Gallego Creek, Socorro County.

Gallegos sandstone[1]

Pennsylvanian(?): Central northern New Mexico.

Original references; C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257–259; 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 3, 7.

Sandia Mountains.

Gallinas shale[1]

Cretaceous: New Mexico.

Original reference: C. R. Keyes, 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 2, 7.

Well developed on Gallinas Creek, near Las Vegas, San Miguel County.

Gallitzin Limestone (in Conemaugh Formation)[1]

Pennsylvanian: Western Pennsylvania.

Original reference: J. P. Lesley, 1880, Pennsylvania 2d Geol. Survey Rept. H_5, p. 312.

Armstrong County.

Gallup Sandstone (in Mesaverde Group)

Gallup Sandstone Member (of Mesaverde Formation)[1]

Upper Cretaceous: Northwestern New Mexico.

Original reference: J. D. Sears, 1925, U.S. Geol. Survey Bull. 767.

W. S. Pike, Jr., 1947, Geol. Soc. America Mem. 24, p. 9, 39–35. Pescado tongue (new) of Mancos shale splits Gallup member of Mesaverde into upper and lower parts.

J. E. Allen and Robert Balk, 1954, New Mexico Bur. Mines Mineral Resources Bull. 36, p. 91. Rank raised to formation in Mesaverde group. In Fort Defiance-Tohatchi quadrangles, basal unit of group; underlies Crevasse Canyon formation (new).

E. C. Beaumont, C. H. Dane, and J. D. Sears, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2156. Nomenclature of Mesaverde, in San Juan basin, revised. Gallup sandstone as a formation replaces Gallup sandstone member, and also, in its northward extension, replaces in its entirety Tocito sandstone lentil of Mancos shale.

C. H. Dane, A. A. Wanek, and J. B. Reeside, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 2, p. 187, 188 (fig. 2), 190, 191. Cretaceous section in Alamosa Creek valley area, Catron and Socorro Counties, reinterpreted, and stratigraphic names used in San Juan basin extended into valley. Gallup sandstone is split into upper and lower units by D–Cross tongue (new) of Mancos shale. Name Gallego sandstone retained but applied to upper sandstone member of Gallup rather than to member of Miguel formation which is herein abandoned. Overlies Mancos shale; underlies Crevasse Canyon formation (Dilco coal member). Gallup as identified, correlated, and described in this report, corresponds with only the upper part of La Cruz Peak formation of Tonking (1955) which includes also the underlying part of the Mancos down to a sandstone identified by him as Tres Hermanos(?) sandstone member of Mancos.

Named for town of Gallup.

Galton facies (of Belt Series)

Precambrian: Northwestern Montana, and southern British Columbia, Canada.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1877. Within its northern basin, Belt series is divisible into facies that differ in lithology, stratigraphic sequence, thickness, recorded conditions of deposition, fauna, and flora. Galton facies is a transitional stage between Glacier Park and Purcell facies. Distinguished from former by more clastics in the Siyeh and Helena; from the latter by finer clastics below Siyeh and presence of Altyn siliceous dolomites.

In MacDonald-Galton Ranges.

Galton Series[1]

Precambrian: Northwestern Montana, and southeastern British Columbia. Canada.

Original reference: R. A. Daly, 1913, Canada Dept. Int., Rept. Chief Asst. 1910, v. 2, p. 97, pl. opposite p. 178.

Gallatin Range, Montana-British Columbia.

Galum Limestone Member (of Carbondale Formation)

Galum Limestone (in McLeansboro Group)

Galum Limestone Member (of McLeansboro Formation)[1]

Pennsylvanian: Southern Illinois.

Original reference: A. H. Bell, C. Ball, and L. McCabe, 1931, Illinois Geol. Survey Press Bull. 19.

C. L. Cooper, 1946, Illinois Geol. Survey Bull. 70, p. 16 (fig. 2). Shown on correlation chart as Galum limestone in McLeansboro group. Underlies Cutler limestone; overlies Bankston Fork limestone.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 11. Correlation chart shows Galum limestone in Sparland cyclothem. Type locality given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 34, 48 (table 1), pl. 1. Reallocated to member status in Carbondale formation (redefined). Occurs above Allenby coal member (new) and below Danville (No. 7) coal member. Presentation of new rock-stratigraphic classification of Pennsylvanian stata in Illinois.

Type locality: North center sec. 13, T. 6 S., R. 4 W., Perry County. Well exposed along Galum Creek near Pinckneyville.

Galveston Sand

Recent: Eastern North Carolina.

W. B. Wells, 1944, Elisha Mitchell Sci. Soc. Jour., v. 60, no. 2, p. 132, pls. 63, 64. Vertical cliff exposes four layers (or horizons) which show progressively decreasing consolidation upward; each lies unconformably on the preceding. Maximum thickness of exposure a little more than 9 feet. Galveston sand is a thin top stratum representing recent wind deposited sand from adjacent strand. Overlies Pine sand (new).

Exposure between Kure's Beach fishing pier and Ethyl Dow Bromine Plant on lower Cape Fear Peninsula.

Galway Formation[1]

Upper Cambrian: East-central New York.

Original reference: J. M. Clarke, 1910, New York State Mus. Bull. 140, p. 11–12, map.

D. W. Fisher and G. F. Hanson, 1951, Am. Jour. Sci., v. 249, no. 11, p. 802, 803 (fig. 2), 810. Name Galway formation substituted for beds previously termed "Theresa" in Saratoga Springs area. Formation redefined to comprise sandy dolomites, dolomitic sandstones, and calcareous sandstones lying below the Hoyt limestone and above the Potsdam sandstone. Formation has total thickness of 125 feet in area, and top lies 12 feet below *Cryptozoon proliferum* reef of Hoyt limestone; strata formerly classed as lower Hoyt are now included in the Galway. Embraces beds of lower Franconia through Trempealeau age. In area of Mosherville, unconformably underlies Mosherville sandstone (new). Type locality designated.

Type locality: Two railroad cuts and roadcut along New York State Highway 9–K, 3 miles northwest of Saratoga Springs. Named for Galway, Saratoga County.

Gamboa Formation

Oligocene(?): Panamá.

Karl Sapper, 1905, Petermanns Mitt. Erganzungsbd. 32, no. 151, p. 38, 39. Terms Gesteine von Gamboa, Gamboa formation, and Gamboagesteinen used in text discussion.

W. P. Woodring, 1960, *in* R. Hoffstetter and others, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 335–336. Name has not been used in recent literature but is available as a name to include Bas Obispo formation and Las Cascadas agglomerate.

Game Lodge Granite

Precambrian: Western South Dakota.

G. L. Taylor, 1935, Am. Jour. Sci., 5th ser., v. 29, no. 171, p. 281–282. Fine-grained gray biotite-granite which consists essentially of quartz, feldspars, and biotite. More compact and darker than most of Harney Peak granite which intrudes it. Occurs as intrusive masses into Precambrian sediments. Field evidence did not indicate relative ages of Game Lodge to Little Elk gneissoid granite (new), Harney Peak granite, or igneous amphibolites.

Exposed west of Game Lodge Hotel, which is in valley of Galena Creek, vicinity of Custer, Black Hills.

Gamerco Formation

Recent: Northwestern New Mexico.

L. B. Leopold and C. T. Snyder, 1951, U.S. Geol. Survey Water-Supply Paper 1110–A, p. 6–9. At type locality, consists of (ascending) 1 to 2 feet of fine gravel partly cemented with caliche; about 2 feet of brown compact silty sand with white mottling of caliche; 2 feet of reddish- to reddish-brown silty fine compact sand containing hard calcareous concretions. Disconformably underlies Nakaibito formation (new); disconformably overlies shale and sandstone of Gibson coal member of Mesaverde.

Type locality: In outskirts of Gallup about 300 yards east of El Rancho Hotel. Crops out in gully wall of Puerco River. Name derived from Gamerco, a suburb of Gallup, McKinley County. Most exposures occur where bedrock, the Mesaverde formation, crops out in gully channel.

Game Refuge Formation (in Jackfork Group)

Mississippian (Chesterian): Southeastern Oklahoma.

B. H. Harlton, 1959, *in* The geology of the Ouachita Mountains—a symposium: Dallas, Tex., Dallas Geol. Soc. and Ardmore Geol. Soc., p. 131 (fig. 1), 135–136. Replaces name Union Valley sandstone extended into this area (Harlton, 1938). Consists of approximately 250 to 350 feet of gray to dark-gray shale and intercalated massive and thin-bedded fine to medium subangular sandstone. Intercalations of fine to medium-coarse fossiliferous limonitic sandstones with abundance of crinoid columnals and plant remains present in upper half of formation. Overlies Wesley shale; underlies unit referred to as Johns Valley shale of published reports. Included in Pushmataha series considered to be of Carboniferous age.

L. M. Cline and O. B. Shelburne, 1959, *in* The geology of the Ouachita Mountains—a symposium: Dallas, Tex., Dallas Geol. Soc. and Ardmore Geol. Soc., p. 179 (table 1), 190 (table 2), 192–193. Referred to as Game Refuge sandstone. Approximately 350 to 400 feet thick in western Ouachitas; thins northward in frontal Ouachitas and disappears north of Ti Valley fault. Underlies Johns Valley shale. Mississippian (Chesterian).

Name derived from State Game Refuge at Jerusalem Hollow in western Kiamichi Range in secs. 28 and 29, T. 1 S., R. 18 E., about 6 to 7 miles southwest of Clayton, Pushmataha County. [Referred to as type locality by Cline and Shelburne.] Best exposures are in Round Prairie syncline in sec. 2, T. 2 S., R. 12 E., along Campbell Creek, but name Campbell Creek is preoccupied.

Gammon Ferruginous Member (of Pierre Shale)[1]

Upper Cretaceous: Northeastern Wyoming, southeastern Montana, and northwestern South Dakota.

Original reference: W. W. Rubey, 1930, U.S. Geol. Survey Prof. Paper 165–A.

W. A. Cobban, 1952, Billings Geol. Soc. Guidebook 3d Ann. Field Conf., p. 87. Well exposed in common corner of Montana, Wyoming, and South Dakota, where it is about 800 feet thick and divisible into three units. Lower consists of 600 feet of gray mudstone that is slightly calcareous in basal 150 feet; middle unit is Groat sandstone bed, about 50 feet thick; and upper is 150 feet of gray mudstone with ferruginous and calcareous concretions. Underlies Mitten black shale member.

C. S. Robinson, W. J. Mapel, and W. A. Cobban, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 1, p. 104–107, measured sections. Traced across northern end of Black Hills and along western side as far south as Beaver Creek, which is a few miles southeast of Osage, Weston County, Wyo. Pedro bentonite beds crops out at base of member near Osage. Groat sandstone bed present about 150 feet below top of member. Thickness 700 to 800 feet in vicinity of Osage. Underlies Mitten black shale member; overlies Niobrara formation.

Named for exposures along Gammon Creek, T. 57 N., Rs. 67 and 68 W., Crook County, Wyo.

Gamsetu (Gamusetsu) Agglomerate

Eocene: Caroline Islands (Babelthuap)

Risaburo Tayama, 1939, Brief report on the geology and ore resources of Babelthuap Island (Palau Island proper): Tropical Industry Inst., Palau, South Sea Islands Bull. 3 [English translation in library of U.S. Geol. Survey, p. 15, 18]; 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 64, table 4 [English translation in library of U.S. Geol. Survey, p. 75–76]. Group of rocks resembling quartz trachyte. Lower member greenish breccia; upper member a liparite agglomerate. Underlies Babelthuap agglomerate.

Typically developed at Gamusetsu on north shore of Ngatpang (Gasupan) Bay.

Ganado Series[1]

Tertiary or Pleistocene: Northeastern Arizona.

Original reference: A. B. Reagan, 1932, Kansas Acad. Sci. Trans., v. 35, p. 253–258.

Caps an irregularly shaped mesa north of Ganado, Apache County.

Gander Run Shale Member[1] (of Mahantango Formation)

Middle Devonian: South-central Pennsylvania.

Original references: Bradford Willard, 1935, Geol. Soc. America Proc. 1934, p. 361; 1935, Geol. Soc. America Bull., v. 46, no. 8, p. 1279, 1282.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Gander Run shale listed on correlation chart at base of Mahantango formation, and below Chaneysville sandstone, and above Marcellus shale. Middle Devonian.

Named for stream occupying valley underlain by these strata 6 to 8 miles north of Chaneysville, Bedford County.

Gannett Group[1]

Lower Cretaceous: Southeastern Idaho and southwestern Wyoming.

Original reference: G. R. Mansfield and P. V. Roundy, 1916, U.S. Geol. Survey Prof. Paper 98–G, p. 76, 82, 83.

L. S. Gardner, 1944, U.S. Geol. Survey. Bull. 944–A, p. 7. In Irwin quadrangle, where Draney limestone is top of group, underlies Bear River formation. Overlies Stump sandstone. Thickness 940 feet.

G. R. Mansfield, 1952, U.S. Geol. Survey Prof. Paper 238, p. 39, 43, pl. 1. In Paradise Valley quadrangle, Idaho, Ephraim conglomerate is only representative of group. In Ammon quadrangle, group comprises Ephraim conglomerate, Peterson limestone, and Bechler conglomerate. Underlies Wayan formation.

C. A. Moritz, 1953, Intermountain Assoc. Petroleum Geologists [Guidebook] 4th Ann. Field Conf., p. 63–68. Restricted to exclude Tygee sandstone which is here included in overlying Bear River formation. Uppermost unit of group is unnamed discontinuous redbed unit above Draney limestone. Lower Cretaceous.

H. R. Wanless, R. L. Belknap, and Helen Foster, 1955, Geol. Soc. America Mem. 63, p. 53–57. Described in Jackson Hole area where all formations —(ascending) Ephraim conglomerate, Peterson limestone, Bechler conglomerate, Draney limestone, and Tygee sandstone—are recognized. Here group is much thinner than in type area, nearly 100 miles southwest, and cannot be divided into separate formations as conveniently. Lower Cretaceous.

Named for Gannett Hills, in Bannock County, Idaho, and Lincoln County, Wyo., in eastern part of Wayan quadrangle, where all of its formations are well exposed.

Gannett Peak Stage

Gannett Peak Stage

Recent: Rocky Mountain region.

G. M. Richmond, 1953, Friends of the Pleistocene Rocky Mountain Sec. [Guidebook] 2d Ann. Field Trip, Oct. 4–5, correlation chart. In proposed time-stratigraphic standard for Rocky Mountains, the Recent epoch includes (ascending) Castle Valley, Temple Lake, Spanish Valley, and Gannett Peak stages.

G. M. Richmond, 1957, Internat. Assoc. for Quaternary Research, 5th Cong., Madrid, p. 157. Two stages of Recent glaciation recognized in Rocky Mountain region, an early Recent stage, Temple Lake, and a late Recent stage, Gannett Peak. Unweathered moraines of the Gannett Peak occur in front of existing glaciers or in recently evacuated cirques.

Gano Shale (in Wabaunsee Group)

Pennsylvanian (Virgil Series): Northeastern Oklahoma.

C. C. Branson, 1956, Oklahoma Geology Notes, v. 16, no. 11, p. 122–123, 124–126. Name applied to shale, limestone, and sandstone sequence between top of Emporia limestone and base of Wood Siding formation; base of Wood Siding is at base of Nebraska City limestone member in Osage County, at base of Grayhorse limestone member southward to T. 15 N., and at base of Brownville limestone member in southern Lincoln County. Thickness about 62 feet.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 61–62. First recognizable keybed above Elmont limestone in Pawnee County is "Grayhorse" limestone. Between the Elmont and "Grayhorse" is shale-sandstone sequence which in Kansas is subdivided into more than a dozen stratigraphic units on basis of persistent limestones which occur in section there. All of these limestones pinch out north of Pawnee County; consequently there is no basis for subdivision of Pawnee County section. Branson (1956) applied name Gano shale to this shale-sandstone sequence. Upper limit is lowermost recognizable key bed in Wood Siding formation. As result of southward pinchout of progressively higher key beds in lower part of Wood Siding, the Gano-Wood Siding boundary migrates upward in the section toward south. In Pawnee County, this boundary is base of "Grayhorse" limestone. Thickness 35 to 50 feet in Pawnee County.

Type section: Exposed in hills northeast of Gano, a refinery village northeast of Cushing, Wayne County.

Gansevoort[1]

Gansevoort Shale Member (of Canajoharie Shale)

Middle Ordovician: Eastern New York.

Original reference: Rudolf Ruedemann and G. H. Chadwick, 1935, Science, new ser., v. 81, no. 2104, p. 400.

Rudolf Ruedemann, 1947, Geol. Soc. America Mem. 19, p. 118. Referred to as Gansevoort shale member of Canajoharie. Overlies Chuctenunda shale member; underlies Sprakers shale member.

Type locality and derivation of name not given, but may have been named for Gansevoort, Saratoga County.

†Gant Bed[1]

†Gant Limestone[1]

Silurian (Niagaran): West-central Tennessee.

Original reference: A. F. Foerste, 1903, Jour. Geology, v. 11, p. 576, 582–583.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 262. Foerste named Gant limestone and Gant bed from exposures in Wayne County. Gant limestone included 30 feet of limestone and is equivalent to Bob limestone as recognized by Miser, Jewell, Wilson, and Pate and Bassler at some localities. If name Bob had not become so well established, it would be recommended here that Bob limestone be dropped in preference to Gant.

Named for A. B. Gant homestead, about 1 mile northeast of Martin's Mill, Wayne County.

†Gap Latite[1]

Miocene: Southwestern Colorado.

Original reference: E. S. Larsen, 1917, Colorado Geol. Survey Bull. 13.

Platoro-Summitville region.

Gap Sandstone Member (of Tallant Formation)

Gap Sandstone Member (of Nelagoney Formation)[1]

Pennsylvanian (Missouri Series): Northeastern Oklahoma.

Original reference: M. I. Goldman, 1920, U.S. Geol. Survey Bull. 686–W, p. 330, 333.

W. F. Tanner, 1956, Oklahoma Geol. Survey Circ. 40, p. 38. Reallocated to Tallant formation. Goldman (1920) correlated this lenticular member with the Revard sandstone; present study indicates that unit is northward continuation of Bigheart sandstone, except south of Caney River, where it falls at top of or above the Revard sandstone member.

Named for occurrence at top of Gap Ridge, in SW cor. T. 29 N., R. 13 E., in northwest corner of Washington County.

Gap Ridge Sandstone Member (of Stanley Shale)

Pennsylvanian: Southwestern Arkansas.

N. H. Stearn *in* J. M. Hansell and J. C. Reed, 1935, Am. Inst. Mining Metall. Engineers Trans., v. 115, p. 245. Consists of (ascending) a 300-foot sandy zone, a 200-foot shaly zone, and a 100-foot sandy zone. Occurs about 1,000 feet below top of Stanley shale and about 700 feet above the Parker Hill sandstone member (new).

J. C. Reed and F. G. Wells, 1938, U.S. Geol. Survey Bull. 886–C, p. 25, pls. 2, 3. Stratigraphically restricted to the lower 300-foot sandstone.

Named from Gap Ridge mine, an important mining development in that horizon. Mine is in sec. 11, T. 7 S., R. 26 W., Pike County.

Gaps Flow or Tongue (of Clayton Basalt)

Late Cenozoic: Northeastern New Mexico.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 112, 133, 134, 143 (fig. 20). East of type locality, Clayton basalt consists of many long tongues. For purpose of this report, these tongues have been named, from south to north, the Carrizo, Herringa, Clayton Mesa, Apache, Seneca, Gaps, and Van Cleve flows. All basalts rest on sand and gravel of Ogallala-like material in ancient valleys. Vents that gave rise to these basalts are unknown.

Well exposed along east side of Sand Gap, eastern Union County.

Gaptank Formation[1]

Pennsylvanian: Western Texas.

Original reference: J. A. Udden, C. L. Baker, and E. Böse, 1916, Texas Univ. Bur. Econ. Geology and Tech. Bull. 44, p. 47.

P. B. King, 1937, U.S. Geol. Survey Prof. Paper 187, p. 73–92. Gaptank, as originally defined, evidently included strata now known as Wolfcamp formation. Later the Gaptank was restricted to exclude *Uddenites* zone which Böse believed to be of Permian age. Further knowledge of fossils near Pennsylvanian-Permian boundary obtained in recent years has led to conclusion that *Uddenites* zone is of Pennsylvanian age, and top of Gaptank is now placed above this zone. West of Marathon are exposures of strata, here considered to be part of Gaptank formation, which were variously placed in Tesnus (Baker and Bowman, 1917, Texas Univ. Bull. 1753), Haymond (Böse, 1917, Texas Univ. Bull. 1762) and Gaptank by Baker, Böse, and Udden. Term Dugout beds (Baker, 1928, Am. Assoc. Petroleum Geologists Bull., v. 12, no. 11) has also been proposed for them. Gaptank formation crops out only in northern part of Marathon basin [this report]. Type area of Gaptank lies north of region of this report, but problematic strata exposed on Dugout Creek and here considered to be part of Gaptank formation crop out over wide area in northwestern part of Monument Spring quadrangle. Thickness at type locality about 1,800 feet; overlies Haymond formation; underlies Wolfcamp formation. In most places the Gaptank is separated from Wolfcamp by strong angular unconformity.

R. C. Moore and M. L. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 3, p. 289 (fig. 1). Desmoinesian, Oklan series.

C. A. Ross, 1959, Washington Acad. Sci. Jour., v. 49, no. 9, p. 299, 300 (fig. 1). Discussion of Wolfcamp series (Permian) and new species of fusulinids, Glass Mountains, Tex. Nealranch formation (new) overlies Gaptank formation, which, according to chart, contains "grey limestone" included in Wolfcamp formation by King (1937) and *Uddenites* shales. Boundary between Pennsylvanian and Permian is taken at unconformity at top of "grey limestone."

Occurs at Gaptank, 24 miles northeast of Marathon, Brewster County. Named for tank, sometimes locally called Gap Tank, located in a gap locally called Stockton Gap and Marathon Gap.

Garanon Member (of Santa Rosa Island Formation)

Pleistocene, upper: Santa Rosa Island, California.

P. C. Orr, 1960, Geol. Soc. America Bull., v. 71, no. 7, p. 1113, 1115. Consists of a basal marine facies and upper terrestrial facies. Thickness about 25 feet. Marine facies is commonly a light-gray calcareous clay containing fossil bones of whale, sea lion, sea otter, shore birds, and occasional dwarf mammoth as well as organic remains and quantities of "rotted" asphalt. Thickness at least 2 feet except for a few erosional channels.

Garanon platform and member exposed along sea cliffs between Jaw Gulch on west and Tecolote Canyon on east. Present locally between Survey Point and Arlington Canyon.

Garber Sandstone[1]

Permian: Northwestern, central, and south-central Oklahoma.

Original reference: F. L. Aurin, H. G. Officer, and C. N. Gould, 1926, Am. Assoc. Petroleum Geologists Bull., v. 10, p. 786–799.

C. C. Branson, 1954, Shale Shaker, v. 4, no. 6, p. 7, 12. Thick sequence of deep-pink sandstones and intervening red shales. Overlies Wellington formation; underlies Hennessey shale. Leonardian.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped in northwestern, central, and south-central parts of State.

Named for exposures at Garber, Garfield County.

Garceno Sandstone Member (of Cook Mountain Formation)

Eocene (Claiborne): Western Texas.

J. M. Patterson, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 2, p. 259 (fig. 2), 261–262. Name applied to basal sandstone member of formation. With exception of a 50-foot dark-colored marine shale about 150 feet above the base, member is composed of glauconitic marine sandstone beds that are highly fossiliferous. Thickness approximately 500 feet. Underlies Veleno member (new); overlies Mount Selman formation.

Name is taken from Garceno ranchhouse, located on an outcrop of the sandstone, 9 miles northwest of Zapata, Mexico. Ranchhouse is on American side of Rio Grande.

Garcia Formation (in Armendaris Group)

Pennsylvanian (Des Moines Series): Central New Mexico.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 27 (table 2), 42–43 (fig. 4), 50–51. Name introduced for all sediments between top of Whiskey Canyon limestone (new) below and base of Bolander group (new). Type section is composed of about 213 feet of rocks, including essentially pure highly fossiliferous limestone, argillaceous to slightly arenaceous and cherty limestones, several thin gray to red shales, and a 50-foot bed of highly conglomeratic sandstone at its base. Formation is wide spread and varies considerably lithologically.

Type locality: East of westernmost box canyon of Whiskey Canyon in northern part of Mud Springs Mountains, sec. 1, T. 13 S., R. 5 W., Sierra County. Name derived from Garcia Road, 4 or 5 miles west of Mud Springs Mountain.

Gardeau Shale Member (of West Falls Formation)

Gardeau Shale Member (of Portage Formation)[1]

Gardeau Shale or Formation

Upper Devonian: Western and west-central New York.

Original reference: J. Hall, 1840, New York Geol. Survey 4th Rept., p. 390–392, 452–455.

J. F. Pepper and Wallace de Witt, Jr., 1950, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 37. Gardeau shale and overlying Nunda sandstone make up sedimentary cycle which begins as series of silty gray shales containing a few thin siltstones and grades upward through flaggy siltstones and a few silty shales into massive siltstone and shale at top. The Gardeau is predominantly shale, silty shale, and various amounts of intercalated siltstones. Locally some massive siltstones occur in the Gardeau, and member or formation names have been given to them, for example, Table Rock sandstone (Chadwick, 1933). Naming of such beds serves little purpose because they cannot be positively identified beyond their type exposure.

R. G. Sutton, 1951, Rochester Acad. Sci. Proc., v. 9, nos. 5–6, p. 393–394. Formation, in Batavia quadrangle, overlies Grimes sandstone and underlies Nunda sandstone. Table Rock sandstone not present in this area. Thickness 200 to 550 feet, thinning is westward.

J. F. Pepper, Wallace de Witt, Jr., and G. W. Colton, 1956, U.S. Geol. Survey Oil and Gas Inv. Map OC–55. Hall proposed name Gardeau for sequence of rocks between top of Cashaqua shale and base of his Portage group, later called Nunda group, which crops out along gorge of Genesee River in area that is now Letchworth Park. Gardeau is herein designated shale member of West Falls formation (new). In this report, Gardeau shale along gorge of Genesee River in Letchworth Park area includes rocks between top of Rhinestreet shale member and base of West Hill member. In Naples-Hammondsport area, overlies Grimes siltstone member. In westernmost outcrops, Gardeau intertonques with Angola shale member, and base is not sharply marked. Thickness 12 feet in western Wyoming County; 525 feet in vicinity of Letchworth Park; 350 feet at Naples.

Extensively exposed along Gardeau Reservation, Livingston and Wyoming Counties.

Gardena Intraglacial Substage

Pleistocene (Wisconsin): North-central United States.

M. M. Leighton, 1960, Jour. Geology, v. 68, no. 5, p. 549. Name applied to Iowan-Tazewell intraglacial substage. Radiocarbon dates show deposition of Iowan loess was completed about 1,700 years before advent of Tazewell glacier.

Name derived from village of Gardena, Tazewell County, Ill.

Garden City Formation

Garden City Limestone[1]

Lower and Middle Ordovician : Northern Utah and southeastern Idaho.

Original reference: G. B. Richardson, 1913, Am. Jour. Sci., 4th, v. 36, p. 407, 408.

G. B. Richardson, 1941, U.S. Geol. Survey Bull., 923, p. 13, 14, 16. As originally defined, included succession of thick and thin beds of gray limestone approximately 1,000 feet thick lying between St. Charles limestone and Swan Peak quartzite. St. Charles is restricted to lower 400 feet (approximately) as defined by Walcott, and upper 900 feet (approximately) is included in Garden City limestone. Thickness of expanded Garden City 1,900 feet.

J. S. Williams, 1948, Geol. Soc. America Bull., v. 59, no. 11, p. 1135–1136. Thickness in Green Canyon, northeast of Logan, Utah, 1,400 feet. Deiss (1938) erred in attempt to redefine St. Charles formation in Blacksmith Fork section; the 258 feet of limestones and intercalated and intraformational conglomerates which he included at top of St. Charles is basal Garden City and contains Ordovician fossils.

R. J. Ross, Jr., 1949, Am. Jour. Sci., v. 247, no. 7, p. 472–491. Formation divided into two members: lower comprising approximately two-thirds of formation is composed of numerous alternations of interbedded and interlensed intraformational conglomerates, and crystalline, aphanitic and muddy limestones; and upper characterized by high content of chert nodules, stringers, and interbeds occurring for the most part in irregularly laminated limestone and dolomitic limestone. Thickness 1,200 feet on east to 1,800 feet on northwest of Logan quadrangle.

J. K. Rigby, 1958, Utah Geol. Soc. Guidebook 13, p. 26–30. Term extended into Stansbury Mountains where it is used for sequence of argillaceous limestones and dolomites that occur above Ajax limestone and below Fish Haven and Kanosh formations. Four units recognized (ascending): interbedded series of cherty limestone and dolomite; well-bedded medium-gray argillaceous limestone; interbedded, evenly bedded argillaceous limestone and shale or shaly limestone; and very cherty and sandy limestone. Thickness 1,100 to 1,300 feet.

U.S. Geological Survey currently designates the age of the Garden City Formation as Lower and Middle Ordovician.

Named for exposures in Garden City Canyon, Rich County, Utah.

Garden Creek Phyllite[1]

Cambrian(?) : Southern central Idaho.

Original reference: C. P. Ross, 1932 (Idaho correlation chart compiled by M. G. Wilmarth).

C. P. Ross, 1937, U.S. Geol. Survey Bull. 877, p. 11, 12, pl. 1. Composed exclusively of dark-gray or nearly black phyllite with silvery sericite on cleavage surfaces. Thickness several hundred feet; base not exposed. Underlies Bayhorse dolomite.

L. L. Sloss and C. A. Moritz, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 10, p. 2140 (fig. 5). Middle Cambrian age shown on chart.

Named for Garden Creek on which Challis is located.

Garden Gulch Member (of Green River Formation)[1]

Eocene: Northwestern Colorado and northeastern Utah.

Original reference: W. H. Bradley, 1931, U.S. Geol. Survey Prof. Paper 168.

D. C. Duncan and N. M. Denson, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map. 94. Described in Garfield County, Colo., where it is essentially gray marlstone with some gray and brown shale and a few thin shales. Thickness 630 to 720 feet. Underlies Parachute Creek member; overlies Douglas Creek member. Parachute Creek, Garden Gulch, and Douglas Creek members interfinger with unit referred to as lower sandy member of Green River.

M. D. Williams, 1950, Utah Geol. Soc. Guidebook 5, p. 102, 107–108. In this report, the Green River is considered to be middle Eocene in age.

F. M. Swain, 1956, Intermountain Assoc. Petroleum Geologists [Guidebook] 7th Ann. Field Conf., p. 130. Garden Gulch, where it is developed in Piceance Creek and eastern Unita Basin, is herein considered to represent lower part of Green River; Douglas Creek member is referred to unit termed Colton-Green River transition beds.

Named for exposures in buffs near mouth of Garden Gulch a tributary of Parachute Creek, in secs. 7 and 8, T. 6 S., R. 96 W., Garfield County, Colo.

Garden Island Formation

Lower Devonian: Northeastern Michigan.

G. M. Ehlers *in* K. K. Landes, G. M. Ehlers, and G. M. Stanley, 1945, Michigan Dept. Conserv. Geol. Survey Div. Pub. 44, Geol. Ser. 37, p. 34, 35 (table 1), 73–80. Proposed for a dolomite and dolomitic limestone which occupies a position between Upper Silurian St. Ignace formation (new) and Middle Devonian Bois Blanc formation (new). Thickness at type locality probably not more than 3 feet; maximum thickness probably not more than 25 feet, and average thickness not more than 15 feet. Included in Deerpark group.

Type locality: On Garden Island, which is north of Beaver Island, in Lake Michigan. Underlies narrow belt of land having east-northeast trend across the island.

Garden Valley Formation

Permian: Central Nevada.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 67–68. Consists of four unnamed members: (1) a basal limestone; (2) one made up of conglomerate, sandstone, and shale; (3) a resistant siliceous conglomerate; and (4) a sequence of purple and red shales and conglomerates. Maximum thickness is about 3,000 feet. Overlies Vinini formation with angular unconformity. Permian (?).

U. S. Geological Survey currently considers this unit to be of Permian age.

Described from occurrence along east side of Garden Valley on western slope of Sulphur Spring Range, vicinity of Eureka, Eureka County.

Gardiner River Rhyolite-Basalt Complex

Tertiary: Northwestern Wyoming.

R. E. Wilcox, 1944, Geol. Soc. America Bull., v. 55, no. 9, p. 1047–1052, pls. 2, 3. Term applied to complex that is part of the lava filling of a valley eroded in main mass of Yellowstone Plateau rhyolites. Includes Lodgepole rhyolite and Cataract basalt (both new). Younger than Meadow rhyolitic tuff (new); older than Elkhorn basalt and Sheepeaters basalt (both new).

Main body of complex lies 5 miles south of Mammoth Hot Springs and three-quarters mile down stream from Sevenmile Bridge at point where Gardiner River begins to descend its canyon on north side of plateau, Yellowstone Park.

Gardiners Clay[1]

Pleistocene: Southeastern New York (Long, Gardiners, and Fishers Islands) and islands of southern New England (Block, Nantucket, Marthas Vineyard, No Mans Land, and probably Cape Cod).

Original reference: M. L. Fuller, 1905, Geol. Soc. America Bull., v. 16, p. 367–390.

K. E. Lohman, 1939, U.S. Geol. Survey Prof. Paper 189–H, p. 229–235. Discussion of Pleistocene diatoms from Long Island. Because all species, with one exception, are represented in living floras in about the same latitude, an age no older than some interglacial stage of Pleistocene is indicated. Similarity of floras suggests contemporaneous deposition, and tentative correlation of Gardiners clay with Cape May formation of New Jersey is proposed.

Lawrence Weiss, 1954, U.S. Geol. Survey Prof. Paper 254–G, p. 143–163. Gardiners clay in eastern Long Island is variable in thickness, lithology and fossil content. Foraminferal assemblage in clay is indicative of shallow water, probably brackish-water deposition and suggests a depositional environment similar to bays that fringe southern shore of Long Island today. Most abundant Foraminifera—those which might possibly be used as guide fossils—are *Elphidium clavatum* and *E. florentinae.* Clay, in western part of Long Island, overlies Jameco gravel; in eastern part, lies directly above Upper Cretaceous deposits (Magothy?). Described as bluish clay in central part of Long Island and as red and green clay near eastern end of island. At type locality, a succession of black, green, and red clays, 28 feet thick, merging upward into Jacob sand. Gardiners clay underlying Brookhaven area is a green-gray silty clay 10 to 20 feet thick. In general, zones of true clay are fossiliferous, and sand and gravel are not. Samples from wells of Riverhead Water District, about 10 miles northeast of Brookhaven Laboratory, reveal 11 feet of greenish fossiliferous Gardiners clay lying beneath 7 feet of fossiliferous sand and gravel and above 10 feet of fossiliferous sand and gravel. Microfaunal assemblage of the clay is almost identical with that of the two zones of sand. Surface of this predominantly coarse-grained fossiliferous zone in Riverhead is 70 feet below sea level. It is overlain by about 45 feet of unfossiliferous gray and brown clay which is overlain by about 50 feet of typical glacial sand. Many sections of the clay contain gravel, and some contain sand lenses. Fuller (1914, U.S. Geol. Survey Prof. Paper 82) reported outcrops of Gardiners clay beneath Jacob sand on north shore of Long Island at Roanoke Point and Jacobs Hill, 3 miles north of Riverhead.

Recent evidence indicates that Gardiners clay is 70 feet below sea level 3 miles south of Roanoke Point and Jacobs Hill. Because Gardiners clay seems to thin toward north and to grade into a shoreline sand and gravel facies, it is believed that clays described by Fuller are not part of Gardiners clay but are equivalent to 45-foot section of unfossiliferous clay that overlies the Gardiners in Riverhead area. Most recent work on Gardiners Island shows that beds called the interglacial Gardiners clay actually consist of two clays of entirely different origin. The upper part (probably red clay referred to by Fuller) is reddish-brown varved glacial clay, and lower part is predominantly green fossiliferous interglacial clay. The reddish-brown varved clay on Gardiners Island and the gray-brown clays at Roanoke Point and Jacobs Hill both grade upward into Jacob sand; perhaps these clays are correlative, as Fuller suggested. They are not part of the interglacial Gardiners clay but a younger glacial deposit.

Named for Gardiners Island, at east end of Long Island.

Gardison Limestone

Lower Mississippian : Central Utah.

M. D. Crittenden, Jr., 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 63, 65, 69 (fig. 3). Basal beds, which are conformable with underlying Fitchville formation (new), consist of 20 to 50 feet of coarse-grained, crossbedded black clastic dolomite; these are overlain by 200 to 250 feet of banded rock consisting of blue-gray fine-grained fossiliferous limestone in beds 2 to 4 inches thick with ¼ to ½ inch partings of tan to brownish-gray-weathering silty dolomite; upper part of unit consists of massive cliff forming beds of dolomite and limestone containing pods and lenses of white chert increasing in abundance upwards. Conformably underlies Deseret limestone; contact drawn at base of a black carbonaceous shale. Name credited to Morris and Lovering who applied name in East Tintic Mountains to body of dark limestone, most of which was originally included in Gardner dolomite and which in Wasatch Mountains has commonly been called Madison.

In Provo area, formation is well exposed in American Fork Canyon at several places along road between Timpanogos Cave National Monument and mouth of South Fork. Type locality and derivation of name not stated.

†Gardner Dolomite[1]

Lower Mississippian : Central northern Utah.

Original reference : G. F. Loughlin, 1919, U.S. Geol. Survey Prof. Paper 107.

T. S. Lovering and others, 1951, (abs.) Geol. Soc. America Bull., v. 62, no. 12, pt. 2, p. 1506. Restricted to exclude beds now known to contain an Upper Devonian fauna. These beds are included in underlying Pinyon Peak limestone. The restricted Gardner is about 535 feet thick and contains lower Mississippian fossils in its basal bed.

H. T. Morris, 1957, Utah Geol. Soc. Guidebook 12, p. 14. Name Madison limestone is preferred to name Gardner dolomite for rocks of Lower Mississippian age in East Tintic Mountains inasmuch as Gardner dolomite, as originally defined by Loughlin (1919), erroneously included some beds of Late Devonian age, and name was essentially restricted in its usage to East Tintic Mountains. Term Madison will be used as group name to include two new formations in report currently being prepared.

Names have not been officially adopted by U.S. Geological Survey, and, hence, are not used in present report.

J. K. Rigby, 1958, Utah Geol. Soc. Guidebook 13, p. 38 (fig. 5), 40–43. Described in Stansbury Mountains, Tooele County, where it consists of a lower member 200 to 650 feet thick and an upper member 475 to 1,110 feet thick. Underlies Pine Canyon formation; overlies Pinyon Peak limestone. Report states that U.S. Geological Survey has revised Mississippian nomenclature in Tintic district, but because names have not been officially proposed term Gardner is used in essentially same sense as applied by Lovering and others (1949, Econ. Geology Mon. 1). Gardner, as used in present report, includes all the Madison group of Morris (1957) except the upper cherty beds, which are mapped separately as basal unit of Pine Canyon formation.

H. J. Bissell, 1959, Utah Geol. Soc. Guidebook 14, p. 38–43, 46 (fig. 10), 155–157, pl. 1. Described in southern Oquirrh Mountains where it is about 812 feet thick and consists of two members: lower, 344 feet thick, chiefly dolomite; and upper, 468 feet, chiefly limestone with some chert at top. Lower member includes Gilluly's (1932, U.S. Geol. Survey Prof. Paper 173) Jefferson(?) dolomite; upper member includes approximately lower half of Gilluly's (1932) Madison. Disconformably overlies Opex formatiom (upper part of Lynch of Gilluly); stratigraphically above Stansbury formation; underlies Pine Canyon limestone which here includes some of upper strata of what Gilluly mapped as Madison. Described and mapped in Fivemile Pass and North Boulter Mountains quadrangles where it consists of lower and upper member. Name is used in preference to Madison.

First described in Tintic district where fossils were collected on spur west of Gardner Canyon.

Garfield Formation[1]

Precambrian: Southwestern South Dakota.

Original reference: J. O. Hosted and L. B. Wright, 1923, Eng. and Mining Jour.-Press, v. 115, p. 793–799, 836–843, maps.

R. J. Berg, 1946, South Dakota Geol. Survey Rept. Inv. 52, p. 6, 14, geol. map. Discussion of Galena-Roubaix district. In north and northwest parts of district, rocks which are described and mapped as Garfield and Northwestern formations, strike northwestward toward outcrops of Garfield and Northwestern formations in Lead district. They cannot be traced directly into Lead district because of Cambrian and Tertiary igneous cover. Formation characterized by graphitic slates. Overlies Northwestern formation; underlies Pluma formation. In Lead system.

Occurs in Lead district, Lawrence County.

Garfield Formation[1]

Pennsylvanian: Central Colorado.

Original reference: R. D. Crawford, 1913, Colorado Geol. Survey Bull. 4, p. 66.

R. L. Langenheim, Jr., 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 4, p. 559. Crawford's (1913) Garfield formation includes Belden, Gothic, and possibly some Maroon, and is defined in an area of rather intense metamorphism. These factors make its interpretation uncertain and its usage undesirable.

Named for Garfield, Chaffee County.

Garfield Member (of Muldoon Formation)

Upper Mississippian : Central and eastern Idaho.

M. R. Thomasson, 1959, Dissert. Abs., v. 20, no. 3, p. 999. Underlies Iron Mine member (new) ; overlies Copper Creek member (new).

Deposited in Muldoon trough, aligned N. 30° W.

Garfield Sandstone (in Chester Group)[1]

Mississippian : Western central Kentucky.

Original reference: A. F. Foerste, 1910, Kentucky Geol. Survey Rept. Prog. 1908 and 1909, p. 79, 84.

Named for Garfield, Breckinridge County.

Garim Limestone

Pleistocene : Caroline Islands (Garim, island off Yap)

Risaburo Tayama, 1935, Topography, geology, and coral reefs of the Yap Islands: Tohoku Univ. Inst. Geology and Paleontology Contr. in Japanese Language, no. 19, p. 27–29 [English translation in library of U.S. Geol. Survey, p. 24–25] ; 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 63, table 4 [English translation in library of U.S. Geol. Survey, p. 74]. Hard white limestone that resembles Mariana limestone. Primarily coral limestone and secondarily *Halimeda* limestone. Believed to overlap Tomil agglomerate nonconformably, though contact not observed.

Constitutes Garim Island and Irikku Island at southern extremity of Yap proper.

†Garland Conglomerate (in Pottsville Formation)[1]

Pennsylvanian : Northwestern Pennsylvania.

Original reference: J. F. Carll, 1875, Pennsylvania 2d Geol. Survey Rept. I, p. 38, 45–46.

At Garland quarries, about 1 mile northwest of Garland, Warren County.

Garland Peak Syenite

Carboniferous (?) : East-central New Hampshire.

Alonzo Quinn, 1937, Geol. Soc. America Bull., v. 48, no. 3, p. 377, 389, 400. A small pluglike body of light- to dark-gray, yellow-weathering syenite. Contains many needlelike grains of amphibole, increasing in quantity toward margin causing darker appearance. Irregular texture. Belongs to White Mountain magma series.

Best exposed on Garland Peak, a hill on east side of Red Hill, Carroll County. Also crops out in area southwest of the peak.

Garley Canyon Sandstone Member (of Mancos Shale)[1]

Upper Cretaceous : Central eastern Utah.

Original reference: E. M. Spieker and J. B. Reeside, Jr., 1925, Geol. Soc. America Bull., v. 36, no. 3, p. 438.

W. A. Cobban and J. B. Reeside, Jr., 1952, Geol. Soc. America Bull., v. 63, no. 10, chart 10b (column 38). As shown on correlation chart, occurs near middle of formation stratigraphically above Ferron sandstone member and below Emery sandstone member.

Named for exposures in Garley Canyon, Carbon County.

Garlock Series

Permian: Southern California.

T. W. Dibblee, Jr., 1952, California Div. Mines Bull. 160, p. 12 (fig. 1), 15–19, pls. 1, 2, 3. Thick series of slightly metamorphosed Paleozoic sediments and volcanics, in part if not all of Permian age. About 22,000 feet of section exposed; possibility of repetition by isoclinal folding within the section, or even by strike faulting, should not be overlooked. Occurs as a large inclusion within a granitic batholith. Shown on columnar section as underlying unnamed quartzite conglomerate and hornfels below newly defined Goler formation and overlying newly named Mesquite schist.

Crops out in northeastern part of El Paso Mountains, Saltdale quadrangle, Kern County. Exposed continuously from Mesquite Canyon northeastward, striking about N. 20° W., across mountains and dipping steeply to the northwest.

Garnavillo Member (of Guttenberg Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., figs. 3, 9. Shown on columnar section as basal member of Guttenberg formation. Underlies Glenhaven member (new); overlies Spechts Ferry formation or where Spechts Ferry is absent, the Strawbridge member (new) of Quimbys Mill formation.

In copy of guidebook used by compiler, in fig. 3, the name Glenhaven had been crossed out and the name Garnet written in. However, in figure 9, the name Garnet had been used to replace the name Garnavillo. Since compiler had no way to determine what changes, if any, had been made in other copies of the guidebook, it was impossible to be certain which names should be retained.

Occurs in Dixon-Oregon area.

Garner Formation (in Strawn Group)[1]

Garner Formation (in Lone Camp Group)

Middle Pennsylvanian: North-central Texas.

Original reference: E. H. Sellards, 1933, Texas Univ. Bull. 3232, p. 106, 108.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Reallocated to Lone Camp group (new).

R. J. Cordell and others, 1954, Abilene Geol. Soc. Guidebook, Field Trip Nov. 19–20, p. 6 (fig. 2). Suggested revision on basis of faunal break in Brazos River sandstone member; upper part of Brazos River sandstone reallocated to base of East Mountain shale.

Leo Hendricks, 1957, Texas Univ. Bur. Econ. Geology Pub. 5724, p. 20, fig. 3, pl. 1. Underlies East Mountain formation; overlies Grindstone Creek formation. Type section established; section is chosen where the best and most nearly continuous exposure occurs; approximately basal 45 feet of formation not exposed at type section, and section does not exhibit a thin coal seam or lensing limestones present in other localities. Rank designations suggested by Cheney (1940) are accepted in this paper.

Type section: Along the Millsap to Mineral Wells Highway as it ascends scarp 2½ miles west of Millsap, Parker County. Name derived from town of Garner.

Garnet Member (of Guttenberg Formation)

See Glenhaven Member and Garnavillo Member of Guttenberg Formation.

Garner Mountain Andesite

Pliocene: Northern California.

H. A. Powers, 1932, Am. Mineralogist, v. 17, no. 7, p. 261–262. Dark-colored fine-grained porphyry in which glassy plagioclase phenocrysts are only easily determined component.

Occurs on Garner Mountain in Modoc Lava-Bed quadrangle.

Garnet Canyon Tongue (of Sanup Plateau Member of Muav Formation)

Lower and (or) Middle Cambrian: Northwestern Arizona.

E. D. McKee, 1945, Carnegie Inst. Washington Pub. 563, p. 14 (fig. 1), 29, 92. Rusty-brown or snuff-colored dolomite unit. Grades laterally into limestone to the west and into clastic sediments toward the east. Thickness averages about 12 feet. Older than Lava Falls tongue (new); younger than Elves Chasm tongue (new).

Upper of two very conspicuous dolomite units which form low but persistent cliffs from Garnet Canyon to Hermit Creek in eastern Grand Canyon.

Garnet Mountain Andesite

Probably lapsus for Garner Mountain Andesite.

Garnet Range Formation[1]
Garnet Range Quartzite } (in Missoula Group)

Precambrian (Belt Series): Central western Montana.

Original reference: C. H. Clapp and C. F. Deiss, 1921, Geol. Soc. America Bull., v. 42, p. 681, figs. 2, 3.

D. A. Andrews, G. S. Lambert, and G. W. Stose, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim, Map 25, Sheet 1, Formation underlies Sheep Mountain quartzite and overlies McNamara formation, all in Missoula group.

W. H. Nelson and J. P. Dobell, 1959, U.S. Geol. Survey Misc. Geol. Inv. Map I–296. In Bonner quadrangle Montana, Garnet Range quartzite overlies McNamara argillite and underlies Pilcher quartzite (new).

Type locality: On north side of Blackfoot Canyon from Johnson Gulch 2 miles east of Bonner eastward to 1 mile from mouth of West Twin Creek. Blackfoot Canyon forms northwest boundary of Garnet Range, the western part of which is composed largely of rocks of Garnet Range formation, Missoula to Helena region.

Garnett Limestone[1]

Pennsylvanian: Eastern Kansas.

Original reference: E. Haworth and M. Z. Kirk, 1894, Kansas Univ. Quart., v. 2, p. 110, 120–121.

Named for Garnett, Anderson County.

Garnuan series[1]

Precambrian: New Mexico.

Original reference: C. R. Keyes, 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 4, 7.

Garo Sandstone

Jurassic(?): Central Colorado.

D. B. Gould and others, 1947, Rocky Mountain Assoc. Geologists Guidebook Field Conf., June 16–19, p. 39 (road log). Name applied to yellow sandstone that underlies Morrison; has been mapped as Dakota sandstone by some workers.

J. T. Stark and others, 1949, Geol. Soc. America Mem. 33, p. 47–48, 160, pl. 1. Except for basal beds, which are coarse and in a few localities conglomeratic, consists of medium- to fine-grained sandstone. Color varies from red, pink, white, cream, gray, to brownish gray; generally red to the north and lighter to the south. Beds massive; crossbedding on large scale is especially characteristic. Thickness varies: 409 feet at Badger Spring near type locality; 132 feet at Red Hill; 85 feet west of Hartsel; 10 to 12 feet southeast of Hartsel. Unconformably overlies Maroon formation but locally overlaps on Precambrian; separated by unconformity from Morrison, generally regarded as Upper Jurassic. Nonfossiliferous.

Named from exposures in sec. 36, T. 11 S., R. 76 W., near town of Garo, Park County. Also present in fault block north of Hartsel.

Garrard Sandstone (in Eden Group)[1]

Garrard Sandstone Member (of Eden Formation)

Garrard Siltstone Member (of Maysville Formation)

Upper Ordovician: Central Kentucky.

Original reference: M. R. Campbell, 1898, U.S. Geol. Survey Geol. Atlas, Folio 46, p. 2.

D. K. Hamilton, 1950, Kentucky Geol. Survey, ser. 9, Bull. 5, p. 17. Garrard sandstone member present in upper part of Eden formation in southern Fayette and Jessamine Counties.

J. L. Rich, 1951, Geol. Soc. America Bull., v. 62, no. 1, p. 18. Referred to as Garrard siltstone member of Maysville formation.

W. H. Twenhofel and others, 1954, Geol. Soc America Bull., v. 65, no. 3, chart 2 (column 44). Shown on correlation chart as Garrard siltstone.

Named for Garrard County.

Garren Group

Tertiary: Western Texas.

Hugh Hay-Roe, 1957, Texas Univ. Bur. Econ. Geology Geol. Quad. Map 21. Term proposed to embrace Tertiary extrusive rocks of the area (Wylie Mountains and vicinity) which consist of up to 2,500 feet of lava rock and tuff. Consists of seven formations (ascending): Hogeye tuff, Pantera trachyte porphyry, Moon trachyte, Fairbury trachyte, Means trachyte, Zopilote breccia, and Bell Valley andesite (all new). Lies with marked angular unconformity upon unevenly eroded Cretaceous and Permiun strata; overlain by bolson deposits.

Group constitutes eroded northwest portion of Davis Mountains volcanic field in Wylie Mountains, Culberson and Jeff Davis Counties. Name taken from Guy Garren Ranch, on which all but the youngest formation are exposed.

Garrett conglomerate[1]

Lower Cretaceous (Comanche Series) : Northeastern New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257–259; 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 2, 7.

Derivation of name not stated.

Garrett Mill Sandstone Member (of Warsaw Formation)[1]

Upper Mississippian: North-central Tennessee and southeastern Kentucky.

Original reference: C. Butts, 1922, Kentucky Geol. Survey, ser. 6, v. 7, p. 89, 107, 122.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 15, 16, 212, 227, pl. 6. Throughout Kentucky belt, Butts (1922) identified three members of the Warsaw (ascending) : Wildie sandstone, Somerset shale, and Garrett Mill sandstone. Wildie sandstone of Butts is included in Wildie siltstone member of Muldraugh formation (new) ; Somerset shale is member of Salem formation; Garrett Mill sandstone of Butts is in upper part of Salem.

Named for exposures at Garrett Mill, on Eagle Creek, 3 miles north-northeast of Livingston, Overton County, Tenn.

Garrett Ranch Volcanic Group

Oligocene (?) : East-central Nevada.

W. M. Winfrey, Jr., 1958, Am. Assoc. Petroleum Geologists Rocky Mountain Sec., Geol. Rec., p. 77–78, 79 (fig. 2). Unconformably overlies Eocene Sheep Pass formation (new). Consists of basal conglomerate followed by volcanics (welded tuff and flows).

Egan Range, White Pine County.

†Garrison Shale (in Council Grove Group)[1]

Permian: Eastern Kansas, southeastern Nebraska, and northern Oklahoma.

Original reference: C. S. Prosser, 1902, Jour. Geology, v. 10, p. 712.

R. C. Moore, 1936, Kansas Geol. Survey Bull. 22, p. 50 (fig. 12). In diagram showing comparison of old and revised classification of beds referred to lower part of Big Blue series of "Permian" age, Garrison shale is replaced by (ascending) Beattie limestone (includes Florena and Morrill limestone members), Stearns shale, Bader limestone (includes Eiss limestone, Hooser shale, and Middleburg limestone members), Easly Creek shale, Bigelow limestone (includes Crouse limestone, Blue Rapids shale, and Funston limestone members), and Speiser shale.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 103–105. As used in this report, Garrison shale is top unit of Council Grove group. Includes beds upward from top of Cottonwood limestone to base of Wreford limestone. Name was discarded by Moore (1936) who raised various members of Garrison formation to formation rank. Formations constituting Garrison section in Kansas cannot be identified in Pawnee County, and general term Garrison shale has been retained. Interval consists of poorly exposed heterogeneous sequence of red shales and red to tan lenticular sandstones. Thickness difficult to determine. About 140 feet in subsurface, slightly west of outcrop.

Named for exposures at Garrison, Pottawatomie County, Kans.

Gartra Grit Member (of Ankareh Formation)

Gartra Grit Member (of Stanaker Formation)

Upper Triassic: Northeastern Utah and northwestern Colorado.

H. D. Thomas and M. L. Krueger, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 8, pt. 1, p. 1260 (fig. 2), 1271–1274. Name applied to basal conglomerate of Stanaker formation (new). Along south flank of Uinta Mountains, from Weber River to Skull Creek, and at Vermillion Creek, member is gray, poorly sorted coarse-grained felspathic quartz grit with sporadic quartz pebbles as large as 1 inch in diameter. At Manila, on north flank of mountains, consists of lenses of purplish-red crossbedded sandstone. Thickness 18 to 88 feet. At type locality, overlies Woodside shale.

Bernhard Kummel, 1954, U.S. Geol. Survey Prof. Paper 254–H, p. 166 (fig. 8), 180. Reallocated to member status in Ankareh formation. Overlies Mahogany member (new); underlies Stanaker member.

W. F. Scott, 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 101–104. Discussion of Triassic sequence in Wasatch and Uinta Mountains. Names Gartra and Stanaker considered unnecessary. Terms Shinarump(?) and Chinle preferred.

S. S. Oriel and L. C. Craig, 1960, Guide to the geology of Colorado: Rocky Mountain Assoc. Geologists, p. 43, 48. Because Shinarump member of Chinle formation is now known to be of far more limited extent than formerly believed, name is not applied to rocks in northwestern Colorado. Name Gartra grit seems more suitable. Not determined whether name should be given member or formation status because status of name Ankareh in northwestern Colorado is not yet settled.

Type section: At point where Vernal-Manila Highway crosses Brush Creek, about 10 miles north of Vernal, in north part of sec. 5, T. 3 S., R. 22 E., Uintah County, Utah. Name derived from Gartra Spring, sec. 11, T. 2 S., R. 21 E.

Garukiyoku Limestone

See Ngarekeukl Limestone.

Garzas Beds, Sandstone, or Formation (in Orestimba Group)

Upper Cretaceous: California.

F. M. Anderson, 1937, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 21, no. 12, p. 1612. Moreno group is faunally and lithologically divisible into Moreno beds below and Garas [Garzas] beds above. Chico series.

A. S. Huey, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 335. Cretaceous in Tesla quadrangle consists of Upper Horsetown, Chico, Panoche, Moreno, and Garzas. The Garzas formation is fossiliferous sandstone differentiated from top of Moreno.

F. M. Anderson, 1940, 6th Pacific Sci. Cong. Proc., v. 1, p. 395 [1939]. Orestimba group begins with stratigraphic unit of unique character as described by Anderson and Pack (1915) who termed it "Moreno formation." Its sediments are largely organic. This shaly unit has thickness of 2,000 feet, which in district of Orestimba Creek is overlain by 3,000 feet or more of sandy formation, termed Garzas from next important stream south of the Orestimba.

F. M. Anderson, 1943, California Div. Mines Bull. 118, pt. 2, p. 185 (fig. 69), 186 [preprint 1941]. Moreno group, highest division of Chico series, is 5,000 feet or more thick on west side of San Joaquin Valley, and includes three stages, Moreno, Quinto, and Garzas. Garzas member, highest part of Moreno group, is near top of Cretaceous succession.

L. I. Briggs, Jr., 1953, California Univ. Pub. Geol. Sci., v. 29, no. 8, p. 421. In eastern part of Diablo Range, the Upper Cretaceous sequence (Chico series) has been subdivided into two formations: Panoche at base and Moreno shale at top. North of Pacheco Pass, a third unit, Garzas sandstone, overlies the Moreno, and this formation can be traced for some 20 miles.

Named for exposures on Garzas Creek, Stanislaus and Merced Counties.

Gasconade Dolomite[1]

Lower Ordovician: Eastern and central Missouri.

Original reference: F. L. Nason, 1892, Missouri Geol. Survey, v. 2, p. vii, 12, 93, 114–115, pl. 3.

O. R. Grawe, 1954, Missouri Geol. Survey and Water Resources, 2d ser., v. 30, p. 52 (fig. 2), 55–57. Basal part of formation contains pebbles of chert and sometimes of Precambrian igneous rocks derived from older formation, but commonly it is marked by sandstone or sandy dolomite, 15 to 25 feet thick. This basal zone is known as Gunter. It is overlain by 80 to 125 feet of thin- to medium-bedded cherty dolomite which in some Missouri Survey reports is referred to as Van Buren formation, and this in turn is overlain by massively bedded cherty dolomite, 141 to 200 feet thick. In those reports in which term Van Buren formation is used, term Gasconade is restricted to this upper cherty dolomite. In present report, term Gasconade is used in its earlier unrestricted sense to include all strata between the Eminence and the Roubidoux.

R. D. Knight, 1954, Missouri Geol. Survey and Water Resources Rept. Inv. 17, p. 57. Includes Gunter member at base. Term Van Buren not used. Lower Ordovician.

Named for exposures on Gasconade River, central Missouri.

Gasconadian Series or Stage

Ordovician (Canadian): North America.

R. H. Flower, 1957, New Mexico Bur. Mines Mineral Resources Mem. 2, p. 18. Divisions within Canadian system favor natural division into four major units: Gasconadian, Demingian, Jeffersonian, and Cassinian. Gasconadian includes equivalents of the Van Buren and Gasconade of Ozark region, and their equivalents. Recognizable in general are: (1) an initial phase, often restricted geographically, with rather local faunas: (2) widespread beds of Gasconade in restricted sense; (3) late beds comprising *Kainella* zone, known as yet only from Cordilleran region. This division is late Ozarkian of Ulrich, with reservation that the Gasconade and Tribes Hill are equivalents and not successive intervals of deposition. Classification based principally on cephalopod distribution.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 7, p. 28–32. Canadian series includes Gasconadian, Demingian, Jeffersonian, and Cassinian stages.

†Gasper Formation or Oolite (in Chester Group)[1]

Upper Mississippian: Kentucky, northern Alabama, northwestern Georgia, and southwestern Virginia.

Original reference: C. Butts, 1917, Mississippian formations of western Kentucky: Kentucky Geol. Survey, pt. 1, p. 64–84.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 374–381. In Virginia, the Gasper limestone lies between Ste. Genevieve limestone below and Glen Dean limestone or Bluefield shale above, as along northwest belt of Appalachian Valley, or between Ste. Genevieve limestone and Fido limestone, as in Greendale syncline. Thickness 1,025 feet northwest of Greendale, Washington County; 515 feet northeast of Bluefield, W. Va.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 828. From Todd County to Grayson County, Ky., Bethel sandstone is absent, and Renault and Paint Creek formations together form limestone unit that cannot be easily subdivided. Name Gasper has been used for this limestone, but persistent miscorrelation has resulted in such confusion that name is no longer useful. These beds are now known as Girkin limestone.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 164–169. Butts (1917) named Gasper limestone from exposures in Warren County, Ky. Sutton and Weller stated that Gasper is unsuitable formation name because it was never adequately defined nor was its type locality clearly indicated. In this report [Burkes Garden quadrangle], name Gasper is used in tentative sense for limestones above the "Ste. Genevieve" and below Bluefield shale. Average thickness 425 feet. Chester series.

Charles Butts, 1948, Georgia Geol. Survey Bull. 54, p. 42, 46–47. Geographically extended into northwestern Georgia where, at north end of Lookout Mountain, it is about 100 feet thick and consists of a thick-bedded gray, rather coarsely crystalline limestone. Overlies Ste. Genevieve limestone; underlies Golconda limestone.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 163, chart 5. Type Gasper appears to consist of both Renault and Paint Creek strata; type Ohara consists of the Levias member of the Ste. Genevieve and the Renault formation; thus the two names overlap.

S. W. Welch, 1958, U.S. Geol. Survey Oil and Gas Inv. Chart OC–58. Wagnon member of Pride Mountain formation (both new) includes the lower part of the strata referred to by Butts (1926, Alabama Geol. Survey Spec. Rept. 14) as Gasper formation.

Named for exposures in bluffs along Gasper River, Warren County, Ky.

Gasport Limestone Member (of Lockport Dolomite)[1]

Gasport Limestone (in Lockport Group)

Middle Silurian: Western New York, and Ontario, Canada.

Original reference: E. M. Kindle, 1913, U.S. Geol. Survey Geol. Atlas, Folio 190.

E. R. Cumings, 1939, Geologie der Erde, North America, v. 1, p. 596 (fig. 7), 597. Basal member of Lockport. Underlies Suspension Bridge member (new); overlies Decew. Thickness 15 feet.

B. F. Howell and J. T. Sanford, 1947, Wagner Free Inst. Sci. Bull., v. 22, no. 4, p. 34. Member of Lockport formation. Overlies DeCew waterlime member; underlies Goat Island member (replaces preoccupied name Suspension Bridge).

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. Basal formation in Lockport group. Underlies Goat Island limestone; overlies Decew dolomite. Lockportian stage. Middle Silurian.

Named for exposures at Gasport, Niagara County, N.Y.

Gasport shaly channel[1] (in Lockport Limestone)

Silurian: Western New York.

Original reference: R. Ruedemann, 1925, New York State Mus. Bull. 265, p. 5–14.

Gassaway Member (of Chattanooga Shale)

Gassaway Formation (in Chattanooga Shale)

Upper Devonian: Northern Tennessee, north-central Alabama, and central southern Kentucky.

Guy Campbell, 1946, Geol. Soc. America Bull., v. 57, no. 9, p. 881, 884, 886, pl. 2. Hard slaty fissile black shale with conspicuous joints, abundant *Lingula melie*, conodonts, and small fish scales; contains conspicuous phosphatic nodules at different levels. Thickness varies from 9 to 13½ feet north and east of the basin, except in Macon County where it is 5 feet; here total thickness of Chattanooga is only 13 feet. Includes Bransford sandstone member (new) at base. Underlies Eulie shale (new); overlies Dowelltown formation (new); at type section underlies Maury shale which in this area is about 8 inches thick. Mississippian.

S. W. Maher, 1954, (abs.) Geol. Soc. America Bull., v. 65, no. 12, pt. 2, p. 1363. Referred to as upper member of Chattanooga shale. Contains numerous sandstone beds and a series of thinly laminated siltstones.

W. H. Hass, 1956, U.S. Geol. Survey Prof. Paper 286, p. 20–23. Member is chiefly a thin-bedded grayish-black shale, though along part of Eastern Highland Rim it can be subdivided into two black shale units and an intervening thin zone consisting of gray mudstone and black shale. Thickness between 12 to 21 feet along Eastern Highland Rim; thinner in south-central Tennessee and north-central Alabama; about 46 feet in Pulaski, Ky. Overlies Dowelltown member. Contains two distinct conodont faunas. Upper Devonian.

Type locality: On Highway 63, 5 miles south of Gassaway, Cannon County, Tenn.

Gassetts Schist[1]

Upper Cambrian (?): Southeastern Vermont.

Original reference: C. H. Richardson, 1929, Vermont State Geologist 16th Rept., p. 210, 225.

Crops out at Gassetts, Ludlow quadrangle, in northern part of Chester Township, Windsor County.

Gastineau Volcanic Group[1]

Upper Triassic: Southeastern Alaska.

Original reference: G. C. Martin, 1926, U.S. Geol. Survey Bull. 776, p. 92, 247, chart opposite p. 120.

Named for Gastineau Peak, Juneau region.

Gatecliff Formation

Silurian: Central Nevada.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 12, p. 97 (fig. 3), 98 (fig. 4). Named on cross section and structure section in report on Paleozoic continental margin in central Nevada. Overlies Perkins Canyon formation (new), Pogonip formation, or Caesar Canyon formation (new); underlies Masket formation (new).

Toquima Range, Nye County.

Gates Limestone[1]

Silurian: Western New York.

Original reference: G. H. Chadwick, 1918, Geol. Soc. America Bull., v. 29, p. 335, 356, 358, 359, 360, 361, 364.

H. L. Alling, 1946, Rochester Acad. Sci. Proc., v. 9, no. 1, p. 52–53. Term Gates, in sense proposed by Chadwick, is a formation, for he says it is separated from the Rochester [restricted] below. Gates is a rock facies, and the retention of the name as a formation or a member of the Rochester is deemed inadvisable.

Named for town in Monroe County.

Gatesburg Formation[1]

Upper Cambrian: Central Pennsylvania.

Original reference: Charles Butts, 1918, Am. Jour. Sci., 4th, v. 46, p. 527, 534, 537.

J. L. Wilson, 1952, Geol. Soc. America Bull., v. 63, no. 3, p. 281–303. Stratigraphically expanded upward to include Mines dolomite (Butts, 1918) as uppermost member. As thus expanded, includes (ascending) Stacy dolomite member, lower sandy member, Ore Hill dolomite member, upper sandy member, and Mines dolomite member. Thickness about 1,700 to 1,800 feet. Overlies Warrior limestone; relation to overlying beds is obscure because upper contact of Mines member is not exposed but probably unconformably underlies Ordovician Larke dolomite or its limestone facies, the Stonehenge formation. Gatesburg rock types grade southeastward into the Conococheague-type limestone over a distance of about 40 miles; younger sediments cover the transition beds except in a small area along axis of a reverse-faulted anticline in Fulton County.

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook Field Trips Pittsburgh Mtg., p. 8. Thick-bedded bluish, coarsely crystalline dolomite, with interbedded quartzite layers up to 10 feet thick. Includes Stacy dolomite member at base and Ore Hill limestone member near middle. Underlies Mines formation. Overlies Warrior formation.

Named for Gatesburg Ridge, Centre County.

Gatesville Formation (in Fredericksburg Group)[1]

Lower Cretaceous (Comanche Series): North-central Texas.

Original reference: S. A. Thompson, 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 10, p. 1508, 1530, 1531–1533, 1536.

F. E. Lozo and others, 1959, Texas Univ. Bur. Econ. Geology Pub. 5905, p. 3 (fig. 2), 5–6. Formation mentioned in symposium on Edwards limestone in central Texas.

Type locality: Near State Training School for Boys, north of Gatesville, Coryell County.

Gateway Formation[1]

Precambrian (Belt Series): Northwestern Montana, and southern British Columbia, Canada.

Original reference: R. A. Daly, 1912, Canada Geol. Survey Dept. Mines Mem. 38, maps 2, 3, 4.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1899. Discussion of Belt series in Glacier Park region. In MacDonald and Galton Ranges of British Columbia, Daly describes 2,025 feet of Gateway (equivalent to Sheppard) strata, which the writers [Fenton and

Fenton] group into two members as follows: sandstone, 125 feet; and siliceous thin-bedded light-gray to greenish-gray argillite, 1,850 feet.

Named for exposures on heights east of Gateway, Mont.

Gateway Granodiorite

[Cretaceous]: Eastern California.

J. F. Everden, G. H. Curtis, and J. Lipson, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 9, p. 2123 (fig. 2). Shown on map in paper dealing with potassium-argon dating of igneous rocks. Age shown on map legend as 92.9 millions of years. Younger than Arch Rock granite; older than El Capitan granite. [Calkins (1930, U.S. Geol. Survey Prof. Paper 160) referred to granodiorite at the Gateway. Compiler was unable to locate reference to Gateway granodiorite.]

Occurs in Yosemite National Park.

Gateway Canyon Member (of Muav Formation)

Lower and (or) Middle Cambrian: Northwestern Arizona.

E. D. McKee, 1945, Carnegie Inst. Washington Pub. 563, p. 14 (fig. 1), 29, 105–109. At type locality, consists of thin beds of mottled, aphanitic limestone separated by parting planes of yellow-brown siltstone. Thickness 137 feet. Base determined by weak zone which everywhere forms bench at top of Kanab Canyon member. Upper limit indicated by flat-pebble conglomerate zone at bottom of overlying cliff. Westward from type locality to and beyond Granite Park, member fairly constant in character; beds become thicker, and silt partings less numerous, but total thickness remains about the same. From Diamond Creek westward, however, marker beds at base are absent, and member cannot be differentiated from lithologically similar underlying units. Eastward from Gateway Canyon, member is progressively less massive, contains more clastic materials, and is thinner bedded. Older than Havasu member (new); younger than Kanab Canyon member (new).

Type locality: At mouth of Gateway Canyon in east-central Grand Canyon.

Gatún Formation[1]

Miocene, middle and upper: Panamá.

Original reference: E. Howe, 1907, Isthmian Canal Comm. Rept., app. E., p. 113–114.

H. N. Coryell and Suzanna Fields, 1937, Am. Mus. Novitates no. 956, p. 1. At Cativa, includes Cativa marl (new) in lower part.

W. P. Woodring, 1957, U.S. Geol. Survey Prof. Paper 306–A, p. 42–47, 51 (fig. 4), pl. 1. Chiefly massive medium to very fine grained sandstone and siltstone. Estimated thickness at least 500 meters. On faunal basis, divided into lower, middle, and upper parts; lower part not represented at type region; middle part includes best known strata. Overlies Caimito formation with contact covered by waters of Gatún Lake; farther east, overlaps Caimito and lies directly on Cretaceous(?) basement; underlies Chagres sandstone. Lower and middle Miocene. Gatún formation was named by Howe (1907). Hill (1898, Harvard Coll. Mus. Comp. Zool. Bull., v. 28, no. 5) had used names Monkey Hill formation and Mindi Hill beds. Howe used both Gatún formation and Monkey Hill formation in structure section, and in later publication (1908, Am. Jour. Sci., 4th ser., v. 26, p. 228) used only Monkey Hill formation. MacDonald's usage (1913, Isthmian Canal Comm. Ann. Rept., 1913, app. S., p. 530) apparently established preference of Howe's name. Howe (1907) excluded oldest strata near Garun from Gatún formation and grouped them into Bohió formation. It is now known that oldest outcropping part of formation is not represented in type region.

Type area: From Gatún to Mount Hope (Monkey Hill of Howe's time), C.Z.

Gatuna Formation

Pleistocene: Southeastern New Mexico.

W. B. Lang, 1938, *in* T. W. Robinson and W. B. Lang, New Mexico State Engineer 12th–13th Bienn. Rept., p. 84–85 [1939]. Name given to an assemblage of rocks of various kinds that were laid down in Pecos Valley in post-High Plains time and apparently after completion of maximum cycle of erosion. Terrestrial; fine red sand dominant; conglomerates, stream gravels, gypsum, limestone also present; gray, purplish, and red. Mantles many places to depth of only a few feet; more than 100 feet in Pierce Canyon; may exceed 300 feet at head of Cedar Canyon. Overlies Rustler formation.

Name derived from Gatuna Canyon, northeastern Eddy County, N. Mex.

Gatuncillo Formation

Gatuncillo Shale

Eocene, middle and upper: Panamá.

T. F. Thompson, 1944, Geological explorations in the vicinity of Rio Quebrancha for the Panamá Cement Company: Panamá Spec. Eng. Div., p. 12–13. Gatuncillo shale consists of thick sequence of soft, finely bedded, uniformly fine, and even grained yellowish-gray or buff-colored shales and impure bentonite beds with occasional thin siltstone layers. Overlies basement complex. Older than Quebrancha limestone (new). Many forms of microfossils are related to those identified from the so-called Tranquilla shales of upper Eocene age, which formerly cropped out within Madden Reservoir basin now inundated.

W. P. Woodring and T. F. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 2, p. 227–228, 246 (fig. 2). Gatuncillo formation, in type region, consists chiefly of mudstone, siltstone, impure bentonite, and thin lenses of limestone. Unless it is duplicated by faults, which would be difficult to detect, its thickness is as much as 3,000 feet. Unconformably overlies basement complex; underlies Bohío formation. Upper Eocene. Name Tranquilla shale was proposed for late Eocene strata in Madden basin (Coryell and Embich, 1937). That name was inadequately defined and specified type locality is now flooded by Madden Lake.

W. P. Woodring, 1957, U.S. Geol. Survey Prof. Paper 306–A, p. 13–22, 51, 56, 148. Middle and upper Eocene.

Type region: Quebrancha syncline.

Gavilan Peak Gabbro

Jurassic(?): Southern California.

E. F. Osborn, 1939, Geol. Soc. America Bull., v. 50, no. 6, p. 1925–1926. Dark, massive, medium to coarse grained, and hypidiomorphic. Intrudes schist believed to be Triassic.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 481, table 4. Listed as oldest of late Mesozoic plutonics in Riverside-Elsinore-Coahuila area. Older than Virginia quartz norite.

Occurs in Perris fault block, Riverside County.

Gaviota Formation[1]

Gaviota Stage

Eocene or Oligocene: Southern California.

Original reference: W. L. Effinger, 1935, Pan-Am. Geologist, v. 65, no. 1, p. 75.

B. L. Clark and H. E. Vokes, 1936, Geol. Soc. America Bull., v. 47, no. 6, p. 853 (fig. 1), 868–871. Defined as a stage based on faunal assemblages. Covers an interval at top of marine Eocene sequence above Tejon stage.

R. M. Kleinpell, 1938, Miocene stratigraphy of California: Tulsa, Okla., Am. Assoc. Petroleum Geologists, fig. 14. Gaviota formation shown in Refugian stage (Oligocene).

F. R. Kelley, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 1, p. 3 (fig. 2), 6. In Canada de Santa Anita area, Santa Ynez Mountains, overlies Sacate formation (new).

T. W. Dibblee, Jr., 1950, California Div. Mines Bull. 150, p. 29–30, 38 (fig. 2), pls. 1–6. Type Gaviota formation (west of Las Cruces) is about 1,600 feet thick and consists of three members, each about 500 feet thick. Lower member is a massive soft gray siltstone; middle member is light-buff thick-bedded well-sorted fine- to medium-grained concretionary sandstone; upper member a gray sandy siltstone with some interbedded fine-grained sandstone. Conformably underlies Sacate formation; conformably overlies Alegria formation (new). Oligocene.

Type locality: Canada de Santa Anita west of Gaviota Pass, Santa Barbara County.

Gay Hill terrace deposit

Pleistocene: Southern Texas.

A. W. Weeks, 1941, (abs.) Am. Assoc. Petroleum Geologists Program 26th Ann. Mtg., p. 20; 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 12, p. 1695 (fig. 1), 1697 (fig. 2), 1703, 1717 (fig. 16). Quaternary section of Texas Coastal Plain between Brazos River and Rio Grande is divided into 11 terraces and terrace deposits. Name Gay Hill is proposed for a terrace and terrace deposit of siliceous gravel at elevation of 372 feet in Fayette County. Younger than the Willis (herein considered to be Pleistocene); older than Bastrop Park (new) terrace deposit.

Named from Gay Hill cemetery. Exposed north of Colorado River, 6 miles northeast of Colorado County line, and along La Grange-Columbus Highway.

Gaylord Mountain Basalt or Flow (in Clayton Basalt)

Late Cenozoic: Northeastern New Mexico.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 126, pl. 1–b, 11. Ten basalt flows in what is termed Folsom sequence of Clayton basalt are named and mapped. Stratigraphic position of six of these basalts has been determined, but stratigraphic position of Gaylord Mountain, Sierra Grande, Purvine Mesa, and Dunchee Hill is not known. Gaylord Mountain is younger than Purvine Mesa.

Gaylord Mountain (also known as Carr Mountain) is an irregularly eroded cone, 4 miles east of Folsom, Union County.

Gaysport cyclothem

Pennsylvanian (Conemaugh Series): Southeastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 94 (table 11), 140–143. Embraces interval between Ames cyclothem (new) below and Duquesne cyclothem (new) above. An incomplete cyclothem. Includes (ascending) Gaysport shale and (or) sandstone and Gaysport limestone members. Thickness about 13 feet. In area of this report, the Conemaugh series is discussed on a cyclothemic basis; 15 cyclothems are named. [For sequence see Mahoning cyclothem.]

Present in Athens County.

Gaysport Member (of Conemaugh Formation)[1]

Gaysport limestone member

Pennsylvanian: Southeastern Ohio.

Original reference: W. Stout, 1918, Ohio Geol. Survey, 4th ser., Bull. 21, p. 258.

R. E. Lamborn, 1951, Ohio Geol. Survey, 4th ser., Bull. 49, p. 29, 32. In this report, the Conemaugh is considered a series, and the Gaysport is referred to both as a limestone and a member.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 55–56. Gaysport is a thin sandy limestone which is discontinuous in Morgan County [this report]. Average thickness about 4 inches. Occurs from 16 to 23 feet above Ames limestone and about 10 to 15 feet below Skelley limestone. Interval between Gaysport and Skelley is the position of Duquesne shale, clay, and coal member of geologic column of Ohio. Conemaugh series.

M. T. Sturgeon and others, 1958. Ohio Geol. Survey Bull. 57, p. 94 (table 11), 142–143, 144. Gaysport limestone included in Gaysport cyclothem (new). Separated from underlying Ames limestone by unit referred to as Gaysport shale and (or) sandstone member of cyclothem. Gaysport limestone as used in this report [Athens County] may be a split from Ames limestone. Conemaugh series.

Well developed in vicinity of Gaysport, Bluerock Township, Muskingum County.

Gazelle Formation

Silurian and Lower Devonian: Northern California.

F. G. Wells, G. W. Walker, and C. W. Merriam, 1959, Geol. Soc. America Bull., v. 70, no. 5, p. 646–649. Name applied to a sequence of clastic rocks with included limestone reefs. Consists essentially of hard fine-grained siliceous graywacke, dark-gray to black siltstone and mudstone, and siliceous and feldspathic grit; also contains appreciable quantities of chert, conglomerate, limestone, and limestone conglomerate. Five members have been distinguished (ascending): dark-gray to black siliceous mudstone—600 feet; graywacke—1,000 feet; black siliceous mudstone and green shale—300 feet; limestone lenses in chert conglomerate—500 feet; and siltstone, sandstone, and volcanic debris—200 feet. In most places in continuous exposures, one or more of these members is lacking or poorly exposed, and all vary markedly in thickness. Total thickness exceeds 2,400 feet. Formation is in fault contact with older Duzel formation (new) on the north, south, and west sides; on the east side, locally overlain by Devonian sedimentary and volcanic rocks and has been intruded by diorite and peridotite.

Michael Churkin, Jr., and R L. Langenheim, Jr., 1960, Am. Jour. Sci., v. 258, no. 4, p. 259 (fig. 1), 260–266. Described in Yreka quadrangle, Siskiyou County, where it is 85 to 713 feet thick and subdivided to include Payton Ranch limestone member at top. Member is 75 to 188 feet thick. Some outcrops of formation west of Payton Ranch limestone exposures are possibly younger than the member. Formation is interbedded sequence of shale, sandstone, bedded chert, conglomerate, limestone, and tuff; shale and sandstone predominate, but lateral gradation from one lithologic type to another is widespread; bedded chert, conglomerate, and limestone occur abundantly as discontinuous lenses and layers; one outcrop of andesitic lapilli tuff is only evidence of volcanic rock noted in formation in area. Base unexposed; folded thrust fault brings metamorphic rocks into contact with Gazelle. Contains trilobite and brachiopod fauna. Formation crops out in central part of area and forms east-west trending ridge between North and Middle Branches of Willow Creek.

U.S. Geological Survey designates the age of the Gazelle Formation as Silurian and Lower Devonian on the basis of a study now in progress.

Crops out in Siskiyou County in valley of East Fork of Scott River, across the Gazelle Mountain, and throughout northern part of valley of Willow Creek, and area of about 60 square miles.

Gazley Creek Sands and Clays[1]

Eocene: Southern central Texas.

Original reference: W. A. Price and K. V. W. Palmer, 1928, Jour. Paleontology, v. 2, p. 22.

Occurs on south bank of Colorado River at mouth of Gazley Creek, in western edge of Smithville, Bastrop County.

†Gebo Formation[1]

Upper Cretaceous: Northwestern Wyoming.

Original reference: D. F. Hewett, 1914, U.S. Geol. Survey Bull. 541, p. 91, 100.

Named for Gebo, near Thermopolis, Park County.

Geddes Limestone

Middle Cambrian: Eastern Nevada.

H. E. Wheeler and D. M. Lemmon, 1939, Nevada Univ. Bull., Geology and Mining ser., no. 31, p. 13, 20–23, fig. 3. Proposed for flaggy limestone beds between Eldorado dolomite and overlying paper shale of Secret Canyon formation; both contacts sharp. Bluish gray, moderately fine grained. Where unweathered, rock is black owing to carbonaceous impurities. Beds vary from ½ inch to 12 inches in thickness, most being 2 to 6 inches. Thickness about 335 feet. Unit complicated by faulting. Tentatively assigned to early Middle Cambrian.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 11–12, pl. 2. Described in stratigraphic section in vicinity of Eureka. Contact with Eldorado dolomite appears to be gradational, although in places this may result from folding or faulting rather than interlayering. On northwest nose of Prospect Ridge, the two formations interfinger; here a bed of massive limestone 10 or more feet thick and resembling beds of Eldorado can be mapped within Geddes near its base. Upper contact not well exposed, but appears to be sharp. Wheeler and Lemmon (1939) section referred to as type locality.

Type locality: Geddes and Bertrand mine, in Secret Canyon. Exposed as band of variable width east of outcrop of Eldorado dolomite, from south end of Secret Canyon, north along east side of Prospect Ridge as far as Diamond Tunnel of Diamond mine; occurs in two bands on either side of Mineral Hill from Eureka Tunnel at head of Goodwin Canyon nearly to Ruby Hill.

Geers Corners Gabbro

Precambrian: Northeastern New York.

A. F. Buddington, 1936, 16th Internat. Geol. Cong. Rept., v. 1, p. 348; 1939, Geol. Soc. America Mem. 7, p. 57, 59, 61. Banded gabbro that varies from place to place in composition and texture. Locally, there are repeated composite bands about 1 inch thick consisting successively, from bottom to top, of pyroxenite, gabbro, and anorthosite. The banding, as well as the foliation of surrounding country rock, indicate the nose of a syncline pitching west and having steep limbs.

Occurs at Geers Corners, 2½ miles north-northwest of Harrisville, Lake Bonaparte quadrangle, Lewis County.

Geertson Formation

Oligocene, upper, or Miocene, lower: Eastern central Idaho.

A. L. Anderson, 1957, Idaho Bur. Mines and Geology Pamph. 112, p. 13, 14, 17–18, pl. 1. Consists of light-colored shaly beds with some intercalated bentonite, sandy shales, sandstones, and pebble conglomerate and locally thin beds of impure lignite. Beds of pebble conglomerate are thin, discontinuous, but rather numerous and widespread in formation northeast of Lemhi River. No such pebble beds observed southwest of river. Thickness is some hundreds of feet. Rests unconformably on each of the other Tertiary formations described in Baker quadrangle and is overlain unconformably by Carmen formation.

A. L. Anderson, 1959, Idaho Bur. Mines and Geology Pamph. 118, p. 26–27. Thickness about 800 feet in North Fork quadrangle, Lemhi County. In area of this report, formation is almost entirely conglomerate with minor thin partings of sandy shale. Formation passes unconformably under Kirtley formation (new name to replace preoccupied Carmen) and spreads unconformably over eroded surface of Kriley (new) and Kenney formations and Challis volcanics. Late Oligocene or early Miocene.

Named for Geertson Creek along which more or less typical exposures are to be found. Confined to Lemhi Valley, Lemhi County.

Geiser Quarry Member (of Dutchtown Formation)

Lower Ordovician: Southeastern Missouri.

H. S. McQueen, 1937, Missouri Geol. Survey and Water Resources 59th Bienn. Rept., app. 1, p. 18–19. Name applied to middle member of formation; lower and upper members unnamed. Consists of dark-brown to black argillaceous limestone; calcareous hard platy and fissile shale; calcareous siltstone; locally contains light-colored finely crystalline limestone with fine but distinct granular texture. Thickness about 10 feet.

Well exposed in abandoned quarry on Arnold Geiser Farm in southeast portion of U.S. Survey 214, approximately SW cor. NW¼NW¼ sec. 20, T. 30 N., R. 13 E., Cape Girardeau County.

Gem Hill Formation (in Tropico Group)

Miocene(?) : Southern California.

T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 1, p. 138 (fig. 2), 140. Name applied to lower unit of group in Rosamond district. Consists mainly of stratified light-colored rhyolitic lithic tuff, tuff-breccia, tuffaceous sandstone, volcanic agglomerate, and some conglomerates of both volcanic and granitic clasts; locally, thin basalt flows at or near the top. Thickness at Gem Hill 1,250 feet; at Antelope Buttes about 1,200 feet; thinner elsewhere. Overlies quartz monzonite; underlies Fiss fanglomerate (new), contact gradational at Gem Hill and sharp, locally unconformable contact elsewhere. In Soledad Mountains, includes Bobtail quartz latite member (new) at base.

Type locality: Gem Hill, in S½ sec. 25, SE¼ sec. 26, and NE¼ sec. 35, T. 10 N., R. 13 W., San Bernardino Base and Meridan, 5½ miles northwest of Rosamond, Rosamond quadrangle, Kern County. Exposed nearly continuously from Gem Hill southeastward 7 miles to Red Hill; other exposures at Little Buttes, Middle Buttes, Soledad Mountain, and ridge north of Bissell.

Gemini Limestone[1]

Ordovician : Central northern Utah.

Original reference: G. W. Crane, 1915, Am. Inst. Mining Engrs. Bull. 106, p. 2149–2151.

Probably named for Gemini mine, Tintic district.

Gemuk Group

Carboniferous(?) to Lower Cretaceous : Southwestern Alaska.

W. M. Cady and others, 1955, U.S. Geol. Survey Prof. Paper 268, p. 21 (table), 27–34, pl. 1. Chiefly dense dark massive siltstone, with which are interbedded smaller amounts of chert and volcanic rock, and thin interbeds of limestone, graywacke, and breccia. Siltstone and breccia beds made up of fragments unsorted as to size. Volcanic rocks chiefly of andesitic lava. Exposed part estimated to be 15,000 to 25.000 feet thick. A good section favorable for determinations of thickness occurs along Cinnabar Creek, comprises chiefly massive siltstone, 10,000 to 15,000 feet thick above and between 5,000 to 10,000 feet of thinly bedded siltstone below. Conformably underlies Kuskokwim group (new). Carboniferous(?), Permian(?), Triassic, and Lower Cretaceous.

J. M. Hoare and W. L. Coonrad, 1959, U.S. Geol. Survey Misc. Geol. Inv. Map I–285. Rocks of Gemuk group in lower Kuskokwim region have yielded sparse fossil collections ranging in age from Mississippian(?) to Early Cretaceous. Thickness 15,000 to 25,000 feet. Map bracket shows age Carboniferous(?) to Cretaceous.

Type locality and also most favorable exposures lie north of lower middle course of Gemuk River. Rocks crop out in several irregular areas near axis of Kuskokwim Mountains southwest of Kuskokwim River. Largest mapped area of group extends northward about 15 miles from northwest side of Gemuk River valley into drainage basins of Atsaksovluk and Chikululnuk Creeks, and thence northeastward about 15 miles into headwater area of main fork of Holokuk River.

Gene Autry Shale

Pennsylvanian (Morrow Series) : South-central Olahoma.

M. K. Elias, 1956, *in* Ardmore Geol. Soc., Petroleum Geology of Southern Oklahoma—a symposium, v. 1: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 70 (table 2), 99–101. Uniformly soft clayey shale, gray to light gray; yellow-brown to red and maroon ferruginous concretions along bedding planes; contains one fossiliferous concretionary lentil, 2 or 3 feet thick, about 105 feet below what is considered top of formation. Thickness at type locality about 700 feet; dip almost vertical. Overlies Primrose sandstone; top is taken as base of concretionary fossiliferous lentil which is correlated with Jolliff formation.

Type section: North and west of center of NW¼ sec. 34, T. 3 S., R. 4 E., Carter County. Exposed in a series of ravines on both sides of Santa Fe Railroad track, about 2 miles north of town of Gene Autry.

Genesee Formation

Genesee Group[1]

Genesee Member (of Jennings Formation)

Middle and Upper Devonian: New York, Maryland, Pennsylvania, and West Virginia.

Original reference: L. Vanuxem, 1842, Geology of New York, pt. 3, p. 168–169.

W. H. Bradley and J. F. Pepper, 1938, U.S. Geol. Survey Bull. 899–A, pl. 3. Columnar section shows Genesee group comprises (ascending) Geneseo shale with Genundewa limestone lentil, Standish flagstone, and West River shale. Overlies Tully limestone of Hamilton group; underlies Middlesex shale.

R. L. Bates, 1939, Virginia Geol. Survey Bull. 51–B. p. 41 (table 1), 62–63, pl. 6. In Lee County, entire Genesee formation consists of fissile coal black shale. Thickness about 200 feet. Overlies Helderberg formation; underlies Portage formation.

H. P. Woodward, 1943, West Virginia Geol. Survey, v. 15, p. 385, 390. Genesee group not now recognized in outcrop area. Unit previously called "Genesee black shale" appears to be southwestern extension of Harrell shale of central Pennsylvania, and this term is considered appropriate for outcrops in West Virginia.

W. L. Grossman, 1944, Geol. Soc. America Bull., v. 55, no. 1, p. 41–76. Group, traced westward from Lake Erie, changes facies in central Finger Lakes region. In western New York, Geneseo and West River shales form lower and upper units. Sherburne-type rocks penetrate the West River of Finger Lakes region, and intertonguing units are named Penn Yan and Milo tongues of West River and Starkey tongue of the Sherburne. Term Genundewa is abandoned. Name Sherburne includes rocks between top of Penn Yan tongue and base of Middle Middlesex remnant in Cayuga Valley. Term Genesee group is used to include interval from base of Geneseo shale to base of Middlesex shale from Lake Erie to Cayuga Lake. To the east, the formational divisions do not correspond to those of western New York, and for all practical purposes Genesee group ends at Cayuga Lake. Overlies Tully limestone. Group is in Senecan series. An attempt to apply Caster's (1934, Bulls. Am. Paleontology, v. 21, no. 71) system of facies classification to Genesee rocks was not wholly successful.

Ernst Cloos, 1951, Maryland Dept. Geology, Mines and Water Resources Washington County [Rept. 14], p. 90, 99 (table 4). Member of Jennings formation. Consists of black fissile argillaceous shale. Thickness 90 to 100 feet, west of Wills Mountain near Cumberland; thins eastward and disappears before it reaches Washington County. Underlies Woodmont member; overlies Romney formation.

R. G. Sutton, 1951, Rochester Acad. Sci. Proc., v. 9, nos. 5–6, p. 381–386, pl. 1. In Batavia quadrangle, Genesee group comprises Geneseo formation and West River shale. Overlies Leicester marcasite member (new) of Moscow formation; underlies Middlesex black shale of Naples group.

Wallace de Witt, Jr., and G. W. Colton, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2810–2828. Genesee group of Chadwick (1935) is here called Genesee formation. Includes all rocks between top of Tully limestone—or top of Moscow shale of Hamilton group where the Tully is absent—and base of Middlesex member of Sonyea formation in western half of New York. Formation is composed of seven intertonguing facies which are designated as members. In vicinity of Canandaigua Lake and Genesee River valley, formation consists of (ascending) Geneseo shale, Penn Yan shale, Genundewa limestone, and West River shale members. At Cayuga Lake, 30 miles east, comprises (ascending) Geneseo shale, Penn Yan shale, Sherburne flagstone, Renwick shale, Ithaca, and West River shale members. Top of formation is about 600 feet higher stratigraphically than top of Genesee group of previous workers. Thickness at reference section (herein designated) 125 feet; 850 to 940 feet near Ithaca; 595 feet near Sheldrake Creek on west side Cayuga Lake.

W. H. Hass, 1959, (abs.) Geol. Soc. America Bull., v. 70, no. 12, pt. 2, p. 1615. Discussion of conodont faunas from Devonian of New York and Pennsylvania. Parts of Geneseo shale [member of Genesee] placed in Middle Devonian. Leicester marcasite regarded as transgressive basal bed of Genesee formation; Leicester oldest east of Canandaigua where de Witt, Colton, and writer [Hass] found it above Tully limestone and youngest in western New York, where on Eighteen Mile Creek, Erie County, it includes Hinde's (1879, [Geol. Soc. London Quart. Jour., v. 35]) "Conondont bed"; its fauna there is mixture of high Middle and low Upper Devonian (pre-Genundewa and Genundewa) conodonts.

Reference section: At Beards Creek, near Leicester, western Livingston County. Named for exposures along Genesee River and valley, New York, especially in gorge of Genesee River below Portage.

Genesee Valley Limestone and Shales[1]

Triassic: Northern California.

Original reference: J. P. Smith, 1910, Jour. Geology, v. 18, chart opposite p. 220.

Name probably derived from occurrence in Genesee Valley, east of Genesee, Plumas County.

Geneseo Shale Member (of Genesee Formation)

Geneseo Shale (in Genesee Group)[1]

Middle and Upper Devonian: New York.

Original reference: G. H. Chadwick, 1920, Geol. Soc. America Bull., v. 31, p. 118.

W. L. Grossman, 1944, Geol. Soc. America Bull., v. 55, no. 1, p. 47 (fig. 2), 54–59. Basal formation of Genesee group. Extends from Lake Erie to

Cayuga Lake, beyond which its black shale facies is recognized as far as Chenango Valley. East of Cayuga Lake, upper part of the Geneseo grades laterally into the coarser facies characterizing the higher beds; the black shale facies thins and disappears a short distance east of Chenango Valley. Formation thickens from a 2-inch sliver at Lake Erie to 125 feet at Cayuga Lake; thins eastward from this meridian to 40 feet at Cayuga Lake. Underlies Penn Yan tongue (new) of West River shale. Overlies Tully limestone.

Wallace de Witt, Jr., and G. W. Colton, 1959, Am. Asso. Petroleum Geologists Bull., v. 43, no. 12, p. 2814 (fig. 3), 2815, 2816–2818, 2820. The 44 feet of black shale that overlies Moscow shale of Hamilton group in Menteth Gully, on west side of Canandaigua Lake 14 miles north of Naples, comprises Geneseo shale member of Genesee formation as defined in this paper. At reference section, herein designated, consists of homogeneous black shale and brownish-black shale containing a few layers of argillaceous limestone concretions 7 inches to 3 feet in diameter. Name Geneseo shale was proposed by Chadwick for exposures of about 82 feet of very dark gray calcareous mudrock and irregularly fissile shale containing some beds of black shale, many limestone concretions, and layers of nodular limestone in vicinity of Fall Brook. The Geneseo member is herein restricted at Fall Brook locality to a 5-foot tongue of black shale at the base and a 5-foot tongue of black shale 26 to 31 feet above the base of the 82-foot sequence. The lighter colored and less fissile rocks, which were originally included in the Geneseo by Chadwick, are herein placed in lower part of Penn Yan shale between and above tongues of the Geneseo shale member. The two tongues of black shale that comprise the Geneseo member at Fall Brook thicken eastward and coalesce near Hemlock Lake about 10 miles east of Geneseo. Member thins westward from about 45 feet at Canandaigua Lake to feather-edge in eastern Erie County. Thickness 113 to 135 feet at Cayuga Lake. Overlies Tully limestone.

W. H. Hass, 1959, (abs.) Geol. Soc. America Bull., v. 70, no. 12, pt. 2, p. 1615. Discussion of conodont faunas from Devonian of New York and part of Geneseo shale [member of Genesee formation] placed in Middle Devonian. Determination made on basis of conodont faunas.

Reference section: In Menteth Gully, on west side of Canandaigua Lake 14 miles north of Naples, Ontario County. Named for exposures at Fall Brook, 1½ miles south of Geneseo, Livingston County.

Geneva Limestone[1] **or Dolomite**

Middle Devonian: Central and southeastern Indiana.

Original reference: J. Collette, 1882, Indiana Dept. Geology and Nat. History 11th Ann. Rept., p. 63, 81, 82.

D. G. Sutton and A. H. Sutton, 1937, Jour. Geology, v. 45, no. 3, p. 331. Geneva is northward facies of Jeffersonville formation of Onondaga age as shown by Onondaga faunules of Jeffersonville which continue into Geneva at same horizons and by lateral transition from dolomitic Geneva to purer Jeffersonville limestone. Term Jeffersonville is synonym of Geneva, and by custom of priority latter name should be applied to all Indiana rocks of Onondaga age.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Lower or Middle Devonian.

J. B. Patton and T. A. Dawson *in* H. H. Murray, 1955, Indiana Geol. Survey Field Conf. Guidebook 8, p. 37–38, pl. 1. Indiana Geological Survey uses name Geneva dolomite. Consists of buff to chocolate-brown granular thin-bedded to massive dolomite and contains white crystalline calcite masses that range from a fraction of an inch to more than 1 foot in cross section; carbonaceous material present in bands and partings. From Shelby, Rush, and Bartholomew Counties, where maximum thickness is 35 feet, Geneva thins regularly southward to its pinchout in northern Clark County. In most places, overlies Louisville limestone but locally overlies Waldron shale or Laurel limestone; throughout southern Indiana, outcrop underlies Jeffersonville limestone; relationship to lower Jeffersonville not clear from Jennings County northward, but recent data prove that middle and upper Jeffersonville maintain their characteristics throughout this area and overlie the Geneva.

Named for Geneva, Shelby County.

†Geneva Quartzite[1]

Lower Ordovician: Northeastern Utah.

Original reference: E. Blackwelder, 1910, Geol. Soc. America Bull., v. 21, p. 519, 526–527, 542.

Well exposed in northern part of Wasatch Range.

†Geneva Sands[1]

Pleistocene: Southeastern Alabama and Georgia.

Original reference: E. A. Smith, 1894, Alabama Geol. Survey geol. map of Alabama, explanatory chart.

Probably named for Geneva or Geneva County, southeastern Alabama.

†Genevieve Group[1]

Mississippian: Missouri.

Original reference: H. S. Williams, 1891, U.S. Geol. Survey Bull. 80, p. 169.

Named for exposures in Ste. Genevieve County.

Gennet Creek Formation (in Chester Group)[1]

Mississippian: Southwestern Indiana.

Original reference: M. A. Harrell, 1935, Indiana Dept. Conserv. Pub. no. 133, p. 78.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 839. In Indiana, the Clore limestone is known as Gennet Creek formation and consists of 10 to 35 feet of predominantly shaly beds.

C. A. Malott, 1952, Stratigraphy of Ste. Genevieve and Chester formations of southern Indiana: Ann Arbor, Mich., The Edwards Letter Shop, p. 6. Name Clore limestone extended into Indiana and applied to shale and limestone interval underlying Degonia sandstone and overlying Palestine sandstone. [This appears to be interval to which name Gennet Creek was applied].

Type locality and derivation of name not given.

Genoa Member (of Oneota Formation)

Lower Ordovician: Southwestern Wisconsin.

G. O. Raasch, 1952, Illinois Acad. Sci. Trans., v. 45, p. 88–90, 91–92. Comprises two divisions, the lower of which is light buff, or buffy mottled dolomite commonly in beds 2 to 3 feet thick. Beds are dull in lustre, compact, homogeneous, and generally finely crystalline. Many of the strata studded with globose, nut-size cavities, horizontal burrows conspicuous in many beds, and chert nodules, in rows parallel to bedding at a few localities. Ripple marks at one locality. Thickness ranges from 8 feet in north to 29 feet in south. Upper division of white, dull, homogeneous, and finely crystalline dolomite, which readily breaks to flagstone slabs 2 to 6 inches thick. Nut-sized cavities generally present. Thickness ranges from 3 feet in north to more than 8 feet in south. Thickness of member ranges from 11 feet in northeast to 46 feet in southwest part of quadrangle. Underlies Stoddard member (new) with transitional contact; overlies Mount Ridge member (new).

Type section: Quarry and Mississippi bluff in NE¼SE¼ sec. 32, T. 13 N., R. 7 W., Stoddard quadrangle, 1 mile south of Genoa, Vernon County.

Genshaw Formation[1] (in Traverse Group)

Middle Devonian: Northeastern Michigan.

Original reference: A. S. Warthin, Jr., and G. A. Cooper, 1935, Washington Acad. Sci., Jour., v. 25, no. 12, p. 524–526.

A. S. Warthin and G. A. Cooper *in* G. A. Cooper and others. 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1762, chart 4. Originally proposed for thin limestones and shales between Ferron Point formation and Killians limestone. Recent work has shown that black limestone of Killians facies appears in the Genshaw. Therefore, Genshaw is redefined to include the Killians and lower 15 feet of Alpena limestone which contains many Genshaw species.

A. S. Warthin, Jr., and G. A. Cooper, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 5, p. 579 (fig. 3), 582–584. Redefined Genshaw described in Thunder Bay region where composite section shows thickness of 116 feet. Killians limestone is excellent horizon marker in region and is here considered a named member of the Genshaw. Underlies Newton Creek limestone; overlies Ferron Point formation. Included in Traverse group.

W. A. Kelly and G. W. Smith, 1947, Am. Assoc. Petroleum Geologists, Bull., v. 31, no. 3, p. 448 (fig. 1), 451–453. Described in Afton-Onaway area where top is represented by Killians black limestone member. Separated from overlying Koehler limestone (new) by an interval which includes a buff limestone referable, possibly to the Newton Creek. Six faunal zones recognized in formation in area. Overlies Ferron Point formation.

Type locality: NE¼ T. 32 N., R. 8 E., Alpena County. Name derived from Genshaw School in SE¼ sec. 13.

Gent facies[1] (of Carwood Formation)

Lower Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv., Div. Geology Pub. 98, p. 77, 178–184.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 127–128, pl. 2. Mississippian facies nomenclature discussed. Correlation chart lists Gent facies of Carwood formation. Includes Lampkins sandstone member of Carwood.

Named from an old inland post office, Gent, located on a now abandoned part of Bloomington-Brownstown Road at middle of east line of NE¼ sec. 27, T. 8 N., R. 1 E., 9 miles east of Bloomington, Monroe County.

Gentile Valley Group[1]

Tertiary, upper, or Pleistocene: Southwestern Idaho.

Original reference: A. C. Peale, 1879, U.S. Geol. and Geog. Survey Terr. 11th Ann. Rept., p. 612, 642, map.

In Portneuf Canyon, on east side of Cache Valley, and in Gentile Valley.

Gentry Coal Member (of Caseyville Formation)

Pennsylvanian: Southeastern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 29, 44 (table 1), 61, pl. 1. Name applied to member of Caseyville (redefined). Overlies Sellers limestone member; underlies Pounds sandstone member. Thickness 2 feet in type section of Caseyville. Owen (1856) termed this Battery Rock coal, but Battery Rock has been more widely used for the sandstone and is so restricted in this report. Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification.

Type locality: Sec. 26, T. 11 S., R. 10 E., southwestern Hardin County.

Genundewa Limestone Member (of Genesee Formation)

Genundewa Limestone Lentil (of Geneseo Shale)[1]

Genundewa Limestone Member (of Geneseo Formation)

Upper Devonian: Western and west-central New York.

Original reference; J. M. Clarke, 1897, New York State Geologist 15th Ann. Rept.

W. H. Bradley and J. F. Pepper, 1938, U.S. Geol. Survey Bull. 899–A, p. 9, 10, pl. 3. Limestone lentil at top of Geneseo shale. Underlies West River shale. A bed of black, very dark gray limestone, in most places less than 1 foot thick. At Firtree Point, on west shore of Seneca Lake, abnormally thick.

W. L. Grossman, 1944, Geol. Soc. America Bull., v. 55, no. 1, p. 45. Term Genundewa abandoned because beds to which it refers are not considered a formation but rather a discontinuous shell limestone facies of the West River. These lenses are referred to as the *Styliolina* or pteropod facies of the West River. Impure limestone layers overlying the Geneseo in Seneca-Cayuga Lake region have been called Genundewa. They differ in lithology from the *Styliolina* beds to west and are discussed as limy facies of Penn Yan tongue (new) of West River.

R. G. Sutton, 1951, Rochester Acad. Sci. Proc., v. 9, nos. 5–6, p. 384. Referred to as limestone member of Geneseo formation.

Wallace de Witt, Jr., and G. W. Colton, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2814 (fig. 3), 2815 2816, 2817 (fig. 4), 2818–2819, 2827. Redefined as member of Genesee formation. In type area, composed of about 12 feet of nodular layers of dark-gray fossiliferous limestone 1 to 10 inches thick interbedded with dark-gray calcareous shale. A few thin beds of black shale present. Thins toward west and locally absent near Lake Erie; thins toward east and grades laterally into Crosby sandstone in southeastern Ontario County. Overlies Penn

Yan shale member and underlies West River shale member at reference section of Genesee; thickness 3 feet. The Genundewa at Canandaigua Lake is lateral equivalent of Crosby sandstone of Torrey and others (1932) at Keuka Lake and is tentatively correlated with Williams Brook coquinite of Caster (1933) at Williams Brook near south end of Cayuga Lake.

Typically exposed at Genundewa Point, locally spelled Genundewah, on east side of Canandaigua Lake, about 9 miles north of Naples.

Geode Creek Basalt

Miocene and (or) Pliocene: Northwestern Wyoming.

A. D. Howard, 1937, Geol. Soc. America Spec. Paper 6, p. 19–21, 78 (table 9), pl. 4. Olivine basalt, with labradorite and augite. Characteristically massive, but locally may be highly vesicular. Weathers into stubby plates, up to 1 foot in length. Contains no secondary silica. Gray color and fine texture in contrast to color and texture of Crescent Hill basalt (new). Northern exposure about 60 feet high. Lies unconformably on unnamed breccia.

Exposed in two small patches, one east of Geode Creek and other about 1 mile northwest of Crescent Hill, Yellowstone National Park. The southern patch, the higher of the two, reaches elevation between 7,300 and 7,400 feet.

Georges Fork Sandstone Member (of Atoka Formation)[1]

Middle Pennsylvanian: Eastern Oklahoma.

Original reference: C. W. Wilson, Jr., 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 4, p. 503–520.

C. W. Wilson, Jr., and N. D. Newell, 1937, Oklahoma Geol. Survey Bull. 57, p. 29. Composed of thin to massively bedded sandstone. Thickness 35 feet at type locality. Separated by unnamed shale intervals from underlying Pope Chapel member and overlying Dirty Creek member.

Named for exposure east of Georges Fork, in secs. 24 and 25, T. 22 N., R. 19 E., Muskogee County.

Georgetown Limestone (in Washita Group)[1]

Georgetown Group or Subgroup

Lower Cretaceous (Comanche Series): Central and southern Texas.

Original reference: T. W. Vaughan, 1900, U.S. Geol. Survey Geol. Atlas, Folio 64.

T. L. Bailey, F. G. Evans, and W. S. Adkins, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 2, p. 172–173. Washita group in Tyler basin is divided into eight stratigraphic units which can be traced in the subsurface. Except for Maness shale, which is not known at outcrop, and the Buda, which has been found at surface only as far north as southern Denton County, outcrop belts of each of the units in northeast Texas are readily mappable. Each unit is given formational rank, following Adkins and others (1933, Texas Univ. Bull. 3232). Lower five units are lumped into the Georgetown, which is here recognized as a subgroup. In central Texas where it is only 60 to 100 feet thick and where most of marls that separate the interval into mappable units are missing, it becomes an undifferentiated subgroup or formation and is called Georgetown limestone. Subgroup comprises (ascending) Duck Creek formation, Fort

Worth limestone, Denton shale, Weno formation, Pawpaw formation, and Main Street limestone.

Elliot Gillerman, 1953, U.S. Geol. Survey Bull. 987, p. 11 (table 1), 25–26, 27. In Eagle Mountains area, formation consists of interbedded blue-gray shales and black limestone at least 800 feet thick. Overlies Kiamichi formation; underlies Carpenter limestone member (new) of Grayson formation.

F. E. Lozo and others, 1959, Texas Univ. Bur. Econ. Geology Pub. 5909, p. 3–4, 15–18, 122–130. Discussed in symposium on Edwards limestone. Formation includes (ascending) Duck Creek, Fort Worth, Denton, Weno, Pawpaw, and Main Street members. Overlies Kiamichi formation; underlies Grayson formation.

Named for Georgetown, Williamson County.

Georgia Slate[1]

Lower Ordovician: Northwestern Vermont.

Original reference: Edward Hitchcock, 1861, Vermont Geologist Rept., v. 1, p. 357-386.

Charles Schuchert, 1937, Geol. Soc. America Bull., v. 48, no. 7, p. 1014, 1021, 1025, 1045, 1052. Overlies Rockledge breccia (new). Upper Cambrian.

A. B. Shaw, 1958, Geol. Soc. America Bull., v. 69, no. 5, p. 550. In previous publications, names Georgia slate, Corliss breccia, Grandge slate, and upper Gorge formation have been used for Ordovician rocks in St. Albans area. In present report, name Georgia slate is abandoned because Walcott's name for Lower and Upper Cambrian rocks should not be extended to lower Ordovician.

Named for town of Georgia, Franklin County.

†Georgian Series[1] or Epoch[1]

Lower Cambrian: North America.

Original reference: C. D. Walcott, 1891, U.S. Geol. Survey Bull. 81, p. 360.

A. B. Shaw, 1954, Geol. Soc. America Bull., v. 65, no. 11, p. 1046. Walcott (1891, U.S. Geol. Survey 10th Ann. Rept., pt. 1) used name *Olenellus* zone essentially in sense of series term after he had established correct relative positions of *Olenellus* and *Paradoxides* faunas. Later, he (1891) applied name Georgian series to Lower Cambrian, referring to standard section described by him (1886, U.S. Geol. Survey Bull. 30) west of Georgia Center, Vt. Name Georgian was replaced by Waucoban series (Walcott, 1912) because Georgian was at that time also used for a formation, Georgia slate. Section at Waucoba has been studied recently. Believed that, in view of present state of knowledge, the Waucoba section is not a satisfactory standard. Term Georgian should be reinstated for the following reasons: (1) Georgia section, as opposed to that at Waucoba Springs, is well known, and its contained fossils are properly located stratigraphically. (2) Fauna of Georgia section, and especially of Parker slate, is varied and abundant. Fossils are not common and do not seem to be so varied in most of Waucoba section. (3) Name Georgian is no longer used for any other stratigraphic unit. [Georgia slate abandoned in this report.]

Named for section at west of Georgia Center, Vt.

Gering Formation[1] **or Sandstone** (in Arikaree Group)

Gering facies (of Monroe Creek Formation)

Miocene: Western Nebraska and southeastern Wyoming.

Original reference: N. H. Darton, 1898, U.S. Geol. Survey 19th Ann. Rept., pt. 4, p. 735, 747–755.

C. B. Schultz, 1938, Am. Jour. Sci., 5th ser., v. 35, no. 210, p. 441–444. Arikaree group redefined to include Gering formation as basal unit. Underlies Monroe Creek formation.

C. B. Schultz and T. M. Stout, 1941, Guide for a field conference on the Tertiary and Pleistocene of Nebraska: Nebraska Univ. State Mus. Spec. Pub., p. 28. In most places, formation is disconformable on upper Oligocene Whitney member of Brule formation, and change in lithology from massive clay to gray or grayish-blue sand is commonly quite pronounced.

L. K. Wenzel, R. C. Cady, and H. A. Waite, 1946, U.S. Geol. Survey Water-Supply Paper 943, p. 70–72, pl. 2. Formation described in Scotts Bluff County where it is primarily a fine soft gray sandstone, strongly laminated and locally crossbedded. Occupies channel cut in upper surface of Brule formation. Maximum thickness about 200 feet, 6 miles south-southwest of Gering; thins toward the south and southwest and toward the north and northeast. Overlying Monroe Creek and Harrison formations cannot be distinguished in this area.

R. C. Cady and O. J. Scherer, 1946, U.S. Geol. Survey Water-Supply Paper 969, p. 20. Referred to as Gering sandstone.

P. O. McGrew, 1953, Wyoming Geol. Soc. Assoc. Guidebook 8th Ann. Field Conf., p. 62 (chart), 63. Geographically extended into southeastern Wyoming.

C. B. Schultz and T. M. Stout, 1955, Nebraska Univ. State Mus. Bull., v. 4, no. 2, p. 46, fig. 10. Bayard paleosol complex caps top of Whitney member of Brule formation and extends into Gering formation in Castle Rock section near Bayard.

S. G. Collins, 1960, Geology of the Patricia quadrangle (1:62,500): South Dakota Geol. Survey. Monroe Creek formation includes two mappable facies tentatively correlated with Gering channel sand and Mellette limestone.

Well developed southwest of Gering, Scotts Bluff County, Nebr.

†Gerlane Formation[1]

Pleistocene: South-central Kansas.

Original reference: G. L. Knight, 1934, Geol. Soc. America Proc. 1933, p. 91.

J. C. Frye, 1945, Jour. Geology, v. 53, no. 2, p. 91–92. Term Gerlane formation has been applied to Pleistocene beds only in Barber County. These deposits underlie floor of lowland surface that extends westward as far as eastern Meade County: topographically below Tertiary-capped upland to north. Deposits similar to the Gerlane occur in Clark County and eastern Meade County, Kans., and in Beaver and Harper Counties, Okla. These deposits, loosely referred to as Ashland-Englewood terrace beds, are shown by their physiographic relations and fauna to be late Pleistocene in age, but their exact correlation with named formations in Meade Basin and elsewhere in central and western Kansas is unknown. Age and stratigraphic relations of Gerlane formation and associated beds are problems for further study.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 110. Name appears in list of units that consist in part or entirely of deposits known to be of Illinoian or younger age and that are properly classed, at least in part, as Sanborn formation.

Type locality: Near Gerlane, Barber County.

Germania Formation (in Chadakoin Group)

Germania Formation (in Conneaut Group)

Germania Member (of Chadakoin Formation)

Upper Devonian: Northwestern Pennsylvania and southwestern New York.

J. G. Woodruff, 1942, New York State Mus. Bull. 326, p. 17 (fig. 1), 47–50. Uppermost formation in Conneaut group. Overlies Whitesville formation (new); underlies Wolf Creek member of Cattaraugus formation. Thickness about 70 feet. Consists of thin green sandstones interbedded with red shales, with the "Catskill" crossbedded sandstone and conglomerate beds at different horizons, varying with the locality. Base of formation is recognized by the red color of the soil marking the earliest appearance of the real reds of the "Catskill."

I. H. Tesmer, 1955, New York State Mus. Sci. Service Circ. 42, p. 10 (fig. 1), 15. Upper member of Chadakoin formation. Overlies Whitesville member; underlies basal Wolf Creek (Panama) member of Cattaraugus formation.

L. V. Rickard, 1957, New York State Geol. Assoc. [Guidebook] 29th Ann, Mtg., p. 17 (table 2), 19. Uppermost formation in Chadakoin group. Inasmuch as Upper Devonian strata are still not thoroughly understood, a more or less permanent classification satisfactory to a majority of workers may not be obtained for some time.

Type outcrop: On south flank of Marshfield anticline, near Germania, Potter County, Pa. Can be traced over most of Wellsville quadrangle, Allegany County, N.Y.

Germer Tuffaceous Member (of Challis Volcanics)[1]

Oligocene, upper, or Miocene, lower: Southern central Idaho.

Original reference: C. P. Ross, 1932, Idaho correlation chart compiled by M. G. Wilmarth.

A. L. Anderson [1949], Idaho Bur. Mines and Geology Pamph. 83, p. 9. In most places, Germer member is interbedded with and overlies the flows of the basal latite-andesite member, but in Yankee Fork district it is in part stratigraphically equivalent to the flows and in part older.

Named for Germer Basin, on south side of Salmon River, nearly opposite mouth of Bayhorse Creek, Custer County.

Gerome Andesite[1]

Oligocene: Northeastern Washington.

Original reference: C. E. Weaver, 1920, Washington Geol. Survey Bull. 20, p. 98, map.

U.S. Geological Survey currently considers the Gerome Andesite to be Oligocene in age.

Named for exposures near town of Gerome, Stevens County.

†Geronimo Series[1]

Pennsylvanian(?): Southwestern Oklahoma.

Original reference: H. F. Bain, 1900, Geol. Soc. America Bull., v. 11, p. 135, 140–141.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 101. Abandoned by Oklahoma Geological Survey. Named for Apache chief and thus not a geographic name.

Sequence occurs in Wichita Mountain region.

Gerster Formation[1] **or Limestone** (in Park City Group)

Permian: Western Utah.

Original references: T. B. Nolan, 1930, Washington Acad. Sci. Jour., v. 20, no. 17, p. 421–432; 1935, U.S. Geol. Survey Prof. Paper 177, p. 39–41.

R. K. Hose and C. A. Repenning, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 9, p. 2183 (fig. 5), 2184–2185. Termed Gerster limestone. Assigned to Park City group in Confusion Range where it is highest Permian unit. Overlies Plympton formation (new); underlies Thaynes formation. Consists almost entirely of resistant ledge-forming light-brownish-gray limestone interbedded with slope-forming yellowish-gray or rusty-brown argillaceous limestone; most limestone beds bioclastic. Aggregate thickness about 1,100 feet.

Grant Steele, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 91–113. Nolan (1935) placed lower contact of the Gerster at top of "Oquirrh formation," and upper contact at base of overlying Triassic limestone and shales. As determined in present study, lower 170 feet of Nolan's Gerster formation is lithologically equivalent to Kaibab formation. Would seem appropriate to restrict the Gerster to those limestones above gray cherty carbonates of the Kaibab. The Gerster appears to grade laterally into shales and cherts of the Phosphoria as the unit is traced north and northwest to Leach Mountains and Burnt Canyon Range. At several localities west of Gold Hill, upper contact of the Gerster is placed at base of a chert pebble conglomerate sequence believed to correlate with third member of Nolan's Garden Valley formation. Upper Guadalupian.

Named for exposures in Gerster Gulch, in northwestern corner Gold Hill quadrangle, Tooele County.

Gerty Sand[1]

Pleistocene: Southeastern Oklahoma.

Original reference: J. A. Taff, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 3, p. 439.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Pleistocene.

O. D. Weaver, Jr., 1954, Oklahoma Geol. Survey Bull. 70, p. 85–88. Averages 35 feet thick across Hughes County. Typically reaches maximum of 40 feet in central parts of its outcrop. Overlies Pennsylvanian sandstones and shales.

W. F. Tanner, 1956, Oklahoma Geol. Survey Bull. 74, p. 115. Validity of the Gerty, as anything more than a terrace level in Seminole County, questioned. Farther to southeast, geomorphic evidence lends support to Gerty concept.

Named for Gerty (formerly spelled Guertie), Hughes County.

Getaway Limestone Member (of Cherry Canyon Formation)

Permian (Guadalupe Series): Western Texas.

P. B. King *in* A. K. Miller and W. M. Furnish, 1940, Geol. Soc. America Spec. Paper 26, p. 9. Incidental mention.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 580, 585 (fig. 7), pl. 2; 1948, U.S. Geol. Survey Prof. Paper 215, p. 35–36, pl. 3 [1949]. Consists of black or dark-gray limestone, with some lighter gray granular very fossiliferous limestone and some sandstone partings. Locally 200 feet thick; in some areas, feathers out. Lies 100 to 200 feet above base of formation: lies below South Wells limestone member which in turn lies about 600 feet above base of formation.

Type locality: Getaway Gap, 6 miles southeast of Guadalupe Peak and 6 miles southeast of El Capitan, Culberson County.

Getmuna Rhyolite Group

Paleocene(?) to Miocene(?): Southwestern Alaska.

W. M. Cady and others, 1955, U.S. Geol. Survey Prof. Paper 268, p. 21 (table), 50–53, pl. 1. Tuff comprises major part of formation though some lava crops out in small tract of about 3 square miles at southwest end of area in which group is exposed. Tuff beds and lava flows are rhyolitic. Lava is light purplish brown; weathered surface is buff colored. Tuff is mottled with contrasting light and dark shades of the fragmental materials; weathered surface is more uniform buff color. At least 500 feet thick. Maximum thickness estimated to be about 1,500 feet. Believed to cover folded and dissected Kuskokwim group (new) and to postdate Iditarod basalt (new). Probably older and extends beneath Holokuk basalt (new) exposed nearby.

Named for Getmuna Creek in central Kuskokwim region. Occupies elongate area, about 15 square miles north of Horn Mountains, that trends northeast across middle course of Getmuna Creek, a southwestern tributary of Crooked Creek.

Getsuyoto Beds or Formation

See Getuyoto Beds or Formation.

Gettysburg Shale (in Newark Group)[1]

Gettysburg sandstone lithofacies

Upper Triassic: Southern Pennsylvania and central Maryland.

Original reference: A. I. Jonas, 1926, Pennsylvania Geol. Survey Topog. and Geol. Atlas 178, p. 17, New Holland sheet.

G. W. Stose and A. I. Jonas, 1939, Pennsylvania Geol. Survey, ser. 4, Bull. C–67, p. 115–120. Gettysburg shale, upper formation of Newark group, consists of red shale and red sandstone, with lenticular zone near base containing thick beds of conglomerate herein named Conewago conglomerate member, a series of hard gray sandstone near middle, called Heidlersburg member, and beds of limestone and conglomerate and quartzose fanglomerate at top. Thickness 15,500 to 18,100 feet. Overlies New Oxford formation.

A. J. Stose and G. W. Stose, 1946, Maryland Dept. Geology, Mines and Water Resources Carroll and Frederick Counties Rept. Geographically extended to Maryland.

D. B. McLaughlin and R. C. Gerhard, 1953, Pennsylvania Acad. Sci. Proc., v. 27, p. 136, 137. Termed sandstone lithofacies in Lebanon and Lancaster Counties, southeastern Pennsylvania. Includes Furnace Ridge conglomerate (new) in lower part, sandstone units at bottom, middle, and top, and a second conglomerate unit below the top sandstone. Conspicuous changes in lithology along strike. Interfingers with New Oxford subarkosic lithofacies and is the northern and generally overlying unit; transition marked by extensive interbedding of feldspathic and nonfeldspathic sandstones.

M. E. Kauffman, 1960, Pennsylvania Geologists Guidebook 25th Ann. Field Conf., Oct. 22–23, p. 23. Formation comprises Elizabeth Furnace conglomerate member at base and shale member at top. Upper Triassic.

Named for exposures at Gettysburg, Adams County, Pa.

Getuyoto Beds or Formation

Miocene: Caroline Islands (Truk).

Risaburo Tayama, 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 69, table 5 [English translation in library of U.S. Geol. Survey, p. 84]; S. Hanzawa *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 29. Getuyoto (Getsuyoto) beds (formation) of Truk are included in East Caroline beds (formation).

†Geuda salt measures (in Sumner Group)[1]

Permian: Eastern Kansas.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 1–48.

Named for town of Geuda Springs, Sumner County.

Geuda Springs Shale Member (of Wellington Formation)

Permian: Central Kansas.

W. A. Ver Wiebe, 1937, Wichita Municipal Univ. Bull., v. 12, no. 5, p. 5, 12–14. Thick sequence of drab and bluish-grey shales and clays and anhydrite. Not well exposed; only a few feet at any one place. Thickness 230 feet (based on core sample). Includes three claystone layers which occasionally become limestones and can be traced for some distance along the strike; these are here named Prairie Creek, Sanitorium, and Udall limestone lentils. Underlies Annelly gypsum member (new); overlies Hollenberg limestone member (new).

Type locality: At sanitorium half a mile east of Geuda Springs, sec. 7, T. 34 S., R. 3 E.

Geyser Bentonite Bed (in Colorado Formation)

Cretaceous: Southwestern Montana.

Great Northern Railway Co. Mineral Research and Development Department, 1960, Great Northern Railway Co. Mineral Research and Devel. Dept. Rept. 12, pt. 2, p. 33–38, 41. Bed divided into two parts: lower bentonite member 3 to 16 feet thick, displaying "popcorn" bloom, overlying hard black shale; and upper hard siliceous shale member, 10 to 30 feet thick, weathering to a white outcrop. About 500 feet above base of Colorado formation; about 250 feet below Greenhorn bentonite bed (new).

Thirty miles of outcrop traced within distance of about 45 miles between Geyser and Windham, Judith Basin County.

Giannonatti facies

See **Cannonball Member** and **Ludlow Member** (of Fort Union Formation).

Giants Range Granite[1]

Precambrian: Northeastern Minnesota.

Original reference: J. E. Spurr, 1894, Minnesota Geol. Nat. Hist. Survey 22d Ann. Rept., p. 119–124.

F. F. Grout and others, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1039, 1042. Giants Range granite is a batholith about 100 miles long and as much as 15 miles wide. Has several facies. Intrudes Knife Lake group. In some areas lies beneath Pokegama quartzite.

Forms core of Giants Range, Vermilion and Mesabi districts.

Gibbons Conglomerate Lentil (in Marble Falls Formation)

Gibbons Conglomerate Member (of Big Saline Formation)

Lower Pennsylvanian (Bend Series): Central Texas.

F. B. Plummer, 1945, Texas Univ. Bur. Econ. Geology Pub. 4401, p. 65–66. A basal conglomerate that marks the contact of the Marble Falls and the Barnett formation in some places. Consists of a dark-gray coarse fossiliferous glauconitic sand containing numerous subrounded cobbles from a fraction of an inch up to 10 inches in diameter; conglomerate grades upward into a coarse sandstone layer about 1 foot thick. Lentil is about 30 feet long east and west, 1 foot thick at each end and about 4 feet in the middle.

F. B. Plummer, 1947. Jour. Geology. v. 55, no. 3, pt. 2, p.196 (table 2), 197. Rank raised to member status in Big Saline formation. East of Ridge Cavern, underlies Aylor member; west of Ridge Cavern, underlies Brook Ranch member.

F. B. Plummer, 1950, Texas Univ. Bur. Econ. Geology Pub. 4329, p. 61–62, 63. At type section, the Gibbons is thin pebble conglomerate 6 to 12 inches thick.

Type section: One-fourth mile north of San Saba-Brady Road on the Gibbons Ranch 2½ miles south of Hall, San Saba County.

Gibson Coal Member (of Crevasse Canyon Formation)

Gibson Coal Member (of Mesaverde Formation)[1]

Upper Cretaceous: Northwestern New Mexico.

Original reference: J. D. Sears, 1925, U.S. Geol. Survey Bull. 767.

L. B. Leopold and C. T. Snyder, 1951, U.S. Geol. Survey Water-Supply Paper 1110–A, p. 6–9. Disconformably underlies Gramerco formation (new).

J. E. Allen and Robert Balk, 1954, New Mexico Bur. Mines Mineral Resources Bull. 36, p. 90, 92, 93, p. 1. Lower Gibson reallocated to member status in Crevasse Canyon formation (new). Overlies Dalton sandstone member; underlies Hosta tongue of Point Lookout sandstone.

E. C. Beaumont, C. H. Dane, and J. D. Sears, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2157. Coal-bearing zone, originally named Gibson, is split into lower and upper part northeast of Gallup by wedging in of Point Lookout (formerly Hosta) sandstone. By newly adjusted terminology of Measaverde, lower and upper parts become respectively uppermost member of Crevasse Canyon and, in San Juan basin, lowest member of Menefee formation. Name Gibson coal member is restricted to lower split zone, and upper zone is here named Cleary coal member of Menefee formation. Southwest of point where Point Lookout (formerly

Hosta) sandstone wedges out, Cleary coal member and restricted Gibson coal member of Crevasse Canyon are in direct contact.

Named for village of Gibson, McKinley County.

Gibson Limestone Member (of Grindstone Creek Formation)

Pennsylvanian (Strawn) : North-central Texas.

H. T. Mann *in* R. J. Cordell, H. J. Fitzgeorge, and J. B. Sparks, 1954, Abilene Geol. Soc. Guidebook Nov. 19–20, p. 22, 25 (fig. 16). Name applied to member of Grindstone Creek. Lies below Goen limestone member and above Santo limestone member. Unit had been mapped as Santo by Plummer and Hornberger (1936, Texas Univ. Bull. 3534) and as Goen by Nickell (1939, Texas Univ. Bur. Econ. Geology Mineral Resources Survey Circ. 26).

Named for exposures along Gibson Creek, Erath County.

Gila Conglomerate[1] or Group

Tertiary, middle(?) to Pleistocene: Southeastern Arizona and southwestern New Mexico.

Original reference: C. K. Gilbert, 1875, U.S. Geog. and Geol. Survey 100th Mer., v. 3, p. 540–541.

L. A. Heindl, 1954, (abs.) Geol. Soc. America Bull., v. 65, no. 12, pt. 2, p. 1262. Reexamination of type section areas shows that term Gila conglomerate is unsatisfactory because it includes large proportion of deposits other than conglomerates; it suggests that deposits in separate basins are identical; its use masks sequences of alluvial deposits within individual basins; and it oversimplifies a complex Cenozoic history. Suggested that these deposits be separated into two major divisions wherever possible: an upper division consisting of conformable units and a lower division of older Cenozoic alluvial deposits. Upper division Pliocene to Pleistocene; lower division Oligocene(?) to Miocene(?).

James Gilluly, 1956, U.S. Geol. Survey Prof. Paper 281, p. 8–9 (table), 118–120, pl. 5. Described in central Cochise County, Ariz., where it is essentially conglomerate, sandstone, silt, and clay several hundred feet thick; in southern Dragoon Mountains unconformable above S O volcanics (new) and in Sulphur Spring Valley unconformable above Pearce volcanics (new). Pliocene.

P. A. Wood, 1959, Arizona Geol. Soc. Guidebook 2, p. 60. Three units distinguished in Gila conglomerate in Safford Valley area, Arizona. Bonita beds (lowest), Solomonsville beds, and Frye Mesa beds. Pliocene and Pleistocene.

U.S. Geological Survey currently designates the age of the Gila Conglomerate or Group as middle(?) Tertiary to Pleistocene.

Well exposed along gorges of upper Gila River and its tributaries.

Gila cyclothem (in McLeansboro Group)

Gila cyclothem (in Mattoon Formation)

Pennsylvanian: Southeastern Illinois.

W. A. Newton and J. M. Weller, 1937, Illinois Geol. Survey Rept. Inv. 45, p. 9, 27–28; J. M. Weller, 1942, Illinois Acad. Sci. Trans., v. 35, no. 2, p. 145 (table 1). Lies below the Woodbury cyclothem (new) and above the Greenup cyclothem (new). Thickness at type locality about 20 feet; thins northeastward. Includes Gila limestone.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 52 (table 2), 55 (table 3), pl. 1. In Mattoon formation (new). Above Greenup cyclothem and below Woodbury cyclothem. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type locality: Along Mint Creek in sec. 31, southeast of Gila, Jasper County.

Gila Limestone Member (of Mattoon Formation)

Gila Limestone (in McLeansboro Group)

Pennsylvanian: Southeastern Illinois.

W. A. Newton and J. M. Weller, 1937, Illinois Geol. Survey Rept. Inv. 45, p. 28. Dense fine-grained brittle limestone that contains small fragments of carbonaceous material; medium-gray, weathers nearly white. Thickness 1 to 4 inches. Included in Gila cyclothem.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 12, pl. 1. Correlation chart shows Gila limestone in McLeansboro group below Woodbury limestone and above Greenup limestone. Gives type locality same as Gila cyclothem.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 40, 51 (table 1), pl. 1. Reallocated to member status in Mattoon formation (new). Occurs above Greenup limestone member and below Woodbury limestone member. Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois.

Type locality Mint Creek, NE¼SW¼ sec. 31, T. 8 N., R. 9 E., Jasper County.

Gilbert Andesite

Pliocene: Southwestern Nevada.

H. G. Ferguson, S. W. Muller, and S. H. Cathcart, 1953, Geology of the Coaldale quadrangle. Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–23]. Flows and agglomerates, dominantly andesitic but also containing basalt, cover crest of Monte Cristo Range. Typically dark porphyritic lava. Few flows of hornblende andesite and hypersthene and olivine basalt. Locally sandstone, conglomerate, and fanglomerate between flows; andesite agglomerates widespread in adjacent Mina quadrangle. Also small intrusive masses of hornblende andesite. Between 500 and 1,000 feet thick in Monte Cristo Range.

H. G. Ferguson and S. H. Cathcart, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–40. In Round Mountain quadrangle, underlies Toyabe quartz latite (new).

Type locality: Southern part of Gilbert district, Monte Cristo Range.

Gilbert Limestone (in McMillan Formation[1] or Group)

Upper Ordovician: Central Kentucky.

Original reference: A. F. Foerste, 1912, Denison Univ. Sci. Lab. Bull. 17, p. 18, 23.

A. C. McFarlan, 1943, Geology of Kentucky: Lexington, Ky., Kentucky Univ., p. 26, 27. In southern Blue Grass region, McMillan group includes (ascending) Tate formation, Gilbert limestone, and Mount Auburn formation. Gilbert is a zone of dove to grey fine-grained to dense hard limestone that grades into Mount Auburn; fossiliferous. Thickness 0 to 20 feet.

Probably named for Gilbert, Lincoln County.

Gilbert Sandstone (in Kanawha Formation[1] or Group)

Pennsylvanian (Pottsville Series) : Southern West Virginia.

Original reference: R. V. Hennen and D. B. Reger, 1914, West Virginia Geol. Survey Rept. Logan and Mingo Counties, p. 217–219.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey Greenbrier County, p. 215, 221. Lower Gilbert sandstone of Hennen and Reger (1914) is massive, grayish-white, coarse grained, and 30 to 80 feet thick. Overlies Gilbert shale. New River group, Pottsville series. Upper Gilbert sandstone not present in county.

Named for Gilbert, Mingo County.

Gilbert Shale[1]

Pennsylvanian(?) : Northeastern Arkansas.

Original reference: D. D. Owen, 1858, First report geol. reconn. northern counties of Arkansas, p. 68–69.

Exposed 3 miles northwest of Searcy, White County, at "bald point," in vicinity of Widow Gilbert's Farm.

Gilbert Shale (in Kanawha Formation[1] or Group)

Pennsylvanian (Pottsville Series) : Southern West Virginia.

Original reference: R. V. Hennen and R. M. Gawthrop, 1915, West Virginia Geol. Survey Rept. Wyoming and McDowell Counties, p. 168.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey Greenbrier County, p. 221. Shale in Kanawha group, Pottsville series.

First described in connection with Gilbert A coal in Wyoming County.

Gilboa Formation[1]

Upper Devonian: East-central New York.

Original reference: G. A. Cooper, 1934, Am. Jour. Sci., 5th ser., v. 27, p. 1–12.

J. M. Berdan, 1950, New York State Water Power and Control Comm. Bull. GW–22, p. 10, 19. Further described as gray medium- to fine-grained sandstone, thin-bedded siltstone, and dark-gray shale in Schoharie County.

Type section: In west face of Reed Hill, Schoharie Valley. Best section at Intake Building and along road from this building which connects with road to Hardenburg Falls and Grand Gorge [near southern end of Schoharie-Delaware County line]. [Probably named for Gilboa, Schoharie County, or Gilboa Reservoir.]

Gilboy Sandstone Member (of Monongahela Formation)[1]

Gilboy Sandstone (in Monongahela Group)

Gilboy sandstone and shale member

Upper Pennsylvanian: Northern West Virginia, eastern Ohio, and southwestern Pennsylvania.

Original reference: I. C. White, 1903, West Virginia Geol. Survey, v. 2, p. 150.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 100, 124 (fig. 29), 126. Lies below Waynesburg coal, which is considered top of Monongahela group; separated from underlying Waynesburg limestone by Little Waynesburg coal. Thickness as much as 20 feet in Fayette County.

D. L. Norling, 1958, Ohio Geol. Survey Bull. 56, p. 10 (fig. 3), 86, geol. map. In Morgan County, Gilboy sandstone and shale member (Monongahela series) consists of 13 to 20 feet of sandstone and sandy shales, with some gray to red shales. Where overlying Waynesburg (No. 11) coal is not present, sandstone section extends upward so that demarcation of Pennsylvanian-Permian contact is not possible.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 158 (table 13), 188. Lowest member of Waynesburg cyclothem in report on Athens County. In many sections, member is in part a gray massive medium-grained sandstone very resistant to weathering. These zones give way laterally and vertically to less resistant lithologies, as fine- to medium-grained, thin- to medium-bedded sandstone or shaly sandstone interbedded with sandy platy shale. Average interval from top of Gilboy to Waynesburg coal bed is 9 feet, but this is variable because upper part grades laterally into redbeds; this results in thickening and thinning of both Gilboy sandstone member and redbed member (Waynesburg redbed member). Thickness of Gilboy 8 to 40 feet; average 11. In some areas, thick sandstone sequence begins at stratigraphic position of Gilboy and is continuous vertically to Waynesburg sandstone, with which member it is coalesced. When coalesced, the two sandstones cannot be separated or distinguished.

Named for exposure in Gilboy cut on Baltimore & Ohio Railroad east of Mannington, Marion County, W. Va.

Gilchrist Shale (in Carbondale Formation)

Gilchrist Shale (in Pottsville Formation)[1]

Pennsylvanian: Northwestern Illinois.

Original reference: H. R. Wanless, 1929, Illinois Geol. Survey Bull. 57, p. 49, 73, 83, 88, 122, 142.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 84. In Carbondale formation, a little below Colchester (No. 2) coal.

Exposed in shale pits north of Gilchrist, Mercer County.

Gile Mountain Formation

Gile Mountain Schists

Devonian: East-central Vermont and northwestern and west-central New Hampshire.

C. G. Doll, [1944]. Vermont State Geologist 24th Rept. 1943–1944, p. 18–19, pl. 3, 4. Light- to dark-gray chiefly quartz-mica schists. Less abundant are thin beds of massive and sheared quartzite, occasional coarse feldspathic schists, calcareous beds, and some graphic layers. Becomes more highly metamorphosed toward western part of outcrop belt where predominantly coarse amphibolites are prevalent. Thickness (excluding Meetinghouse slates) estimated about 6,500 feet. Meetinghouse slates, which are gradational westward into the schists, are the upper member of unit. Lower Devonian.

W. S. White and M. P. Billings, 1951, Geol. Soc. America Bull., v. 62, no. 6, p. 654–656, 662, pl. 1. Formation restricted to exclude rocks exposed in southeast corner of Strafford quadrangle, east of Ammonoosuc thrust, which Doll mapped as Gile Mountain schist[s]. Tentatively assigned to Middle Ordovician.

M. P. Billings, 1955, Geologic map of New Hampshire (1:250,000) : U.S. Geol. Survey. Geographically extended to New Hampshire. Middle Ordovician(?).

J. G. Dennis, 1956, Vermont Geol. Survey Bull. 8, p. 19–22, pl. 1. Discussion of gradational relationship with underlying Waits River formation. Included in St. Francis group. Lower to Middle Devonian.

M. P. Billings, 1956, The geology of New Hampshire, pt. 2, bedrock geology: Concord, New Hampshire State Plan. Devel. Comm., p. 10–11, 94–98, geol. map. Correlation chart shows Gile Mountain formation stratigraphically above Standing Pond volcanics and below Meetinghouse slate. Waits River, Standing Pond, Gile Mountain, and Meetinghouse formations are probably Middle Ordovician; may possibly be Silurian and (or) Devonian. Map bracket shows Gile Mountain as Middle Ordovician(?).

V. R. Murthy, 1958, Jour. Geology, v. 66, no. 3, p. 276–287. If structural interpretation given in present paper is correct, the calcareous rocks in East Barre quadrangle, here termed "Waits River formation" are youngest in Vermont sequence. Westmore and Gile Mountain formations, in all probability, are one and the same, being repeated on limbs of a syncline.

L. M. Hall, 1959, Vermont Geol. Survey Bull. 13, p. 28–34, 36–40. Formation described in St. Johnsbury quadrangle where it consists mainly of 5,000 feet of interbedded quartz-mica schist, micaceous quartzite, and minor amounts of feldspathic granulite and calc-silicate rock. Overlies Waits River formation; underlies Meetinghouse slate. Most workers agree age is Silurian and (or) Devonian. Discussion of age relations of rocks in Vermont sequence. According to one theory, Waits River and Gile Mountain could be equivalent in age, but, according to another theory, the Gile Mountain could be older than Waits River.

W. M. Cady, 1960, Geol. Soc. America Bull., v. 71, no. 5, p. 576, pl. 3. Formation of northeast Vermont is believed to be in section stratigraphically above Ammonoosuc volcanic rocks in west limb of Boundary Mountain anticlinorium. Billings (1956) suggests that Gile Mountain may be in higher stratigraphic position than the Ammonoosuc, although in an earlier interpretation (1955, map) he had tentatively placed the Gile Mountain in a stratigraphic position well beneath the Ammonoosuc. In northernmost Vermont, the Gile Mountain is continuous westward in Connecticut Valley-Gaspe synclinorium with identical slate, graywacke, and quartzite referred to Westmore formation (Doll, 1951), although farther south in Vermont belts of silty limestone are included in such terrane. Where this occurs, the belts of limestone are variously referred to as Waits River formation (Dennis, 1956; White and Jahns, 1950), or Barton River formation (Doll, 1951), or both (Murthy, 1957, Vermont Geol. Survey Bull. 10). Similar rocks with limestone interbeds crop out east of Gile Mountain formation in northern New Hampshire, where they have been referred to Waits River formation (Billings, 1955; 1956). Devonian.

Named for exposures on Gile Mountain in southern part of Strafford quadrangle, Vermont.

Giles Formation[1]

Silurian and Lower Devonian: Southwestern Virginia and southeastern West Virginia.

Original references: M. R. Campbell, 1894, Geol. Soc. America Bull., v. 5, p. 171, 177, pl. 4; 1896, U.S. Geol. Survey Geol. Atlas, Folio 26, p. 2.

Named for Giles County, Va.

Gilford Gabbro[1]

Devonian or Carboniferous: East-central New Hampshire.

David Modell, 1936, Geol. Soc. America Bull., v. 47, no. 12, p. 1895, 1898–1899, pl. 1. Dark gabbro with an unusual texture. Groundmass is a diabasic intergrowth of feldspar and greenish augite; in this are set large black clotlike hornblende spheroids each of which is a single crystal but poikilitically encloses numerous feldspar crystals similar to those in the matrix. Hornblende stands out in relief on weathered surfaces. Older than Endicott diorite; younger than Moat volcanics. Contacts not exposed. Assigned to White Mountain magma series.

Crops out one-fourth mile east of Gilford Station in northwestern corner of Belknap Mountains area. Best exposures found at 600-foot elevation on small bench which forms westernmost spur of Locke's Hill.

Gill Breccia (in Vieja Group)

Tertiary: Southwestern Texas.

R. K. DeFord, 1958, Texas Jour. Sci., v. 10, no. 1, p. 13, 14–17. Name proposed for a series of flow breccias consisting of three rock types: medium gray fragments in a grayish-red matrix; mottled fragments (pink, green, yellow, gray, and brown) in a dark-greenish-gray to orange-pink matrix; brecciated to massive light-olive-green to greenish-gray fine-grained rock. Contains blocks of massive Lower Cretaceous limestone, some of them as large as a three-story building. Maximum thickness 300 feet in type section. In most exposures, Gill breccia is concordant with underlying Jeff conglomerate; where Jeff conglomerate is absent or difficult to detect, the Gill forms the basal unit of the group; upper surface of Gill appears to form buried hills under the Colmena tuff (new).

Type section: Colmena Canyon (Gill Canyon) in the Rim Rock country, Presidio County.

†Gillespie Formation (in Trinity Group)[1]

Lower Cretaceous (Comanche Series): Central Texas.

Original reference: R. T. Hill and T. W. Vaughan, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 2, p. 221.

V. E. Barnes, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1955. Used in a quote sense and described as red beds occurring locally within Travis Peak formation. They are derived from red Cambrian sandstones and are at different stratigraphic levels, depending upon location of sandstone from which they were derived.

Probably named for Gillespie County.

Gilliam Limestone

Gilliam Thin-Bedded Member (of Capitan Limestone)[1]

Permian (Guadalupe Series) : Western Texas.

Original reference: J. A. Udden, C. L. Baker, and E. Böse, 1916, Texas Univ. Bur. Econ. Geology and Tech. Bull. 44, p. 52.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 654–656, pl. 2. All beds of upper Guadalupe age have been placed in Capitan limestone, a chronologic unit that included Altuda, Vidrio, and Gilliam members. Capitan is herein restricted to that part of former Vidrio member, or reef facies, that is upper Guadalupe (post-Word) in age; both Altuda and Gilliam are given formational rank. Altuda, in western part of Glass Mountains, consists of siliceous shales and thin limestones that were laid down near margins of Delaware Basin; Capitan, in central part of mountains, is reef deposit, and Gilliam, in eastern part, a back-reef (shelf) deposit. Each formation grades into the other, and all are approximately of same age.

Exposed in Gilliam Canyon, Glass Mountains, Marathon region, Brewster County.

Gilman Quartzite[1]

Lower Cambrian : Southern Quebec, Canada, and northwestern Vermont.

Original reference: T. H. Clark, 1934, Geol. Soc. America Bull., v. 45, no. 1, p. 6, 10.

T. H. Clark, 1936, Royal Canadian Inst. Trans., v. 21, pt. 1, p. 137, 144–146. Light-gray or buff quartzite which weathers to a lighter color. At base is a coarse grit; beds of conglomerate occur near top. Thickness 3,000 feet. Underlies Dunham dolomite conformably; overlies West Sutton slate. Type locality cited.

V. H. Booth, 1950, Geol. Soc. America Bull., v. 61, no. 10, p. 1135, 1136, 1148–1149. Geographic extension into northwestern Vermont.

A. B. Shaw, 1958, Geol. Soc. America Bull., v. 69, no. 5, p. 523–525, 532 (fig. 5), pl. 1. Thickness about 500 feet in St. Albans area, Vermont. Base not exposed. Underlies Dunham dolomite. Lower Cambrian (Georgian series). Unit has been called Brigham Hill graywacke by Jacobs (1935), but this name has not been generally adopted.

Type locality: Oak Hill, Sutton quadrangle, Quebec. Named for Gilman, 3 miles east of Sweetsburg.

Gilman Sandstone Member (of Leadville Dolomite)

Lower Mississippian : West-central Colorado.

Ogden Tweto and T. S. Lovering, 1947, Colorado Mineral Resource [Bull], p. 380, (chart). Gray sandstone, black cherty dolomite, and breccia containing much black clay. Thickness 20 to 50 feet.

Ogden Tweto, 1949, Colorado Sci. Soc. Proc., v. 15, no. 4, p. 152 (table 1), 177–184. Reproposed for sandstone and associated breccia at base of Leadville limestone (or dolomite). Consists of lenticular beds of sandstone, dolomitic sandstone, or local quartzite, at base, overlain by sandy and locally cherty dolomite which at most places is interbedded with and overlain by breccia of dolomite and chert; sandstone is yellow, buff, or light gray, medium to coarse grained, and slightly arkosic; individual sandstone beds 2 to 24 inches thick; sandy dolomite is dense, dark, and weathers light; typically brecciated and contains chert in fragments, nodules, and lenticles. Thickness commonly 10 to 20 feet; range from 5 to 50 feet observed. Underlies massive gray dolomite member; in most places, contact is a few feet of fine-grained structureless soft dark-brownish-gray dolomite; separated from underlying Chaffee formation (Dyer dolomite member); by unconformity.

L. R. Litsey, 1958, Geol. Soc. America Bull., v. 69, no. 9, p. 1157. Noted at Wellsville and Calcite, Fremont County.

Named for exposures on cliffs of Eagle Canyon at Gilman, Pando area, Eagle County.

Gilmanton Monzodiorite[1]

Devonian or Carboniferous: East-central New Hampshire.

David Modell, 1936, Geol. Soc. America Bull., v. 47, no. 12, p. 1902–1903, pl. 1. Monzodiorite with striking differences in texture and composition of ferromagnesian minerals. Most characteristic type is equigranular to subporphyritic, yellow to pinkish. Feldspar is main constituent. Darker colored and medium grained with an even granular texture on Piper Mountain; biotite is chief dark mineral. Light colored and distinctly subporphyritic on Goat Pasture Hill; oblong phenocrysts of white feldspar are set in matrix of anhedral finer grained feldspar, and augite and hornblende are often concentrated along phenocryst borders. Intrudes older schists of the area. Older than Albany quartz syenite and Belknap syenite. Assigned to White Mountain magma series.

Named from township of Gilmanton, Belknap County. Occupies broad band along southwestern edge of Belknap complex extending from Piper Mountain on the northwest to Goat Pasture Hill on southeast.

Gilmer Schist

See Hurricane Graywacke.

Gilmore Limestone

Gilmore Limestone (in Greene Formation)[1]

Permian: Northern West Virginia.

Original reference: R. V. Hennen, 1909, West Virginia Geol. Survey Rept. Marshall, Wetzel, and Tyler Counties, p. 173.

Thomas Arkle, Jr., 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 118 (table 1). Table of classification and nomenclature lists Gilmore in Greene series above Upper Rockport limestone and below Gilmore coal.

Probably named for association with Gilmore coal.

Gilmore Sandstone Member (of Greene Formation)[1]

Permian: Southwestern Pennsylvania, eastern Ohio, and northern West Virginia.

Original reference: J. J. Stevenson, 1876, Pennsylvania 2d Geol. Survey Rept. K, p. 38–39.

Thomas Arkle, Jr., 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 118 (table 1). Table of classification and nomenclature lists Gilmore sandstone in Greene series above Gilmore coal and below Windy Gap coal.

Named for exposures in Gilmore Township, Greene County, Pa.

Gilmore City Limestone[1]

Gilmore City Limestone (in Easley Group)

Mississippian (Kinderhook Series) : North-central Iowa.

Original reference: F. M. Van Tuyl, 1925, Iowa Geol. Survey, v. 30, p. 113–114.

J. M. Weller, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 101, 146, 150, chart 5. Shown on standard Mississippian stratigraphic section as uppermost formation in Easley group (new) underlying Fern Glen formation and overlying Sedalia formation. In Iowa overlies Iowa Falls dolomite. Also termed Alden formation.

L. A. Thomas, 1960, Tri-State Geol. Soc. Guidebook 24th Ann. Field Conf., p. [3–5, 17–18]. Van Tuyl (1925) considered that there was an erosional surface of about 75 feet of relief upon Iowa Falls dolomite and that Gilmore City limestone was decidedly younger than Iowa Falls dolomite. Present study suggests that Iowa Falls dolomite is in part a dolomitized lateral equivalent of Gilmore City limestone.

Exposed in Gilmore Portland Cement Co.'s quarry, 1½ miles northwest of Gilmore City, Pocahontas County.

Gilmore Gulch Formation[1]

Miocene, pre-upper (?) : Central Nevada.

Original reference: H. G. Ferguson, 1933, Nevada Univ. Bull., v. 27, no. 3, p. 21.

Named for exposures in Gilmore Gulch, Tybo district, Nye County.

Gimlet cyclothem[1] (in McLeansboro Group)

Gimlet cyclothem (in Modesto Formation)

Pennsylvanian : Northern, western, and southern Illinois.

Original reference: H. R. Wanless, 1931, Illinois Geol. Survey Bull. 60, p. 182, 192.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 60, 116–117, 193, 194, pls. 2, 5. Thickness of cyclothem 15 to 85 feet. Includes (ascending) Gimlet sandstone, Gimlet coal, and Lonsdale limestone. Gimlet sandstone has maximum thickness of 50 to 60 feet but is locally absent in some localities where higher Gimlet beds rest on Farmington shale; sandstone fills channels that cut from 50 feet above coal No. 7 to about 5 feet above Brereton limestone. Cyclothem is separated by erosional unconformities from Sparland cyclothem below and Trivoli and Exline cyclothems above. Derivation of name given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 52 (table 2), 55 (table 3). In Modesto formation (new). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Named for exposure on Gimlet Creek in SE¼ sec. 16, T. 12 N., R. 9 E., Marshall County.

Gimlet Limestone[1] (in McLeansboro Formation)

Pennsylvanian : Central western Illinois.

Original reference: H. R. Wanless, 1931, Illinois Geol. Survey Bull. 60, p. 179–193.

Derivation of name not stated.

774–954—vol. 2—66——5

Gimlet Sandstone Member (of Modesto Formation)

Gimlet Sandstone (in McLeansboro Group)

Pennsylvanian: Western northern Illinois.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 60, 116–117. Gimlet sandstone has maximum thickness of 50 to 60 feet but is locally absent. Fills channels that cut from 50 feet above coal No. 7 to about 5 feet above Brereton limestone. Unconformable on Farmington shale. In Gimlet cyclothem, McLeansboro group.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 38, 49 (table 1). Included in Modesto formation (new). Occurs above Farmington shale member and below Lonsdale limestone member. Type locality stated. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type locality: On Gimlet Creek in SE¼ sec. 16 T. 12 N., R. 9 E., Marshall county.

Ginseng Siltstone Member (of Brodhead Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 76, 151–152. Lower member of Brodhead formation, Athertonville facies (new). Massive slightly calcareous buff drab siltstone 35 feet thick. In type area, underlies Rolling Fork limestone member (new), Athertonville facies (new), and overlies New Providence formation, Junction City facies (new).

Type section: Along road leading up hill west of old Ginseng post office, southeastern LaRue County.

Girard Shale Member (of Chemung Formation)[1]

Girard Formation (in Conneaut Group)

Upper Devonian: Northwestern Pennsylvania and southwestern New York.

Original reference: I. C. White, 1881, Pennsylvania 2d Geol. Survey Rept. Q_4, p. 118–119, 251.

Bradford Willard, 1937, Pennsylvania Acad. Sci. Proc., v. 11, p. 32. Generalized succession for marine Upper Devonian of northwestern Pennsylvania and southwestern New York listed. Girard formation (I. C. White's Girard shale) is shown in Conneaut group. Includes Cuba sandstone.

I. H. Tesmer, 1955, New York State Mus. Sci. Service Circ. 42, p. 17. Girard shale is here included in Northeast shale member of Canadaway formation.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. As mapped, Conneaut group includes "pink rock" of drillers and "Chemung" and "Girard" formations of northwestern Pennsylvania.

Well exposed along Elk Creek above Girard, Erie County, Pa.

Girardeau Limestone[1]

Lower Silurian: Southeastern Missouri and southwestern Illinois

Original reference: G. C. Swallow, 1855, Missouri Geol. Survey 2d Ann. Rept., pt. 1, p. 109.

J. M. Weller, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 56. Girardeau limestone normally overlies Orchard Creek shale, which is considered to be southward continuation of some part of Maquoketa shale generally conceded to be Upper Ordovician in age. There is no sharp break between the Girardeau and Orchard Creek. It it possible that Girardeau limestone should also be referred to Ordovician.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown on correlation chart in Alexandrian group, Albion series. Underlies Edgewood limestone.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, p. 260, chart 2. Shown on correlation chart as Ordovician, Cincinnatian. Age of Thebes sandstone, Orchard Creek shale, and Girardeau limestone is still under study. They may belong at base of Silurian.

Named for outcrops 1½ to 2 miles above Cape Girardeau, Cape Girardeau County, Mo.

Gird[1] (shales)

Lower Cretaceous: Montana.

Original reference: C. R. Keyes, 1926, Pan-Am. Geologist, v. 46.

Derivation of name not stated.

Girkin Formation[1]

Girkin Limestone

Upper Mississippian: Western Kentucky and northern Alabama.

Original reference: A. H. Sutton and J. M. Weller, 1932, Jour. Geology, v. 40, no. 5, p. 430, 440, 441.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 766 (fig. 1), 828. From Todd County to Grayson County, Ky., the Bethel sandstone is absent and Renault and Paint Creek formations together form a limestone that cannot be easily subdivided. Name Gasper has been used for this limestone, but persistent miscorrelation has resulted in such confusion that name is no longer useful. Hence, beds are now known as Girkin limestone. The Girkin consists almost entirely of massive light-gray limestone which cannot be distinguished from underlying Ste. Genevieve except by fossil content. Chester series.

Well exposed in hills that nearly surround village of Girkin, Warren County, Ky.

Gizzard Formation (in Lee Group)[1]

Gizzard Member (of Lookout Sandstone)

Gizzard Group

Gizzard Member (of Lee Formation)

Lower Pennsylvanian: Eastern Tennessee and northern Georgia.

Original reference: J. M. Safford, 1869, Geology of Tennessee, p. 369–370.

H. R. Wanless, 1939, (abs.) Geol. Soc. America Bull., v. 50, no. 12, p. 1941. Listed as member of Lee formation.

V. H. Johnson, 1946, Coal deposits on Sand and Lookout Mountains, Dade and Walker Counties, Georgia: U.S. Geol. Survey Prelim. Map. Geographically extended into northern Georgia where it is reduced to member status in Lookout sandstone. Consists of gray shales and fine-grained sandstone; on Lookout Mountains, shale is minor part of member; in Cole City area, a silty saccharoidal carbonaceous sandstone as much as 150 feet thick occurs 30 to 50 feet below Sewanee member.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 1, 4, 19, pls. 2, 3, 4. Rank raised to group. Includes all strata between top of Mississippian and base of Sewanee conglomerate. Thickness as much as 700 feet; at type locality 224 feet. Includes (ascending) Raccoon Mountain formation (new), Warren Point sandstone, and Signal Point shale (new); group is so subdivided on basis of wide distribution of Warren Point sandstone. Pottsville series. Type locality stated.

Type section: In gorge of Big Fiery Gizzard Creek (Gizzard Cove), about 2 miles south of Tracy City, Grundy County, Tenn.; geographic names used here are those on White City quadrangle, rather than "Little Fiery Gizzard" of Stafford.

Glacier Park facies (of Belt Series)

Precambrian: Western Montana, and southern Alberta and southern British Columbia, Canada.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1877. Within its northern basin, Belt series is divisible into facies that differ in lithology, stratigraphic sequence. thickness, recorded conditions of deposition, fauna, and flora. Glacier Park facies is the development of the series in Glacier National Park, Mont., Waterton Lakes National Park, Alberta, and westward to the Flathead trough. Grades into the dominantly clastic Purcell facies.

In Glacier-Waterton Parks.

Glacier Peak Volcanics[1]

Quaternary: Washington.

Original reference: H. C. Culver, 1936, Washington Div. Geology Bull. 32, p. 21.

Glacier Peak, Snohomish County.

Glacier Point Glaciation

Glacier Point glacial stage[1]

Pleistocene: Eastern California.

Original reference: F. E. Matthes, 1929, Science, new ser., v. 70, p. 75–76.

Ernst Antevs, 1945, Am. Jour. Sci., v. 243A, table 2. Correlated with McGee glaciation.

Change of name from stage to glaciation made in accordance with adoption of stratigraphic code, June 1961.

Named for occurrence of erratic boulders above Glacier Point, Yosemite National Park.

Glacier Ridge Agglomerate

Quaternary: Southwestern Alaska.

G. C. Kennedy and H. H. Waldron, 1947, U.S. Geol. Survey Alaskan Volcano Inv. Rept. 2, pt. 2, pl. 2. Name appears on geologic map legend.

Mapped on south flank of Pavlof Volcano, Alaska Peninsula.

Glacier Ridge Andesite

Quaternary: Southwestern Alaska.

G. C. Kennedy and H. H. Waldron, 1947, U.S. Geol. Survey Alaskan Volcano Inv. Rept. 2, pt. 2, pl. 2. Name appears on geologic map legend.

Mapped on south flank of Pavlof Volcano, Alaska Peninsula.

†Glade Sandstone[1]

Devonian or Carboniferous: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 202.

Gladeville Sandstone

Gladeville Sandstone (in Pottsville Group)[1]

Middle Pennsylvanian: Southwestern Virginia and southeastern Kentucky.

Original reference: M. R. Campbell, 1893, U.S. Geol. Survey Bull. 111, p. 28, 33.

H. R. Wanless, 1946, Geol. Soc. America Mem. 13, p. 141. Sandstone between the Wise (above) and Norton formations.

U.S. Geological Survey does not use the term Pottsville Group in Kentucky.

Named for Gladeville (now called Wise), Wise County, Va.

Glady Fork Sandstone[1] (in Bluestone Group)

Glady Fork Sandstone Member (of Bluestone Formation)

Mississippian (Chesterian): Southwestern Virginia and southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 294, 321.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 182–183, p. 15. Geographically extended into Virginia and redefined as member of Bluestone formation. Overlies Pipestem shale member; underlies Mud Fork member. Thickness 25 to 40 feet. In Chester series.

Type locality: In end of ridge between Brush Creek and Glady Fork, southeast of Princeton, Mercer County, W. Va.

Glance Conglomerate[1] (in Bisbee Group)

Lower Cretaceous (Comanche Series): Southeastern Arizona.

Original reference: F. L. Ransome, 1904, U.S. Geol. Survey Prof. Paper 21, p. 56, 57.

James Gilluly, 1956, U.S. Geol. Survey Prof. Paper 281, p. 71, pl. 5. Described in central Cochise County. Thickness varies rapidly in short distances owing to irregularities in surface of unconformity beneath. Thickness of several thousand feet reported at Bisbee. Unconformable above older rocks; locally overlies Pinal schist; underlies Morita formation.

Named for Glance, on El Paso and SW Railroad near Glance mine, Bisbee quadrangle.

Glasco Limestone

Glasco Limestone Lentil (of Rondout Waterlime)

Upper Silurian: Southeastern New York.

G. H. Chadwick, 1944, New York State Mus. Bull. 336, p. 44, 46, 47, 51 [1946]. Name proposed for limestone lentil near top of Rondout. Maximum thickness 10 feet.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. Glasco and Cobleskill limestones appear to be youngest fossil-bearing Silurian in New York. Name Glasco is preferred to that of Le Fever because the latter has never been adequately described. Chart shows Glasco above Rosendale waterlime and below Whiteport waterlime.

Type exposure on West Wood Farm, Route 9–W, west of Glasco, Ulster County.

Glassboro Gravel[1]

Glassboro phase (of Bridgeton Formation)

Pleistocene: New Jersey and southeastern Pennsylvania.

Original reference: H. C. Lewis, 1881, Philadelphia Acad. Nat. Sci. Proc., v. 32, p. 296–309.

J. C. Martens, 1956, Rutgers Univ. Bur. Mineral Research Bull. 6, p. 72–74. Glassboro phase of Bridgeton (Salisbury and Knapp, 1917, New Jersey Geol. Survey, v. 8) occurs south and west of line drawn from Berlin down Mullica River to Atlantic Coast. Phase includes greater part of formation and consists of fine sand and gravel with a few boulders and some clay.

Probably named for occurrence at Glassboro, Gloucester County, N.J.

Glass Buttes Series[1]

Miocene: Central southern Oregon.

Original reference: A. Waters, 1927, Jour. Geology, v. 35, p. 442–452.

Forms main part of Glass Butte Range, Lake County.

†Glass Mountain Formation (in Cimarron Group)[1]

Permian: Southern Kansas and northwestern Oklahoma.

Original reference: F. W. Cragin, 1897, Am. Geologist, v. 19, p. 353, 355.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 101. Abandoned by Oklahoma Geological Survey. An indefinite Permian unit.

Exposed in Glass Mountains of Major County, Okla.

Glass Mountain Lava

Recent: Northern California.

C. A. Anderson, 1941, California Univ. Dept. Geol. Sci. Bull., v. 25, no. 7, p. 374, 375–376. Name applied to lava of recent eruptions at Glass Mountain. Material is mostly rhyolite pumice and obsidian. Flows mark close of volcanic history in area.

Occurs in Medicine Lake Highland, approximately in center of Modoc Lava Bed quadrangle.

†Glass Mountains Formation[1]

Permian: Western Texas.

Original reference: P. B. King, 1933, Historical Geology, by R. C. Moore, p. 325.

Glass Mountains.

Glastonbury Formation

Glastonbury Granite Gneiss[1]

Paleozoic (pre-Pennsylvanian? or Ordovician?) Central Connecticut and southern Massachusetts.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 114, 115, map.

W. G. Foye, 1949, Connecticut Geol. Nat. History Survey Bull. 74, p. 51. Mapped as Monson orthogneiss.

G. E. Collins, 1954, Connecticut Geol. Nat. History Survey Quad. Rept. 4, p. 9–14, 26. Gneiss recognized in Ellington quadrangle as a unit separate from the belt of Monson gneiss which occurs east of Bolton formation exposures. Follows nomenclature of Gregory (1906). Eastern part of unit, here discussed, is light gray; western part is darker. Grades eastward into Bolton garnet-muscovite schist, and westward into a hornblende schist. Pre-Mississippian.

Norman Herz, 1955, Connecticut Geol. Nat. History Survey Quad. Rept. 5, p. 8–16. Areal variation in relative amounts of constituent minerals and degree of foliation and lineation. Four facies described in Glastonbury quadrangle: schistose, porphyroblastic, flaser gneiss, and highly felsic eastern border. Aplite dikes and pegmatites common. Devonian (?).

J. M. Aitken, 1955, Connecticut Geol. Nat. History Survey Quad. Rept. 6, p. 5–6, 15–16. Termed a formation.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Pre-Triassic. Derivation of name given.

Frederick Stugard, Jr., 1958, U.S. Geol. Survey Bull. 1042–Q, p. 619, 627–630, pl. 56. Pegmatites of Middletown area cut metasediments of Bolton schist of pre-Mississippian (?) age and, in ascending order of sequence, mafic gneisses, Glastonbury granite gneiss. Maromas granite gneiss, and Monson gneiss. Position of these formations in stratigraphic column cannot be determined with accuracy; their maximum age is indicated by their relation to the pegmatities, which have been dated by uranium- and thorium-lead ratios as about 260 million years old, presumably Mississippian.

John Rodgers, R. M. Gates, and J. L. Rosenfeld, 1959, Connecticut Geol. Nat. History Survey Bull. 84, p. 19, 21, fig. 3. Unconformably underlies Collins Hill formation (new). Ordovician (?).

Named for town of Glastonbury, Hartford County, Conn. An elongate body of biotite gneiss, 4½ miles in maximum width; extends from Great Hill, Middletown area, Connecticut, northward into Massachusetts.

Gleeson Quartz Monzonite

Triassic or Jurassic: Southeastern Arizona.

James Gilluly, 1956, U.S. Geol. Survey Prof. Paper 281, p. 8, 55–59, pl. 5. Consists of three principal facies. The first two facies—collectively called main facies—differ chiefly in the obvious alteration that has affected one and not the other and are mapped together. Main facies is coarse-grained light-gray rock that ranges to greenish gray where highly chloritized and to pink where it contains sufficient pink microcline; weathered surfaces commonly rusty brown. Practically all stages of alteration of main facies of the quartz monzonite recognized, from nearly unaltered normal igneous rocks to recrystallized gneissic rocks, though most of the formation is crystalloblastic-cataclastic in texture and some parts practically entirely cataclastic and grade into true mylonites. Third facies—alaskite facies—differs from other two in being practially devoid of dark minerals. Rock ranges from practically white through pale to pinkish gray. Rock ranges from fine aplitic-appearing material to fairly coarse in texture. Nearly all contacts of Gleeson quartz monzonite are with alluvium or are faults; overlapped by some of the S O volcanics (new) locally; cuts Pinal schist near South Pass.

Crops out over an area of nearly 30 square miles, in Tps. 18 and 20 S., Rs. 24 and 25 E., in southern part of Dragoon Mountains, and in pediment to south and east of it, central Cochise County. Town of Gleeson is at eastern side of the mass, and the Gleeson-Tombstone Road crosses it near its center.

Glenarm Series[1]

Lower Paleozoic (?) : Maryland, New Jersey, Pennsylvania, and Virginia.

Original reference: E. B. Knopf and A. I. Jonas, 1922, Geol. Soc. America Bull., v. 33, p. 110.

A. I. Jonas and G. W. Stose, 1938, Washington Acad. Sci. Jour., v. 28, no. 8, p. 346–347. In Frederick County, Md., includes Wakefield marble, Silver Run limestone, Ijamsville phyllite, Urbana phyllite, and Marburg schist (all new).

G. W. Stose and A. I. Jonas, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. C–67, p. 95–96, 103, 106. Peach Bottom slate and Cardiff conglomerate considered Ordovician (?) ; hence, they are removed from Glenarm series.

Ernst Cloos and Anna Hietanen, 1941, Geol. Soc. America Spec. Paper 35, p. 207. Detailed discussion in connection with geology of Martic overthrust in Pennsylvania and Maryland. It is not possible to determine age of the Glenarm definitely; it certainly is not Precambrian. Further detailed work will be necessary to furnish data on basis of which more definite conclusions can be based.

F. M. Swartz, 1948, Am. Assoc, Petroleum Geologists Bull., v. 32, no. 8, p. 1506–1512. In present review, there is much evidence favoring opinion that Glenarm series, as developed south of Chester Valley, is Cambro-Ordovician in age and less reason for supposition of Precambrian age.

Norman Herz, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 980. Includes (ascending) Setters quartzite, Cockeysville marble, Wissahickon schist, Peters Creek schist, Cardiff conglomerate, and Peach Bottom slate. Age probably early Paleozoic.

G. J. Wasserburg, F. J. Pettijohn, and J. Lipson, 1957, Science, v. 126, no. 3269, p. 355–357. Report discusses A^{40}/K^{40} ages of micas and feldspars from Glenarm series near Baltimore. Concluded that both the age and the metamorphism of Glenarm series and the time of pegmatite injection was about 350 million years ago corresponding to the end of the Ordovician period on the Holmes time scale. The absolute age is thus seen to coincide with ages of pegmatites in New England and North Carolina. This evidence supports view that whole eastern Appalachian region was "simultaneously" subject to igneous and metamorphic activity about 350 ± 20 million years ago. Thesis that Glenarm series is Precambrian because of its degree of metamorphism is untenable on basis of date presented here. These A^{40}/K^{40} dates do not, however, preclude the possibility that series was originally deposited during Precambrian time.

P. W. Choquette, 1960, Geol. Soc. America Bull., v. 71, no. 7, p. 1029 (table 1). Series comprises (ascending) Setters, Cockeysville, Wissahickon, and Peters Creek formations. Pre-Silurian.

Named for typical development near Glenarm, 13 miles northeast of Baltimore, Md.

Glencairn Shale Member (of Purgatoire Formation)[1]

Lower Cretaceous: Eastern Colorado.

Original reference: G. I. Finlay, 1916, U.S. Geol. Survey Geol. Atlas, Folio 203.

K. M. Waagé, 1953, U.S. Geol. Survey Bull. 993, p. 6 (fig. 2), 7, 9–11, pls. 1, 2, 4, 5. Name extended to include subdivisions of Purgatoire in Fremont, Pueblo, and Huerfano Counties. Finlay's description is not sufficiently detailed to indicate certainly that his unit corresponds exactly to Glencairn as used in this report, but the discrepancy, if any, is not great. Consists of alternating units of olive-brown thin-bedded sandstone and gray and black shale totaling between 70 and 100 feet in thickness. Common sequence is three units of shale alternating with three units of sandstone. Pattern of six alternating units of shale and sandstone within the Glencairn is typical of member in Canon City embayment area, although pattern is obliterated locally by thickening of sandstone units at expense of shale units. At base of lower sandstone, and commonly separated from it by thin bed of silty shale, is a bed of conglomeratic sandstone from 2 to 18 inches thick; this conglomeratic bed rests on planed surface that truncates cross lamination in underlying Lytle sandstone member. Disconformably underlies Dakota sandstone.

Named for a tract of land a few miles north of Lytle, Colorado Springs region.

Glen Canyon Group[1]

Triassic and Jurassic: Southern and eastern Utah, northern Arizona, southwestern Colorado, and northwestern New Mexico.

Original reference: A. A. Baker and others, 1927, Am. Assoc. Petroleum Geologists Bull., v. 11, no. 8, p. 787 (table 1).

James Gilluly and J. B. Reeside, Jr., 1928, U.S. Geol. Survey Prof. Paper 150–D, p. 68–73. Includes (ascending) Wingate sandstone, Todilto(?) formation, and Navajo sandstone. Underlies San Rafael group; overlies Chinle formation. Jurassic(?).

A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1936, U.S. Geol. Survey Prof. Paper 183, p. 4–6, pls. Includes (ascending) Wingate sandstone, Kayenta formation (previously designated "Todilto" and "Todilto?" formation), and Navajo sandstone.

A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 9, p. 1667–1668. Includes (ascending) Wingate sandstone, Kayenta formation, and Navajo sandstone. New conclusions as to correlation of units pose problem in stratigraphic nomenclature. Strict application of principles of priority would require that name Wingate be applied to unit heretofore called Entrada and would require that new name be applied to Wingate sandstone of Utah and adjacent regions. In current usage for Colorado Plateau and surrounding areas, these names apply to distinctive and widespread formations, and names are firmly entrenched in literature. Abandonment of this nomenclature through principles of priority would be confusing. Name Entrada is extended to include sandstone at type locality of Wingate sandstone, and name Wingate is retained for sandstone forming lower part of group, with understanding that original type locality of Wingate has been abandoned. Name Glen Canyon group extended to include undivided equivalents of Navajo, Kayenta, and Wingate that crop out below Entrada sandstone and Chinle formation in parts of New Mexico and Arizona.

F. W. Cater, Jr., 1954, Geology of the Bull Canyon quadrangle, Colorado: U.S. Geol. Survey Geol. Quad. Map [GQ–33]. In southwestern Colorado, includes Wingate sandstone, Kayenta formation, and Navajo sandstone. Overlies Chinle formation; underlies San Rafael group.

Paul Averitt and others, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 12, p. 2515–2535. Includes Moenave formation (new).

L. C. Craig and D. D. Dickey, 1956, Intermountain Assoc. Petroleum Geologists [Guidebook] 7th Ann. Field Conf., p. 93–97; J. C. Wright and D. D. Dickey, 1958, Intermountain Assoc. Petroleum Geologists Guidebook 9th Ann. Field Conf., p. 172–173. In southeastern Utah, includes (ascending) Wingate sandstone, Kayenta formation, and Navajo sandstone.

J. E. Harshbarger, C. A. Repenning, and J. H. Irwin, 1957, U.S. Geol. Survey Prof. Paper 291, p. 3 (fig. 2), 5–53, pl. 2. Described in Navajo country. Overlies Chinle formation; contact lies between Gregory's (1917, U.S. Geol. Survey Prof. Paper 93) "A" and "B" divisions of the Chinle. This reassignment of the Chinle "A" is based upon intertonguing between Wingate sandstone and Chinle "A" in several areas. Underlies various units of San Rafael group—Entrada sandstone, Carmel formation, or Entrada and Carmel undifferentiated. In Kachina Point and Navajo Creek areas, Arizona, includes (ascending) Wingate sandstone, Moenave formation, Kayenta formation, and Navajo sandstone; in Fort Wingate area, New Mexico, includes only Wingate sandstone (Lukachukai member).

R. G. Petersen, 1959, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–215. In Emmett Wash NE quadrangle, Coconino County, Ariz., group comprises (ascending) Moenave formation, Kayenta formation, and Navajo sandstone. Overlies Chinle formation. Upper Triassic(?) Lower Jurassic(?).

Named for exposures in Glen Canyon of Colorado River, Kane County, Utah.

Glendale Beds[1]

Eocene (Jackson): Eastern Texas.

Original reference: A. C. Ellisor, 1933, Am. Assoc. Petroleum Geologists Bull., v. 17, no. 11, p. 1302, 1316.

Crops out at Glendale, Trinity, and south of Groveton, Trinity County.

Glendale Granite[1]

Precambrian(?): Central northern Colorado.

Original reference: R. D. Crawford, 1909, Colorado Univ. Studies, v. 6, p. 97–131.

Occurs on both sides of Lefthand Canyon in vicinity of Glendale and Rowena, Boulder County.

Glendale Member (of Denmark Formation)

Middle Ordovician (Trentonian) : Northwestern New York.

P. A. Chenoweth, 1952, Geol. Soc. America Bull., v. 63, no. 6, p. 530–535. Even-bedded hard blue-gray calcilutites, calcareous shales, and coquinal calcarenites. Distinctive calcilutites rapidly disappear northward. Thickness 35 feet. Underlies upper unnamed member; overlies Camp member (new). Upper limit of unit arbitrarily placed above last zone of abundant calcilutites.

Named for Glendale, Lewis County.

†Glendale Shale[1]

Lower Mississippian : Southeastern Tennessee.

Original reference : J. H. Swartz, 1924, Am. Jour. Sci., 5th, v. 7, p. 24–26.

W. H. Hass, 1956, U.S. Geol. Survey Prof. Paper 286, p. 13. Swartz (1924) named the upper gray-shale unit of Hayes' "Chattanooga black shale" the Glendale shale. Swartz was of the opinion that beds he identified as Glendale were, prior to his work, a part of Fort Payne chert. Name "Glendale shale" is not used herein; beds so named by Swartz are called Maury formation.

Named for exposures at Glendale Station, just outside Chattanooga, on electric road to Signal Mountain.

Glen Dean Limestone[1] or Formation

Glen Dean Limestone (in Homberg Group)

Glen Dean Limestone (in Stephensport Group)

Upper Mississippian (Chester Series) : Kentucky, southern Illinois, southern Indiana, Tennessee, and southwestern Virginia.

Original reference: C. Butts, 1917, Mississippian formations of western Kentucky : Kentucky Geol. Survey, p. 97.

J. M. Weller, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 131, 135; J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 766 (fig. 1), 832–833. Uppermost formation in Homberg group (new). Underlies Tar Springs sandstone; overlies Hardinsburg sandstone.

T. G. Perry and N. M. Smith, 1958, Indiana Geol. Survey Bull. 12, p. 90–101, pl. 1. Described in Indiana where it attains thickness of 27 to 60 feet. Consists of gray or tan massive crystalline limestone in oolitic fossiliferous limestone in lower part; dark-gray shale and thin beds of impure limestone. Overlies Hardinsburg sandstone; underlies Tar Springs sandstone. Term Homberg group not applied in Indiana.

H. H. Gray, R. D. Jenkins, and R. M. Weidman, 1960, Indiana Geol. Survey Bull. 20, p. 36 (table 5), 38–39, pl. 1. Uppermost formation in Stephensport group (redefined). Formation has been defined as including a lower or main limestone member and an upper interbedded shale and limestone. Proposed here to restrict name Glen Dean to the more persistent main limestone member. In Huron area, only main limestone is present; in other areas, this restriction will reduce the Glen Dean to about one-half its former thickness. The interbedded shale and limestone should be placed in overlying Tar Springs formation. Thickness about 30 feet in Huron area [this report]. Conformably overlies Hardinsburg formation; unconformably underlies Mansfield formation. Chester series.

Named for exposures along railroad on both sides of Glen Dean, Breckenridge County, Ky.

Glendo Shale (in Phosphoria Group)

Glendo Shale Member (of Lykins Formation)

Permian: Eastern Wyoming, northeastern Colorado, and southwestern South Dakota.

G. E. Condra, E. C. Reed, and O. J. Scherer, 1940, Nebraska Geol. Survey Bull. 13, p. 2 (fig. 2), 5, 6, 10, 19 (fig. 6), 36, 45. Consists of red shale, partly sandy. Comprises the interval between the Forelle and Minnekahta limestones. Thickness 43 to 56 feet.

T. L. Broin, 1958, Dissert. Abs., v. 19, no. 1, p. 114. Member of Lykins formation in eastern Colorado. Underlies Forelle limestone; overlies Falcon tongue of Minnekahta limestone.

Type locality: In Spring Creek valley, 1 mile south and 2 miles west of Glendo, Wyo.

Glendon Limestone Member (of Byram Formation)

Glendon Limestone (in Vicksburg Group)[1]

Glendon Member (of Vicksburg Formation)

Oligocene: Alabama, Florida, and Mississippi.

Original reference: O. B. Hopkins, 1917, U.S. Geol. Survey Bull. 661–H, p. 298, 300.

F. F. Mellen, 1939, Mississippi Acad. Sci. Jour., v. 1, p. 18, 19. Member of Vicksburg formation. Includes Mint Spring facies at base. Overlies Forest Hill member; underlies Byram member.

H. V. Howe, 1942, Jour. Paleontology, v. 16, no. 2, p. 264–271. Discusses fauna at type locality of Glendon formation.

F. S. MacNeil, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 9, p. 1315 (fig. 1), 1316, 1329–1332. Rank reduced to member status in Byram formation. Underlies unnamed marl member; overlies sandy facies of Marianna limestone. At type section, lower 12 feet consists of coarsely porous, crumbly to hard, crystalline, orbitoidal limestone with well developed but unevenly cemented ledges and interbedded less resistant zones; hard ledges characteristically weather to "horsebone," and locally entire interval is more evenly indurated and so weathered; above the coarse limestone, and constituting remainder of type section, are at least three hard smooth yellowish-brown limestone ledges interbedded with soft fossiliferous argillaceous marl. Evidence indicates that the hard crystalline limestone and open-spaced coquinas of type section pass westward into thicker, more uniform section of buff to cream hard to soft argillaceous marlstone and tough limestone. Sharper faunal break exists between Marianna and Glendon in Alabama than around Vicksburg. Eastward from type locality, member becomes more uniformly indurated and difficult to differentiate from Marianna. In vicinity of Marianna, Fla., largely altered to dolomite; thickness at Marianna about 18 feet.

E. C. Tonti, 1955, Dissert. Abs., v. 15, no. 8, p. 1372. In stratigraphic investigation of Vicksburgian deposits in Mississippi, Alabama, and western Florida, two sedimentary cycles were identified. Lowermost cycle extends from disconformity at base of Mint Springs-Marianna formation to simlar break at top of Byram (in this report excludes Bucatunna marl).

Name Glendon redefined and applied to alternating crystalline limes and marls located, in part, stratigraphically above type section. Typical "horsebone" lithology is extremely variable weathering phenomenon which may develop on any limestone bed immediately beneath lower Bucatunna disconformity. Reference section designated.

Type locality: Glendon, a flag station on Southern Railway between Jackson and Walker Springs, in southern part of sec. 31, T. 7 N., R. 3 E., Clarke County, Ala. Reference section: St. Stephens Quarry, St. Stephens, Ala.

Glendora Volcanics

Miocene: Southern California.

J. S. Shelton, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 63. Series of flows, chiefly andesitic, breccias, tuffs, and related intrusives.

J. S. Shelton, 1955, Geol. Soc. America Bull., v. 66, no. 1, p. 45–89, pl. 1. Includes undisturbed tuffs, tuff breccias, massive flows, autobrecciated flows, dikes, probable vent fillings of various kinds, volcanic conglomerates, and possibly local fumarolic alteration products; in the field, 22 mappable varieties or members recognized. Thickness varies from a few hundred to over 3,000 feet. Includes Spadra felsophyre, Elephant Hill breccia, and Johnstone Peak tuff breccia (all new). Overlies pre-Upper Cretaceous crystalline rocks of the basement complex which here includes Mountain Meadows dacite. In some areas, upper part of volcanics is interbedded with upper Miocene Topanga formation; more commonly unconformably underlie some part of upper Miocene Puente formation.

Exposed in foothills of San Gabriel Mountains in vicinity of Glendora, in South Hills, and at northeast end of San Jose Hills, Los Angeles County.

Glen Ellen Formation

Pliocene(?) and Pleistocene: Northwestern California.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 16 (table 3), 98–99, pl. 6. Fluviatile gravel, sand, clay, and boulder deposits composed of materials derived from andesite and tuffs. Largest area of exposure, north and northwest of Glen Ellen, consists of stratified gravels and sands alternating with thick layers and lenses of conglomerates composed of andesite cobbles averaging 3 to 6 inches in diameter; at least 300 feet thick. Deposits may have been formed in part contemporaneously with gravels and sands of Huichica formation (new). Because formation rests upon folded Sonoma volcanics, it is believed to be Pleistocene but cannot be dated more definitely.

G. T. Cardwell, 1958, U.S. Geol. Survey Water-Supply Paper 1427, p. 26 (table 6), 47–54. As used in this report [Santa Rosa and Petaluma Valleys], formation consists of thick sequence (0 to about 3,000 feet) of deformed continental deposits that discontinuously overlie and locally interfinger with Sonoma volcanics and interfinger with Merced formation. The Glen Ellen includes the Glen Ellen of Weaver, the upper part of the Sonoma group of Gealey (1950 [1951]), and the older Quaternary alluvium of Travis (1952, California Div. Mines Bull. 162). Pliocene(?) and Pleistocene.

Named from Glen Ellen in eastern part of Santa Rosa quadrangle, Sonoma County. Exposed intermittently in a northwest-southeast direction for a distance of more than 13 miles; lies within old structural valley of which Kenwood and Sonoma Valleys are now a part.

Glenerie Limestone (in Oriskany Group)[1]

Lower Devonian: Southeastern New York.

Original reference: G. H. Chadwick, 1908, Science, new ser., v. 28, p. 346–348.

G. H. Chadwick, 1944, New York State Mus. Bull. 336, p. [83], 85–88 [1946]. Mapped as Glenerie limestone and chert. Composition ranges from limestone to solid chert beds, soft shale, and conglomerate. Beds are very blue to nearly black in fresh exposures; characteristically weather buff brown. Thickens greatly into limestone southward; northward in the Helderberg, grades into thin sandstone. Thickness about 30 feet in type exposure, which is described. Overlies Port Ewen beds in map area, the Catskill and Kaaterskill quadrangles; farther south overlies Connelly conglomerate. Derivation of name stated.

Type exposure at old quarry on east side of Route 9–W, ¼ mile north of Glenerie Mills, 4 miles below Saugerties, Ulster County. Named from old Glenerie white-lead mills on Esopus Creek at Glenerie Falls.

Glen Eyrie Shale Member (of Fountain Formation)[1]

Glen Eyrie Formation

Pennsylvanian: Eastern Colorado.

Original reference: G. I. Finlay, 1907, Jour. Geology, v. 15, p. 586–589.

K. P. McLaughlin, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 11, p. 1939 (fig. 2), 1942–1947. As used in this report [Colorado Springs quadrangle], Glen Eyrie is considered formation (this follows Finlay's original usage). Most completely developed and best exposed section, approximately 360 feet thick, is in and near Black Canyon at north edge of Manitou embayment and approximately three-fourths mile southwest of Finlay's probable type locality. Most of exposures are in cuts along Rampart Range Road and Black Canyon loop, both constructed in recent years. Overlies Madison limestone; gradationally underlies Fountain formation.

Well exposed on Glen Eyrie Creek, El Paso County. Glen Eyrie Creek now known as Queens Canyon.

Glenham Gneiss[1]

Precambrian; Southeastern New York.

Original reference: C. E. Gordon, 1911, New York State Mus. Bull. 148, p. 11, 18, 25–27, 33, 34, 78, 79, 85, 104.

Exposed between Fishkill Landing and New Beacon Mountain, Poughkeepsie quadrangle.

Glenhaven Member (of Guttenberg Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., figs. 3, 9. Dolomite, about 3 feet thick. Shown on columnar section as underlying Buckhorn member (new) of Dunleith formation (new) and overlying Garnavillo member (new) of Guttenberg formation.

In copy of guidebook used by compiler, in figure 3, name Glenhaven had been crossed out and name Garnet inserted. However, in figure 9, the name Garnet had been used to replace the name Garnavillo. Since the compiler had no way to determine what changes, if any, had been made in other copies of guidebook, it was impossible to be certain which names should be retained.

Occurs in Dixon-Oregon area.

Glenkirk Limestone[1]

Silurian (Niagaran) : West-central Tennessee.

Original reference: A. F. Foerste, 1903, Jour. Geology, v. 11, p. 566, 578–582, 692.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 251. Foerste used name Glenkirk to include lithologically indistinguishable Laurel and Lego limestones where the Waldron shale cannot be recognized. This report does not consider name Glenkirk necessary.

Named for Glenkirk Landing, Wayne County.

Glenmary Shale (in Crooked Fork Group)

Pennsylvanian (Pottsville Series) : Eastern Tennessee.

C. W. Wilson Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 6, 19, pls. 2, 3, 4. Includes beds between top of Coalfield sandstone (new) and base of Wartburg sandstone. Thickness usually 40 to 80 feet; at type locality 50 feet; 64 feet in Crooked Fork section; in southeast corner of Barthell Southwest quadrangle 20 feet; disappears in northern part of this quadrangle as it is overlapped by Wartburg sandstone.

Named from Glenmary, Robbins quadrangle, Scott County.

†Glenn Formation[1]

Pennsylvanian: Central southern Oklahoma.

Original reference: J. A. Taff, 1903, U.S. Geol. Survey Geol. Atlas, Folio 98.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 101. Abandoned by Oklahoma Geological Survey. Unit is a lumping of four series; name applies to all rocks below the Pontotoc and above the Caney shale.

Named for Glenn, Carter County.

Glenn Creek Shale Member (of Jefferson Limestone)[1]

Upper Devonian: Northwestern Montana.

Original reference: C. F. Deiss, 1933, Montana Bur. Mines and Geology Mem. 6, p. 42.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1768, chart 4 (facing p. 1788). Correlation chart shows age as Upper Devonian.

Type locality: On south side of southwestern peak of White Ridge. Named for Glenn Creek, whose middle branch heads at eastern base of White Ridge. On Saypo topographic sheet the names Glenn Creek and Moose Creek have been interchanged.

Glennon Limestone Member (of Lykins Formation)

Permian: North-central Colorado.

L. W. LeRoy, 1946, Colorado School Mines Quart., v. 41, no. 2, p. 31, 36–40, fig. 8. Divided into number of distinct lithic units, several of which are persistent throughout the area. They are (ascending) hard brittle pinkish laminated limestone that ranges in thickness from 2 inches to 2½ feet; gray to white fine-crystalline limestone with frequent vugs and laminated chert concretions; pink to gray irregularly laminated limestone; silty, impure laminated limestone; gray and pink limestone with distorted laminae; pink to gray regularly laminated limestone; and gray to pink coarsely crystalline vuggy imperfectly laminated limestone. Thickness at type locality 14 feet. Underlies Strain shale member (new); overlies Bergen shale member (new). Has been referred to commonly by various workers as "crinkled limestone."

Type locality: In quarry on south side of Turkey Creek, about 800 feet west of Glennon-Turkey Creek confluence, Golden-Morrison area, Jefferson County. Named from Mount Glennon, between Bear Creek and Turkey Creek and southeast of town of Morrison.

Glen Park Formation[1]

Glen Park Limestone Member (of Sulphur Springs Formation)

Glen Park Formation (in Hannibal Group)

Mississippian: Central eastern Missouri and southwestern Illinois.

Original reference: E. O. Ulrich, 1904, Missouri Bur. Geology and Mines, 2d ser., v. 2, p. 110.

L. E. Workman and Tracey [Tracy] Gillette, 1956, Illinois Geol. Survey Rept. Inv. 189, p. 8 (fig. 1), 20–23. In this report, name Hannibal is used for formations that lie above the Louisiana limestone and beneath the Chouteau. Glen Park, at base of group, unconformably overlies Louisiana limestone and conformably underlies Maple Mill formation.

M. G. Mehl, 1960, Denison Univ. Jour. Sci. Lab., v. 45, no. 5, p. 76–78. Ulrich proposed name Glen Park for oolitic limestone, the middle member of three constituting Sulphur Springs formation. Term Sulphur Springs abandoned in this report. Ulrich did not designate type locality, but it is evident that he had in mind the vicinity of Glen Park, a small community on Mississippi River in Jefferson County, Mo. Outcrops near there are designated as type locality. Thickness varies from a few inches to more than 20 feet. At type locality, probably no more than 30 inches should be assigned to formation. Separated from underlying strata by unconformity involving Kimmswick, Maquoketa, Chattanooga, and Plattin. Underlies Bushberg formation and in some areas Massie Creek sandstone (new). Upper Devonian. Outcrops form northwest-southeast trending band roughly paralleling Mississippi River through Ste. Genevieve, Jefferson, Franklin, St. Louis, St. Charles, and Warren Counties.

Type locality (Mehl, 1960): In SE cor. SE¼ NE¼ sec. 5, T. 41 N., R. 6 E., in old quarry face along river bluff above Missouri Pacific Railroad, south of Glen Park, Jefferson County, Mo.

Glenray Limestone (in Bluefield Formation[1] or Group)

Mississippian: Southeastern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 301, 432.

P. H. Price and E. T. Heck, 1938, West Virginia Geol. Survey [Rept.] Greenbrier County, p. 255, 264. Glenray limestone of Reger (1926) is represented in Greenbrier County by 10 to 60 feet of more or less impure limestone. Commonly a bluish-gray siliceous thick-bedded very fossiliferous limestone, belonging 100 to 150 feet above base of Mauch Chunk series. Above Lillydale shale and below Webster Springs sandstone. Bluefield group.

Type locality: On northwestern side of Greenbrier River, opposite Glenray, Summers County, W. Va.

Glenrock Limestone[1] Member (of Red Eagle Limestone)

Permian: Southeastern Nebraska and northeastern Kansas.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 84, 86, 88.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 48. Consists of gray and brown limestone, impure in northern part of outcrop area, purer in central and northern part; fusulines common. Thickness in northern part of Kansas 1 to 2 feet; in central Kansas as much as 19 feet. Underlies Bennett shale member; overlies Johnson shale. Wolfcamp series.

Named for exposures high in valley side just northwest of Glenrock, Nemaha County, Nebr.

Glen Rose Limestone[1] or **Formation** (in Trinity Group)

Glen Rose Limestone Member (of Shingle Hills Formation)

Lower Cretaceous: Texas.

Original reference: R. T. Hill, 1891, Geol. Soc. America Bull., v. 2, p. 504, 507.

R. T. Hazzard, 1939, Shreveport Geol. Soc. Guidebook 14th Ann. Field Trip, p. 155–165. Glen Rose subgroup of Trinity group consists of Lower Glen Rose formation, Glen Rose anhydrite, and Upper Glen Rose formation. Lower Glen Rose includes Pine Island member below and Rodessa member above. Overlies "Travis Peak" formation; underlies Paluxy formation. Subsurface data.

V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Rept. Inv. 2, p. 5, 8. Rank reduced to member status in Shingle Hills formation (new). Overlies Hensell sand member.

F. E. Lozo and F. L. Stricklin, 1956, Gulf Coast Assoc. Geol. Soc. Trans., v. 6, p. 67–78. At generalized reference section of Trinity division, Glen Rose limestone consists of lower unit and an upper unit. Lower subdivision, that is interval below *Corbula* bed, is predominantly massive medium- to thick-bedded limestone with local moundlike concentrations of corals and caprinids in basal and upper parts. The lower Glen Rose above the massive limestone is largely shale alternating with thin-bedded limestones and is highly fossiliferous with several levels of *Orbitulina*, the large Foraminifera used as a subsurface Glen Rose marker. Trinity section above *Corbula* bed consists predominantly of buff-colored shales and fine-grained dolomites in lower and upper parts with darker shales and more resistant fossiliferous limestone in middle. The alternating relation of these lithic types resulted in early designation of "Alternating Beds" for the Glen Rose strata. Formal name was proposed by Hill (1891) from exposures near Glen Rose, Somervell County. Upper limit of Glen Rose in this area is placed at concordant contact of uppermost dolomitic section with overlying limestones similar to those higher in Fredericksburg division. Glen Rose is completely exposed from Hamilton Pool eastward to the Shingle Hills and has local thickness of 525 feet. Overlies Hensell sand. Lower Glen Rose contains basal coral reef at narrows of Blanco River.

774–954—vol. 2—66——6

J. M. Forgotson, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 10, p. 2328–2363. Terms Glen Rose, Glen Rose undifferentiated, and Glen Rose subgroup, as used in this report [stratigraphy of Comanchean Cretaceous Trinity group], all refer to those rocks below top of Glen Rose as defined in Austin area and above top of either Pearsall formation or its equivalent. These terms are used in areas where the Ferry Lake is not recognizable. Undifferentiated Glen Rose time-stratigraphic unit is defined to include those rocks below isochronous surface contemporaneous with top of Glen Rose as defined in Austin area and above isochronous surface contemporaneous with base of Rodessa formation as defined in type area. Rusk formation (new) occupies stratigraphic interval formerly termed upper Glen Rose formation and Paluxy formation. Top of Trinity group, as term is used in present report, is defined as top of Glen Rose formation of the Austin area and its equivalents. Subsurface data.

Named for Glen Rose, Somervell County.

Glens Falls Limestone (in Trenton Group)[1]

Middle Ordovician: Eastern New York and northwestern Vermont.

Original reference: R. Ruedemann, 1912, New York State Mus. Bull. 162.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 260 (table 3), 262–263, 265 (fig. 10), 266 (table 4). Discussed under formations of Hull age of Trenton group. Includes Larrabee and Shoreham members (both new). In some areas, overlies Isle la Motte formation and in others Amsterdam formation; underlies Canajoharie formation. In some areas, Shoreham is member of Sherman Fall formation.

W. M. Cady, 1945, Geol. Soc. America Bull., v. 56, no. 5, p. 524 (table), 557–558. In west-central Vermont, overlies Orwell limestone (new) and underlies Hortonville shale. Consists of thin-bedded dark blue-gray rather coarsely granular limestone. Thickness about 115 feet. Kay's (1937) Larrabee and Shoreham members not readily distinguished in strongly folded beds east of Champlain thrust.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, p. 31, 34. Trenton units recognized by Cady in west-central Vermont continue southward into Castleton quadrangle, although the Glens Falls is not certainly identified. A blue marble that may be Shoreham member is called Whipple marble in this report. Larrabee member may be present along Taconic overthrust in Ira, but name Whipple is used until correlation with Glens Falls is certain.

R. B. Erwin, 1957, Vermont Geol. Survey Bull. 9, p. 30–32, 61–62. Formation described on Isle la Motte and South Hero Island, Vt., where both Larrabee and Shoreham limestone members are present. Overlies Lowville and Isle la Motte limestones; underlies Cumberland Head formation.

Named for exposures at Glens Falls, Warren County, N.Y.

Glenwood Shale or **Formation**

Glenwood Shale Member (of Platteville Formation)[1]

Glenwood Subgroup (of Ancell Group)

Middle Ordovician: Northeastern Iowa, western Illinois, southern Minnesota, and southern Wisconsin.

Original reference: S. Calvin, 1906, Iowa Geol. Survey, v. 16, p. 60, 61, 75.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., p. 11 (fig. 3). Shown on columnar section as Glenwood subgroup of Ancell group (new). Includes (ascending) Kingdom, Daysville, Loughridge, and Harmony Hill formations (all new).

M. P. Weiss and W. C. Bell, 1956, Geol. Soc. America Guidebook for Field Trips Minneapolis Mtg., Field Trip 2, p. 57, 58 (table 1) ; M. P. Weiss, 1957, Geol. Soc. America Bull., v. 68, no. 8, p. 1030. Referred to as a formation overlying the St. Peter sandstone and underlying Platteville formation.

A. F. Agnew and others, 1956, U.S. Geol. Survey Prof. Paper 274–K, p. 275–277. Further described as shale member of Platteville. Type locality stated.

Type locality : Sec. 6, T. 98 N., R. 7 W., Winneshiek County, Iowa.

Glenwood Tongue (of Weber Sandstone)

Pennsylvanian-Permian : Western Colorado.

D. W. Vanderwilt, 1953, Rocky Mountain Assoc. Geologists Guidebook Field Conf., May 14–16, p. 15, fig. facing p. 12. Shown on columnar section below South Canyon Creek dolomite member of Maroon formation. Gray sandstone 200 feet thick.

Glenwood Springs area.

Glenwood Tuff

Pleistocene : Hawaii Island, Hawaii.

J. B. Stone, 1926, Bernice P. Bishop Mus. Bull. 33, p. 26, 27. Red clayey material about 10 feet thick; unstratified except for thin carbonaceous streaks. Correlated with Pahala ash.

C. K. Wentworth, 1938, Hawaiian Volcano Observatory 3d Spec. Rept., p. 55–56. Maximum thickness about 12 feet. Underlies Olaa agglomerate (new).

D. A. Davis and G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 83. Considered to be part of Pahala ash. Pleistocene.

Occurs on east slope of Mauna Loa near Glenwood, Ferndale, and Olaa.

Glenwood Canyon Member (of Dotsero Formation)

Upper Cambrian : Central northwestern Colorado.

N. W. Bass and S. A. Northrop, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 5, p. 892 (fig. 2), 893–894, 897–899. Proposed to apply to all beds in Dotsero lying below a ledge-forming algal limestone herein named Clinetop algal limestone member. Lower half of member consists of thin beds of light-gray to tannish-gray dolomite, and a few thin beds of flat-pebble dolomite conglomerate, interbedded with thin beds of light greenish-gray very dolomitic shale; upper half consists of thin beds of flat-pebble limestone conglomerate and interbedded light greenish-gray very limy shale. Thickness about 91 feet. Overlies Sawatch quartzite.

Type locality: In Glenwood Canyon in SE¼ sec. 16, T. 5 S., R. 87 W., Garfield County.

†Globe Limestone[1]

Devonian and Carboniferous : Southeastern Arizona.

Original reference : F. L. Ransome, 1903, U.S. Geol. Survey Prof. Paper 12.

Named for development at and around Globe, Gila County.

Glorieta Sandstone[1]

Glorieta Sandstone Member (of San Andres Formation)

Permian: Central northern New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257, 262; Conspectus of geologic formations of New Mexico, p. 2, 7.

C. E. Needham and R. L. Bates, 1943, Geol. Soc. America Bull., v. 54, no. 11, p. 1662–1664. Because of its wide distribution, persistence of lithology, bold topographic expression, and stratigraphic importance, Glorieta is considered to be formation. Overlies Yeso formation; underlies San Andres formation. Maximum thickness 278 feet in Zuni Mountains. Type locality designated.

C. B. Read and D. A. Andrews, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 8. Shown on columnar section as basal member of San Andres formation. Thickness 100 to 250 feet. Underlies unnamed limestone member; overlies Yeso formation.

G. O. Bachman, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM–137. Member described in northwestern Mora County where it is about 266 feet thick near Ocate. Underlies Bernal formation; overlies Yeso formation in extreme southwestern part of mapped area and elsewhere Sangre de Cristo formation.

W. H. Tonking, 1957, New Mexico Bur. Mines Mineral Resources Bull. 41, p. 7 (fig. 2), 10, 11, pl. 1. Member described in Puertecito quadrangle where it is about 230 feet thick. Underlies unnamed middle evaporite member. Gradationally overlies Los Vallos member of Yeso formation; contact placed above uppermost siltstone bed, so that basal part of Glorieta consists entirely of sandstone, which is pinkish at base.

C. H. Dane and G. O. Bachman, 1957, U.S. Geol. Survey Misc. Geol. Inv. Map I–224. Considered of formational rank.

Type section: Glorieta Mesa 1 mile west of village of Rowe, San Miguel County. Section lies in south-central part T. 15 N., R. 12 E.

Gloucesterian (Gloucester) Stage or Substage

Middle Ordovician (Trentonian): Eastern North America.

G. M. Kay, 1937, Geol. Soc. America Proc. 1936, p. 82. Collingwood and Gloucester are stages in latest Trenton.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 7, p. 30–31. Trenton group was divided by Raymond (1916, Harvard Coll. Mus. Comp. Zoology Bull., v. 56) into succession of faunal zones that he thought time-stratigraphic but which he called formations. In time these became stages: Rocklandian, Kirkfieldian, Shorehamian, Denmarkian, Cobourgian, Collingwoodian, and Gloucesterian of Kay (1937; 1943; 1948). The Cobourg-Collingwood-Gloucester seems to be time-equivalent to Utica group, but name Utica is strongly associated with black shale facies. Hence, term Pictorian stage is applied to uppermost Trentonian.

Name derived from Gloucester Township, Carleton County, Ontario, Canada, for which Gloucester shale is named.

Goathaunt Member (of Siyeh Formation or Limestone)[1]

Precambrian (Belt Series): Northwestern Montana.

Original reference: C. L. Fenton and M. A. Fenton, 1931, Jour. Geology, v. 39, no. 7, p. 670–679.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1895. Limestones, dolomites, and subordinate oolites, dolomitic sandstones, and argillites, thickly bedded; prevailingly dark gray. Mud breccias, abundant in northern exposures. Mud cracks common in carbonaceous layers. Thickness 2,000 to 3,200 feet. Overlies a *Collenia symmetrica* zone; separated from overlying Granite Park member by *C. frequens* zone. Type locality designated.

Richard Rezak, 1957, U.S. Geol. Survey Prof. Paper 294–D, p. 137, 138. Discussion of stromatolites of Belt series. Goathaunt member of Fenton and Fenton is represented in *Collenia symmetrica* zone 1.

Type locality: South wall of cirque between Mount Goathaunt and Mount Cleveland, Glacier National Park. Well exposed in high peaks of Waterton-Glacier Parks.

Goat Island Member (of Lockport Formation)

Middle Silurian (upper Niagaran): Western New York, and southern Ontario, Canada.

B. F. Howell and J. T. Sanford, 1947, Wagner Free Inst. Sci. Bull., v. 22, no. 4, p. 34. Name proposed to replace preoccupied name, Suspension Bridge, first used for a lower Ordovician formation in New Brunswick. Underlies Eramosa member; overlies Gasport limestone member.

T. E. Bolton and B. A. Liberty *in* A. J. Mozola, chm., 1955, Michigan Geol. Soc. [Guidebook] Ann. Field Trip [no. 19], p. 29. Described in Niagara Escarpment of Ontario as a thick sequence of dolomites. Essentially thick-bedded gray to buff dolomite. Abundant chert nodules and lenses occur at base. Upper limit arbitrarily drawn at first occurrence of bituminous material characteristic of Eramosa member. Maximum thickness 80 feet in Hamilton region.

Named for Goat Island at brink of Niagara Falls, N.Y.

Goat Rock pyroclastic deposits.

Quaternary: Southwestern Washington.

Jean Verhoogen, 1937, California Univ. Dept. Geol. Sci. Bull., v. 24, no. 9, p. 274–277. Name applied to pyroclastic deposit consisting of angular blocks, some of them weighing several tons, scattered in a loose fine muddy matrix. Deposit is characterized by occurrence of "bread-crusted" bombs. Deposit is narrow; greatest width nowhere exceeds five-eights of a mile.

Occurs in an area between the northeast corner and the outlet of the small glacier which hangs between Goat Rock and "The Lizzard", on north side of Mount St. Helens.

Goat Seep Limestone or Dolomite

Permian (Guadalupe Series): Western Texas and eastern New Mexico.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 588–589, pl. 2; 1948, U.S. Geol. Survey Prof. Paper 215, p. 38–41, pls. 2, 3. Along west side of Guadalupe Mountains north of Bone Spring, Getaway, and South Wells, limestone members of Cherry Canyon formation thicken northward, and intervening sandstones disappear. On projecting point of escarpment, 1½ miles north of the spring, upslope from top of Bone Spring flexure, the limestones coalesce into solid mass, here termed Goat Seep limestone. Thickens rapidly from 700 feet at southernmost exposure to Bartlett Peak, 1 mile north, where it is 1,200 feet thick. On

Bartlett Peak, consists of gray dolomitic limestone, which forms thick beds in lower half of formation; upper half is single mass with few traces of bedding. The thick-bedded and massive limestones are probably reef deposits. Interfingers with Manzanita limestone member of Cherry Canyon formation; overlies sandstone tongue of Cherry Canyon; underlies Carlsbad limestone; interfingers with Queen sandstone member of Chalk Bluff formation. Unit was described by Crandall (1929, Am. Assoc. Petroleum Geologists Bull., v. 13, p. 933) who called it Chupadera limestone, and by Lang (1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 7) who called it Dog Canyon limestone; this latter name now abandoned.

N. D. Newell and others, 1953, The Permian reef complex of the Guadalupe Mountains region, Texas and New Mexico: San Francisco, W. H. Freeman and Co., p. 42–43. It has been determined that Queen formation is equivalent to much, if not all, of shelf phase of King's Goat Seep dolomite. Because of confusion introduced by applying name Goat Seep to shelf, reef, and forereef facies, it is proposed to restrict name Goat Seep to reef and forereef talus facies, a nomenclatural device that has served well with Capitan formation.

Name is taken from Goat Seep, on western slope of Guadalupe Mountains, 1½ miles northwest of Guadalupe Peak, Culbertson County, Tex.

Gobbler Formation (in Magdalena Group)

Pennsylvanian (Morrowan?-Missourian) : Southeastern New Mexico.

L. C. Pray, 1954, New Mexico Geol. Soc. Guidebook 5th Field Conf., p. 93. Appears only on columnar section. Consists of limestone, sandstone, and shale. Coarse quartz sandstone in lower part. Includes massive gray cherty Bug Scuffle limestone member which grades laterally into sandstone and shale. Thickness as much as 1,600 feet. Underlies newly named Beeman formation and overlies Helms formation.

In Sacramento Mountains, Otero County.

Gober Tongue (of Austin Chalk)[1]

Upper Cretaceous : Northeastern Texas.

Original reference: L. W. Stephenson, 1927, Am. Assoc. Petroleum Geologists Bull., v. 11, p. 8–12, pl. 1.

L. W. Stephenson, 1937, U.S. Geol. Survey Prof. Paper 186–G, p. 133–146. Mentioned in discussion of stratigraphic relations of Austin, Taylor, and equivalent formations.

Named for occurrence at village of Gober, Fannin County.

Goble Volcanic Series

Goble Volcanics Member (of Cowlitz Formation)

Eocene, upper : Northwestern Oregon and southwestern Washington.

W. C. Warren, Hans Norbisrath, and R. M. Grivetti, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map. 42. Name applied to a section of widespread basic flows and pyroclastic rocks with some associated sediments. Basal part of series interfingered with tuffaceous sediments which contain a Cowlitz (upper Eocene) fauna. Thickness 5,000 feet or more, measured along U.S. Highway 99 between Woodland and Kelso, Wash.

D. A. Henriksen, 1956, Washington Div. Mines and Geology Bull. 43, p. 16 (fig. 5), 59–62, 65. Described in lower Cowlitz River-eastern Willapa Hills area, southwestern Washington. Here Goble volcanics are represented by basaltic flows and flow breccia interbedded with both marine and coal-bearing Cowlitz sediments. Aggregate thickness of intercalated rocks less than 1,000 feet. In this area, name Goble volcanics member of Cowlitz formation is used for rocks which constitute a much thicker unit of formational rank elsewhere. Volcanics interfinger with sediments of underlying Olequa Creek member (new) and thin and wedge out toward northwest of mapped area.

Named for exposures in vicinity of Goble, Columbia County, Oreg. Series crops out along both the Oregon and Washington sides of Columbia River.

Goddard Shale Member (of Springer Formation)

Goddard Formation or Shale (in Springer Group)

Pennsylvanian: Oklahoma.

M. G. Cheney and others, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 2, p. 140 (chart 2), 143. Proposed to replace term "Pennsylvanian Caney." Consists of uniform dark shales with some thin concretionary layers between top of Mississippian rocks (commonly the Caney shale of Meramec age according to Ulrich, 1927, Oklahoma Geol. Survey Bull. 45) and base of Rod Club sandstone. Thickness at least 2,000 feet in type area. Springer series. Name credited to J. M. Westheimer.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped as member at base of Springer. Pennsylvanian.

M. K. Elias, 1956, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 1: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 70 (table 2), 74–89. In southern Arbuckle Mountains, includes Redoak Hollow sandstone member (new) in middle part. Mississippian (Chester).

J. M. Westheimer, 1956, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 1: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 392–396. Name was proposed for pre-Springer "Pennsylvanian" sediments. Because Goddard shales are indistinguishable from shales above the Rod Club sandstone, it had been proposed that base of Springer group be extended downward to top of the Caney. In view of new faunal evidence, the Goddard should not be included in the Springer and Mississippian-Pennsylvanian boundary should be drawn at base of Rod Club.

C. W. Tomlinson and William McBee, Jr., 1959, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 2: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 6 (fig. 2), 8–10. Formation comprises lower half (Chesterian part) of Springer group as defined here.

C. W. Tomlinson, 1959, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 2: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 323. Includes Grindstone Creek member (new) in upper part. Mississippian (precise systemic boundary open to question).

C. W. Tomlinson and Allan Bennison, 1960, Oklahoma Geology Notes, v. 20, no. 5, p. 123–124. Tiff member proposed to replace preoccupied name Grindstone Creek member of Tomlinson, 1959.

Type locality: Along Oil Creek, secs. 19 and 20, T. 3 S., R. 4 E., on Goddard Ranch about 7 miles east of Gene Autry (Berwin on older maps), Johnston County. Section starts on west side of Oil Creek in SE¼ sec. 18 where contact between Caney and Goddard shales is well exposed, and extends in southwesterly direction to base of Rod Club sandstone.

Godfrey Shales (in Asuncion Group)

Upper Cretaceous: West-central California.

N. L. Taliaferro, 1943, California Div. Mines Bull. 118, pt. 2, p. 132 [preprint]. Underlies Cantinas sandstones (new); overlies Piedras Altas formation (new).

Santa Lucia Range is mountainous area, between Salinas Valley and the coast, which extends from Monterey Bay to central part of San Luis Obispo County.

Godfrey Flat Shale

See Godfrey Shales (in Asuncion Group).

†Godiva Limestone[1]

Ordovician to Mississippian: Central northern Utah.

Original reference: G. W. Tower, Jr., and G. O. Smith, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 3, p. 624.

Tintic district.

Godiva[1] or Goldiva limestone[1]

Eocene: Utah.

Original reference: C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 279, 308.

Tintic district.

Gods Pocket Dacite

Pliocene(?): Northeastern Nevada.

R. R. Coats, 1957, U.S. Geol. Survey Trace Elements Inv. Rept. TEI-690, Book 2, p. 306. Sequence of dacite flow material about 700 feet thick. Disconformably overlies Jarbidge rhyolite (new) and locally separated from it by 30 to 50 feet of pale-gray vitric tuff.

U.S. Geological Survey currently considers the Gods Pocket Dacite to be Pliocene(?) in age.

In northeastern quarter of Jarbidge quadrangle.

Goen Limestone (in Millsap Lake Formation)[1]

Goen Limestone Member (of Grindstone Formation)

Pennsylvanian: Central northern Texas.

Original reference: F. B. Plummer, 1929, Geologic map of Pinto County: Texas Bur. Econ. Geology.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Reallocated to member status in Grindstone Creek formation.

Leo Hendricks, 1957, Texas Univ. Bur. Econ. Geology Pub. 5724, p. 19–20, fig. 3. In Parker County, limestone is 1 to 2 feet thick and is gray to yellowish gray. Limestone either lenses out to east, or its eroded edge is covered by debris from dissected dip slope of underlying sandstone. Occurs at top of formation. Overlies unnamed sandstones above the Santo limestone member; underlies Mingus member of Garner formation. Report follows classification of Cheney (1940) [but also refers to this unit as a limestone bed].

Well exposed on north side of Millsap-Brazos Road one-half mile northeast of Goen Cemetery entrance, Palo Pinto County.

†Goff coal group (in Williams Fork Formation)[1]

Upper Cretaceous: Northwestern Colorado.

Original reference: E. T. Hancock and J. B. Eby, 1930, U.S. Geol. Survey Bull. 812, p. 206.

Meeker quadrangle.

†Gogebic Series[1]

Precambrian: Michigan.

Original reference: C. R. Van Hise and C. K. Leith, 1909, U.S. Geol. Survey Bull. 360, p. 137, 308–309.

Gogebic district, Lake Superior region.

Golconda Formation[1]

Golconda Formation (in Homberg Group)

Golconda Limestone (in Stephensport Group)

Upper Mississippian (Chester Series): Southern Illinois, northwestern Alabama, northwestern Georgia, southern Indiana, western Kentucky, southeastern Missouri, and western Tennessee.

Original references: A. D. Brokaw, 1916, Illinois Geol. Survey Extr. from Bull. 35; 1917, Illinois Geol. Survey Bull. 35, p. 19–29.

J. M. Weller, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 131, 136; J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 766 (fig. 1), 830–831. Assigned to Homberg group (new). In standard Mississippian section, underlies Hardinsburg sandstone and overlies Cypress sandstone. Attains maximum thickness of more than 100 feet. Youngest formation present in Perry and Ste. Genevieve Counties, Mo., where it is gray crystalline limestone; in Perry County, overlaps the Ruma and rests unconformably on Paint Creek formation. In Indiana, overlies Indian Springs shale.

Charles Butts and Benjamin Gildersleeve, 1948, Georgia Geol. Survey Bull. 54, p. 42, 47–48. Geographically extended into Georgia where it occurs on Lookout Mountain. Underlies Hartselle sandstone; overlies Gasper limestone.

A. C. McFarlan and others, 1955, Kentucky Geol. Survey, ser. 9, Bull. 16, p. 5–25. Golconda section is (ascending) Beech Creek (lower Golconda) limestone, Fraileys (middle Golconda) shale (new) or Big Clifty, and Haney (upper Golconda) limestone (new). Section overlies Cypress sandstone and underlies Hardinsburg sandstone.

D. J. McGregor, T. G. Perry, and W. J. Wayne, 1957, Indiana Geol. Survey Field Conf. Guidebook 9, p. 6, pl. 3. Shown on chart of evolution of stratigraphic nomenclature in Chester series of Indiana as Golconda formation; underlies Hardinsburg formation and overlies Big Clifty formation, here used to replace Cypress sandstone. As shown on chart, Golconda includes unit formerly termed Indian Springs shale. Thickness 40 to 50 feet. Term Homberg group not used in Indiana.

S. W. Welch, 1958, U.S. Geol. Survey Oil and Gas Inv. Chart OC–58. In northwestern Alabama, strata referred to by Butts (1926, Alabama Geol. Survey Spec. Rept. 14) as Golconda formation are included in Green Hill member of Pride Mountain formation (both new).

H. H. Gray, R. D. Jenkins, and R. M. Weidman, 1960, Indiana Geol. Survey Bull. 20, p. 36 (table 5), 39–40, pl. 1. Included in Stephensport group (redefined). In Indiana, as recently as 1957 rocks considered to belong to Golconda formation have included an upper limestone member and a lower shale member. The shale appears to be more closely related to underlying Big Clifty formation, and it is here proposed to restrict name Golconda to the limestone and refer to unit as Golconda limestone. Thickness in Huron area [this report] 19 to 32 feet. Conformably overlies Big Clifty formation: underlies Hardinsburg formation with contact transitional.

Named for Golconda, Pope County, Ill.

Gold Basin Formation

Recent: Southeastern Utah.

G. M. Richmond, 1956, Dissert. Abs., v. 16, no. 6, p. 1128. Consists of two members comprising 10 lithofacies. Tills form two sets of small cirque moraines or rock glaciers. Weakly developed Spanish Valley soil is developed on lower member. No soil, or only a faint humus, is formed on upper member. Younger than Beaver Basin formation (new).

Located in La Sal Mountains area.

Gold Butte Granite

Precambrian: Southeastern Nevada and northwestern Arizona.

C. R. Longwell, 1936, Geol. Soc. America Bull., v. 47, p. 1405–1406. Pinkish gray, coarse-grained, and distinctly porphyritic granite. Unconformably underlies Cambrian rocks.

Prominent in Gold Butte, Nev., from which it takes its name. Distributed widely in southern Virgin Mountain block. Exposed at head of Virgin Canyon.

Gold Creek Quartzite[1]

Middle(?) Cambrian: Northern Idaho.

Original reference: E. Sampson, 1928, Idaho Bur. Mines and Geology Pamph. 31, p. 9.

C. E. Resser, 1938, Smithsonian Misc. Colln., v. 97, no. 3, p. 2. Estimated average thickness 400 feet. Distinguished from underlying Beltian strata by coarser grain. Underlies Rennie shale. Middle Cambrian.

Named for exposures on North and South Gold Creeks near Lakeview. Conspicuous outcrops on summit of ridge above cement rocks plant at Port Rock.

†Golden Formation or Group[1]

[Upper Cretaceous]: Central Colorado.

Original reference: A. C. Veatch, 1907, Jour. Geology, v. 15, p. 548.

Probably named for Golden, Jefferson County.

Golden Member (of Arapahoe-Denver Formation)

Tertiary: North-central Colorado.

L. W. LeRoy, 1946, Colorado School Mines Quart., v. 41, no. 2, p. 100 (fig. 23), 103, 104. Light-tan to light-brown silts, clays, silty shales, clayey sands, and some medium-grained sandstones. Thickness ranges from 60 feet on South Table Mountain to 76 feet on north side of North Table

Mountain. Overlies Pleasant View member (new); immediately underlies capping basalt flow of North and South Table Mountains.

Type section: On eastern extremity of South Table Mountain; NW¼ sec. 31, T. 3 S., R. 69 W., Morrison quadrangle, Jefferson County. Recognized only on slopes of Table Mountains.

Golden Eagle Limestone[1]

Pennsylvanian: Southwestern Illinois.

Original reference: H. E. Culver, 1925, Illinois Geol. Survey Coop. Min. ser., Bull. 29, p. 20.

Probably named for exposures at or near Golden Eagle, Calhoun County.

†Golden Gate Formation

Upper Cretaceous (Chico Series): Northern California.

J. M. Kirby, 1942, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 26, no. 5, p. 899. Listed as basal formation in Chico series; underlies Mills formation (new).

J. M. Kirby, 1943, California Div. Mines Bull. 118, pt. 3, p. 606. Described as a sandstone varying in thickness from 3,000 to 3,500 feet. Derivation of name given.

J. M. Kirby, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 3, p. 282 (footnote). Name preoccupied; replaced by Venado formation.

Name derived from prominent gap in the sandstone rimrock in W½ sec. 9, T. 17 N., R. 4 W., through which Funks Creek flows, Colusa County.

†Golden Gate Series[1]

Jurassic(?): Western California.

Original reference: H. W. Fairbanks, 1895, Jour. Geology, v. 3, p. 416–426.

Named for development on north and south shore of Golden Gate, San Francisco County.

Golden Gate Hill Andesite

Neocene: Central California.

F. L. Ransome, 1899, U.S. Geol. Survey Geol. Atlas, Folio 63, p. 6. Consists in main of andesitic-breccia and conglomerate capped by thick mass of hornblende-andesite similar to Jackson Butte andesite (new).

Forms Golden Gate Hill, Calaveras County, Mother Lode district.

Golden Horn Granodiorite

Post-Lower Cretaceous: Northwestern Washington.

Peter Misch, 1952, The Mountaineer, v. 45, no. 13, p. 4 (geol. map), 17–18. Later than Lower Cretaceous sediments and their folding. Intrudes Black Peak granodiorite and quartz diorite (new).

Golden Horn Peak is in Okanogan County. Composes a number of peaks including Methow Pinnacles and Mount Hardy, Golden Horn, the Needles, and Tower Mountain, Cutthroat Peak, Liberty Bell, and Silver Star.

Golden Ray Limestone[1]

Middle Cambrian: Central northern Utah.

Original reference: G. W. Crane, 1915, Am. Inst. Mining Engrs. Bull. 106, p. 2149–2151.

Probably named for Golden Ray mine, Tintic district.

Goldens Ranch Formation

Eocene: Central Utah.

Siegfried Muessig, 1951, Science, v. 114, no. 2957, p. 234. Series of tuffs, bentonites, and volcanic boulder conglomerates; includes Sage Valley member (new) 820 feet above base. Conformably overlies Green River limestone. Volcanic conglomerates grade laterally into volcanic breccias that are part of latite series in northern part of area and in Tintic district.

Well exposed in roadcuts along U.S. Highway 91, in Long Ridge area, southwest of Levan, Juab County. Derivation of name not stated.

Golden Valley Formation

Eocene: Southwestern North Dakota.

W. E. Benson and W. M. Laird, 1947, (abs.) Geol. Soc. America Bull., v. 58, no. 12, pt. 2, p. 1166–1167. Consists of fine-grained micaceous sands with minor amounts of light-colored clays and shales; these sands and shales overlie a basal sequence of hard white to dark-gray clays, and locally, lignites; middle part of basal sequence is characteristically mottled reddish yellow on weathered surfaces and forms good marker bed. Formation includes beds bearing fossil fern *Salvinia preauriculata*. Unit has been referred to as unnamed formation of Wasatch group. Overlies Sentinel Butte shale member of Fort Union; unconformably underlies Oligocene White River group.

W. E. Benson, 1949, (abs.) Geol. Soc. America Bull., v. 60, no. 12, pt. 2, p. 1873–1874. Conformably overlies Tongue River member of Fort Union.

E. G. Meldahl, 1956, North Dakota Geol. Survey Rept. Inv. 26. Overlies Sentinel Butte shale herein considered member of Tongue River formation.

Great Northern Railway Co. Mineral Research and Devel. Dept., 1958, Great Northern Railway Co. Mineral Research and Devel. Dept. Rept. 5, p. 5–23. In area of Mountrail County, includes White Earth, South Ross, Lakeside, and East Tioga clay beds.

Type exposure: Near town of Golden Valley, Mercer County.

†Golden Wall Sandstone (in Blair Formation)[1]

Upper Cretaceous (Montana): Southwestern Wyoming.

Original reference: J. W. Powell, 1876, Geology of eastern portion of Uinta Mountains, p. 40, 48, 155.

Forms main scarp surrounding Baxter Basin, Sweetwater County. This scarp is commonly referred to as the "golden wall."

Gold Hill Conglomerate[1]

Triassic(?): Southwestern Colorado.

Original reference: J. D. Irving, 1905, U.S. Geol. Survey Bull. 260, p. 56.

Gold Hill, Ouray district.

Gold Hill Formation[1]

Cambrian: Central Nevada.

Original reference: H. G. Ferguson, 1924, U.S. Geol. Survey Bull. 723.

H. G. Ferguson and S. H. Cathcart, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–40. No fossils were found in formation of Manhattan district, Toquima Range, but trilobite of Early Cambrian age (*Olenellus gilberti* Meek) was found in rocks of same lithology and stratigraphic position in

Toyabe Range near Jett Canyon. Therefore, established formation name is extended to Cambrian of both ranges. Consists chiefly of quartzite, quartz mica schist with some slate, and beds of crystalline dolomitic limestone, with locally some oolitic limestone in its upper part. Base not exposed; estimated exposed thickness at least 3,000 feet in Toyabe Range north of Summit Creek. Conformably underlies Ordovician Palmetto formation. Probably equivalent to Silver Peak group (Turner, 1902).

Type locality: Gold Hill in Manhattan district, Toquima Range.

Gold Hill Phyllite

Age(?): Northwestern Washington.

J. A. Vance, 1957, Dissert. Abs., v. 17, no. 9, p. 1984. A low grade metamorphic rock.

Occurs in Sauk River area in northern Cascades.

†Gold Hill Porphyry[1]

Eocene: Western central Colorado.

Original reference: S. F. Emmons, 1898, U.S. Geol. Survey Geol. Atlas, Spec. Folio 48.

On Gold Hill, Tenmile district.

Gold Mountain Phyllite

Age not stated: Northern Washington.

R. W. Jones, 1959, Dissert. Abs., v. 20, no. 3, p. 994. Much of eastern part of map area is underlain by broad belt of Gold Mountain phyllite which is flanked on west by belt of Finney greenschist (new). In fault contact with Sutter Mountain unit (new). Occurs in anticlinorium.

Report discusses geology of Finney Peak area, northern Cascades.

Gold Park Gabbro-Diorite

Precambrian: Southern California.

W. J. Miller, 1938, Geol. Soc. America Bull., v. 49, no. 3, p. 419–420. Consists of a variety of rather basic igneous rocks, but average mineral composition is about that of gabbro-diorite. Includes a massive facies and a "salt and pepper" facies. Considered older than Palms granite (new). Cut by White Tank monzonite (new).

Named from an occurrence in Gold Park Canyon, near Twenty-nine Palms, Riverside County.

Gold Road Latite[1]

Tertiary, middle or upper: Northwestern Arizona.

Original references: F. L. Ransome, 1923, U.S. Geol. Survey Bull. 743; Carl Lausen, 1931, Arizona Bur. Mines Bull. 131, Geol. Ser. 6, p. 34, map.

Named for settlement and mine, both of which are called Gold Road, Oatman district.

Goler Formation

Eocene to Miocene, lower: Southern California.

T. W. Dibblee, Jr., 1952, California Div. Mines Bull. 160, p. 12 (fig. 1), 19–25, pls. 1, 2, 3. Consists of some 6,500 feet of terrestrial conglomerate, sandstone, and clay. Comprises two unnamed members. Unconformably underlies Ricardo formation; unconformably overlies basement rocks; southwest from type section the Goler is overlapped by the Ricardo. Age shown on columnar section as Eocene-Oligocene-Miocene.

M. C. McKenna, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 4, p. 512–515. Paleontological evidence indicates that most and probably all of formation is at least as old as early Tertiary.

Type section: Exposed in drainage area of Goler Gulch and northwestward to east slope of Black Hills, Saltdale quadrangle, Kern County.

Golf Course Formation (in Dornick Hills Group)

Pennsylvanian (Morrow Series): Southern Oklahoma.

B. H. Harlton, 1956, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 1: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 137 (fig. 2), 138–139. Includes Primrose sandstone member at base and Otterville member at top. Primrose sandstone, and shale between it and the Otterville, are transferred from the Springer group to the Dornick Hills. Thickness at type locality 1,400 to 1,500 feet. Entire sequence, which carries large and varied Morrow fauna, includes all rocks generally recognized as of Morrow age in Ardmore basin. South of Ardmore, Jolliff conglomerate is lowest unit so recognized. In Harrisburg trough, formation is divided into (ascending) Rowland (new), Limestone Gap, and Otterville members. Unconformably underlies Lake Murray formation (new); unconformably overlies rocks of Springer group.

C. W. Tomlinson and William McBee, Jr., 1959, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 2: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 6 (fig. 2), 18. Morrowan series, in Ardmore basin, includes maximum of about 2,000 feet of strata from base of Primrose sandstone to a horizon above Otterville limestone and below Bostwick conglomerates. This is sequence of strata which Harlton (1956) has designated Golf Course formation.

Type locality: Along a creek in SW¼SW¼ sec. 7, T. 4 S., R. 2 E., Carter County. Name derived from golf course of Dornick Hills Country Club, type locality of Dornick Hills group.

Goliad Sand[1]

Goliad Formation

Pliocene: Southern Texas.

Original reference: J. T. Lonsdale and J. R. Day, 1933, Ground-water resources of Webb County, Texas: U.S. Geol. Survey Press Bull. 68861.

A. W. Weeks, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 12, p. 1726–1732. Termed formation. Includes Lagarto and Lapara formations of Dumble as members. Unconformably underlies Willis or younger Pleistocene. Composed of limestone, gray and black chert, and fossil wood, all commonly interbedded with sand or intermixed with clay balls. Dips coastward about 25 feet per mile; near downdip edge of outcrop, probably reaches average thickness of about 500 feet.

J. H. Quinn, 1952, (abs.) Geol. Soc. America Bull., v. 63, no. 12, pt. 2, p. 1292. On basis of fauna, considered late-upper Miocene.

Named for exposures along San Antonio River at Goliad, Goliad County.

Gonic Formation[1]

Pennsylvanian (?): Southeastern New Hampshire and southwestern Maine.

Original reference: F. J. Katz, 1917, Washington Acad. Sci. Jour., v. 7, p. 199.

Jacob Freedman, 1950, Geol. Soc. America Bull., v. 61, no. 5, p. 460. Katz (1917) assigned to Gonic formation schists, in Dover quadrangle to the east, that are continuous with Littleton formation in Mount Pawtuckaway quadrangle [this report].

Named for exposures near Gonic, Strafford County, N.H.

Gonzales Limestone Member (of Graham Formation)[1]

Gonzales Formation (in Graham Group)

Gonzales Shale (in Caddo Creek Group)

Upper Pennsylvanian: Central northern Texas.

Original reference: C. S. Ross, 1921, U.S. Geol. Survey Bull. 726–G, p. 307.

Wallace Lee and others, 1938, Texas Univ. Bur. Econ. Geology Pub. 3801, p. 18–19. Member of Graham formation. Well exposed on high westward-facing bluff in southside of Brazos River and southeast of Salem Bend, where it is 18 feet thick. This is only place where complete unweathered section was noted in area of this report [Brazos River valley]. Separated from underlying Salem School member (new) by unnamed interval of shale and sandstone; underlies sandstone interval below Bunger limestone member.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Shown on correlation chart as formation in Graham group. Includes Salem School limestone member. Occurs below North Leon formation and above Home Creek limestone in Caddo Creek group. Cisco raised to series rank in this report.

C. E. Davis, 1956, *in* North Texas Geol. Soc. Field Guidebook, May 25–26, p. [6], fig. 2. Shown on correlation chart as Gonzales shale in Caddo Creek group.

Named for Gonzales Creek, Stephens County.

†Gonzales Shale[1]

Pennsylvanian: Central northern Texas.

Original references: F. B. Plummer, 1929, Geologic map of Palo Pinto County: Texas Bur. Econ. Geology; O. F. Hedrick, E. Owens, and P. A. Myers, 1929, Geologic map of Shackelford County: Texas Bur. Econ. Geology.

Palo Pinto, Shackelford, and Stephens Counties.

Gonzales Creek Shale Member (of Graham Formation)[1]

Pennsylvanian: Central northern Texas.

Original references: F. B. Plummer and R. C. Moore, 1922, Jour. Geology, v. 30, p. 24, 31; 1922, Texas Univ. Bull. 2132, p. 127–134.

Named for Gonzales Creek in Eastland County.

Goodbread Sandstone Member (of Manning Formation)

Eocene (Jackson): East-central Texas.

W. L. Russell, 1955, Gulf Coast Assoc. Geol. Soc. Trans., v. 5, p. 166–171. Name applied to a sandstone in the Manning formation about 100 to 150 feet above the top of the Carlos sandstone. Thickness near type locality 5 to 30 feet; in Brazos County 40 to 50 feet. Separated from overlying Tuttle sandstone [member] (new) by a 75-foot interval that contains shales, shaly sandstone, lignitic beds, and ash beds. Unit had been mapped as part of Carlos sandstone by Renick (1936).

Type locality: On Lake Creek 1 mile west of Carlos, Grimes County.

Goodenough Member (of Franconia Sandstone)[1]

Upper Cambrian: Southwestern Wisconsin.

Original reference: A. C. Trowbridge and others, 1935, Kansas Geol. Soc. Guidebook 9th Ann. Field Conf., p. 81, 92, 134, 140, 159, 446, 449, 455.

C. R. Stauffer, G. M. Schwartz, and G. A. Thiel, 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1239. Name Taylor Falls member (new) used in Minnesota in preference to extending term Goodenough member.

R. R. Berg, 1953, Jour. Paleontology, v. 27, no. 4, p. 553, 554, 555; 1954, Geol. Soc. America Bull., v. 65, no. 9, p. 858 (fig. 1), 864. Name abandoned. Franconia member names used by Twenhofel, Raasch, and Thwaites (1935) are geographic names applied to faunal zones. New member names are proposed to designate rock types, because distribution of faunal zones in formation is largely independent of natural rock units. Goodenough member is *Conaspis* zone. This fauna occurs most abundantly in Tomah member and less abundantly in underlying Birkmose and overlying Reno members.

Type locality: Goodenough Hill, between Elroy and Mauston, Juneau County.

†Good Hope Formation[1]

Pliocene(?): District of Columbia and southern Maryland.

Original reference: W. B. Clark, 1890, Johns Hopkins Univ. Circ., v. 9, no. 81, p. 69–70.

Named for Good Hope Hill, D.C.

Goodland Limestone (in Fredericksburg Group)[1]

Goodland Formation (in Fredericksburg Group)

Lower Cretaceous (Comanche Series): Southwestern Arkansas, central southern and southeastern Oklahoma, and northeastern Texas.

Original reference: R. T. Hill, 1891, Geol. Soc. America Bull., v. 2, p. 504, 514.

B. F. Perkins, 1957, Dissert. Abs., v. 17, no. 6, p. 1310; 1960, Geol. Soc. America Mem. 83, p. 9 (fig. 3), 12 (fig. 4), 15–21, pl. 2. Formation described in Fort Worth-Weatherford area, Texas, where it is subdivided into Marys Creek marl member below and Benbrook limestone member above (both new). Thickness about 120 feet. Conformably and gradationally overlies Walnut marl; conformably underlies Kiamichi formation.

L. V. Davis, 1960, Oklahoma Geol. Survey Bull. 86, p. 16–17, 31–34, pl. 1. Described in McCurtain County, Okla., where it is 25 to 50 feet thick, conformably overlies Paluxy sand and conformably underlies Kiamichi formation. Walnut clay, which underlies Goodland in other parts of Oklahoma and Texas, not identified in McCurtain County.

F. E. Lozo and others, 1960, Texas Bur. Econ. Geology Pub. 5905, p. 4. East of type locality, formation thickens to as much as 75 feet of more massive and purer limestone with rudists common in upper part and is in part same facies developed in Edwards limestone of Brazos River valley, Texas. Along outcrop south of Red River, formation thickens to about 125 feet west of Fort Worth. Near Tarrant-Johnson County line upper part is marked by massive beds containing rudists, lower part becomes argillaceous, and formation passes by transition into the Edwards, Comanche Peak, and upper Walnut of Brazos Valley section.

In northeastern Texas only, formation includes Walnut Shaly Member. Elsewhere the Walnut is considered formation in Fredericksburg Group.

Named for Goodland, Choctaw County, Okla. Old settlement of Goodland is present site of Good Switch on St. Louis and San Francisco Railroad, 3 miles south of Hugo, not present-day Goodland, 3 miles southwest of Hugo.

Goodnight Formation[1]

Pliocene: Northwestern Texas.

Original reference: W. F. Cummins, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 201–203.

Named for Goodnight, Armstrong County.

Goodrich Quartzite[1] (in Baraga Group)

Precambrian (Animikie Series): Northern Michigan.

Original reference: C. R. Van Hise and W. S. Bayley, 1895, U.S. Geol. Survey 15th Ann. Rept., p. 591.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 36. Lowermost formation of newly defined Baraga group. Underlies Hemlock formation; overlies Vulcan iron-formation.

Named for exposures at Goodrich mine in Marquette Range, Iron County.

†Goodridge Formation[1]

Goodridge Limestone

Pennsylvanian: Southern Utah.

Original reference: E. G. Woodruff, 1912, U.S. Geol. Survey Bull. 471, p. 80.

W. H. Easton and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 1, p. 146 (fig. 2). Appears on correlation chart as Goodridge limestone. Pennsylvanian.

Named for town of Goodridge, now known as Mexican Hat.

Goodsprings Dolomite[1]

Upper Cambrian to Devonian(?): Southeastern Nevada and southeastern California.

Original reference: D. F. Hewett, 1931, U.S. Geol. Survey Prof. Paper 162, p. 10, 11.

D. F. Hewett, 1956, U.S. Geol. Survey Prof. Paper 375, p. 38–40, pl. 1. Described in Ivanpah quadrangle (California-Nevada), where it is mapped in San Bernardino County, Calif. Underlies Sultan limestone; overlies Bright Angel shale or Pioche shale. Upper Cambrian to Devonian. Hazzard and Mason, working in Providence and Marble Mountains, and Hazzard, working in Nopah Range, have made fossil collections, and, with other workers, have attempted to correlate faunal zones found in beds equivalent to the Goodsprings dolomite; as a result they have given formation names to following units: Cadiz formation, about 700 feet thick, probably Middle Cambrian; Bonanza King formation, about 1,500 feet thick, Middle Cambrian; Cornfield Springs, about 3,000 feet thick, Middle Cambrian; and Nopah formation, Upper Cambrian. Hazzard also recognizes units equivalent to Pogonip limestone (Lower Ordovician), Eureka quartzite (Middle Ordovician), Ely Springs dolomite (Upper Ordovician), and an unnamed unit of Silurian age. Validity and significance of faunal zones and correlations not discussed in this report.

Named for exposures near town of Goodsprings, Goodsprings quadrangle, Clark County, Nev.

Goodwin Limestone (in Pogonip Group)

Goodwin Formation[1]

Goodwin Formation (in Mount Hamilton Group)

Lower Ordovician: Central Nevada.

Original reference: C. D. Walcott, 1923, Smithsonian Misc. Colln., v. 67, no. 8, p. 466–467, 475.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 25–27. Goodwin limestone lowest formation in Pogonip group (redefined), stratigraphically restricted to exclude beds now assigned to Windfall formation (new) which originally were included in Goodwin formation (of Walcott). Composed dominantly of well-bedded fairly massive light-gray limestone. Platy limestones occur locally. Light-gray to white chert common in lower 350 feet of unit; decreases in amount in higher beds. Much of limestone very fine grained or aphanitic. Thickness ranges from 900 to 1,100 feet in Eureka area, and about 1,650 feet in Antelope region. Underlies Ninemile formation (new); overlies Windfall formation.

F. L. Humphrey, 1960, Nevada Bur. Mines Bull. 57, p. 17–19, pl. 1. Reallocated to Mount Hamilton group (new). Comprises two members: lower, platy yellow and blue limestone about 800 feet thick; and upper, dolomite, about 700 feet thick. Basal formation of group; underlies Pogonip formation; overlies Dunderberg shale. Upper Cambrian. In White Pine district, forms peak of Mount Hamilton and extends along ridge from Seligman thrust south to Ophir fault; makes up greater part of upper plate of Monte Cristo thrust. [Editor's note states that since completion of Humphrey's ms., unit here called Goodwin has been named Windfall formation at Eureka by Nolan, Merriam, and Williams (1956) and Goodwin has been used by them for basal formation of their Pogonip group.]

Type locality: On either side of Goodwin Canyon just east of Hill 7708 of Eureka mining district quadrangle, where limestone is well exposed. Also recognized in Antelope Valley area. Named for Goodwin Canyon.

Goodwinian series[1]

Lower Ordovician: Nevada.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 53, 78.

Goodwyn Sandstone (in Hinton Formation)[1]

Mississippian: Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 297, 358.

Type locality: Along Princeton-Narrows Road on Fivemile Creek, at Goodwyn Chapel, Mercer County.

Goodwyn Shale (in Hinton Formation)[1]

Mississippian: Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 297, 359–360.

Type locality: Along Princeton-Narrows Road on Fivemile Creek, at Goodwyn Chapel, Mercer County.

Goose Creek Granite[1]

Precambrian: Central southern Montana.

Original reference: T. S. Lovering, 1929, U.S. Geol. Survey Bull. 811A, p. 16.

Occurs in Cooke district, southeastern corner of Park County. Goose Creek flows over it for practically its entire length.

†Goose Creek Marl[1] or phase[1]

Pliocene: Southern South Carolina.

Original references: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, advance copies; published in 1908, in South Carolina Geol. Survey, ser. 4, Bull. 2; 1907, Summary of mineral resources of South Carolina, p. 12, 18, 19.

Named for exposures at Yeaman's Hall, on Goose Creek, north of Charleston, Berkeley County.

Goose Egg Formation

Permian and Lower Triassic: Eastern Wyoming and central northern Colorado.

C. A. Burk and H. D. Thomas, 1956, Wyoming Geol. Survey Rept. Inv. 6, p. 3–10. Sequence of interbedded red to ocher shales and siltstone, thin limestones, gypsums, and limestone breccias. Unconformably overlies Tensleep, Casper, Hartville, or Minnelusa formations; conformably underlies Chugwater or Spearfish formations. At typical exposure, unit is 380 feet thick; overlies Casper formation and underlies Chugwater formation. Measured section at Goose Egg post office shows that formation comprises (ascending) shale and siltstone, 70 feet, represents Opeche shale of central and eastern Wyoming; gray fossiliferous limestone, 10 feet, represents Minnekahta tongue of Phosphoria; shale and siltstone, 58 feet, represents Glendo shale of central and eastern Wyoming: gray to purple limestone, 22 feet, represents Forelle tongue of Phosphoria; unnamed shale and siltstone, 40 feet; gypsum with interbedded limestone, 98 feet; purple to gray limestone, 6 feet, Ervay member; shale and siltstone, 48 feet; limestone and sandstone, 18 feet, Little Medicine member; and shale and siltstone, 10 feet, known to be facies of Dinwoody and Phosphoria formations of western Wyoming. Middle Permian and Lower Triassic.

N. C. Privrasky and others, 1958, Wyoming Geol. Assoc. Guidebook 13th Ann. Field Conf., p. 48–55. Formation divided into several mappable units all of which had been assigned names prior to definition of formation. Comprises (ascending) Opeche shale, Minnekahta limestone, Glendo shale, Forelle limestone, lower unnamed shale member, Ervay limestone, upper unnamed shale, and Little Medicine members. Top of formation can be mapped on surface when Little Medicine member can be identified, but, where Little Medicine grades into gypsum anhydrite sequence in Powder River Basin, it is generally difficult to determine top of formation; the top, however, can be picked accurately in subsurface. Permian-Triassic.

J. C. Stewart, 1958, Geology of the Dryhead-Garvin Basin, Bighorn and Carbon Counties, Montana (1:63,360): Montana Bur. Mines and Geology. Maximum thickness 60 feet. Composed of two members: basal red shale and upper carbonate member. Where upper carbonates are not present, it is impossible to distinguish redbeds of Goose Egg from those of Chugwater formation. Overlies Tensleep formation. In this area, rocks of Goose Egg are of Permian age only.

S. S. Oriel and L. C. Craig, 1960, *in* Guide to the geology of Colorado: Rocky Mountain Assoc. Geologists, p. 43, 45. Red beds and interbedded evaporites, including anhydrite, dolomite, and limestone, formerly included in basal part of Chugwater, are now assigned to Goose Egg formation in central and eastern Wyoming and in northern part of central northern Colorado.

Typically exposed near Goose Egg post office, NW¼ sec. 12, T. 32 N., R. 81 W., Natrona County, Wyo.

Goose Lake Clay

Pennsylvanian: Northeastern Illinois.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 25–26, 84, pl. 5. Composite of two or more underclays of lower Carbondale and upper Pottsville age. Occurs below Colchester coal. Approximately equivalent to Cheltenham fire clay of Missouri.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 33. Goose Lake clay is trade name and not recognized as part of Illinois stratigraphic nomenclature.

Named for occurrence near Goose Lake, east Grundy County. Used as a refractory clay.

Goosenest Flows

Recent: Northern California.

Howel Williams, 1949, California Div. Mines Bull. 151, p. 49, pls. 1, 2. Name applied to flows from Goosenest Volcano. Lithologically flows are extremely uniform. All are true block lavas; that is, they have crusts composed of smooth-faced blocks, as much as several yards across, that pass downward through a shattered layer into massive, unbroken lava.

Goosenest is conspicuous landmark in Macdoel quadrangle, Siskiyou County.

†Goose Pond Limestone[1]

Precambrian: Massachusetts.

Original reference: B. K. Emerson, 1899, U.S. Geol. Survey Bull. 159, p. 51–52.

Exposed north and east of Goose Pond, eastern Berkshire County.

Gorbut Member (of Gravel Point Formation)

Middle Devonian: Northern Michigan.

W. A. Kelly and G. Smith, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 3, p. 448 (fig. 1), 449, 457. Sequence of dark-colored to black limestone and black shale that occurs near middle part of formation. Thickness 10 feet.

Well exposed in LeGrand quarry northeast of Gorbut School, Cheboygan County.

Gordo Formation (in Tuscaloosa Group)

Upper Cretaceous: West-central Alabama and east-central Mississippi.

L. C. Conant and W. H. Monroe, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 37. Overlies Coker formation. Provisionally defined as the interbedded series of nonmarine gravel, sand, and clay beds between the horizon [top of Coker formation] at which gravel first appears consistently and abundantly and the base of the McShan formation (new). Base of unit is marked by abrupt appearance of abundant chert gravel and gravelly sand, the gravel gradually decreasing in abundance upward. Consists of two unnamed members: the lower consists of 130 feet of gravel and sand, and the upper chiefly of clay and nongravelly sand and ranges in thickness from a little less than 200 feet west of Warrior River to about 60 feet east of river.

W. H. Monroe, L. C. Conant, and D. H. Eargle, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 2, p. 200–204. Designated type section is an exposure of middle third of formation showing typical gravelly sand and mottled clay; thickness 92 feet. Geographically extended into Tishomingo County, Miss., where it is overlapped by Eutaw formation.

C. W. Drennen, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 3, p. 537. Recent study reveals evidences of a marine origin of at least part of formation.

W. S. Parks, 1960, Mississippi Geol. Survey Bull. 87, p. 22 (table 2), 23–26. In present report [Prentiss County], name Gordo refers to those sediments overlying Paleozoic basement and underlying McShan formation. Thickness 87 feet. Basal contact not exposed in area of report. Gulf series.

Type locality: South-facing slope of Little Bear Valley, sec. 20, T. 20 S., R. 13 W., 2 miles southeast of Gordo, Pickens County, Ala.

Gordon Sandstone (in Strawn Formation)[1]

Pennsylvanian: Central northern Texas.

Original references: E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., p. lxv, pl. 3; F. B. Plummer, 1919, Am. Assoc. Petroleum Geologists Bull., v. 3, p. 138.

Probably named for Gordon, Palo Pinto County.

Gordon Shale[1]

Middle Cambrian: Northwestern Montana.

Original references: C. D. Walcott, 1917, Smithsonian Misc. Colln., v. 67, no. 1, pub. 2444, p. 7–8; no. 2, pub. 2445, p. 16–19.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1076, 1082, 1087–1088, 1089–1090. Deiss (1933, Montana Bur. Mines and Geology Mem. 6) divided Cambrian of northwestern Montana into 11 formations (ascending): Flathead quartzite, Wolsey shale, Damnation limestone, Nannie Basin limestone, Dearborn limestone, Steamboat limestone, Pagoda oolite, Pentagon shale, Gordon Mountain limestone, Switchback limestone and Devils Glen dolomite. This sequence is revised as follows: Flathead sandstone, Gordon shale (instead of Wolsey), Damnation limestone (redefined to include Nannie Basin), Dearborn limestone. Pagoda limestone, Pentagon shale, Steamboat limestone (replaces Gordon Mountain limestone), Switchback shale, and Devils Glen dolomite. All appear to be Middle Cambrian. Thickness Gordon shale 140 to 274 feet.

Charles Deiss, 1943, Geol. Soc. America Bull., v. 54, no. 2, p. 219–220. Described in Saypo quadrangle where it is approximately 220 feet thick; overlies Flathead sandstone and underlies Damnation limestone.

Type locality: On Gordon Creek, 6 miles from South Fork of Flathead River, Ovando quadrangle, Powell County.

Gordon Creek Shale Member (of Cook Mountain Formation)

Gordon Creek Shale Member (of Wautubbee Formation)

Eocene: Eastern Mississippi.

E. P. Thomas, 1942, Mississippi Geol. Survey Bull. 48, p. 54, 57–59, profile B. Defined as uppermost member of Wautubbee formation in eastern Mississippi. Carbonaceous shale to blocky clay, chocolate-brown to light-yellowish-gray to red; basal 2 feet sandy and glauconitic and heterogeneous; typical feature of member is a thin ledge of white, sparingly glauconitic, siliceous siltstone that occurs 2 feet above base. Thickness 15 to 25 feet. Overlies Potterchitto member (new) with contact conformable and sharply defined; overlies Cockfield formation.

F. S. MacNeil, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 29. Considered uppermost member of Cook Mountain formation.

Type section: Along U.S. Highway 11 from Basic City to Pachuta, Clark, and Lauderdale Counties. Name taken from Gordon Creek which flows through Wautubbee Station and which is crossed by U.S. Highway 11 a short distance south of the station.

†Gordon Mountain Limestone[1]

Middle or Upper Cambrian: Northwestern Montana.

Original reference: C. F. Deiss, 1933, Montana Bur. Mines and Geol. Mem. 6, p. 39.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1089; 1939, Geol. Soc. America Spec. Paper 18, p. 35, 100. Name dropped from sequence of Cambrian formations recognized in northwestern Montana. Steamboat limestone, as used in 1933 sequence, has proved to be part of massive upper Dearborn limestone which was repeated in the Dearborn section by low-angle overthrust. Therefore, rocks to which name Steamboat was applied do not exist, and this name is freed for use and here applied to limestone and shale formerly designated Gordon Mountain limestone, which lies between the Pagoda or Pentagon and overlying Switchback formation.

Type locality: Middle part of cliffs which form lower part of east side of a peak, 8,300 feet elevation, the top of which is just 1 mile S. 48° E. of top of Pentagon Mountain. Forms top of central and principal peak of Gordon Mountain.

Gore Limestone (in Pottsville Formation)[1]

Pennsylvanian: Southeastern Ohio.

Original reference: E. Orton, 1878, Ohio Geol. Survey, v. 3, p. 889, 898, 903, pls. facing p. 889, 900, 912, 921.

Can be traced from Hocking Valley to Ohio River. Probably named for occurrence at Gore, Hocking County.

Gore Mountain Gabbro

Precambrian (Algoman): Northeastern New York.

M. H. Krieger, 1937, New York State Mus. Bull. 308, p. 28–32, 36. Chiefly medium-grained massive hypersthene-olivine gabbro or norite; speckled appearance on weathered surface. Bounded on the north and east by body of gabbroic and Whiteface-type anorthosite, on the south by a hornblende-garnet deposit, and on the west by Marcy-type and gabbroic anorthosite. Nowhere in contact with syenite, although syenite occurs within 100 to 300 feet of the gabbro on south side of garnet deposit. North of gabbro and between it and the anorthosite is a narrow zone of garnet gneiss. Considered younger than Grenville series.

Occurs in vicinity of Gore Mountain, Thirteenth Lake quadrangle.

Gorge Formation[1]

Upper Cambrian: Northwestern Vermont.

Original reference: Charles Schuchert, 1933, Am. Jour. Sci., 5th ser., v. 25, p. 359, 367, 368, 375–377.

Charles Schuchert, 1937, Geol. Soc. America Bull., v. 48, no. 7, p. 1052–1057. Lithogically separable into two parts: upper Gorge consists of 145 feet of thin-bedded dolomite and limestone, black dolomitic slate, at least eight intraformational flat-pebble breccia beds, and thick beds of sandstone; lower Gorge, about 75 feet thick, is massive dolomite, more or less replete with thick-bedded black dolomite inclusions, making whole series conglomeratic. Separated from overlying Highgate by thrust plane; overlies Hungerford slates (new). Keith (1924) called upper series of beds Missisquoi, but term was preoccupied.

A. B. Shaw, 1958, Geol. Soc. America Bull., v. 69, no. 5, p. 523 (table 1), 532 (fig. 5), 548–549, pl. 1. In this report [St. Albans area, Vermont], all rocks below Highgate thrust are assigned to Gorge formation. North of type section only, the lower dolomite is generally exposed. This dolomite is 550 feet near Highgate Center; 60 to 75 feet at international boundary overlying shale-limestone-shale sequence present only at type locality where it is more than 400 feet thick. Overlies Hungerford slate; underlies Highgate formation. Most contacts with Highgate are faults.

W. M. Cady, 1960, Geol. Soc. America Bull., v. 71, no. 5, p. 572, pl. 3 (correlation chart). Crops out in west limb of St. Albans synclinorium in Quebec, notably at Rosenberg, where it plunges north, at axis of minor anticline beneath Highgate formation. Cut out to west at Champlain overthrust. Gorge is uppermost formation in terrane that Clark (1934, Geol. Soc. America Bull., v. 45, no. 1) referred to "Milton dolomite."

Type locality: Highgate Gorge at Highgate, St. Albans quadrangle.

Gorgora Shale Member (of Fayette Formation)

Eocene (Jackson): Western Texas.

J. M. Patterson, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 2, p. 259 (fig. 2), 268–269. Name applied to a thick, predominantly shaly group of beds lying between Sanchez sandstone tongue above and Roma sandstone tongue below. Basal 30 feet are marine or lagoonal gray shales with some lignite beds; middle part made up of blue and green and red bentonitic shales, thin sandstones, and oyster beds usually less than 1 foot thick; upper 30 feet is persistently marine or brackish-water shale. Electric logs show member about 500 feet thick; in Zapata County, it increases to 900 feet, for the most part at expense of Roma sandstone.

Named from Gorgora Hill, located 1 mile northeast of Roma, Roma quadrangle. Beds make a north-south valley across Starr County and south half of Zapata County.

Gorman Formation (in Ellenberger Group)

Lower Ordovician: Central Texas.

V. E. Barnes and P. E. Cloud, Jr., 1945, Texas Univ. Bur. Econ. Geology Mineral Resources Circ. 34, p. 1, 8–19. Limestone and dolomite. Thickness 426 feet. Overlies Tanyard formation (new); underlies Honeycut formation (new). Cherokee Creek section, San Saba County described.

P. E. Cloud, Jr., V. E. Barnes, and Josiah Bridge, 1946, Texas Univ. Bur. Econ. Geology Pub. 4301, p. 144–146, pls. 4, 6 [1945]. Proposed that name Gorman formation be used to designate rocks similar to and correlative with those in the composite type section (herein designated). Basal zone characterized by varicolored and very fine grained dolomites—yellows, pinks, browns; upper calcitic facies consists principally of sublithographic, thickly to thinly bedded limestone with locally interbedded microgranular to fine-grained dolomite; a sequence of pure, unusually thick-bedded limestone present in top 40 to 60 feet of formation. Dolomitic facies 81 to 230 feet thick; calcitic facies 237 to 393 feet. Chert common. Where not thinned by post-Ellenburger truncation, between 426 and 498 feet thick.

P. E. Cloud, Jr., and V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Pub. 4621, p. 9–10, 39–40, 137–138, 158–159, 195–197, 227–229, 235–239, pls. 9, 35 [1946]. Type section described in detail. Stratigraphy described by areas.

Type section: Along and near gorge of Colorado River in vicinity of Gorman Falls, in southeastern San Saba County. Also present in McCulloch, Mason, Gillespie, Lampasas, and Burnet Counties.

Goshen Schist[1]

Precambrian: North Carolina and central southern Virginia.

Original reference: F. B. Laney, 1917, Virginia Geol. Survey Bull. 14, p. 19, 23, map.

Named for typical occurrence in vicinity of Goshen, in southeastern part of Virgilina district, North Carolina.

Goshen Schist[1]

Silurian(?): Western Massachusetts, southwestern New Hampshire, and southeastern Vermont.

Original reference: B. K. Emerson, 1898, U.S. Geol. Survey Geol. Atlas, Folio 50; 1898, Mon. 29, p. 177–183, pl. 34.

C. G. Doll, 1943, Am. Jour. Sci., v. 241, no. 11, p. 678. Age of mica schist designated Lower Devonian.

Typical region: Around Goshen, Mass.

Goshute Canyon Formation

Precambrian or Cambrian: Western Utah.

K. F. Bick, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 5, p. 1065–1066, 1068. Prospect Mountain quartzite, in Deep Creek Mountains, Utah, restricted at base to exclude 3,000 feet of alternating quartzite and shale units herein named Goshute Canyon formation. In absence of fossils, formation does not warrant a date more exact than Precambrian or Cambrian or both.

Type section: In and south of Goshute Canyon, Deep Creek Mountains. Section begins in NE¼ sec. 1, T. 11 S., R. 18 W., and ends in SW¼ sec. 36, T. 10 S., R. 18 W.

Gospel Hill Gneiss

Carboniferous: Eastern Massachusetts.

W. R. Hansen, 1956, U.S. Geol. Survey Bull. 1038, p. 39–41, pl. 1. Name suggested for a large mass of granitic rocks of Carboniferous age that Emerson (1917) mapped as a variant of Andover granite but in this area is regarded as a granitized product of Nashoba (new) and Marlboro formations. Medium to coarse textured and composed chiefly of microcline albite, quartz, muscovite, and biotite.

Well exposed on southeast slope of Gospel Hill in Hudson, the locality from which it was named. Extends from Concord quadrangle southwestward across Maynard quadrangle through corner of Hudson quadrangle and into Marlboro quadrangle.

Gosport Sand (in Claiborne Group)[1]

Eocene, middle: Southern Alabama and Georgia.

Original reference: E. A.Smith, 1907, Alabama Geol. Survey Bull. 9, p. 5, 18.

C. W. Cooke, 1939, Jour. Paleontology, v. 13, no. 3, p. 337–340. Gosport sand of Alabama, heretofore classified as topmost formation of Claiborne group, and the only known formation of upper Claiborne age, is nearly equivalent to Moodys marl of Mississippi, basal formation of Jackson group. Recommended that name Gosport be replaced by Moodys and that Claiborne group be restricted to formations heretofore classified as lower Claiborne.

L. D. Toulmin, Jr., 1944, Southeastern Geol. Soc. [Guidebook] 1st Field Trip, p. 11. Formation is here considered to include overlying lithologically and faunally similar *Poriachus* bed or "*Scutella*" bed which was formerly considered to be basal bed of Jackson group. Entire formation exposed at Claiborne Bluff where it is 24 to 26 feet thick; thickness 35 feet at Willow Branch in Choctaw County. Disconformably overlies Lisbon formation; conformably underlies Moodys Branch marl.

F. S. MacNeil, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 29. Correlation chart of outcropping Tertiary formations of Eastern Gulf region shows Gosport sand, in Claiborne group, above Lisbon formation and present in Alabama and Georgia. Base of Gosport sand, which lies disconformably on different parts of Lisbon formation in central eastern Alabama, passes into upper part of Cockfield formation in Mississippi and becomes indistinct. Gosport pinches out just east of Ocmulgee River in central Georgia, but recurs filling channels in Cretaceous beds for some distance to the east. C. W. Cooke believes that Gosport at type locality is entirely of Jackson age, but that in general it represents a facies different faunally from Moodys Branch formation; he does not believe that name Gosport should be used in Georgia.

Named for Gosport, a landing on Alabama River, a few miles below Claiborne Bluff, in Clarke County, Ala.

Goss Mill limestone facies[1] (of Floyds Knob Formation)

Lower Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv., Div. Geology Pub. 98, p. 76, 197–208.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 127–128, pl. 1. Mississippian facies nomenclature discussed. Correlation chart lists Goss Mill limestone facies of Floyds Knob formation.

Name derived from abandoned post office, Goss Mill, 6½ miles north of Medora, Jackson County.

Gothic Formation

Pennslvanian (Desmoinesian): Western Colorado.

R. L. Langenheim, Jr., 1951, (abs.) *in* Am. Assoc. Petroleum Geologists 36th Ann. Mtg. [Program], p. 29. Introduced for coarse and fine buff clastic rock assemblage overlying Belden shale and underlying Maroon formation (restricted). Thins toward northeast with concurrent thickening of the Maroon.

R. L. Langenheim, Jr., 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 4, p. 550 (fig. 2), 552 (fig. 3), 553–555, 556, 557, 558, 561–563. Thickness varies: 1,763 feet at Jack's Cabin, 1,350 at Granite Basin, 1,266 at Walrod Gulch, 572 at Cement-Taylor Divide, and 1,486 at Copper Creek (type section). Base and top arbitrarily designated; base is bottom of lowest prominent sandstone in section, and top is point where rock becomes predominantly red in color; upper boundary gradational in most places with occasional pink and red beds occurring well below formation boundary. At type section, conformably underlies Maroon formation, and base of section is intrusive contact; overlies Belden shale at Walrod Gulch and Cement-Taylor Divide; base of formation faulted out at Jack's Cabin and Granite Basin, and Gothic directly and unconformably overlain by Entrada sandstone.

Type section: Copper Creek, Crested Butte quadrangle, Gunnison County. Section is measured along top of ridge separating Copper Creek valley and Virginia basin and down wall of unnamed cirque northeast of Virginia basin.

Gould Glacial Substage

Gould Till

Pleistocene (Wisconsin): North-central Colorado.

D. F. Eschman, 1952, (abs.) Geol. Soc. America Bull., v. 63, no. 12, pt. 2, p. 1380. Time of next to oldest of four glacial advances in the area. Marked by a nearly complete moraine at elevation of about 9,000 feet. Followed Owl Mountain advance (new), preceded Silver Creek advance (new).

D. F. Eschman, 1955, Jour. Geology, v. 63, no. 3, p. 203–205, fig. 2, table 1. Deposits of substage mapped as Gould till. Till is more sandy than that of Owl Mountain substage but more clayey than that of Silver Creek substage; light gray brown; reddish-brown clayey streaks common in upper 3 feet.

Substage represented by three rather extensive deposits of till: on north side of Middle Fork Michigan River about one-half mile above village of Gould; between Middle Fork and South Fork Michigan River one-third mile south of Gould; and on southwest side of South Fork Michigan River 1½ miles south of Gould. In North Park.

Gould Shale Member (of Monterey Formation)[1]

Miocene, middle: Southern California.

Original reference: G. M. Cunningham and W. F. Barbat, 1932, Am. Assoc. Petroleum Geologists Bull., v. 16, no. 4, p. 418.

R. R. Simonson and M. L. Krueger, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 10, p. 1616. In Recruit Pass area, an interval of 1,850 feet of well-bedded siliceous light-brown shale, with a minor amount of interbedded tan silt and lentils of massive buff limestone, comprise a single lithologic unit from which have been collected faunules common to both the Gould shale and the Devilwater silt as they are defined on Chico-Martinez Creek. This unit has been termed the Devilwater-Gould member of the Monterey.

L. B. McMichael, chm., 1959, San Joaquin Geol. Soc. Guidebook Field Trip May 9, p. 13 (table) map, topog. profile. Underlies Devilwater silt member; overlies Media shale member of Temblor formation in Chico-Martinez Creek area. Thickness about 550 feet.

Type locality: Near center of W½ sec. 14, T. 29 S., R. 20 E., and continuing to southeast side of Chico-Martinez Creek, Kern County. Name is from Gould Hill near type locality.

Gouldbusk Limestone Member (of Moran Formation)

Permian (Wolfcamp Series): North-central Texas.

R. C. Moore *in* M. G. Cheney, 1948, Abilene Geol. Soc. [Guidebook] Spring Field Trip, June 11–12, p. 5, 13, sheets 3, 4. New name replacing Drake's Horse Creek limestone. Underlies Santa Anna shale member; overlies Watts Creek shale member.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheet 2. Name applied to limestone beds and included thin shale that were called Horse Creek limestone by Drake (1893). Sellards (1933, Texas Univ. Bull. 3232) pointed out duplication by Drake in use of this name, as applied to beds in his Strawn division farther east in Colorado River valley and to limestone, now considered Permian(?) in age, exposed in Coleman County; Sellards restricted application of Horse Creek to beds in the Strawn sequence but did not rename the upper beds, which have continued to be called Horse Creek. Member consists of (1) lower massive blue-gray limestone, 1 to 2 feet thick, that is medium grained and weathers brownish; (2) gray to yellowish clay shale, 2 to 6 feet thick, that is unfossiliferous; and (3) upper gray irregularly thin-bedded limestone of fine-grained texture that weathers in slabs and shelly fragments of light-gray color splotched with tan; average thickness of this bed 3 feet. Thickness about 8 feet.

Type locality: Village of Gouldbusk, southwest Coleman County.

Gourd Head Run Clay (in Conemaugh Formation)[1]

Pennsylvanian: Southwestern Pennsylvania.

Original reference: I. C. White, 1878, Pennsylvania Geol. Survey Rept. Q, p. 159–161, 308.

In Allegheny County.

Gourdhead Run Limestone in Conemaugh Formation)[1]

Pennsylvanian: Southwestern Pennsylvania.

Original reference: I. C. White, 1878, Pennsylvania 2d Geol. Survey Rept. Q, p. 159–161, 308.

Crops out locally in valley of Gourdhead Run in Hampton Township, Allegheny County.

Gouverneur Granite[1]

Precambrian: Northern New York.

Original reference: H. P. Cushing and D. H. Newland, 1925, New York State Mus. Bull. 259, p. 40–41.

Occurs just northwest of Gouverneur, St. Lawrence County.

Gouverneur Limestone[1]

Precambrian (Grenville Series) : Northwestern New York.

Original reference: A. F. Buddington, 1934, New York State Mus. Bull. 296, p. 136–138, map.

In Antwerp, Hammond, and Gouverneur quadrangles, St. Lawrence and Jefferson Counties.

Gove chalk

Cretaceous (Mid-Cretacic) : Northwestern Kansas.

[C. R.] Keyes, 1941, Pan-Am. Geologist, v. 76, no. 4, p. 304 (chart). Name applied to lower formation in Buckskinian series. Consists of chalks about 400 feet thick. Underlies Wallace shale. Overlies Apishapa shale of Pueblan series.

[C. R.] Keyes, 1941, Pan-Am. Geologist, v. 76, no. 5, p. 371–372. Proposed for heavy chalk formation in northwestern Kansas, heretofore regarded as representing Niobrara chalk of upper Missouri River country.

Occurs in Gove, Logan, and Wallace Counties.

Gove Member (of Berwick Formation)

Gove Member (of Littleton Formation)

Probably Ordovician and Silurian: Southeastern New Hampshire.

Jacob Freedman, 1950, Geol. Soc. America Bull., v. 61, no. 5, p. 453 (fig. 2), 460, 464, pl. 1. Chiefly silvery mica-schist, some mica-staurolite schist, mica-sillimanite schist and quartzite. Maximum thickness 200 feet. Member of Littleton formation of Lower Devonian age.

M. P. Billings, 1955, Geologic map of New Hampshire (1:250,000). U.S. Geol. Survey. Reallocated to Berwick formation. Age designated as probably Ordovician and Silurian.

M. P. Billings, 1956, Geology of New Hampshire, pt. 2, Bedrock geology: Concord, New Hampshire State Plan. Devel. Comm., p. 42, 43. Age of Berwick formation tentatively considered Silurian.

Exposed in narrow belt in Mount Pawtuckaway quadrangle between Nottingham Square and Raymond, Rockingham County. Named from Gove School, 2 miles northeast of Raymond.

Governor Diorite

Miocene, upper: Southwestern Colorado.

McClelland Dings, 1941, Geol. Soc. America Bull., v. 52, no. 5, p. 701–707, fig. 1. Essentially a dark fine-grained diorite. Fresh rock is fine grained and greenish gray to greenish black; weathered surfaces range from dull gray to reddish brown. Most prominent lithologic variation occurs along west-central side of Stony Mountain stock where diorite grades into light-colored hornblende-bearing monzonite facies. Most of outer border of diorite is in contact with San Juan tuff. In contrast to usually wide metamorphic cones developed in San Juan tuff, Silverton and Potosi volcanic rocks generally show only slight metamorphism where intruded by diorite. Older than Stony Mountain diorite (new).

Typically exposed a short distance north of Governor mine in Stony Mountain region, which in turn, is located about 5 miles southwest of Ouray in San Juan Mountains. Vertical range of exposures is 1,875 feet; highest outcrop occurs about 275 feet northwest of summit of Stony Mountain, and lowest in extreme southeast, near junction of Governor and Yankee Boy Creeks.

Gowanda Shale Member (of Perrysburg Formation)

Gowanda Shale[1]

Gowanda Shale Member (of Canadaway Formation)

Upper Devonian: Western New York.

Original reference: G. H. Chadwick, 1919, Geol. Soc. America Bull., v. 30, p. 157.

W. H. Bradley and J. F. Pepper, 1938, U.S. Geol. Survey Bull. 899, p. 19, pl. 3. In this report [southwestern New York], the whole series of beds from top of Dunkirk sandstone to highest beds mapped in area—more than 1,000 feet higher—are grouped as Gowanda shale and overlying beds undifferentiated.

Bradford Willard, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 251. Gowanda beds included in Canadaway group.

J. F. Pepper and Wallace de Witt, Jr., 1951, U.S. Geol. Survey Oil and Gas Inv. Chart OC–45. Rank reduced to member status in Perrysburg formation (new). Includes all rocks between top of South Wales member (new) and base of Laona sandstone. In section exposed along Cattaraugus Creek southeast of town of Gowanda, neither base nor top of Gowanda member can be identified although most of member is exposed in high cliffs bordering the creek. Because top of member has not been found east of Little Indian Creek, Perrysburg quadrangle, Cattaraugus County, name Gowanda is not applied to rock sequence to the east, and local names are used for units found there. Thickness 210 to 276 feet. Figure 4 shows that Canisteo (new), Caneadea, and Gowanda members, although closely related in time of deposition, are not strictly correlative throughout.

I. H. Tesmer, 1954, Dissert. Abs., v. 14, no. 12, p. 2318. Canadaway group reduced to formational status and Gowanda member renamed Forestville member and assigned to new type locality.

I. H. Tesmer, 1955, New York State Mus. Sci. Service Circ. 42, p. 10 (fig. 1), 15. Member of Canadaway formation. Overlies South Wales member; underlies Laona siltstone member. Thickness about 240 feet. As the Laona cannot be traced as far east as Gowanda, N.Y., Gowanda shale has no upper limit at its type locality. New type locality is herein assigned; this section described by Pepper and de Witt (1951).

Type locality (Tesmer, 1955): Along Walnut Creek, in vicinity of Forestville. Named for exposures in vicinity of Gowanda, Cattaraugus County.

Gower Dolomite[1]

Silurian (Niagaran): Central eastern Iowa.

Original reference: W. H. Norton, 1899, Iowa Geol. Survey, v. 9, p. 422, 423.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown on correlation chart as underlying Bertram dolomite and overlying Hopkinton dolomite (restricted).

Named for Gower Township, Cedar County.

Graciosa Coarse-Grained Member (of Careaga Sandstone)

Pliocene, upper: Southern California.

W. P. Woodring, M. N. Bramlette, and K. E. Lohman, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 10, p. 1356–1358; W. P. Woodring and M. N. Bramlette, 1950, U.S. Geol. Survey Prof. Paper 222, p. 42–49, pl. 1. Made up of two parts: lower consisting of coarse-grained soft sandstone and conglomerate, and upper consisting of coarse-grained soft sandstone. Thickness 25 to 425 feet. Underlies Paso Robles formation; on Graciosa Ridge, in Orcutt field, Graciosa overlaps Cebada member (new) and rests on Sisquoc formation.

Type region: On north flank of Purisima Hills south of Careaga Station on now-abandoned Pacific Coast Railroad, Santa Maria district.

Graford Formation (in Canyon Group)[1]

Graford Group

Upper Pennsylvanian: Central and central northern Texas.

Original references: F. B. Plummer, 1919, Am. Assoc. Petroleum Geologists Bull., v. 3, p. 133–145; F. B. Plummer and R. C. Moore, 1921, Texas Univ. Bull. 2132.

C. O. Nickell, 1938, Texas Univ. Bur. Econ. Geology Pub. 3801, p. 96–100. Formation redefined for Colorado River area. Winchell member (new) and Cedarton shale member (136 feet thick) are referred to as upper part of Graford and Adams Branch limestone and underlying shale (221 feet) referred to as lower Graford. Interval from top of Palo Pinto limestone of Cheney to top of Winchell member, an interval which may ultimately be found to include parts of Palo Pinto in other areas, is 357 feet. Underlies Brad formation (redefined).

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v 24, no. 1, p. 66 (fig. 1), 88. Rank raised to group. Restricted below to exclude beds nearly equivalent to the Brownwood and here included in Whitt group (new). Underlies Brad group. Includes (ascending) Adams Branch limestone. Cedarton shale, and Winchell limestone.

Robert Roth, 1956, North Texas Geol. Soc. Field Guidebook, May 25–26, fig. 2. Generalized columnar section shows group comprises (ascending) Wolf Mountain shales and sandstone. Staff limestone (Adams Branch limestone), unnamed shale, and Winchell limestone; overlies Whitt group.

D. H. Eargle, 1958, San Angelo Geol. Soc. Guidebook, Apr. 17–19, p. 51. Composite section of Brown and Coleman Counties shows formation comprises (ascending) Brownwood shale, Adams Branch limestone, and Cedarton shale members. Underlies Winchell limestone. Thickness about 300 feet.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 63, pl. 27. Formation as defined by Plummer and Moore (1921) for locality in Palo Pinto County was intended to include a thick limestone forming a prominent cuesta in that country, which they considered to be the Adams Branch, and the underlying shale, down to Palo Pinto limestone. They showed the Palo Pinto to be absent in Colorado River valley and defined basal member of Graford as Brownwood shale (Drake's Brownwood bed), in which they included their Capps limestone lentil and Rochelle conglomerate. They considered Rochelle to underlie Capps lentil, although later workers have found it to be in position of Capps, or to be a channel-fill conglomerate and sandstone of later age which has replaced their Capps. Cheney (1929, Texas Univ. Bull. 2913) showed that limestone at top of Graford in Palo Pinto County was not correlative with Adams Branch, but with part of limestone now called Winchell limestone. Sellards (1933, Texas Univ. Bull. 3232) defined Graford to include his Merriman (equivalent to part of Winchell as later defined) and underlying Cedarton shale of Plummer and Moore (1921) as well as their Adams Branch limestone and Brownwood shale. He included, therefore, in one formation all units he considered equivalent in both Brazos and Colorado River valleys. Graford, as herein redefined for Colorado River valley, includes (ascending) Brownwood shale (redefined), Adams Branch limestone, and Cedarton shale members. Underlies Winchell herein raised to rank of formation; overlies Strawn group. Thickness 285 feet in southern part of Brown County; 340 feet in central part of county.

Named for town of Graford, in Palo Pinto County, Brazos River region.

†Graford Limestone Member (of Graford Formation)[1]

Pennsylvanian: Central and central northern Texas.

Original reference: F. B. Plummer, 1919, Am. Assoc. Petroleum Geologists Bull., v. 3, p. 133–145.

Probably named for town of Graford, Palo Pinto County.

Grafton Formation[1]

Pennsylvanian: Southwestern Pennsylvania.

Original reference: G. H. Ashley, 1926, Pennsylvania Topog. and Geol. Atlas 65, pl. 4.

Punxsutawney quadrangle.

Grafton Member (of Conemaugh Formation)[1]

Pennsylvanian: Pennsylvania.

Original reference: M. E. Johnson, 1929, Pennsylvania Geol. Survey Topog. and Geol. Atlas 27, p. 31.

Pittsburgh quadrangle.

†Grafton Quartzite[1]

Precambrian: Eastern Massachusetts and northern Rhode Island.

Original reference: B. K. Emerson, 1898, U.S. Geol. Survey Mon. 29, p. 18.

Named for occurrence at Grafton, Worcester County, Mass.

Grafton Sandstone (in Conemaugh Formation)[1]

Grafton (upper) shale and sandstone member

Pennsylvanian: West Virginia, western Maryland, and eastern Ohio.

Original reference: I. C. White, 1903, West Virginia Geol. Survey, v. 2, p. 244, 255, 298.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 94 (table 11), 148. Member of Elk Lick cyclothem in report on Athens County. Upper Grafton is used for shale and sandstone, locally massive sandstone, which heretofore has been called Morgantown in Ohio. Thickness 24½ feet. Occurs above Birmingham redbed member and below Elk Lick limestone member. Conemaugh series.

Has been quarried in vicinity of Grafton Hills, Taylor County, W. Va.

Graham Formation (in Cisco Group)[1]

Graham Group

Upper Pennsylvanian: Central and central northern Texas.

Original reference: R. C. Moore, 1921, Am. Assoc. Petroleum Geologists Bull., v. 5, p. 324.

Wallace Lee and C. O. Nickell, 1938, Texas Univ. Bur. Econ. Geology Pub. 3801, p. 12–53, 118–122. Formation, in Brazos River valley, comprises (ascending) channel deposits, Salem School limestone member, shale and sandstone, Gonzales limestone member, shale and sandstone, Bunger limestone member, shale with numerous channels and unconformities, and Wayland shale member. Thickness at least 590 feet, not counting channel deposits (Kisinger channel) at base. Interval from top of Bunger limestone to top of formation are referred to as post-Bunger deposits or post-Bunger cycles. Nine cycles discussed. Group of limestones in No. 8 post-Bunger cycle is herein named Rocky Mound limestone member. Gunsight member, which at its type locality is overlain by Wayland shale, has not been identified in Stephens County. Underlies Avis sandstone member of Thrifty formation. In Colorado River basin, formation is divided into (descending) Wayland shale, Gunsight limestone, and Bluff Creek members. Thickness 243 feet from top of Home Creek limestone of northern Brown County up to base of *Bellerophon* bed of Drake (1893, Texas Geol. Survey 4th Ann. Rept., pt. 1).

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 90. Rank raised to group. Includes following formations (ascending): Gonzales, North Leon, Bunger, post-Bunger cycles 1–7, Gunsight limestone, and Wayland shale. Underlies Thrifty group; overlies Caddo Creek group.

John Kay, 1956, North Texas Geol. Soc. Field Guidebook, May 25–26, fig. 4. Generalized columnar section shows that group comprises (ascending) Salem School limestone, Bunger limestone, Number 3 limestone, Upper Gunsight limestone, Rocky Mound limestone, Wayland shale, Number 9 limestone, Avis sandstone, Ivan limestone, Blach Ranch limestone, Breckenridge limestone.

D. H. Eargle, 1958, San Angelo Geol. Soc. Guidebook, Apr. 17–19, p. 50. Composite section of Brown and Coleman Counties shows that formation comprises (ascending) Bluff Creek shale, Gunsight limestone, Wayland shale, and Ivan limestone. Underlies Thrifty formation; overlies Caddo Creek formation. Thickness about 260 feet.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 58 (table 1), 68–69, pl. 27. Boundary between Graham and Thrifty formations has been defined as base of Avis sandstone member (Sellards, 1933, Texas Univ. Bull. 3232; Lee and Nickell, 1938), a prominent sandstone in Brazos River valley. In Colorado River valley [this report], this boundary is not mappable because only discontinuous lenses of sandstone are present at stratigraphic position of Avis. Also, the Ivan limestone member which overlies the Avis is discontinuous. Recommended that base of Speck Mountain limestone, a persistent member throughout Colorado River valley and probably equivalent to Blach Ranch limestone in Brazos River valley, be designated boundary between Thrifty and Graham formations. In areas where Speck Mountain limestone member has been replaced by channel-fill conglomeratic sandstone, as by Parks Mountain sandstone member in southeastern Coleman County, boundary between the Graham and the Thrifty is considered base of sandstone. Thickness of Graham, as herein defined, is about 265 feet in southeastern Coleman County and about 290 feet in northern Brown County. Comprises (ascending) Bluff Creek shale, Gunsight limestone, Wayland shale, and Ivan limestone members. Overlies Caddo Creek formation of Canyon group.

Type locality: Bluff on Salt Creek, west of Graham, Young County, Brazos River region.

†Graham Jasper (in Niobrara Formation)[1]

Upper Cretaceous: Northwestern Kansas.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 51.

Named for Graham County.

Graham Limestone (in Bluefield Formation)[1]

Mississippian: Southwestern Virginia and southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 299, 387.

Type locality: In a cut of Norfolk & Western Railway, about one-half mile northwest of new station at Graham (now Bluefield), Tazewell County, Va.

Graham Sandstone (in Bluefield Formation)[1]

Mississippian: Southwestern Virginia and southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Marion, and Summers Counties, p. 299, 385.

Type locality: In cut of Norfolk & Western Railway, about one-half mile northwest of new station at Graham (now Bluefield), Tazewell County, Va.

Graham Shale (in Bluefield Formation)[1]

Mississippian: Southwestern Virginia and southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 299, 387.

Type locality: In cut of Norfolk & Western Railway, about one-half mile northwest of new station at Graham (now Bluefield), Tazewell County, Va.

Graham Ferry Formation

Pliocene: Southeastern Mississippi.

G. F. Brown and others, 1944, Mississippi Geol. Survey Bull. 60, p. 45–54. Series of deltaic sediments overlying Pascagoula formation and disconformably underlying Citronelle formation. Continental and brackish-water deposits predominate although type locality contains marine fossils. Thickness ranges from 113 feet in Jackson County to 975 feet at Gulfport.

Type sections: Rice Bluff, NW¼NW¼ sec. 38, T. 5 S., R. 7 W., and bluff beneath power line near center of irregular sec. 38, T. 5 S., R. 7 W., west bank Pascagoula River, Jackson County. Midway between the two bluffs is an old river crossing locally known as Graham Ferry.

Grahamville Formation

Cambro-Ordovician: East-central Vermont.

W. F. Brace, 1953, Vermont Geol. Survey Bull. 6, p. 47–48, tables 2, 3. Dark-gray-green massive albite grit occurs at base. Above is a variety of dark fine-banded sandstones, sandy graphitic phyllites, and, in southern part of outcrop area, buff ankeritic sandstone. At top is Plymouth member consisting of massive gray dolomite and white vitreous thinly bedded quartzite. Total thickness ranges from about 700 feet at Chittenden to 1,500 feet at Plymouth, depending on thickness of middle unit. Underlies Pinney Hollow formation; overlies Tyson formation. Upper boundary difficult to trace in this area because of color similarities of phyllites;

arbitrarily placed beneath lowest green phyllite bed 50 feet or more in thickness. Name credited to Thompson (unpub. thesis).

Well exposed in lower slopes of Ottauquechee and Black River valleys south of West Bridgewater in Rutland area.

Grainger Shale[1] or **Formation**

Mississippian: Northeastern Tennessee, western North Carolina, and southwestern Virginia.

Original references: A. Keith, 1895, Phil. Soc. Washington Bull. 12, p. 74, 78, pl. 1; 1896, U.S. Geol. Survey Geol. Atlas, Folio 27, p. 3.

J. E. Sanders, 1952, (abs.) Geol. Soc. America Bull., v. 63, no. 12, pt. 2, p. 1295. Grainger formation traced and mapped in detail in Greendale syncline northeastward from type locality in Grainger County, Tenn., to Tennessee-Virginia line. Basal member, 200 to 300 feet thick, changes laterally from fissile gray shale in Grainger County to fossiliferous green siltstone in Hawkins County, and to yellowish silty shale near State line. Lower sandstone member composed of 75 to 200 feet of very fine grained medium-bedded sandstone that locally includes pebbly layers and fossiliferous beds. Middle sandstone member predominantly structureless green fossiliferous siltstone with a few beds of fine-grained sandstone, shale, and fossiliferous glauconitic material. Upper sandstone member, 100 to 150 feet thick, is gray, coarse grained, crossbedded feldspathic sandstone and conglomerate. Fossils indicate formation spans part of Kinderhook and probably most of Osage intervals of Mississippian standard section. Grainger formation, as used here, agrees with "Grainger shale" of Campbell (1894, U.S. Geol. Survey Geol. Atlas, Folio 12) and requires that "Grainger shale" of Keith (1896) be redefined in its type section to exclude Devonian beds included by Keith.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, p. 106–107, pt. 1, pls. Formation mapped in eastern Tennessee. Overlies Chattanooga shale; underlies Newman limestone; grades into Fort Payne chert. Thicknesses: 1,100 feet on southeast side of valley in Blount and Monroe Counties; about 900 feet in belt southeast of Clinch Mountain; about 500 feet in belts in Hancock and eastern Claiborne Counties; less than 350 feet at Cumberland Gap.

R. B. Neuman and R. L. Wilson, 1960, U.S. Geol. Survey Geol. Quad. Map GQ–131. In Blockhouse quadrangle, Tennessee, formation consists of siltstone, sandstone, and conglomerate. Gray and blue-gray noncalcareous siltstone dominant in lower two-thirds; gray medium- to coarse-grained, crossbedded calcareous sandstone with layers of pebble conglomerate in upper third. Thickness 1,000 feet. Overlies Chattanooga shale; underlies Greasy Cove formation (new) which replaces term Newman as used in this area. Brachiopods, pelecypods, and bryozoans abundant in some areas suggest correlation with Keokuk limestone of Mississippi Valley.

Named for Grainger County, Tenn.

Grampian Limestone[1]

Cambrian(?) and Ordovician: Southwestern Utah.

Original reference: B. S. Butler, 1913, U.S. Geol. Survey Prof. Paper 80.

E. H. East, 1957, (abs.) Geol. Soc. America Bull., v. 68, no. 12, pt. 2, p. 1825. Upper contact marked by extensive overthrust, and contact with Morehouse quartzite is not conformable as proposed by Butler (1913), necessitating stratigraphic revision to replace Grampian by Ely limestone, Kanosh shale, and unnamed interval of Cambrian beds.

Type locality: Grampian Hills, Frisco district.

Grampian Hills Member (of Nanafalia Formation)

Eocene, lower: Alabama.

B. W. Blanpied and R. T. Hazzard, 1939, Shreveport Geol. Soc. Guidebook 14th Ann. Field Trip, p. 128. Shown on correlation chart as upper member of formation. Overlies Salt Mountain limestone member.

P. E. LaMoreaux and L. D. Toulmin, 1959, Alabama Geol. Survey County Rept. 4, p. 96 (fig. 32), 100, 101, 102, 108 (fig. 38), 109–110, 112, 116, 117, pls. 2, 3. Allocated to member status in Nanafalia formation. Blanpied and Hazzard did not specify type locality or section. At type locality and section, herein designated, entire thickness, including upper and lower contacts, is exposed. Consists of yellowish- to greenish-gray indurated clay or claystone; includes several beds of greenish-gray coarse-grained glauconitic sand and sandstone and, in upper part, gray to greenish-gray massive blocky clay. Thickness 80 to 110 feet in Grampian Hills area. Overlies unnamed middle member of formation; underlies Tuscahoma sand.

Type locality and section: In continuous roadcut along Alabama Highway 41 on south side of Gravel Creek valley, 7.1 miles south of Camden on road to Monroeville, Wilcox County. Named for exposures in Grampian Hills, southern part of Wilcox County.

Grampus Gneiss[1]

Precambrian: Eastern New York.

Original references: H. P. Cushing, 1907, New York State Mus. 60th Ann. Rept., pt. 2; 1907 New York State Mus. Bull. 115, p. 463, 467–469.

Named for exposures around Grampus Lake, Hamilton County.

Granby Conglomerate[1]

Pennsylvanian (?): Southwestern Missouri.

Original reference: E. R. Buckley and H. A. Buehler, 1906, Missouri Bur. Geol. and Mines, v. 4, 2d ser., p. 33, 87, 88, 100, 102, pl. 14.

Probably named for Granby or Granby Junction, Newton County, or for Granby Branch Junction, Jasper County.

Granby Tuff (in Newark Group)[1]

Upper Triassic: Connecticut and south-central Massachusetts.

Original reference: B. K. Emerson, 1891, Geol. Soc. America Bull., v. 2, p. 451–456.

Robert Balk, 1957, Geol. Soc. America Bull., v. 68, no. 4, p. 494–497, pl. 1. Consists of four mappable units: Granby tuff, a brown, purple, or maroon compact or stratified diabase tuff or tuffaceous sandstone; a diabase flow, the Hampden diabase of Emerson (1898), a fine-grained locally altered compact or vesicular diabase; intrusive diabase pipes, dikes and sills of fine-grained diabase; and Black Rock diabase breccia. Maximum thickness 500 feet. Younger than earliest beds of Longmeadow sandstone; older than middle and upper parts of the Longmeadow. Triassic.

E. D. McKee and others, 1959, U.S. Geol. Survey Misc. Geol. Inv. Map I–300, table 1. Correlation chart shows Granby tuff in Connecticut.

Exposed in vicinity of Granby, southeastern Hampshire County, Mass.

Grandad Limestone[1]

Silurian: Southeastern Indiana.

Original reference: W. W. Borden, 1874, Indiana Geol. Survey 5th Ann. Rept., p. 138, 143, 146.

Derivation of name not stated.

Grand Bayou Member (of Hall Summit Formation)

Paleocene (Midway): Northwestern Louisiana and northeastern Texas.

D. P. Meagher and L. C. Aycock, 1942, Louisiana Dept. Conserv. Geol. Pamph. 3, p. 13. Named in stratigraphic summary of Louisiana lignite district. Name credited to G. Murray, Jr.

G. E. Murray, Jr., and E. P. Thomas, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 1, p. 48 (fig. 2), 59; G. E. Murray, 1948, Louisiana Dept. Conserv. Geol. Bull. 25, p. 130–131, pl. 10. Typical carbonaceous shale. Maximum thickness 80 feet on south flank of Sabine uplift. In northeastern part of uplift, believed to thin and merge with overlying Bistineau member; overlies Loggy Bayou member. Paleocene. Type locality designated. Mapped in Texas.

Type locality: Exposures in secs. 19, 20, 29, and 30, T. 14 N., R. 9 W., Red River Parish, La. Outcrop belt extends into Shelby County, Tex.

†Grand Canyon Group[1]

Precambrian: Northern Arizona.

Original reference: C. D. Walcott, 1883, Am. Jour. Sci. 3d, v. 26, p. 440–441.

†Grand Canyon Schist[1]

Precambrian: Northern Arizona.

Original reference: J. W. Powell, 1876, Geology of eastern portion of Uinta Mountains.

Occurs at bottom of Grand Canyon.

Grand Canyon Series[1]

Precambrian: Northern Arizona.

Original reference: J. W. Powell, 1876, Geology of the eastern portion of Uinta Mountains, p. 43, 61–62, 70.

C. E. Van Gundy, 1934, Grand Canyon Nature Notes, v. 9, no. 8, p. 345–346; 1951, Geol. Soc. America Bull., v. 62, no. 8, p. 953–959, pl. 1. Series includes more than 12,000 feet of sediments, diabase, and basalts. Comprises (ascending) Unkar, Nankoweap (new), and Chuar groups. Algonkian.

C. R. Keyes, 1938, Pan-Am. Geologist, v. 38, no. 2, p. 107 (table). Table shows series (Proterozoic) comprises (ascending) Hotauta, Newberry (new), Bass, Hakatai, Shinumo, and Dox formations. Thickness 5,350, feet. Underlies Cardenasan series (new); overlies Proterozoic.

C. A. Anderson, 1951, Geol. Soc. America Bull., v. 62, no. 11, p. 1333. Overlies older Precambrian rocks which include Vishnu schist.

Grand Creek Sand Member (of Nanafalia Formation)

Probably lapsus for **Gravel Creek Sand Member** (of Nanafalia Formation).

Grand Detour Formation (in Platteville Group)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., p. 6, fig. 3. Consists of dolomite or limestone, alternately pure and argillaceous, partly cherty, thin- to thick-bedded. Thickness about 500 feet. Subdivided into seven members (ascending): Dement, Walgreen, Stillman, Clement, Hely, Victory, and Forreston (all new). Underlies Nachusa formation (new); overlies Mifflin formation.

Occurs in Dixon-Oregon area.

Grande limestone[1]

Mississippian: Southwestern New Mexico.

Original reference: C. R. Keyes, 1908, Am. Inst. Mining Engrs. Bi-Monthly Bull. 19, p. 7–21.

At Lake Valley, Sierra County.

Grandeur Member or **Tongue** (of Park City Formation)

Permian: Utah, Idaho, Montana, and Wyoming.

T. M. Cheney and others *in* V. E. McKelvey and others, 1959, U.S. Geol. Survey Prof. Paper 313–A, p. 3 (fig. 1), 12–17, 36–37, pls. 2, 3. Defined as the interbedded carbonate rock, cherty carbonate rock, carbonitic sandstone, and carbonitic siltstone that overlie Weber quartzite in Utah, Wells formation (restricted) in Idaho, Tensleep sandstone in Wyoming, and Quadrant formation in Montana. Underlies Meade Peak phosphatic shale member (new) of Phosphoria. Thickness at type locality about 280 feet. Present at all outcrops of Park City formation in Uinta Mountains except east of Lake Fork on south flank and ranges in thickness from featheredge to about 350 feet.

Type section: About 1 mile southwest of Grandeur Peak, in sec. 36, T. 1 S., R. 1 E., on north side and near mouth of Mill Creek Canyon, Salt Lake County, Utah.

Grand Falls Chert Member (of Boone Formation)[1]

Grand Falls Chert Member (of Keokuk Limestone)

Grand Falls Formation

Lower Mississippian: Southwestern Missouri, southeastern Kansas, and northeastern Oklahoma.

Original reference: A. Winslow, 1894, Missouri Geol. Survey, v. 7, 417–419.

R. C. Moore, G. M. Fowler, and J. P. Lyden, 1939, Geol. Soc. America Spec. Paper 24, p. 3, 10. Named subdivisions of Keokuk are Grand Falls chert, at base, and Short Creek oolite near top. Grand Falls is an irregularly bedded mass of dense "butcher knife" chert, mostly light gray but appears light yellowish brown or dark brown in weathered exposures. Thickness at type locality (including beds below water level) 35 feet. Locally discontinuous but identified over hundreds of square miles in Tri-State district. Osage series.

E. B. Branson, 1944, Missouri Univ. Studies, v. 19, no. 3, p. 197, 204. Report refers to Grand Falls chert at top of Reeds Spring member of Chouteau formation. Also refers to Reeds Spring limestone and quotes at length from unpublished manuscript by Clark (1941) who classed the Grand Falls as member of Reeds Spring.

E. L. Clark and T. R. Beveridge, 1952, Kansas Geol. Soc. Guidebook 16th Field Conf. p. 13 (fig. 1), 14–15 (fig. 2), 38 (fig. 12), 40 (fig. 15), 41 (fig. 16), 53 (fig. 26), 72 (fig. 1). Report refers to Grand Falls formation. Overlies Reeds Spring formation or Pierson formation; underlies Burlington formation or Keokuk formation.

C. H. Behre, Jr., and A. V. Heyl, Jr., 1959, Deutschen Geol. Gesell. Zeitschr. v. 110, pt. 3, p. 517 (fig. 2). Chart shows Grand Falls member of Boone formation below Short Creek member and above Reeds Spring member. Thickness 6 to 38 feet.

Named for development around Grand Falls, Newton County, Mo.

Grand Falls Formation

Lower Cambrian: Central Maine.

Rudolf Ruedemann and E. S. C. Smith, 1935, Am. Jour. Sci., 5th ser., v. 30, no. 178, p. 354. Name proposed for thick sequence of metamorphic shales and sandstones.

R. B. Neuman, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B166–B167. Discussion of pre-Silurian stratigraphy in Shin Pond and Stacyville quadrangles. Grand Falls formation (Ruedemann and Smith, 1935) occurs in this area. Name Grand Falls is preoccupied.

Exposed for several miles along the Grand Falls of the Penobscot River, Penobscot County.

Grandfield Conglomerate[1]

Pliocene or Pleistocene: Southwestern Oklahoma.

Original reference: M. J. Munn, 1914, U.S. Geol. Survey Bull. 547, p. 17, 28–30.

Named for Grandfield, Tillman County.

Grand Forks Schist[1]

Age (?): Southern British Columbia, Canada, and northeastern Washington.

Original reference: R. A. Daly, 1912, Canada Geol. Survey Dept. Mines Mem. 38, maps 9, 10.

Mapped at and around Township of Grand Forks, British Columbia.

Grandge Slate

Lower Ordovician: Northwestern Vermont.

Charles Schuchert, 1937, Geol. Soc. America Bull., v. 48, no. 7, p. 1014. 1072–1074, 1075. Slate containing limestone blocks and calcareous sandstone. Probably several hundred feet thick. Unconformably overlies Highgate formation. May be same unit as Georgia slate.

P. E. Raymond, 1937, Geol. Soc. America Bull., v. 48, no. 8, p. 1080, 1134. Replaces Georgia slate. Type section described as shale.

A. B. Shaw, 1958, Geol. Soc. America Bull., v. no. 5, p. 550. Name Grandge slate abandoned. Included in Highgate formation as herein defined.

Type locality: On Oliver Grandge Farm, 4½ miles north of Highgate Center, Franklin County.

†Grand Gulf Group[1]

Miocene: Gulf Coastal Plain.

Original reference: E. W. Hilgard, 1860, Report on agriculture and geology of the State of Mississippi: [Mississippi Geol. Survey], p. 3, 108, 147–154.

U. B. Hughes and others, 1940, Mississippi Geol. Soc. [Guidebook] Field Trip, Feb. 10, 11, chart. Group includes (ascending) Bucatunna clay, Chickasawhay (lower and upper), Catahoula sand, Hattiesburg clay, and Pascagoula clay. Occurs above Vicksburg group [boundary between Oligocene and Miocene is queried, and Bucatunna and Chickasawhay may be considered part of Vicksburg group].

H. N. Fisk, 1940, Louisiana Geol. Survey Bull. 18, p. 138–174. Term Grand Gulf group revived. Considered to include all sediments exposed in central Louisiana from Vicksburg Oligocene to southernmost exposures of Tertiary sediments in Rapides Parish. As thus defined, includes Catahoula and Fleming formations.

Named for exposures in bluff at Grand Gulf, Claiborne County, Miss.

†Grand Gulf Sandstone[1]

Miocene: Southern Mississippi and southern Alabama.

Original reference: B. L. C. Wailes, 1854, Report on agriculture and geology of Mississippi: [Mississippi Geol. Survey], p. 216–219.

Named for exposures in bluff at Grand Gulf, Claiborne County, Miss.

Grandhaven Limestone Member (of Stotler Limestone)

Grandhaven Limestone (in Wabaunsee Group)[1]

Pennsylvanian (Virgil Series): Northeastern Kansas, southwestern Iowa, and southeastern Nebraska.

Original reference: R. C. Moore, May 1935, Kansas Geol. Survey Bull. 20, table opposite p. 14.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc, Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1), 2275. Rank reduced to member status in Stotler limestone (new). Overlies Dry shale member; underlies Friedrich shale member of Root shale (new).

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 11, fig. 5. Bluish gray, weathers to buff brown, commonly micaceous and argillaceous; upper part tends to be slabby. Thickness about 2 feet. Underlies Friedrich shale; overlies Dry shale. Wabaunsee group. Condra and Reed suggest that their Morton limestone may occupy horizon of Grandhaven limestone.

Type locality: In sec. 31, T. 13 S., R. 14 E., near Grandhaven, Shawnee County, Kans.

Grandian Epoch or Series[1]

Pleistocene (Nebraskan and Aftonian): Illinois and Iowa.

Original reference: G. F. Kay, 1931, Geol. Soc. America Bull., v. 42, pt. 1, p. 449–452.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 38. In Iowa and Illinois, the Pleistocene is classed as a Period (System), and four Epochs (Series) are used to include a glacial-interglacial pair each. These are Grandian (Nebraskan and Aftonian), Ottumwan (Kansan and Yarmouthian), Centralian (Illinoian and Sangamonian), and Eldoran (Wisconsinan and Recent). Of these units, each of first three essentially coincides with a glacial cycle; present data indicate that the youngest (Eldoran) includes two distinct cycles, each of which is complex within itself. These terms have not been adopted for official use in Kansas partly because of this inconsistency and partly because retention of Quaternary as the System-Period with Pleistocene as its contained Series-Epoch would force erection of new category of names to include these terms and thus produce further complication of classification system.

Named for Grand River valley, southwestern Iowa.

Grand Island Formation[1]

Grand Island Member (of Meade Formation)

Pleistocene (Kansan) : Southern and eastern Nebraska, eastern Colorado, western Iowa, and Kansas.

Original reference: A. L. Lugn and G. E. Condra, 1932, Geol. Soc. America Bull., v. 43, no. 1, p. 190.

J. C. Frye, Ada Swineford, and A. B. Leonard, 1948, Jour. Geology, v. 56, no. 6, p. 520 (fig. 3), 521, 522; R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 15. Lower member of Meade formation in Kansas. Underlies Sappa member. Thickness commonly 25 feet.

G. E. Condra and E. C. Reed, 1950, Nebraska Geol. Survey Bull. 15–A, p. 12 (fig. 6). Correlation table shows relation of Nebraska Pleistocene formations to continental glaciations on cyclic basis involving erosion, alluviation, eolation, and soil formation. Grand Island sand and gravel (Kansan) divided into "Upper Grand Island" and "Lower Grand Island". Thickness of Upper Grand Island about 28 feet in Little Sioux Valley, near Harrison-Monona County line, Iowa.

C. B. Schultz, E. C. Reed, and A. L. Lugn, 1951, Science, v. 114, no. 2969, p. 547–548. Proposed that name Grand Island be restricted to Upper Grand Island, and name Red Cloud sand and gravel be applied to Lower Grand Island of Condra and Reed (1950), which includes pro-Kansan sand and gravel. The restricted Grand Island was deposited during retreat and waning of Kansas ice sheet (late Kansan and early Yarmouth Sappa time).

D. R. Hill and J. M. Tompkin, 1953, U.S. Geol. Survey Bull. 1001, p. 9 (table 1), 23–24. Geographically extended into Wray area, Colorado. Does not crop out in natural exposures. Thickness about 10 feet, measured in gravel pits. Overlies Ogallala formation.

C. W. Hibbard, 1958, Am. Jour. Sci., v. 258, no. 1, p. 55 (fig. 1). Chart of revised classification of Kansas Pleistocene shows Grand Island as member of unnamed formation in Meade group.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Shown as formation in Kansas.

Named for exposures at and around Grand Island, Hall County, Nebr.

Grand Lake Member[1] (of Presque Isle Stage)

Middle Devonian : Northeastern Michigan.

Original reference: A. W. Grabau, 1915, unpublished ms., as reported by E. R. Pohl, 1930, U.S. Natl. Mus. Proc., v. 76, art. 14, p. 4, 25.

A. S. Warthin, Jr., and G. A. Cooper, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 5, p. 573, 580. Pohl (1930) showed Presque Isle stage composed of Bell shale, Grand Lake, and Long Lake members. In classification of Traverse rocks of Thunder Bay region, Presque Isle series or stage with its synonym, Long Lake series, are abandoned. It might have been possible to have used name Grand Lake limestone instead of Rockport Quarry, but term Grand Lake had never been adequately described.

Probably named for Grand Lake, eastern part of Presque Isle County.

Grand Ledge cyclothem (in Saginaw Formation)

Pennsylvanian: Southern Michigan.

Michigan Geol. Soc., 1954, *in* Geologic cross section of Paleozoic rocks central Mississippi to northern Michigan: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 28. One of seven cyclothems in the Saginaw. Consists of irregularly laminated sandy shale and shaly sandstone overlain by a hard, fine-textured underclay; underclay is overlain by coal above which are basal beds of a younger cyclothem.

Exposed in vicinity of Grand Ledge, Eaton County.

†Grand Portage Amygdaloid[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: A. R. Marvine, 1873, Michigan Geol. Survey, v. 1, pt. 2, p. 35, 69.

Named for occurrence in old Grand Portage mine, Houghton County.

†Grand Portage flow[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Copper district of Keweenaw Point.

Grand Portage Graywacke[1]

Precambrian (upper Huronian): Northeastern Minnesota.

Original reference: N. H. Winchell, 1899, Minnesota Geol. Nat. History Survey Final Rept., v. 4, p. 510.

Occurs in Grand Portage Indian Reservation, Cook County.

†Grand Prairie Formation[1]

Lower Cretaceous: Eastern Texas.

Original reference: R. T. Hill and R. A. F. Penrose, 1889, Am. Jour. Sci., 3d, v. 38, p. 470.

Named for prairie, known to old travelers as the "Grand Prairie," which extends from 4 miles east of Fort Worth to 7 miles west of Weatherford, Parker County.

Grand Rapids Group[1]

Mississippian: Michigan.

Original reference: A. C. Lane, 1893, Michigan Geol. Survey Rept. 1891 and 1892, p. 66; reported by M. E. Wadsworth.

G. M. Ehlers and W. E. Humphrey, 1944, Michigan Univ. Contr. Mus. Paleontology, v. 6, no. 6, p. 114–117. Discussion of fauna from Point au Gres limestone at Grand Rapids. History of nomenclature reviewed, and references made to work of Lane (1893, 1895, 1899, 1900, 1909). Concluded that Point au Gres instead of "Grand Rapids" or "Bayport" should be used for limestone under discussion. Usage is based on definition of Point au Gres by Douglass (1841 [1839]). Continued reference to limestone as "Bayport" would be unfortunate because this name and "Grand Rapids" were used only in casual manner by Lane.

Named for exposures at Grand Rapids, where Bayport limestone is quarried.

†Grand Rapids Limestone[1]

Mississippian: Michigan.

Original reference: A. C. Lane, 1899, U.S. Geol. Survey Water-Supply Paper 30, p. 81.

Grand Rapids Sandstone[1]

Devonian(?): Northwestern Ohio.

Original references: E. Orton, 1888, Ohio Geol. Survey, v. 6, p. 20; 1890, Ohio Geol. Survey 3d Organization, 1st Ann. Rept., p. 24.

Wood County.

Grand River Formation

Grand River Group

Pennsylvanian: Southern Michigan.

W. A. Kelly, 1936, Michigan Dept. Conserv., Geol. Div. Pub. 40, Geol. Ser. 34, p. 159, 206–214. Pennsylvanian formations in Michigan, which are stratigraphically higher than beds of the Saginaw group, have been variously called Woodville, Ionia, and Red beds. However, either term, Woodville or Ionia, implies correlation of all younger beds than the Saginaw although there are few facts to substantiate such correlation. Grand River group proposed to include various formations, which stratigraphic evidence indicates are younger than Saginaw, though not strictly to be correlated with each other as occupying the same position in the geologic time scale. Group would include Woodville sandstone, Ionia sandstone, Eaton sandstone (new), and any other formations correlated with them.

G. V. Cohee, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 11. Grand River formation, youngest Pennsylvanian formation in area, is present only in northern Eaton and Ingham Counties.

G. V. Cohee, Carol Mach, and Margery Holk, 1951, U.S. Geol. Survey Oil and Gas Inv. Chart OC–41, sheet 5. Recommended that Eaton and Ionia sandstones be considered members of Saginaw formation and that Woodville be restricted to a sandstone in member of lower part of Saginaw.

Michigan Geol. Soc., 1954, *in* Geologic cross section of Paleozoic rocks central Mississippi to northern Michigan: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 28–29. Herein considered a formation with Eaton and Ionia as members.

Formations of group are exposed in mines and quarries, and natural outcrops in valley and drainage basin of the Grand River, from vicinity of Jackson to that of Ionia.

Grand River Limestone

Mississippian (Chester Series): Northeastern Oklahoma.

R. A. Brant, 1941, *in* Tulsa Geol. Soc. [Guidebook] Field Trip, Oct. 18, strat. sections. Fossiliferous, coarsely oolitic limestone as much as 65 feet thick. Overlies Batesville formation; underlies Fayetteville formation. Formerly a part of the "Mayes" formation.

R. C. Slocum, 1955, Oklahoma Geol. Survey Circ. 35, p. 12. Brant (1941) applied term "Grand River" to limestones between Fayetteville shale and "Batesville" siltstone along Grand River in Mayes County. Although term is ideal for this locality, it is preoccupied. Term Hindsville is substituted for purpose of this report.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 107. Abandoned by Oklahoma Geological Survey.

Type section: Along Grand River in sec. 26, T. 20 N., R. 19 E., Mayes County.

Grandstand Formation (in Nanushuk Group)

Lower Cretaceous: Northern Alaska.

R. L. Detterman *in* George Gryc and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 2, p. 235–237, figs. 2, 4, 5. Predominantly marine but contains several interfingering units of Killik tongue (new) of nonmarine Chandler formation in upper part. Thick sandstone beds in lower part, which, consequently, is better exposed. Basal part of formation predominantly fine-grained light-olive-gray to dark-yellow-red sandstone, with thin greenish "salt-and-pepper" sandstone bed at base, and subordinate amounts of siltstone and shale. In upper part, siltstone and silt shale constitute about 50 percent of unit; minor amounts of coal in sequence. Thickness of type section about 1,700 feet. Unconformably overlies Tuktu formation (redefined) ; underlies and intertongues with Killik tongue. Age shown on chart as Lower(?) and Upper (?) Cretaceous.

F. M. Robinson, 1959, U.S. Geol. Survey Prof. Paper 305–J, p. 527, fig. 46. Age given as Lower Cretaceous.

Type locality: On left bank of Anaktuvuk River, where river breaches Grandstand anticline, lat 68°56′ N., long 151°10′ W.

Grand Tower Limestone[1]

Grand Tower Limestone (in Ulsterian Group)

Middle Devonian: Southwestern Illinois and eastern Missouri.

Original reference: C. R. Keyes, 1894, Missouri Geol. Survey, v. 4, p. 30, 42.

J. M. Weller, 1940, Illinois Geol. Survey Rept. Inv. 71, p. 16, 25, 26; 1944, Illinois Geol. Survey Bull. 68, p. 89, 95. Described in Illinois, where it is included in Ulsterian group. Best exposed at Devil's Bakeoven north of Grand Tower; here nearly entire thickness of formation, 124 feet, is present. In northern Union County, outcrops are restricted; formation thins out southward and is not known to extend much south of Highway 146. Succeeds Dutch Creek sandstone conformably but appears to be separated by an unconformity from overlying "Lingle" limestone; this contact has been observed only in hills north of Grand Tower where an abrupt change in lithology and fossils occurs. Strata intervening between the Grand Tower limestone (or Dutch Creek sandstone where Grand Tower is absent) and the Mountain Glen shale (or Springville shale where the Mountain Glen is absent) have been referred by Savage (1920) to the Misenheimer shale and the Lingle and Alto limestones. Restudy of this area suggests that recognition of these formations may be neither stratigraphically logical nor practically feasible.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Age shown as Lower and (or) Middle Devonian.

Carey Croneis, 1944, Illinois Geol. Survey Bull. 68, p. 103 (chart), 115–119, 121. Described in southeastern Missouri where it crops out in synclinal block of Little Saline fault zone southeast of Ozora and in Quarry Hill structure to northeast. Also occurs in small patches in hills south of Little Saline Creek on St. Mary's road south of Ozora. In Perry County, distribution is limited to two exposures: a narrow strip less than 2 miles long in fault zone between Bailey and Burlington escarpments near Union School, and the other, one-half mile south of Ridge School, is bounded on south by faults. Thickness in Ste. Genevieve County 225 to 250 feet; in Perry County 100 feet or less. In Ste. Genevieve County, no basal arenaceous beds are present, contact with Little Saline strata is gradational, and first appearance of cherty limestone is arbitrarily assumed to mark base of formation. Underlies Beauvais formation in Little Saline fault area; in Perry County, underlies St. Laurent formation.

Named for exposures in vicinity of Grand Tower, Jackson County, Ill.

Grand View Dolomite[1]

Upper Devonian: Southern central Idaho.

Original reference: C. P. Ross, 1932, Idaho correlation chart compiled by M. G. Wilmarth.

C. P. Ross, 1947, Geol. Soc. America., v. 58, no. 12, pt. 1, p. 1109–1110, pl. 1. Thickness 2,115 feet in Borah Peak quadrangle, Idaho. Overlies Jefferson dolomite; underlies Three Forks limestone.

Type locality: Grand View Canyon, near center T. 12 N., R. 20 E., south of Challis, Custer County.

Grandview Limestone (in Brazil Group)

Pennsylvanian (Pottsville Series): Southwestern Indiana.

D. W. Franklin, 1944, Illinois Acad. Sci. Trans., v. 37, p. 87 (fig. 1), 89, 90. Light-gray finely crystalline crinoidal limestone with bedded gray chert. Thickness 5 feet. Lies near top of group about 15 feet below Buffaloville coal in Staunton group.

Type exposure: Along State Highway 66 east of Grandview in Ohio River bluffs in SE¼NE¼ sec. 15, T. 6 S., R. 4 W., Spencer County.

Graneros Shale (in Colorado Group)[1]

Graneros Shale Member (of Mancos Shale)

Graneros Shale (in Benton Group)

Lower and Upper Cretaceous: Eastern Colorado, northwestern Iowa, western Kansas, southeastern Montana, Nebraska, northeastern New Mexico, South Dakota, and eastern Wyoming.

Original reference: G. K. Gilbert, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 2, p. 564.

A. J. Collier, 1922, U.S. Geol. Survey Bull. 736, p. 79–84, table. In Osage oil field, Weston County, Wyo., Graneros shale comprises about 1,000 feet of shale in which following members can be distinguished (ascending): Skull Creek shale, Newcastle sandstone, Nefsy shale (new), Mowry shale, and Belle Fourche shale. Overlies Dakota sandstone; underlies Greenhorn limestone. Colorado group.

R. C. Moore, 1935, Rock formations of Kansas *in* Kansas Geol. Soc: Wichita, [Am. Assoc. Petroleum Geologists 20th Ann. Mtg., Mar 21–23]. Overlies Solomon formation (new) of Dakota group.

M. E. Wing, 1940, South Dakota Geol. Survey Rept. Inv. 35, p. 3–6, chart facing p. 10. Formation, in Butte County, comprises lower unit, 250 to 300 feet thick, of dark shale, with sandstone at top that is believed to be Newcastle; middle unit, or Mowry, 250 feet thick; upper unit, about 600 feet thick, of dark shales, with limestone ledge herein named Middle Creek limestone. Overlies Fall River (Dakota) sandstone; underlies Greenhorn limestone.

B. F. Latta, 1941, Kansas Geol. Survey Bull. 37, p. 74. In Hamilton County, conformably overlies Cockrum sandstone (new) of Dakota group.

Norman Plummer and J. F. Romary, 1942, Kansas Geol. Survey Bull. 41, pt. 9, p. 330–331 (fig. 4), 337. Overlies Janssen clay member of Dakota formation.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 15 (fig. 7), 18. Thickness 60 to 70 feet in northeastern Nebraska (near Ponca and Homer) ; 40 to 90 feet in subsurface in Republican Valley; 550 to 700 feet in northern Dawes County; about 900 feet in exposures around Black Hills. Formation changes facially westward becoming the argillaceous Belle Fourche shale above and gray calcareous Mowry shale below in western Nebraska, eastern Wyoming, and southwestern South Dakota. Underlies Greenhorn limestone; overlies Omadi sandstone (new) of Dakota group.

J. B. Reeside, Jr., 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 10. As shown on correlation chart, Graneros shale in southern Great Plains occupies interval between Dakota sandstone below and Greenhorn limestone above. In northern Great Plains, the equivalent interval is occupied by (ascending) Mowry shale and Belle Fourche shale. Newcastle sandstone is shown equivalent to Dakota sandstone, and Skull Creek shale is shown as a Lower Cretaceous formation below the Newcastle and above Fall River sandstone of Inyan Kara group.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 153, 155 (fig. 3). Consists of shale and clay shale, fissile, noncalcareous, and blue black, that weathers to dark gray and coffee brown. Thickens southward across western Kansas. Thickness 30 to 35 feet in Russell County; 65 feet near Colorado line. Overlies Janssen clay of Dakota formation; underlies Lincoln limestone member of Greenhorn limestone. Colorado group; Gulfian series.

B. C. Petsch, 1946, South Dakota Geol. Survey Rept. Inv. 53, p. 43, 44 (fig. 13), 47. Basal formation in Benton group. Underlies Greenhorn limestone; overlies Dakota formation. Outcrops of Graneros present in bluffs along east side of Big Sioux River in Iowa between Westfield and Sioux City.

N. W. Bass, C. E. Straub, and H. O. Woodbury, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 68. As used in this report [Model anticline, Las Animas County, Colo.] Graneros shale is 105 feet thick and includes interval between Dakota sandstone below and Lincoln limestone member of Greenhorn limestone. Includes Thatcher limestone member (new). As originally defined by Gilbert (1896), Graneros shale in vicinity of Pueblo was 200 to 210 feet thick and included in its upper part beds that are herein designated Lincoln limestone and Hartland shale members of Greenhorn limestone. If these younger beds were included in the Graneros, its total thickness over Model anticline would be 153 feet. Upper Cretaceous.

C. H. Dane, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 78. Lowermost member of Mancos shale in area of this report [eastern side of San Juan basin, Rio Arriba County, N. Mex.]. Consists chiefly of gray and black evenly thin-bedded shale; locally shale is sandy in basal 6 to 10 feet. Thin beds of bentonite present, particularly in lower and upper part. Underlies Greenhorn limestone member; overlies Dakota sandstone. Upper Cretaceous.

B. C. Petsch, 1949, South Dakota Geol. Survey Rept. Inv. 65, p. 8–15. In Black Hills region Graneros formation divided into (ascending) Skull Creek shale, Newcastle sandstone, Nefsy shale, Mowry shale, and Belle Fourche shale members. Estimated thickness 1,200 feet in area of this report [Whitewood anticline]. Nefsy not distinguished from Mowry in area of present report. Overlies Dakota (Fall River) formation; underlies Greenhorn formation. Unit termed Middle Creek limestone by Wing (1940) is herein renamed Orman Lake limestone and classified as bed in Belle Fourche member.

A. J. Crowley, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 1, p. 83–107. Newcastle sandstone, formerly regarded as member of Graneros shale, is herein assigned to Lower Cretaceous. Table 1 shows restricted Graneros shale comprises (ascending) Mowry shale and Belle Fourche shale in Black Hills area.

G. O. Bachman, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM–137. Cretaceous system in area of this report [northwestern Mora County, N. Mex.] is represented by Dakota sandstone and Benton formation; the Benton consists of Graneros shale, Greenhorn limestone, and Carlile shale equivalents. Upper Cretaceous.

U.S. Geological Survey currently designates the age of the Graneros as Lower and Upper Cretaceous. This age designation is made on the basis that the base of Colorado Group is drawn at top of Mowry and its equivalents. Base of Colorado group thus drawn is accepted as boundary between Upper Cretaceous and Lower Cretaceous. Where the Mowry is not present the age of the Graneros is designated as Upper Cretaceous.

Named for Graneros Creek, Walsenburg quadrangle, Pueblo County, Colo.

Granger Sandstone Member (of Spoon Formation)

Pennsylvanian: Northern Kentucky and southeastern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 32, 45 (table 1), 65, pl. 1. Proposed to replace Curlew sandstone in order to retain name Curlew for the limestone. In southeastern Illinois, stratigraphically above O'Nan coal member (new) and below Creal Springs limestone (new). Thickness 20 to as much as 60 or 70 feet. Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification retained but is entirely independent of rock-stratigraphic classification.

Type locality: Indian Hill, near Curlew, Union County, Ky. Name derived from village of Grangertown, about 5 miles southeast of Indian Hill.

Granite Creek Granodiorite[1]

Probably Jurassic or Cretaceous: Northern Idaho.

Original reference: J. L. Gillson, 1927, Jour. Geology, v. 35, no. 1.

Named for exposures around mouth of Granite Creek, Bonner County.

Granite Falls Garnetiferous Quartz Diorite Gneiss

Precambrian: Southwestern Minnesota.

E. H. Lund, 1956, Geol. Soc. America Bull., v. 67, no. 11, p. 1481–1482, pl. 2. Forms part of basic complex of area. Characterized by abundant pink garnet. Contains numerous quartz veins and quartz and granite stringers, which in general follow foliation of the gneiss but frequently cut across it. Locally, the large amount of introduced siliceous material results in an abnormally light-gray color. Just south of Minnesota River, the gneiss is characterized by fairly uniform nearly east-west strike of foliation with average dip of 40° to south. Structure is reflected in topography by a number of east-west ridges with scarp-like slopes on north side and more gentle slopes on south side.

Underlies an area of about 2 square miles south of Granite Falls, Yellow Medicine County.

Granite Falls Limestone

Upper Pennsylvanian and (or) Permian: Northwestern Washington.

R. A. Anderson, 1941, Washington State Coll. Research Studies, v. 9, no. 3, p. 189, 201. Fusulinid-bearing limestone composed largely of cryptocrystalline calcite. Lies in contact with a dark basic rock.

Exposed in quarry near E¼ cor. sec. 5, T. 30 N., R. 7 E., about 3 miles northeast of Granite Falls and on south side of Canyon Creek, Snohomish County.

Granite Gap Granite

Precambrian: Southwestern New Mexico.

Elliot Gillerman, 1958, New Mexico Bur. Mines Mineral Resources Bull. 57, p. 9–10, 12, table 1, pl. 1. Where fresh and unaltered, granite is a holocrystalline equigranular medium-grained light-pink to gray rock with a hypidiomorphic texture. Unconformably underlies Bolsa quartzite.

Named from exposures at Granite Gap, where Highway 80 crosses the Peloncillo Range, Hidalgo County. In vicinity of Granite Gap, exposures occupy an area of 1½ miles square. Also crops out in narrow band, a few hundred feet wide to one-half mile, between main ridge of Peloncillo Mountains and smaller ridge north of Preacher Mountain.

Granite Mountain Porphyry[1]

Tertiary, lower(?): Central Arizona.

Original reference: F. L. Ransome, 1919, U.S. Geol. Survey Prof. Paper 115, p. 126, pl. 45.

E. D. Wilson, 1952, Arizona Geol. Soc. Guidebook for Field Trip Excursions in Southern Arizona, p. 8. Age shown as Laramide (Late Cretaceous to early Tertiary).

Principal body is the irregular intrusive mass that makes up much of Granite Mountain.

Granite Park Member (of Siyeh Formation or Limestone)[1]

Precambrian (Belt Series): Northwestern Montana.

Original reference: C. L. Fenton and M. A. Fenton, 1931, Jour. Geology, v. 39, no. 7, p. 670–679.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1896–1897. Thickness ranges from 280 to 900 feet. At type locality, which is here designated, member consists of 285 feet of dolomites, argillites, and thin quartzites, with thin strata of oolite, sandstone, and mud breccia. Clastic materials diminish northwestward on crest of Lewis Range. Represents final stage of Siyeh sedimentation. Separated from underlying Goathaunt member by *Collenia frequens* zone. Underlies Spokane formation.

Richard Rezak, 1957, U.S. Geol. Survey Prof. Paper 294–D, p. 138–139. Discussion of stromatolites of Belt series, *Collenia multiflabella* zone of Siyeh limestone represents Granite Park member of Fenton and Fenton (1937).

Type locality: Cliffs of Continental Divide southeastward from Granite Park, Glacier National Park, where strata are crossed by trail to the dike above Grinnell Glacier. Well exposed in Hole-in-the-Wall Basin, near Boulder Peak, and on trail from Alderson to Carthew Lakes, Waterton Lakes Park.

Graniteville Granite

Precambrian: Southeastern Missouri.

H. B. Graves, 1938, Acad. Sci. St. Louis Trans., v. 29, no. 5, p. 119. Proposed for granites of area [St. Francois Mountains] that appear to be related to the granites at Graniteville. Granite at Graniteville is red and coarse grained, and much of it is porphyritic; pegmatitic phases appear in southern part of area. Similar granite occurs near Cornwall and Coldwater.

Graniteville is in northeastern Iron County.

Grant Conglomerate[1]

Precambrian (probably middle Huronian): Northern Minnesota.

Original reference: J. W. Gruner, 1929, Lake Superior Min. Inst. Proc., v. 27, p. 184–187.

J. W. Gruner, 1941, Geol. Soc. America Bull., v. 52, no. 10, p. 1600. In Knife Lake area, a granite pebble conglomerate lies on greenstone in secs. 10 and 11, T. 65 N., R. 6 W., east of Hanson Lake. It lies in a wedge formed by two faults; hence, its relationship to other members is not clear. Thickness does not exceed 600 feet. It was called Grant conglomerate by Gruner (1929); however, it does not deserve an individual name because it probably does not represent as long an erosion interval as was thought at first.

Well exposed in vicinity of Grant Lake, Lake County.

Grant Shale Member (of Winfield Limestone)

Grant Shale (in Chase Group)[1]

Permian: Eastern Kansas and southeastern Nebraska.

Original reference: G. E. Condra and J. E. Upp, 1931, Nebraska Geol. Survey Bull. 6, 2d ser., p. 50.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 44. Member of Winfield limestone. Consists of gray calcareous fossiliferous shale; a distinct unit except in southern Kansas where it probably has been included in lower part of Cresswell limestone member. Thickness in northern part about 10 to 12 feet; in central about 6 feet. Overlies Stovall limestone member. Wolfcamp series.

Type locality: Between 5 and 6 miles north of Florence, Marion County, Kans. Named for Grant Township in Marion County.

Grant Mills Granodiorite

Grants Mills Granite[1]

Devonian or older: Northern Rhode Island.

Original reference (Grants Mills granite): C. H. Warren and S. Powers, 1914, Geol. Soc. America Bull., v. 25, p. 437 (map), 458.

Alonzo Quinn, R. G. Ray, and W. L. Seymour, 1948, *in* Alonzo Quinn and others, Rhode Island Port and Indus. Devel. Comm. Geol. Bull. 3, p. 15, geol. map. Redescribed as gray to greenish-gray medium-grained granodiorite, generally porphyritic and massive to foliated in structure. Contains inclusions of greenstone, schist, and quartzite. Grades into Esmond granite; relative ages unknown. Intrusive into an unnamed quartz diorite in Olney Pond area. Magmatic origin suggested. Devonian or earlier.

Occurs near Grants Mills, Providence County.

Granton trap[1]

Upper Triassic: Northern New Jersey.

Original reference: N. H. Darton, 1890, U. S. Geol. Survey Bull. 67.

Occurs midway between Jersey City, Hudson County, and Hackensack, Bergen County.

Grantsville Formation

Middle Triassic: Southwestern Nevada.

S. W. Muller and H. G. Ferguson, 1939, Geol. Soc. America Bull., v. 50, no. 10, p. 1592–1594, pl. 2. Divided into two members: a lower conglomerate member with minor argillites and an upper limestone member with minor shales. Thickness of lower member, several hundred feet; upper member 100 to 300 feet. Rests unconformably upon a thick section of altered volcanic rocks and overlain unconformably by Luning formation.

N. J. Silberling, 1959, U.S. Geol. Survey Prof. Paper 322, p. 10–14, pls. 10, 11. Described in Union district, Shoshone Mountains, Nev., where it is about 700 feet thick. Overlies Pablo formation; underlies Luning formation.

Type locality: On crest of spur separating mouth of Union Canyon from next large canyon to the north. Named after mining camp on west flank of Shoshone Mountains in north-central part of Tonopah quadrangle. Outcrops also on ridge due north of Grantsville, at mouth of Grantsville Canyon, and on low isolated hill just south of Union Canyon.

Granville Beds[1]

Mississippian: Central Ohio.

Original reference: L. E. Hicks, 1878, Am. Jour. Sci., 3d, v. 16, p. 217–219.

Named for Granville, Licking County.

Granville Enstatite Serpentine[1]

Silurian: Massachusetts.

Original reference: B. K. Emerson, 1898, U.S. Geol. Survey Mon. 29, p. 90.

Occurs in Old Hampshire County now divided into Franklin, Hampshire, and Hampden Counties.

Granville Formation

Lower Cambrian: West-central Vermont.

P. H. Osberg, 1952, Vermont Geol. Survey Bull. 5, p. 49–55, 116. Typically a gray to black rusty-weathering graphitic albite-quartz-chlorite-miscovite schist. Thin beds of blue-gray quartzite are interbedded with the schist in places. Beds of dark-green albite-epidote-calcite-chlorite schist and lenses of buff-colored dolomitic marble also occur. Thickness about 350 to 400 feet throughout the area with a slight thickening probably toward the northern border. Underlies Pinney Hollow formation; overlies Monastery formation (new).

Named from exposures in township of Granville. Lithology well displayed in outcrops in White River three-tenths of a mile northwest of village of Granville, Rochester quadrangle.

774–954—vol. 2—66——9

Granville shale facies[1] (of Cuyahoga Formation)

Mississippian (Kinderhook) : Central Ohio.

Original reference: J. E. Hyde, 1915, Jour. Geology, v. 23, p. 657, 679–682.

F. T. Holden, 1941, Illinois Acad. Sci. Trans., v. 34, no. 2, p. 172; 1942, Jour. Geology, v. 50, no. 1, p. 43 (fig. 2), 46–47. Includes Black Hand siltstone member and Raccoon shale member. Lies between Toboso conglomerate facies to the northeast and the Hocking Valley conglomerate facies to the southwest.

Occurs in Morrow, Knox, Fairfield, Licking, and Perry Counties.

Grape Creek Limestone Member (of Clyde Formation)

Grape Creek Formation (in Clyde Group)

Grape Creek Shale and Limestone (in Clyde Formation)[1]

Permian: North-central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 412, 427.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Given formational status in the Clyde herein given group status.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheet 2. In Colorado River valley, member constitutes lower three-fifths of formation. Consists of thin beds of uniform blue-gray limestone. Thickness uniformly about 325 feet. Underlies Talpa limestone member; overlies Bead Mountain limestone member of Belle Plains formation. Division of the Clyde into members in this area is not as natural as in the area north of Abilene; in this mapped area they might appropriately be treated as formations.

P. T. Stafford, 1960, U.S. Geol. Survey Bull. 1081–G, p. 275. Grape Creek limestone member, in Brazos River valley, is 20 to 45 feet thick, and consists of upper and lower limestone beds separated by shale. Limestone beds range from 2 to 8 feet in thickness and shale from 15 to 40 feet. Overlies unnamed shale member at base of formation; separated from overlying Talpa limestone member by unnamed shale member.

Named for Grape Creek, Coleman County.

Grapevine conglomerates[1]

Tertiary, lower: Southern California.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 52, 79.

Named for exposures around base of Grapevine Range, on east side of Death Valley, Inyo County.

Grapevine Sandstone (in Kanawha Formation[1] or Group)

Pennsylvanian: Southern West Virginia.

Original reference: R. V. Hennen and D. B. Reger, 1914, West Virginia Geol. Survey Rept. Logan and Mingo Counties, p. 211.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 62, 84. In this report, the Kanawha is considered a group.

Type locality: At mouth of Grapevine Creek, Mingo County.

Grapevine Gulch Formation (in Ash Creek Group)

Precambrian (Yavapai Series) : Central Arizona.

C. A. Anderson and S. C. Creasey, 1958, U.S. Geol. Survey Prof. Paper 308, p. 17–20, pl. 1. Six map units recognized in the formation: coarse-grained lithic tuffaceous sedimentary rock; fine-grained tuffaceous sedimentary rock interbedded with chert and siltstone; volcanic breccia; jasper-magnetite beds; intercalated dacitic flows that in part grade into dacitic intrusive masses; and intercalated andesitic flows. Estimated thickness 8,000 to 10,000 feet. Overlies dacite of Burnt Canyon southwest of Mingus Mountain but elsewhere rests upon and intertongues with Deception rhyolite. Top of formation not exposed.

Well exposed southwest of Mingus Mountain where it forms broad northwestward-trending belt, cut off by Shylock fault to the west and by younger quartz diorite to the south and east. Named from excellent exposures along Grapevine Gulch, Jerome area, Yavapai County.

Graphic lavas[1]

Precambrian: Central northern New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257–259; 1915, Conspectus of geologic formations of New Mexico, Des Moines, Robert Henderson, State Printer, p. 4, 7.

Derivation of name not given.

†Graphic-Kelly Limestone[1]

Mississippian: Central or southwestern New Mexico.

Original reference: C. L. Herrick, 1904, Am. Geologist, v. 13, p. 310–312.

Occurs in Kelly mining district, Socorro County.

Grass Creek Member (of Frontier Formation)

Upper Cretaceous: Northeastern Utah.

L. A. Hale, 1960, Wyoming Geol. Assoc. Guidebook 15th Ann. Field Conf., p. 136 (chart 1), 139 (fig. 1), 140, 141, 143 (fig. 2), 145 (fig. 3). Consists of basal unit, 600 to 700 feet, of lenticular coarse-grained sandstone and reddish clay shales of fluviatile origin; upper unit contains thin-bedded tan sandstone alternating with thin layers of gray shale, 275 to 325 feet thick. Upper unit seems to correlate with Trexler's Meadow Creek sandstone member (new). Contains early Niobrara fauna. Overlies Dry Hollow sandstone member (new); underlies Judd shale member (new).

Named for exposures in lower drainage of Grass Creek valley near Echo Reservoir and in Lewis Canyon southwest of reservoir, Summit County.

Grasselli Dolomite (in Kingsport Formation)

Ordovician (Canadian) : Eastern Tennessee.

C. R. L. Oder and H. W. Miller, 1945, Am. Inst. Mining Metall. Engineers Tech. Pub. 1818, p. 4, 6 (table 2). Composed of dark fine-grained to finely crystalline dolomite through which are scattered a few white spots and at base of which is a green shale and some quartzite grains. Underlain by brown limestone which may be altered to crystalline dolomite; overlain by 3 to 5 feet of fine-grained to finely crystalline mottled and sparsely spotted greenish to pinkish medium-gray dolomite. Thickness about 5 feet.

Named because of its prominent position in ore section in Grasselli mine at New Market, Jefferson County, about 14 miles northeast of Mascot.

Grass Valley Formation

Upper Triassic: North-central Nevada.

S. W. Muller, H. G. Ferguson, and R. J. Roberts, 1951, Geology of the Mount Tobin quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–7]; 1951, Geology of the Winnemucca quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–11]. Dominantly shales and quartzitic sandstones. Shales are mostly slaty, in part micaceous, olive drab, or black, with prominent worm trails. Quartzitic sandstones are white, gray, or black, and locally crossbedded. In Tobin Range, nearly all quartzite; in Stillwater Range, up to 30 percent limestone, mostly in upper part, remainder slate and quartzite; at type locality, limestone lenses near top. Thickness may exceed 2,000 feet. Underlies Dun Glen formation (new); overlies Natchez Pass formation (new).

Type locality: Mountain slope facing Grass Valley, northern part of East Range, Winnemucca quadrangle.

Grass Valley Formation

Tertiary: Southwestern Utah.

E. F. Cook, 1957, Utah Geol. and Mineralog. Survey Bull. 58, p. 16 (fig. 2a), 18–20, 59, 61. Includes, in ascending order, a basal limestone, thin andesite flow, and two ignimbrites. Limestone is hard, dense, and pure, dominantly white with some pale-pink bands; bedding thin but irregular; maximum thickness of 100 feet; well exposed near crest of divide at north end of Grass Valley. Dull black augite amygdaloidal andesite flow attains thickness of about 50 feet. Volcanic sandstone and soft white ashy tuff at base of lowest vitric-crystal rhyolite ignimbrite or red-violet color on fresh surface; thickness up to 700 feet. Upper ignimbrite with brick-red groundmass is about 150 feet thick. Maximum thickness of formation about 1,000 feet. Overlies with apparent angular unconformity all older extrusive rocks in area. Upper ignimbrite truncated by an unconformity. Underlies Atchinson formation (new).

Exposed in Grassy Flat Canyon, on east side of Grass Valley, and in area northwest and west of Pine Valley, Washington and Iron Counties.

Grassy Member (of Blackhawk Formation)

Upper Cretaceous (Montana): Central eastern Utah.

R. G. Young, 1955, Geol. Soc. America Bull., v. 66, no. 2, p. 183, 186, figs. 2, 3, pl. 3. Consists of basal littoral marine sandstone with maximum thickness of about 60 feet and series of coal-bearing rocks with maximum thickness of about 50 feet. Basal white-capped sandstone first appears at Sunnyside and fades into underlying Mancos shale at Coal Canyon. It is a medium-grained, buff sandstone, which grades downward and eastward from massive into thin-bedded sandstone and finally into marine shale tongue. This shale rests disconformably on coal-bearing rocks of Sunnyside member (new). Thin beds of coal present. Disconformably underlies tongue of Mancos shale which separates it from overlying Desert member (new).

Named from exposures in vertical cliffs east of railroad siding of Grassy, Emery County. In Book Cliffs.

Grassy Creek Shale[1]

Grassy Creek Formation (in Sulphur Springs Group)

Grassy Creek Shale (in Champ Clark or Fabius Group)

Upper Devonian or Mississippian: Northeastern Missouri, western Illinois, and southeastern Iowa.

Original reference: C. R. Keyes, 1898, Iowa Acad. Sci. Proc., v. 5, p. 59–63.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 101, chart 5; J. M. Weller, 1948, (abs.) Am. Jour. Sci., v. 246, no. 3, p. 150. Basal formation in Fabius group (new). Underlies Saverton shale. Devonian or Mississippian.

A. G. Unklesbay, 1952, Missouri Geol. Survey and Water Resources, 2d ser., v. 33, p. 39–43. Formation described in Boone County where it is basal formation of Sulphur Springs group. Here, consists of basal, fine- to medium-grained, calcareous sandstone overlain by gray to brown shale. Thickness about 7 feet. Underlies Bushberg formation; overlies Callaway limestone.

L. E. Workman and Tracey [Tracy] Gillette, 1956, Illinois Geol. Survey Rept. Inv. 189, p. 8 (fig. 1), 14–16. Reallocated to Champ Clark group (new) proposed to replace Fabius group of Weller and others (1948). Name Grassy Creek is applied in western and central Illinois and east as far as Champ Clark group can be differentiated. Farther east, the Grassy Creek is equivalent to part of New Albany shale. Overlies discontinuous Sylamore sandstone; underlies Saverton shale; north of area in which Saverton has been differentiated, seems to be directly overlain by Maple Mill shale of Hannibal group.

T. J. Laswell, 1957, Missouri Geol. Survey and Water Resources Rept. Inv. 22, p. 9 (fig. 2), 22–27, pl. 1. Formation described in Bowling Green quadrangle where it is 1 to 44 feet thick and consists of brownish-black fissile shale with a 4- to 8-inch basal conglomerate in some areas. Conformably overlain by Saverton formation; in some areas, lies conformably on Edgewood formation of lower Silurian age; where Edgewood is absent, lies unconformably on Upper Devonian Maquoketa formation. No general agreement as to age of formation. Occurring as it does near disputed Devonian-Mississippian contact, it has been assigned to Devonian by some geologists and to Mississippian by others.

M. G. Mehl, 1960, Denison Univ. Jour. Sci. Lab., v. 45, art. 5, p. 81–85, 105. In Pike County, Mo., includes Turpin sandstone member (new) at base. Discussion of controversy in use of terms Grassy Creek and Saverton. Keyes did not mention precise type locality, but it is evident that he intended type locality to be in vicinity of Louisiana in area of the thin Grassy Creek and not "10 miles west of Grassy Creek," where the shales attain thickness of 30 feet. Type locality designated in this report is type locality of Grassy Creek as amended by Keyes (1913, Am. Jour. Sci., v. 36, 4th ser.). This section is figured by Branson and Mehl (1933, Missouri Univ. Studies, v. 8, no. 3). Branson and Mehl (1933) did not distinguish between their supposed distribution of the Grassy Creek conodont fauna and the distribution of the Grassy Creek shale. Hence, they seem to suggest the substitution of the name Grassy Creek for such regional designations of strata as Noel, Chattanooga, and others. This procedure is now believed to be ill-advised. Considered Upper Devonian.

Type locality (Mehl, 1960): Mississippi River bluff in Pike County, Mo., some distance above Champ Clark Bridge (approximately SW¼NW¼ NE¼ sec. 18, T. 54 N., R. 1 W.). This is same type locality at given for Saverton shale.

Grassy Knob Chert[1]

Lower Devonian: Southwestern Illinois.

Original reference: T. E. Savage, 1925, Am. Jour. Sci., 5th, v. 10, p. 139–144.

J. M. Weller, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 127, 128; 1940, Illinois Geol. Survey Rept. Inv. 71, p. 22–23. Recognized in Illinois only where Backbone limestone can be identified to separate it from Clear Creek chert. Beds assigned by Bassett (1925, Illinois Acad. Sci. Trans., v. 18) to Grassy Knob chert attain thickness of 225 feet at north end of Devonian exposures in Mississippi River bluffs. There appears to be no stratigraphic break between this formation and underlying Bailey limestone, and it is probable that in the midst of this succession unweathered beds have been referred to the Bailey and weathered strata at same horizon have been assigned to the Grassy Knob.

L. E. Workman, 1954, *in* Geologic cross section of Paleozoic rocks central Mississippi to northern Michigan: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 1. There is actually no means of separating the so-called Grassy Knob chert above from the Bailey limestone below. Evidently the chert is a concentration of silica in upper part of a single formation, the Bailey. It is recommended that only the term Bailey be used to designate the strata underlying the Little Saline and overlying Silurian strata.

Type locality: West side of Grassy Knob, 3½ miles southeast of Grand Tower, Jackson County.

Grassy Mountain Basalt[1]

Miocene and Pliocene(?): Southeastern Oregon.

Original references: K. Bryan, 1929, U.S. Geol. Survey Water-Supply Paper 597, p. 55; B. C. Renick, 1930, Jour. Geology, v. 38, p. 506.

E. M. Baldwin, 1959, Geology of Oregon: Ann Arbor, Mich., Edwards Brothers, Inc., p. 109. Overlies Pinnacle Point beds (new).

Named for the fact it caps Grassy Mountain, Malheur County.

Grassy Swale Lavas

Cenozoic. Northern California.

Howel Williams, 1932, California Univ. Pub., Bull. Dept. Geol. Sci., v. 21, no. 8, p. 295. Name applied to lavas that lie near contact between black andesites of Central Plateau and the pale flows of Saddle Mountain (Saddle Mountain lavas), but whether they are older or younger, intrusive or extrusive, is not known.

Grassy Swale shown on map in Lassen Volcanic National Park east of Mount Lassen.

Graters Member (of Brunswick Formation)

Graters Shales (in Brunswick Formation)[1]

Upper Triassic: Southeastern Pennsylvania and western New Jersey.

Original reference: D. B. McLaughlin, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 179.

M. E. Johnson and D. B. McLaughlin, 1957, Geol. Soc. America Guidebook for field trips Atlantic City Mtg., p. 51. Stratigraphic section shows Graters member consists of (ascending) red shale, 220 feet; black and gray shale and argillite, 50 feet; red shale, 42 feet; black and gray shale and argillite, 42 feet. Occurs about 2,000 feet above base of formation.

Named for exposures in Landis Brook just west of Grater's Ford, on Perkiomen Creek, Montgomery County, Pa.

Gratiot Flow (in Portage Lake Lava Series)

Precambrian (Keweenawan) : Northern Michigan.

J. C. Wright and H. R. Cornwall, 1954, Bedrock geology of the Bruneau Creek quadrangle, Michigan: U.S. Geol. Survey Geol. Quad. Map [GQ–35]. Ophitic basalt flow wih numerous pegmatitic layers in upper half. About 850 feet thick near road to Lake Gratiot. Thins rapidly toward southwest and about 1 mile west of Bruneau Creek quadrangle is only 130 feet thick. Where it is thinnest, many thin melaphyre layers occupy the interval between it and the Scales Creek flow.

Exposed near road to Lake Gratiot in sec. 36, T. 58 N., R. 31 W., Bruneau Creek quadrangle.

Gratton Limestone

Middle Ordovician : Southwestern Virginia and northeastern Tennessee.

B. N. Cooper and C. E. Prouty, 1943, Geol. Soc. America Bull., v. 54, no. 6, p. 836–838, 872–873, 884 (fig. 3), pl. 5. In Tazewell County the strata embraced by the Chazyan and Black River groups of Butts (1940, Virginia Geol. Survey Bull. 52, pt. 1) are subdivided into (ascending) 29 zones. Name Gratton limestone applied to lower laminated limestone (zone 14) and overlying third calcilutite (zone 15). Thickness varies from 0 to 120 feet and averages about 60 feet in northeastern half of county. In Clear Fork Valley and in Clinch-Bluestone belt northeast of Five Oaks, directly underlies upper laminated limestone (zone 22, included in newly defined Witten limestone) and overlies Burkes Garden member of Benbolt limestone (both new) ; in other parts of the county, underlies Wardell formation (new) ; between Pisgah and Five Oaks, overlies either Cliffield formation (new) or Shannondale member (new) of Benbolt limestone. The Gratton corresponds to lower part of Butts' Lowville-Moccasin east of Tazewell, but he includes it in his Ottosee formation southwest of Tazewell.

C. E. Prouty, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 7, p. 1165–1166. Geographically extended into northeastern Tennessee. Formation thins toward southwest as underlying Benbolt and overlying Wardell thicken. Between Tazewell and Sharps Chapel, the Gratton rests directly on Beekmantown dolomites and locally has thickness of several hundred feet.

Type section: Tazewell County Farm, Tazewell County, Va. Named for exposures near Gratton, about 5 miles east of Tazewell.

Gratz Shale[1] Member (of Cynthiana Formation)

Middle or Upper Ordovician : Northern Kentucky and southern Ohio.

Original reference: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, p. 416–418, 569, pl. 27.

J. J. Wolford, 1937, Geol. Soc. America Proc. 1936, p. 113. At type locality, Gratz division of the Cynthiana series is 40 feet thick. Middle Ordovician.

A. C. McFarlan and W. H. White, 1948, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 8, p. 1643. Consists of rather barren shale and fine-grained earthy limestone forming upper part of Cynthiana in Henry and Owen Counties. Essentially a barren facies including in its upper part the Rogers Gap. Pre-Cincinnatian.

D. K. Hamilton, 1950, Kentucky Geol. Survey, ser. 9, Bull. 5, p. 18. In northeastern Kentucky, uppermost member of Cynthiana. Overlies Bromley member.

Type locality: Village of Gratz, Owen County, Ky.

Gravel Creek Sand Member (of Nanafalia Formation)

Eocene, lower: Southwestern Alabama.

P. E. LaMoreaux and L. D. Toulmin, 1959, Alabama Geol. Survey County Rept. 4, p. 96 (fig. 32), 98, 99 (fig. 33), 100–106, 110–111, 120–121, pls. 2, 3. Name applied to lowest member of formation. Consists of white to yellow medium- to coarse-grained crossbedded sand with thin lenses of fine gravel and clay pebbles. Thickness 2 to 80 feet; 47 feet at type locality. Thickest in updip exposures; pinches out downdip to south in separate narrowing lenses of sand; absent in some areas. Generally unfossiliferous except for borings of *Halymenites*. Underlies unnamed middle member; unconformably overlies Coal Bluff member of Naheola formation. Transgressive and in places oversteps older formations. Sand beds included in member have been called Fearn Springs sand member (MacNeil, 1946), type locality of which is in Winston County, Miss. Boundary positions at Fearn Springs type locality are in dispute, and stratigraphic relationships with section in Alabama uncertain; hence, new name used in this report.

Type locality: South wall of Gravel Creek, 7.1 miles south of Camden, Wilcox County, on highway to Monroeville. Present in outliers far north of normal outcrop area.

Gravel Point Limestone or Formation

Gravel Point Stage[1]

Middle Devonian: Northwestern Michigan.

Original reference: E. R. Pohl. 1930, U.S. Nat. Mus. Proc., v. 76, art. 14, p. 2–25.

L. L. Sloss, 1939, Jour. Paleontology, v. 13, no. 1, p. 52. For purposes of this report, Pohl's divisions of Traverse beds, Petoskey, Charlevoix, and Gravel Point, are referred to as faunal zones.

G. A. Cooper and A. S. Warthin *in* G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1763, chart 4. At base of Gravel Point limestone (or formation), a foot of calcareous shale contains fossils like those in blue shale 40 feet below top of Alpena limestone; at top of Gravel Point, another blue shale, "the upper blue shale," or zone 6 of Pohl, contains crinoids and brachiopods similar to those of Dock Street clay at top of Alpena. Therefore, interval occupied by Gravel Point is essentially that of upper 40 feet of Alpena.

W. A. Kelly and G. W. Smith, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 3, p. 448 (fig. 1), 455–460. In Afton-Onaway area, formation subdivided to include Gorbut member near middle. Overlies Koehler formation and underlies Beebe School formation (both new).

Named for exposures south of Gravel Point, 1½ miles west of Charlevoix, Charlevoix County.

Graves Creek Formation[1]

Pleistocene: Western Kentucky.

Original reference: L. C. Glenn, 1912, Kentucky Geol. Survey Rept. Prog. 1910 and 1911, p. 26.

On Graves Creek, Webster County.

Graves Gap Group

Pennsylvanian (Pottsville Series) : Eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 1, 11, 19, pls. 2, 3, 4, 6, 8. Includes all strata from top of Indian Bluff group (new) below to base of Redoak Mountain group (new) above; that is, between the top of the Pioneer sandstone and the top of the Windrock coal. In type section where Armes Gap sandstone (new) is thin and Roach Creek sandstone (new) is apparently absent, thickness of group is 365 feet; in Cross Mountain-Briceville-Graves Gap area, thickness averages 360 feet but elsewhere is 200 to 300 feet. Includes (ascending) shale interval, Armes Gap sandstone (new), and Windrock coal.

Type locality: Cross Mountain, Lake City quadrangle, Anderson County. Section begins with top of Pioneer sandstone at Mountain View Church and ends at top of Windrock coal about 80 feet above Cumberland Mountain Church. Name derived from Graves Gap on State Highway 116 in southwestern part of quadrangle.

†Gravina Series[1]

Upper Triassic and Jurassic or Cretaceous : Southeastern Alaska.

Original reference: A. H. Brooks, 1902, U.S. Geol. Survey Prof. Paper 1, p. 40–52, map.

Occurs at Dall Head and elsewhere on southern end of Gravina Island.

Gravoisan glacial epoch[1]

Pleistocene : Missouri.

Orignal reference : C. R. Keyes, 1925, Pan-Am. Geologist, v. 44, p. 140–141.

Named for occurence on Gravois Creek, near Osage River, Morgan County.

Gray Porphyry Group[1]

Upper Cretaceous(?) or Tertiary, lower: West-central Colorado.

Original references: S. F. Emmons, 1882, U.S. Geol. Survey 2d Ann. Rept., p. 215–230; 1883, U.S. Geol. Survey Leadville Atlas; 1886, U.S. Geol. Survey Mon. 12, p. 80; 1927, U.S. Geol. Survey Prof. Paper 148.

C. H. Behre, Jr., 1953, U.S. Geol, Survey Prof. Paper 235, p. 46–47, pl. 1. As used in this report, includes Iowa Gulch, Lincoln, Sacramento, Evans Gulch, and Johnson Gulch porphyries. Mount Zion porphyry not recognized in immediate area [west slope of Mosquito Range].

Term originally applied in Leadville district.

Grayback Flows, Lavas

Pleistocene to Recent: Southwestern Oregon.

Howel Williams, 1942, Carnegie Inst. Washington Pub. 540, p. 37. Probably first dacites erupted by Mount Mazama were those forming Grayback Ridge and southern end of Vidae Ridge. They predate time of maximum glaciation of Mount Mazama and are older than lavas of Llao Rock, Cleetwood Cove, Grouse Hill, and Redcloud Cliff. Grayback flows thicken southward to as much as 1,000 feet in southeast corner of park.

Grayback Ridge is south of Crater Lake.

Grayback Formation[1]

Devonian : Northwestern California.

Original reference: J. H. Maxson, 1933, California Jour. Mines and Geology, v. 29, nos. 1 and 2, p. 128, map.

Occurs at Little Grayback, a peak in Siskiyou County.

Grayback wash[1]

Quaternary : Central southern Colorado.

Original reference: G. M. Butler, 1910, Colorado Geol. Survey Bull. 2, p. 59–61, pl. 2.

In Grayback mining district, Costilla County.

Grayback Mountain Rhyolite Tuff

Upper Cretaceous (?) or (?) Tertiary, lower : West-central Arizona.

C. A. Anderson, E. A. Scholz, and J. D. Strobell, Jr., 1955, U.S. Geol. Survey Prof. Paper 278, p. 1, 21–22, pl. 3. Rather massive welded rhyolite tuff. Classified as lithic-crystal-vitric. About 500 feet of tuff exposed in thicker sections. Rests on an eroded surface of unnamed alaskite porphyry.

Exposed only on Grayback Mountain, in southwestern corner of Bagdad area, Yavapai County.

†Gray Bull Beds[1]

Gray Bull Member[1]

Eocene, lower : Western Wyoming.

Original reference: W. Granger, 1914, Am. Mus. Nat. History Bull., v. 33, p. 202–205.

G. L. Jepson, 1940, Am. Philos. Soc. Proc., v. 83, no. 2, p. 238. Overlies Clark Fork beds in Polecat Bench formation (new).

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 20–21. Although usually considered a faunal zone, Gray Bull should be considered a member of the so-called "Bighorn Wasatch", a formation for which no valid name has yet been proposed.

G. L. Jepson and F. B. Van Houten, 1947, Wyoming Geol. Assoc. Guidebook 2d Ann. Field Conf., p. 148 (chart 1). Chart shows Gray Bull beds in basal part of Willwood formation. Occur below Lost Cabin or Lysite beds.

Named for exposures along Gray Bull River.

Grayburg Formation (in Whitehorse Group or Artesia Group)

Permian (Guadalupe Series) : Subsurface and surface in southeastern New Mexico and subsurface in western Texas.

R. K. DeFord, 1939, *in* Addison Young, Max David, and E. A. Wahlstrom, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 10, p. 1551. Name Grayburg will be proposed by R. I. Dickey.

R. I. Dickey, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 44–47. Basal unit of Whitehorse group. In type well, underlies Queen formation and overlies San Andres formation. Lies between depths of 2,380 feet and 2,647 feet. Predominantly dolomite, gray, pink, white; locally sandy, some beds of anhydrite present.

W. R. Moran, 1954, (abs.) Geol. Soc. America Bull., v. 65, no. 12, pt. 2, p. 1288. At surface type section, herein designated, Grayburg is 475 feet thick, consists of alternating sandstone and dolomites and underlies Queen formation.

P. T. Hayes and R. L. Koogle, 1959, U.S. Geol. Survey Geol. Quad. Map GQ–112. Described in Carlsbad Caverns West quadrangle which contains Moran's type section. Top of formation, as proposed by Moran, is unmodified in this report. Basal contact is probably 40 to 50 feet above that used by Moran who apparently included part or all of what is here mapped as tongue of San Andres formation. Basinward gradation of Grayburg into lower part of Goat Seep limestone (Newell, 1953) is not exposed in this quadrangle but can be seen in quadrangles to west and southwest [Whitehorse group not used in area of this report].

Term Artesia Group (D. B. Tait and others, 1962, Am. Assoc. Petroleum Geologists Bull., v. 46, no. 4) used in preference to Whitehorse Group in New Mexico.

Type well: Cecil H. Lockhart's Root Permit No. 2, in center SW¼SW¼ sec. 7, T. 17 S., R. 30 E., Eddy County, N. Mex. Name derived from Grayburg Pool.

Type section (surface): On a spur and in an unnamed canyon above Sitting Bull Spring in NE¼ sec. 9, T. 24 S., R. 22 E., Eddy County.

†Gray Cliff group[1]

Jurassic(?): Central southern Utah.

Original reference: G. K. Gilbert, 1877, Geology of Henry Mountains, p. 6, 7.

Henry Mountains region.

†Gray Cliff Sandstone[1]

Jurassic(?): Central southern Utah.

Original reference: G. K. Gilbert, 1877, Geology of Henry Mountains, p. 6, 7.

Henry Mountains region.

Graydon Channel Sandstone[1]

Graydon Formation (in Cherokee Group)

Pennsylvanian: Western and central Missouri.

Original reference: A. Winslow, 1894, Missouri Geol. Survey, v. 7, p. 422–425.

T. R. Beveridge, 1951, Missouri Geol. Survey and Water Resources, v. 32, 2d ser., p. 53–55, pl. 11. Youngest indurated formation exposed in Weaubleau Creek area. Underlies Dederick subgroup of the Cherokee (Des Moines series); where the Dederick is absent, lies on deeply eroded Mississippian or Ordovician.

T. J. Laswell, 1957, Missouri Geol. Survey and Water Resources Rept. Inv. 22, p. 47. Name "Graydon" is now used informally by the Missouri Geological Survey to refer to deposits which lie below the Cheltenham clays in northeastern Missouri. Term Graydon applied in southwestern Missouri apparently includes much of the deposits now assigned to the Venteran age, and the deposits below the Cheltenham clays cannot now be assigned with certainty to any part of it.

Named for exposures at Graydon Springs, Polk County.

Graydon Shales[1]

Pennsylvanian : Southwestern Missouri.

Original reference: E. M. Shepard, 1905, Bradley Geol. Field Sta. Drury Coll. Bull., v. 1, p. 56.

Green County.

†Graydon Springs Sandstone and Conglomerate[1]

Pennsylvanian : Western and central Missouri.

Original reference: A. Winslow, 1894, Missouri Geol. Survey, v. 7, p. 422–425.

Probably named for exposures at Graydon Springs, Polk County.

Gray Gulch Formation

Tertiary : Central Utah.

E. M. Spieker, 1949, Utah Geol. Soc. Guidebook 4, p. 37–38, [pl. 1]. Consists of sandstones and shales, some of volcanic derivation and others not; fresh-water limestones; bentonites; ash beds; agglomerates; and other volcanic derivatives, generally gray to blue but locally punctuated by beds and blotches of bright orange. Provisionally divided into two units which may prove on detailed study to be distinct formations. Disconformably overlies Crazy Hollow formation (new) ; unconformably underlies unnamed lava beds. It is possible that formation is same as the Bullion Canyon, and, if so, that name will be used. At present, correlation is too uncertain to allow use of either Moroni or Bullion Canyon.

D. P. McGookey, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 5, p. 605–606. Formation as designated by Spieker (1949) includes strata equivalent to Bald Knoll formation of Gilliland (1951), part of Bullion Canyon volcanics of Callaghan (1939) and a previously unnamed interval that was mapped as Gray Gulch(?) by Lautenschlager (1952, unpub. thesis). Proposed that term Gray Gulch be abandoned. Term Bald Knoll formation used for lower part of interval formerly assigned to Gray Gulch. Name Dipping Vat (new) applied to upper coarse interval of lacustrine beds formerly included in Gray Gulch. Type section stated.

Type section: Exposed in Gray Gulch, W½ sec. 32, T. 21 S., R. 1 E., Salina district.

Grayhorse Limestone Member (of Vanoss Formation)

Grayhorse Limestone Member (of Wood Siding Formation)

Grayhorse Limestone Member (of Caneyville Formation)

Grayhorse Limestone Member (of Sand Creek Formation)[1]

Pennsylvanian (Virgil Series) : Central northern Oklahoma and eastern Kansas.

Original reference: K. C. Heald, 1918, U.S. Geol. Survey Bull. 686–K, p. 130.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 172. Classed as member of Caneyville limestone in Kansas. Overlies unnamed shale ; underlies Pony Creek shale.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2273, 2274 (fig. 1). Reallocated to Wood Siding formation herein redefined. Overlies Plumb shale member (new) ; underlies Pony Creek shale member.

U.S. Geological Survey currently classifies the Grayhorse Limestone as a member of the Vanoss Formation in Oklahoma.

Named for exposure on crest of Little Grayhorse anticline in NW¼ sec. 11, T. 24 N., R. 6 E., Osage County, Okla.

Graylock Formation

Lower Jurassic: Northeastern Oregon.

W. R. Dickinson, 1960, Dissert. Abs., v. 20, no. 11, p. 4367. Overlies Rail Cabin formation (new). Hettangian.

Type locality and derivation of name not stated. Report discusses Izee area, Grant County.

Gray Mesa Member (of Madera Limestone)

Pennsylvanian: West-central New Mexico.

V. C. Kelley and G. H. Wood, 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 47. Thick- to thin-bedded, predominantly cherty and gray to dark-gray ledgy limestone with minor amount of gray shale and gray to brown fine- to coarse-grained sandstone. Thickness 850 to 900 feet. Conformably underlies Atrasado member (new); conformably overlies Sandia formation.

Extends in continuous outcrop from Comanche Arroyo along steep east face of Gray Mesa and southward past Monte de Belen. Another belt extends from Red Tanks Arroyo near Salaido Ranch southeastward into west slopes of Ladron Mountains. Most completely exposed section lies in steep east face of Monte de Belen, Socorro and Valencia Counties.

Grayson Granodiorite Gneiss

Grayson Granite Gneiss[1]

Precambrian: Southwestern Virginia.

Original reference: A. I. Jonas, 1928, Virginia Geol. Survey prelim. ed. of geol. map of Virginia.

A. J. Stose and G. W. Stose, 1957, Virginia Div. Mineral Resources Bull. 72, p. 38–41, pl. 1. Porphyritic gneiss of granodiorite composition; hence, termed Grayson granodiorite gneiss. Injected by aplite and diabase of Mount Rogers volcanic series.

Covers most of Grayson County. Forms crest of Point Lookout Mountain, the southeastern spurs of Brierpatch Mountain, and crest of Buck Mountain. Widely distributed in Elk Creek anticline.

Grayson Marl, or Formation (in Washita Group)

Grayson Marl Member (of Denison Formation)[1]

Upper Cretaceous (Comanche Series): Northeastern Texas, central southern Oklahoma, and northern Mexico.

Original reference: F. W. Cragin, 1894, Colorado Coll. Studies, v. 5, p. 43–48.

R. W. Imlay, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 3. Correlation chart shows Grayson shale in Washita group. Upper Cretaceous (lower Cenomanian). Underlies Buda limestone; overlies Georgetown limestone and in some area, Main Street limestone. [Grayson replaces Del Rio which is abandoned.] Present in Chihuahua, Mex.

L. W. Stephenson, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 10, p. 1538–1541. Discussion of fossils from limestone of Buda age in Denton

County. If it is admitted that this limestone is a facies of Buda age in upper part of Grayson marl, then the Grayson is not exact equivalent of Del Rio but includes equivalents of both Del Rio and Buda.

S. S. Goldich and M. A. Elms, 1949, Geol. Soc. America Bull., v. 60, no. 7, p. 1138 (table 1), 1139–1140, pl. 1. Grayson clay described in Buck Hill quadrangle, Texas, where it is 60 to 76 feet thick; overlies Georgetown limestone and disconformably underlies Buda limestone. Lower Cretaceous.

Elliot Gillerman, 1953, U.S. Geol. Survey Bull. 987, p. 11 (table 1), 27–31, pl. 1. In Eagle Mountains, Tex., formation is divided into (asending) Carpenter limestone (new), reef-limestone, and Eagle Mountains sandstone (new) members. Thickness 200 feet. Overlies Georgetown limestone; underlies Buda limestone. Upper Cretaceous.

L. W. Stephenson, 1953, U.S. Geol. Survey Prof. Paper 243–E, p. 58. Grayson marl (formerly Del Rio clay) unconformably underlies Pepper shale member of Woodbine formation.

Robert Greenwood, 1956, Gulf Coast Assoc. Geol. Soc. Trans., v. 6, p. 167–177. Shale described in Uvalde County, Tex., where it includes West Prong lentil (new) in basal part. West Prong shows penecontemporaneous relationship with overlying volcanic materials of Grayson. Overlies Georgetown limestone; underlies Buda limestone. Thickness 100 to 150 feet. In west and south Texas, formation has been called Del Rio clay.

R. G. Yates and G. A. Thompson, 1959, U.S. Geol. Survey Prof. Paper 312, p. 9–10, pl. 1. Formation described in Terlingua district, Texas, where it is 80 to 200 feet thick; overlies Devils River limestone and underlies Buda limestone. Undifferentiated in this area.

B. F. Perkins, 1960, Geol. Soc. America Mem. 83, p. 9 (fig. 3), 12 (fig. 4), 35–38. In Fort Worth area, Grayson marl member of Denison is about 80 feet thick and divisible into four subdivisions (ascending): yellowish-gray marl 18 feet thick with abundant *Exogyra arientina* Roemer, containing in lower 3 to 5 feet a small number of lenticular bodies of hard highly fossiliferous clastic limestone about 5 to 8 feet long and 1 foot in maximum thickness; unfossiliferous yellow to greenish-gray marly clay 24 feet thick; highly fossiliferous gray marl 21 feet thick with buff marly limestone and clay; greenish-gray marly clay less fossiliferous than underlying unit. Overlies Main Street limestone member; underlies Buda limestone.

Named for numerous outcrops in Grayson County, Tex.

†Graysonton Formation[1]

Lower and Middle Cambrian: Southwestern Virginia.

Original reference: M. R. Campbell, 1894, Geol. Soc. America Bull., v. 5, p. 171, 175, 183, pl. 4.

Named for Graysonton, Montgomery County.

Graysville Limestone

See Grayville Formation.

Graysville Member (of Stonehenge Limestone)

Lower Ordovician (Canadian): Central Pennsylvania.

A. C. Donaldson, 1960, Dissert. Abs., v. 20, no. 9, p. 3693. Overlies Spring Creek member (new); underlies Baileyville member (new). Contains pebbles but lacks oolites which characterize underlying Spring Creek member.

Type locality and derivation of name not stated.

Grayville Formation[1]

Grayville Limestone (in McLeansboro Formation)

Grayville Limestone (in Wabash Formation)

Pennsylvanian: Southeastern Illinois and southwestern Indiana.

Original reference: M. A. Harrell, 1935, Indiana Dept. Conserv. Pub. 133.

J. A. Culbertson, 1932, The paleontology and stratigraphy of the Pennsylvanian strata between Caseyville, Kentucky, and Vincennes, Indiana: Urbana, Ill., Univ. Illinois, Abs. Thesis, p. 3, 7. Gray fossiliferous limestone in McLeansboro formation. Underlies Lawrenceville shale (new); separated from underlying Mumford Hills sandstone (new) by Aldrich coal.

Marshall Harrell, 1935, Indiana Div. Geology Pub. 133, p. 73 (chart). Chart shows post-Alleghenian Grayville formation as a subdivision of the Wabash. In the sequence occurs between Buffkin above and McClearys Bluff formation.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 85. There is some doubt that these beds [Grayville formation] overlie McClearys Bluff beds and underlie Buffkin beds; superposition of formations may be erroneous.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, Chart 6 (col. 25). Correlation chart shows Graysville limestone in Wabash formation below Livingston limestone and above Buffkin limestone.

Named from typical exposures at Grayville, White County, Ill.

Grazier Formation (in Hatter Group)

Grazier Member (of Hatter Formation)

Middle Ordovician (Bolarian): Central and south-central Pennsylvania.

G. M. Kay, 1943, Econ. Geology, v. 38, no. 3, p. 193. Middle member of formation. Described as dark, dense, heavy ledged stylolitic limestone with wavy argillaceous partings; tends to weather with rows of holes. Thickness 33 feet at type section. Underlies Hostler member (new); overlies Eyer member (new). Chazyan series.

G. M. Kay, 1944, Jour. Geology, v. 52, no. 1, p. 10. Thickness 7 to 60 feet; thins southeastward. Conformably underlies more siliceous Hostler member in all exposures. Disconformably overlaps Eyer member northeastward from type section so as to lie on Clover member of Loysburg formation. Contact with Clover is a slightly undulating stylolitic bedding plane separating sharply differing lithologies. Derivation of name.

Marshall Kay, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. [1402], 1407. Rank raised to formation in Hatter group or Hatterian subseries (Bolarian series).

Marshall Kay, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 82, 102. Discussed as a member.

Type section: On two sides of Pennsylvania Railroad cut north of Union Furnace, Huntingdon County. Named for Grazier Mills northeast of Union Furnace.

Greasy Cove Formation

Upper Mississippian: Eastern Tennessee.

R. B. Neuman and R. L. Wilson, 1960, U.S. Geol. Survey Geol. Quad. Map GQ–131. Gray argillaceous limestone (about 40 percent), red shale and fine-grained sandstone (10 percent), gray shale and siltstone (25 percent), and gray fine-grained sandstone (25 percent), all interbedded. Thickness at least 400 feet, top faulted. Overlies Grainger formation. Name replaces Newman limestone formerly used in this area because Newman at its type locality consists of relatively pure limestone.

Type section: Along small unnamed creek southeast of Butterfly Gap, Blockhouse quadrangle. Named from Greasy Cove.

Greasy Creek facies (of Fort Payne Formation)

Lower Mississippian: Northern Tennessee and southern Kentucky.

H. J. Klepser, 1937, Ohio State Univ. Abs. Doctors' Dissert. 24, p. 182. Listed as northern facies of Fort Payne formation.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 49, 53, 76. Variable in lithology, ranging from silty shale to siltstone to crinoidal limestone; gray siltstone, which prevails, is generally massive. Facies overlies Maury formation in Tennessee. Listed under Brodhead formation in Kentucky. Derivation of name given.

Named from Greasy Creek, central Russell County, Tenn.

Great Conglomerate[1] (in Copper Harbor Group)

Precambrian (Keweenawan): Northern Michigan and Wisconsin.

Original reference: R. D. Irving, 1883, U.S. Geol. Survey Mon. 5, p. 186, pls. 17, 18.

T. M. Broderick, C. D. Hohl, and H. N. Eidemiller, 1946, Econ. Geology, v. 41, no. 7, p. 679. Name appears in stratigraphic column of Michigan copper district. Thickness 1,757 feet.

Named for fact it was supposed to be very much thicker than Outer conglomerate.

Great Bend coal group[1]

Paleocene: North Dakota.

Original reference: A. G. Leonard, 1908, North Dakota Geol. Survey 5th Bienn. Rept.

†Great Bend Conglomerate[1]

Pennsylvanian: Pennsylvania.

Original reference: F. A. Randall, 1875, Pennsylvania 2d Geol. Survey Rept. I, p. 51–54.

At Great Bend, Warren County.

Great Bend Limestone (in Chemung Formation)[1]

Upper Devonian: Northeastern Pennsylvania.

Original reference: I. C. White, 1881, Pennsylvania 2d. Geol. Survey Rept. G_5, p. 91.

Occurs at Great Bend, Susquehanna County.

Great Blue Limestone[1] or Formation

Upper Mississippian: Central northern Utah.

Original reference: J. E. Spurr, 1895, U.S. Geol. Survey 16th Ann. Rept., pt. 2, p. 374–376.

H. R. Cramer, 1954, Dissert. Abs., v. 14, no. 10, p. 1681. Discussion of coral zones in Mississippian of Great Basin area. Great Blue limestone, which is stratigraphically and lithologically similar to the more properly though later named Ochre Mountain limestone, is dropped.

H. T. Morris, 1957, Utah Geol. Soc. Guidebook 12, p. 15 (fig. 4), 20–22. Described in East Tintic Mountains where it is 2,400 to 2,600 feet thick; underlies Manning Canyon shale and overlies Humbug formation. Includes (ascending) basal limestone member about 400 feet thick; limestone and shale member about 650 feet; shale and quartzite member 850 to 1,000 feet; and an upper limestone member about 600 feet.

J. K. Rigby, 1958, Utah Geol. Soc. Guidebook 13, p. 38 (fig. 5), 46–48. Described in Stansbury Mountains where it is 980 to 1,300 feet thick; overlies Humbug formation and underlies Manning Canyon formation.

R. E. Cohenour, 1959, Utah Geol. and Mineralog. Survey Bull. 63, p. 12 (table 1), 90–93, 172–173, 174–177, pl. 1. Formation described in Sheeprock Mountains area where it is about 4,139 feet thick and is divided into lower limestone, 911 feet; Chiulos shale member (new), 1,818 feet; and upper limestone, 1,410 feet. Gradationally overlies Humbug formation; in fault contact with Pennsylvanian Oquirrh formation.

J. R. Rigby, 1959, Utah Geol. Soc. Guidebook 14, p. 55–58. Spurr (1895) did not designate type area for formation. Gilluly (1932, U.S. Geol. Survey Prof. Paper 173) applied name only in slightly different manner than used by Spurr, in his study of Stockton and Fairfield quadrangles. Great Blue limestone crops out in much of southwestern part of mapped area [southern Oquirrh Mountains]. Overlies Humbug formation; lower boundary arbitrarily taken in most places at top of highest orthoquartzite, quartzitic sandstone, or calcarenite of significance in the Humbug. Three major divisions: lower limestones, shales below the middle, and limestone above. Gilluly's (1932) Long Trail shale member recognized and mapped.

H. J. Bissell, 1959, Utah Geol. Soc. Guidebook 14, p. 166–167. In Five Mile Pass and northern Boulter Mountain area, comprises three members. Lower consists of 368 feet of massive dark-gray-blue fine to coarse crystalline and medium-grained limestones which weather light blue gray. Upper consists of blue-gray and gray-blue limestones which superficially resemble basal member. Overlies Humbug formation; underlies Manning Canyon shale.

First described in Oquirrh Mountains region.

†Great Falls coal series[1]

†Great Falls Group[1]

Lower Cretaceous: Central northern Montana.

Original references: J. S. Newberry, 1887, School Mines Quart., v. 8, p. 328; 1891, Am. Jour. Sci., 3d v. 41, p. 193.

Great Falls region.

Great Falls Lake Sands

Pleistocene: Northwestern Montana.

J. B. Lyons. 1944, Geol. Soc. America Bull., v. 55, no. 4, p. 449 (fig. 2), 452, pl. 1. Fine-grained, well-bedded yellow sands. Thickness 0 to 250 feet; 150 feet at Craig. Unconformably overlie Adel Mountain volcanics (new). Present only in river valleys.

Derivation of name not stated. Area of report includes about 990 square miles of northern end of Big Belt Range and adjacent plains.

Great Hill Formation

Lower Silurian: Central Connecticut.

G. P. Eaton and L. J. Rosenfeld, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 2, p. 170 (fig. 1), 171 (table 1). Quartzite, quartzite conglomerate, and kyanitic quartz-sericite schist. Unconformably overlies Collins Hill formation; underlies Mine Brook formation (new). Previous workers with the exception of Percival (1842, Report on the Geology of the State of Connecticut: New Haven), grouped the sequence of rocks from Collins Hill schist through Camp Jenkins schist (new) as a single formation, and believed it to be intruded by Glastonbury, Maromas, and Haddom gneisses. Present work shows that these rocks represent four distinct formations, with unconformity separating Collins Hill from the others.

Great Hill is in central part of Middle Haddam quadrangle, Middlesex County.

Great Meadows Formation

Lower Ordovician: East-central New York.

John Rodgers, 1952, *in* M. P. Billings, John Rodgers, and J. B. Thompson, Jr., Geol. Soc. America Guidebook for field trips in New England, p. 35 (table 2). Described as mainly dolomite. Prominent basal crossbedded sandstone. Includes Fort Ann limestone, a persistent layer at top. Thickness 110 feet. Overlies Baldwin Corner formation (new). Refers to R. H. Flower (unpub. ms.).

Occurs in Fort Ann quadrangle.

Great Sitkin Volcanics

Tertiary and Quaternary: Southwestern Alaska.

F. S. Simons and D. E. Mathewson, 1947, U.S. Geol. Survey Alaskan Volcano Inv. Rept. 2, pt. 4, p. 63, pls. 4, 5; 1955, U.S. Geol. Survey Bull. 1028–B, p. 29–31, pl. 5. Comprise the rocks of the main cone of Great Sitkin Volcano. Included are rocks of the cone itself, a newly formed crater dome and five older plugs, basalt flow of Sitkin Valley, and parasitic tuff cone on northwest flank of main cone. Main cone is composite of flows and tuff beds with flows predominating, at least in upper part of cone. Flow rocks predominantly of porphyritic andesite and basalt. Excellent exposures of lavas displayed in walls of crater. Crater occupied by a dome composed of black glassy porphyritic basalt. Basalt flow near head of Sitkin Creek was extruded from flank of cone and is only fairly young flow known; 100 to 125 feet thick, with prominent columnar jointing. Great Sitkin volcanics unconformably overlie Sand Bay volcanics (new). Most of the rocks of main cone buried under thin blanket of pumice and rock fragments.

Great Sitkin Volcano forms northern half of Great Sitkin Island, in central part of Aleutian Islands.

Great Smoky Group

Great Smoky Conglomerate[1]

Great Smoky Formation or Quartzite

Precambrian (Ocoee Series) : Central northern Georgia, eastern Tennessee, and western North Carolina.

Original reference: A. Keith, 1907, U.S. Geol. Survey Geol. Atlas, Folio 143, p. 3.

G. W. Crickmay, 1936, Geol. Soc. America Bull., v. 47, no. 9, p. 1381. In Nantahala, Ellijay, and Tate folios, Great Smoky formation, which is at base of sequence here included in Talladega series, is mapped with unconformable relation to Carolina gneiss. However, there is complete lack of field evidence to support statements that Great Smoky formation, "Hiwassee" schist, or any other formation belonging in Talladega series rests unconformably on Precambrian rocks in Georgia or North Carolina.

G. W. Stose, 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1233; 1949, Geol. Soc. America Bull., v. 60, no. 2, p. 278–282. Great Smoky quartzite included in Ocoee series, Late Precambrian. Overlies Hurricane graywacke (new) and underlies Nantahala slate. Term quartzite considered more appropriate than formation. Consists of lower member of thickbedded white to gray arkosic quartzite, middle member of light- to dark-gray, poorly bedded quartzite containing pebble beds, and upper member of coarse-grained dark quartzite, pebbly in places, and interbedded black slaty graywacke. Extends from northeast end of belt of Ocoee series (Roan Mountain quadrangle) southwestward across northwestern North Carolina and southeastern Tennessee, passes into Georgia, and continues to point 10 miles east of Cartersville. Thickness about 4,100 feet.

P. B. King, 1949, Am. Jour. Sci., v. 247, no. 9, p. 631 (table 4), 639. Conglomerate included in Ocoee series. Thickness in Great Smoky Mountains about 6,000 feet. Underlies Nantahala slate. Type area is in Great Smoky Mountains of Knoxville quadrangle: probably it also includes outcrops of formation in Mount Guyot quadrangle to east. It is here capable of precise delimitation and should be restricted to unit as defined in this area and its equivalents. Further south, as in Nantahala and Ellijay quadrangles, term has come to be used as general expression for rocks of Ocoee type. This usage is improper, and term Ocoee series should be substituted.

G. W. Crickmay, 1952, Georgia Geol. Survey Bull. 58, p. 27, 28. Great Smoky formation included in Talladega series believed to be Precambrian.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, p. 26 (table 2), 31–32, pt. 1, pls. Conglomerate mapped in eastern Tennessee where, southwest of Pigeon River mountain belt, it underlies Nantahala slate and overlies sandstone and slate forming lowest part of Ocoee series.

V. J. Hurst, 1955, Georgia Geol. Survey Bull. 55, p. 7, 8–45, pl. 1, geol. map. In Mineral Bluff quadrangle, Georgia, oldest rocks belong to Great Smoky group, a sequence of graywacke-type metasediments at least 15,000 feet thick, of probable Precambrian age. Group includes (ascending) Copperhill, Hughes Gap, Hothouse, and Dean formations (all new). Underlies Nantahala slate. Cambrian-Precambrian boundary provisionally drawn between Great Smoky group and Nantahala slate.

P. B. King and others, 1958, Geol. Soc. America Bull., v. 69, no. 8, p. 955 (table 1), 957–960. Group, in Great Smoky Mountains, is divided into (ascending) Elkmont sandstone (new), Thunderhead sandstone, Anakeesta formation (new), and unnamed higher strata. Group lies in upper plate of Greenbrier fault, terminates northwestward along trace of fault, and extends thence 20 or 25 miles southeastward. Southwestward, outcrop belt continues more than 100 miles with about same width into northern Georgia. East of Great Smoky Mountains, group is preserved only in isolated downfolds in older Precambrian rocks. Through most of its extent in Great Smoky Mountains, base of group is cut off by Greenbrier fault, but, in southeast part of mountains, it lies conformably on Snowbird group. Near Middle Prong of Little River, as much as 25,000 feet of group is present, but base and top are not exposed. Ocoee series. Late Precambrian.

J. L. Stuckey and S. G. Conrad, 1958, North Carolina Div. Mineral Resources Bull. 71, p. 35, 36; J. L. Stuckey, 1958, Geologic map of North Carolina (1:500,000): North Carolina Div. Mineral Resources. Ocoee series in North Carolina includes (ascending) Snowbird formation, Great Smoky conglomerate, Nantahala slate, and Sandsuck shale. Great Smoky is most extensive member of Ocoee series. Covers large areas in Cherokee, Graham, Swain, and Hayward Counties and smaller areas in Macon, Jackson, and Madison Counties. Precambrian.

Named for extensive development in Great Smoky Mountains, in southern part of Knoxville quadrangle, which adjoins Nantahala quadrangle on north.

Gredal Formation

Gredal Member (of Lodo Formation)

Eocene, upper; Central California.

Martin Van Couvering and H. B. Allen, 1943, California Div. Mines Bull. 118, pt. 3, p. 496–500. Variegated green-red claystone containing occasional sandstone beds and considerable glauconite. Maximum thickness 1,000 feet. Unconformably underlies Point of Rocks sandstone; overlies Mabury formation (new).

V. S. Mallory, 1959, Lower Tertiary biostratigraphy of the California Coast Ranges: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 10, 281–282 Rank reduced to member status in Lodo formation; overlies Mabury member.

Occurs in Devils Den oil field district in northwestern Kern County, adjacent to Kings County line, about 40 miles from Paso Robles and about 60 miles northwest of Bakersfield.

Greece Ranch horizon[1]

Oligocene: Southwestern Washington.

Original reference: B. L. Clark, 1924, Pan-Pacific Sci. Cong., Australia, 1923, Proc., v. 1, p. 877.

Occurs on Greece Ranch locality near Vader, on Cowlitz River, southwestern Lewis County.

Greeley Gypsum (in Sumner Group)[1]

Permian: Central Kansas.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 10.

Named for Greeley Township, Saline County.

Greenbrier Limestone[1] **or Formation**

Greenbrier Limestone Member (of Mauch Chunk Formation)

Greenbrier Limestone (in Mauch Chunk Group)

Greenbrier Series

Upper Mississippian: Northern West Virginia, eastern Kentucky, western Maryland, southern Pennsylvania, and Virginia.

Original reference: W. B. Rogers, 1879, Macfarlane's Geol. Railway Guide, p. 179.

D. B. Reger, 1926, West Virginia Geol. Survey [County Repts.] Mercer, Monroe, and Summers Counties, p. 445–491. Greenbrier series is assemblage of preeminently calcareous rocks lying just below Mauch Chunk series and just above Maccrady series. Includes (ascending) Hillsdale limestone, Sinks Grove limestone, Patton shale and limestone, Taggard shale and limestone, Pickaway limestone, Union limestone, Greenville shale, and Alderson limestone members. Thickness about 1,800 feet.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey [Rept.] Greenbrier County, p. 266–279. Series described in Greenbrier County where thickness varies from about 475 to 750 feet. Subdivisions as named by Reger (1926) recognized.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 3, p. 170, 171, chart 5 (column 102) ; M. N. Shaffer, 1952, Pennsylvania Geol. Survey, 4th ser., Prog. Rept. 141. Correlation chart shows Greenbrier limestone in Mauch Chunk group in Pennsylvania.

R. H. Wilpolt and D. W. Marden, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 38. Chart shows Meramec-Chester age.

T. W. Amsden, 1954, Maryland Dept. Geology, Mines and Water Resources Bull. 13, p. 34–44. Described in Garrett County, Md., as formation. Overlies Pocono formation and underlies Mauch Chunk formation. Includes Loyalhanna member in lower part. Thickness about 250 feet.

R. H. Wilpolt and D. W. Marden, 1959, U.S. Geol. Survey Bull. 1072–K, p. 593–596, 598 (fig. 26), pls. 28, 29. Rocks called Greenbrier limestone in this report have been referred to as Greenbrier series by other writers. Consists of thick sequence of dense and crystalline, highly fossiliferous, locally cherty limestone which commonly ranges in color from gray to brownish gray to black. Hillsdale and Taggard members differentiated in some areas; main body of Greenbrier is undifferentiated. Thickness 250 to 848 feet. Overlies Maccrady; underlies Bluefield formation. Geographically extended into Kentucky.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000) : Pennsylvania Geol. Survey, 4th ser. Mauch Chunk formation includes Greenbrier limestone in Fayette, Westmoreland, and Somerset Counties; Loyalhanna limestone at base in southwestern Pennsylvania.

Named for exposures on Greenbrier River, Pocahontas County, W. Va.

†Greenbrier Shales[1]

Mississippian: West Virginia.

Original reference: W. B. Rogers, 1879, Macfarlane's Geol. Railway Guide, p. 179.

Greenbush Coal Member (of Spoon Formation)

Pennsylvanian: Western Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 33, 46 (table 1), pl. 1. Assigned member status in Spoon formation (new). Occurs above Wiley coal member and below Isabel sandstone member. Coal named by Wanless (1931, Illinois Geol. Survey Bull. 60). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: E¼ sec. 24, T. 8 N., R. 1 W., Warren County.

Greenbush cyclothem (in Spoon Formation)

Greenbush cyclothem[1] (in Tradewater Group)

Pennsylvanian: Western, central, and southern Illinois and western Indiana.

Original reference: H. R. Wanless, 1931, Illinois Geol. Survey Bull. 60, p. 188, 192.

J. M. Weller and others, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 10, p. 1586 (fig. 1), 1589. Underlies Abingdon cyclothem (new). Includes Greenbush limestone.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 63, 81–82, 191, 197, 198, 200, 201, 202. Thickness of cyclothem as much as 14 feet; average 6 to 10 feet. Rests with apparent conformity on Wiley cyclothem; underlies Abingdon cyclothem; Isabel sandstone rests on Greenbush shale with an abrupt contact and truncates shale at some places. Greenbush limestone is discontinuous and is commonly 3 to 6 inches thick and is fine grained, light gray, and nearly lithographic. Cyclothem is present in western Kentucky where it includes the highest beds referred to the Tradewater group. Gives type exposure.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 52 (table 2), pl. 2. In Spoon formation (new). Above Wiley cyclothem and below Abingdon cyclothem. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type exposure: In ravine tributary to Swan Creek in E½ sec. 24, T. 8 N., R. 1 W., Greenbush Township, Avon quadrangle, Warren County, Ill.

Green Canyon Group

Pennsylvanian (Derry Series): Central and southern New Mexico.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 27 (table 2), 31 (fig. 2), 32, 35. Term proposed to include the two basal formations of the Derry series (ascending): Arrey and Apadoca (both new).

Type locality: West facing slope of hill approximately three-fourths of a mile east of Derry, near center of sec. 32, T. 17 S., R. 4 W., Sierra County. Name derived from Green Canyon about one-half mile north of village of Derry.

Greencastle Bed[1] (in Chambersburg Limestone)

Greencastle Formation

Middle Ordovician: South-central Pennsylvania.

Original reference: R. S. Bassler, 1919, Maryland Geol. Survey, Cambrian and Ordovician Volume, p. 49, 120, 133, 140–147, 152, 153, 154.

L. C. Craig, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1964. Rank raised to formation; includes uppermost part of Chambersburg limestone. Consists of black massive limestone with a thin locally occurring basal calcarenite. Thickness 63 feet at type locality. Underlies Martinsburg shale; overlies Mercersburg formation (new) and converges with it in western belts of outcrop in Cumberland Valley. Type locality designated.

L. C. Craig, 1949, Geol. Soc. America Bull., v. 60, no. 4, p. 738–739. Name abandoned. Original use appears to have been inconsistent. Excessive restriction of the bed was necessary in defining the formation. As described at Marion, base was at an indefinite horizon in middle of Kauffman member (new) of Mercersburg formation. In section at Greencastle, base appears to have been drawn at base of Kauffman member; upper part of this section poorly exposed. Replaced by Oranda formation except for *Sinuites* zone at top, which is referred to base of Martinsburg formation.

Type section: Two miles southwest of Marion, Franklin County. [Named for Greencastle, Franklin County.]

Green Cove Beds[1]

Eocene: Western Wyoming.

Original reference: H. E. Wood 2d, 1934, Am. Mus. Nat History Bull. 67, art. 5, p. 245–249.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull. v. 52, no. 1, p. 21, pl. 1. Bridgerian.

Named for section at Green Cove, east of Hailey, Fremont County.

Greendale Limestone Member (of Cynthiana Formation)[1]

Middle Ordovician: Central northern Kentucky.

Original reference: A. F. Foerste, 1906, Kentucky Geol. Survey Bull. 7, p. 10, 19, 211.

A. C. McFarlan, 1943, Geology of Kentucky: Lexington, Ky., Kentucky Univ., p. 11 (footnote), 20–22. Overlies Sulphur Well beds (new) in Jessamine County. Although Bromley is given in literature as post-Greendale in age, it underlies the Greendale at Butler, Pendleton County, and at Clay's Ferry in northern Madison County.

A. C. McFarlan and W. H. White, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1641, 1643. Division of the Cynthiana. There has been little precision in use of name. In general, it has been used for rather fossiliferous limestones and shales around Frankfort and Lexington. Foerste (1909) defined the Greendale as including that part of the Cynthiana below Nicholas limestone. However, because of wedging-out of the Nicholas, Greendale lithologic characteristics and fauna continue to near top of formation. At type locality of Cynthiana, much of exposed section is the Nicholas. More or less equivalent to Millersburg limestone. Term Sulfur [Sulphur] Well member has been used for limestone and shale rich in bryozoans underlying the Greendale and Millersburg in much of thickened Cynthiana section of southern and southwestern Bluegrass. In present report, this pre-Greendale division of the Cynthiana is recognized as facies of upper Lexington, but containing a Cynthiana fauna.

D. K. Hamilton, 1950, Kentucky Geol. Survey, ser. 9, Bull. 5, p. 18. All subdivisions of the interval between the top of the Benson limestone and base of the Eden formation should be referred to as members of the Cynthiana. This includes as members the lithologic and paleontologic units heretofore defined as Brannon, Woodburn, Greendale, Millersburg, Nicholas, Rogers Gap, Bromley, and Gratz.

L. H. Lattman, 1954, Am. Jour. Sci., v. 252, no. 5, p. 265, 268. Rogers Gap limestone and Fulton shale, which cannot be distinguished faunally, rest northwardly on the Nicholas and southwardly on the Greendale. It is suggested that lowest occurrence of *Cryptolithus tesselatus* marks base of Nicholas member; beds below this zone carry a typical Greendale fauna, and name Greendale should be applied to these beds. Cincinnatian series should be extended downward to embrace Cynthiana formation.

Probably named for Greendale, Fayette County.

Greene Formation (in Dunkard Group)[1]

Greene Group

Greene Series

Lower Permian: Southwestern Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: J. J. Stevenson, 1876, Pennsylvania 2d Geol. Survey Rept. K, p. 35–44.

R. E. Lamborn, C. R. Austin, and Downs Schaaf, 1938, Ohio Geol. Survey, 4th ser., Bull. 39, p. 217. Permian rocks of Ohio divided into Washington series below and Greene series above. Each series separated into members. Base of Green series is base of Jollytown "A" coal; top is top of Gilmore sandstone and shale.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 152–153. Green group forms upper part of Dunkard series. Lies above Washington group. Composed of highest and youngest consolidated rocks in Fayette County [this report]. Only lowest part of group preserved in area of this report. Base of group is at top of Upper Washington limestone, and only shales and sandstone have been preserved above this stratum. Group has been divided into nine parts, only lowest of which, Donley sandstone, is preserved in county. Stevenson noted presence of sandstone about 10 feet above top of Upper Washington limestone in his Greene group for Washington County. He did not name the sandstone. In this report, it will be called Dunlap.

Thomas Arkle, Jr., 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 117–121, 135, 138. Washington and Greene groups of Dunkard series are herein ranked as series and considered of equal rank with Pennsylvanian Monongahela series. The Greene is about 700 feet thick. Base is at base of Jollytown coal below Jollytown sandstone; top is at top of Upper Proctor sandstone. Monongahela, Washington, and Greene series crop out in elliptical synclinorium (Huntington-Pittsburgh basin) which extends southwest from Pittsburgh area into eastern Ohio and western West Virginia to Kentucky.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Greene formation consists of cyclic sequences of sandstone, shale, and red beds, limestone and coal; base at top of upper Washington limestone. Permian [Dunkard group not used on map].

H. L. Berryhill, 1960, *in* C. O. Dunbar and others, 1960, Geol. Soc. America Bull., v. 71, no. 12, pt. 1, p. 1789–1790. There are no reasons, lithologic nor faunal-flora, for differentiating Washington and Greene formations anywhere in Dunkard basin. Subdivision of Stevenson (1876) has been handed down through tradition. Stevenson's Washington group is actually a facies. Away from northern edge of basin, Washington "group" has few lithologic characteristics of the "type" area. During recent mapping of Belmont County, Ohio, by U.S. Geological Survey, no bases for subdivision of these rocks were found. In that area, these rocks were classified as Washington-Greene formations undifferentiated.

Named for exposures in central and southwestern parts of Greene County, Pa.

†Greene County Group[1]

Pennsylvanian and Permian: Western Pennsylvania.

Original reference: H. D. Rogers, 1858, Geology Pennsylvania, v. 2, pt. 1, p. 503–507.

Greenefield Bed[1]

Upper Triassic: Central Massachusetts.

Original reference: B. K. Emerson, 1897, Geol. Soc. America Bull., v. 8, p. 65–72.

Occurs in vicinity of Greenfield, Franklin County.

Greeneville Limestone

See Greenville Dolomite.

†Greenfield Dolomite (in Whitehorse Sandstone)[1]

Permian: Southwestern Oklahoma.

Original reference: C. D. Stephenson, 1925, Am. Assoc. Petroleum Geologists Bull., v. 9, no. 3, p. 626–631.

Named for exposures just west of Greenfield, Blaine County.

Greenfield Dolomite[1] Member (of Bass Islands Dolomite)

Greenfield Dolomite or Formation (in Bass Islands Group)

Upper Silurian: Western Ohio and northern Kentucky, and Ontario, Canada.

Original reference: E. Orton, 1871, Ohio Geol. Survey Rept. Prog. 1870, p. 307, fig. 1. facing p. 310.

Wilber Stout, 1941, Ohio Geol. Survey Bull. 42, p. 38–39, chart facing p. 46. Basal formation of Bass Island[s] group in Ohio. Consists of dolomite, thin- to massive-bedded, gray to brown. Thickness commonly 175 to 225 feet. Underlies Tymochtee formation; upper limit very indefinite and fixed more on faunal than stratigraphic evidence. Type locality stated; distribution noted.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Correlation chart shows occurrence in Ontario, Canada.

Type locality: Near Greenfield, Highland County, Ohio. From Greenfield the formation extends northwestward and crops out in belt across parts of Fayette, Logan, Shelby, Auglaize, Allen, Van Wert, and Paulding Counties.

†Greenfield Limestone[1]

Upper Cambrian: Eastern New York.

Original reference: J. M. Clarke, 1903, New York State Mus. Handb. 19, p. 9, 12, table 2.

Probably named for Greenfield, Saratoga County.

Green Gulch Volcanics (in Alder Group)

Precambrian (Yavapai Series): Central Arizona.

C. A. Anderson and S. C. Creasey, 1958, U.S. Geol. Survey Prof. Paper 308, p. 31–32, pl. 1. Comprises basaltic and andesitic flows and sedimentary tuffaceous rocks of variable composition. Flow unit lies east of tuff. Most flows are medium to dark gray with greenish cast. Locally in flows, relict pillow and breccia structures, amygdules, vesicles, and bedding are preserved. Tuffaceous rocks range in composition from rhyolitic to basaltic. Most characteristic rock ranges in color from greenish black to greenish gray or dark to light olive gray. Fine-grained dark-gray siliceous rocks that weather to light pinkish gray and lesser amounts of light-gray porcellaneous slate are also present. Tuffaceous rocks range from finely laminated phyllite to more massive and locally coarser grained rocks. Thickness not known. Outcrop width about 10,500 feet. Formation bounded on east by Chaparral fault; on west, extends beyond map area; to north covered by Cenozoic rocks of Lonesome Valley.

Named for exposures along Green Gulch in southeastern part of Prescott quadrangle, Yavapai County. Forms triangular-shaped mass in extreme southwest corner of Jerome area.

Green Hill Member (of Pride Mountain Formation)

Upper Mississippian: Northern Alabama and northeastern Mississippi.

S. W. Welch, 1958, U.S. Geol. Survey Oil and Gas Inv. Chart OC–58. Light-brownish-gray oolitic thick-bedded limestone in lower part and olive-gray thin-bedded calcareous shale in upper part. Basal limestone is equivalent to upper limestone of Southward Bridge formation of Morse (1928); upper shale is equivalent to the lower part of the Forest Grove formation of Morse (1928), these strata were referred to by Butts (1926) as the Golconda formation. Maximum thickness about 80 feet near Mingo, Miss.; thins to 30 feet or less in Colbert County, Ala., at type locality 20 feet. Conformably overlies Mynot member (new); underlies Hartselle sandstone, contact poorly exposed, but evidence suggests an unconformity of at least local extent.

Named for exposure at roadside near head of Green Hill Branch about 3 miles south of Barton, Colbert County, Ala., in SW¼NW¼ sec. 22, T. 4 S., R. 13 W.

Greenhorn Bentonite Bed (in Colorado Formation)

Cretaceous: Southwestern Montana.

Great Northern Railway Co. Mineral Research and Development Department, 1960, Great Northern Railway Co. Mineral Research and Devel. Dept., Rept. 12, pt. 2, p. 38, 42. About 250 feet above Geyser bentonite bed (new). Thickness about 4 feet. Greenhorn bentonite is 20 to 30 feet below base of Greenhorn equivalent (Vine, 1956, U.S. Geol. Survey Bull. 1027–J).

Most westerly outcrop is north of Arrow Creek in S½ sec. 13, T. 18 N., R. 11 E; easternmost exposures are along Surprise Creek in sec. 36, T. 18 N. R. 11 E., and sec. 30, T. 18 N., R. 12 E.

Greenhorn Calcareous Member (of Cody Shale)

Greenhorn Limestone Member (of Colorado Shale or Mancos Shale)

Greenhorn Limestone[1] **or Formation** (in Colorado Group)

Greenhorn Member or Formation (of Benton Formation or Group)

Upper Cretaceous: Eastern Colorado, northwestern Iowa, western Kansas, southeastern Montana, Nebraska, northeastern New Mexico, and South Dakota.

Original reference: G. K. Gilbert, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 2, p. 564.

W. W. Rubey and N. W. Bass, 1925, Kansas Geol. Survey Bull. 10, p. 45–50. In western Kansas, subdivided into four members (ascending): Lincoln limestone, unnamed member, Jetmore chalk (new), and unnamed member. Thickness about 100 feet. Overlies Graneros shale; underlies Fairport chalky shale member (new) of Carlile shale.

N. W. Bass, 1926, Kansas Geol. Survey Bull. 11, p. 31–35, 66–71. In Ellis County comprises (ascending) Lincoln limestone, Hartland shale (new), Jetmore chalk, and Pfeifer shale (new) members. In Hamilton County, comprises (ascending) Lincoln limestone, Hartland shale, and Bridge Creek limestone (new) members.

J. B. Reeside, Jr., 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 10. As shown on correlation chart, Greenhorn limestone overlies Belle Fourche shale and underlies Carlile shale in northern Great Plains region.

R. C. Moore, J. C. Frye and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 153. Consists of chalky limestone and calcareous shale interbedded, thin-bedded, light-gray to dark-gray; weathers yellow gray to light gray. Thickness 85 feet in Barton County; 95 feet in Ellis County; 132 feet in Hamilton County. Comprises (ascending) Lincoln limestone, Hartland shale, Jetmore chalk, and Pfeifer shale members. Where Pfeifer shale and Jetmore chalk cannot be distinguished, they are termed Bridge Creek member. Overlies Graneros shale; underlies Carlile shale. Colorado group. Gulfian.

B. C. Petsch, 1946, South Dakota Geol. Survey Rept. Inv. 53, p. 17 (fig. 5), 46. Middle formation of Benton group. Crops out on east side of Big Sioux River north of Sioux City, Iowa. Underlies Carlile formation; overlies Graneros formation.

N. W. Bass, C. E. Straub, and H. O. Woodbury, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 68. Greenhorn limestone, as used in this report [Model anticline, Las Animas County, Colo.], is 93 feet thick and consists of (ascending) Lincoln limestone, Hartland shale, and Bridge Creek limestone members. Underlies Codell member of Carlile shale; upper boundary drawn on basis of faunal change and placed within a zone that lies about 35 feet above base of Bridge Creek member; overlies Graneros shale.

C. H. Dane, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 78. Member of Mancos shale in area of this report [eastern side San Juan basin, Rio Arriba County, N. Mex.]. Consists of alternating beds of marl and limestone. Thickness about 70 feet. Overlies Graneros shale member; underlies Carlile shale member. Upper Cretaceous.

W. A. Cobban and J. B. Reeside, Jr., 1951, Wyoming Geol. Assoc. Guidebook 6th Ann. Field Trip, p. 61 (fig. 2). In Black Hills area, includes Orman Lake limestone member at base. Overlies Belle Fourche shale; underlies Carlile shale.

P. W. Richards and C. P. Rogers, Jr., 1951, U.S. Geol. Survey Oil and Gas Inv. Map OM-111. In Hardin area, Big Horn and Yellowstone Counties, Mont., the Greenhorn is classed as calcareous member of Cody shale.

W. A. Cobban, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 10, p. 2183–2187, 2197 (fig. 2). Formations in Black Hills that are equivalent to Colorado shale of central and northwestern Montana are (ascending) Fall River sandstone, Skull Creek shale, Newcastle sandstone, Mowry shale, Belle Fourche shale, Greenhorn formation, Carlile shale, and Niobrara formation. Greenhorn formation attains maximum known thickness of 360 feet on east flank of Colony-Albion anticline in E½ sec. 9, T. 57 N., R. 61 W., Crook County, Wyo. In Carter County, Mont., formation thins sharply to 180 feet or less and, in addition, becomes less calcareous.

G. O. Bachman, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM-137. In northwestern Mora County, N. Mex., the Benton shale is represented by equivalents of Graneros shale, Greenhorn limestone, and Carlile shale.

W. J. Mapel, 1959, U.S. Geol. Survey Bull. 1078, p. 47–48, 56, pls. Described as calcareous member of Cody shale in Buffalo-Lake De Smet area, Johnson and Sheridan Counties, Wyo. Thickness about 136 feet. Overlies lower unnamed shale member and underlies Carlile shale member.

U.S. Geological Survey currently classifies the Greenhorn Limestone as a member of the Colorado Shale in the Cleveland quadrangle, Blaine County, Mont., on the basis of a study now in progress.

Named for Greenhorn Station, 14 miles south of Pueblo, Colo., and for Greenhorn Creek [Pueblo and Walsenburg quadrangles].

Greenhorn Mountain Quartzite

Precambrian (Belt Series): West-central Montana.

Adolph Knopf, 1950, Am. Mineralogist, v. 35, nos. 9–10, p. 839. Notably feldspathic; feldspar consisting of clear limpid microcline. Lower part of formation is massive quartzite, in places showing festoon cross-lamination; upper third is well stratified in beds of uniform thickness ranging from 1 to 2 inches. Thickness 1,800 feet. Overlies Marsh formation; top is bounded by erosion surface on which rests Flathead quartzite (Middle Cambrian). In extant geologic maps, Greenhorn Mountain quartzite has been included with "undifferentiated Devonian and Cambrian" strata, with the result that the Flathead, which averages 100 feet in thickness over a distance of scores of miles, is implied to have thickness of several thousand feet on Greenhorn Mountain.

Constitutes country rock of Continental Divide, making up bulk of Greenhorn Mountain, which forms highest summit between Mullan Pass and Marysville.

Greenian series[1]

Eocene: Wyoming.

Original reference: C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 36, 66, 279, 308.

Greenland Sandstone Member (of Atoka Formation)

Pennsylvanian (Atoka Series) : Northwestern Arkansas.

L. G. Henbest, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 8, p. 1946–1947, 1948 (fig. 2). Consists of silty ripple-marked flaggy sandstone with shaly partings. Locally, marine quartz-gravel conglomerate, which alters on exposure to contorted limonite-cemented sand, lies at base of unit or interfingers with it at higher levels. In some areas, lenses of marine quartz-gravel sandstone that are more or less massive or cross-bedded either interfinger or partly cut out parts of the member. Overlies Kessler limestone lentil of Bloyd shale.

Named from characteristic exposures and development in vicinity of Greenland, Washington County.

†Greenleaf Sandstone[1]

Lower Cretaceous: Southwestern Kansas.

Original reference: G. N. Gould, 1898, Am. Jour. Sci., 4th ser., v. 5, p. 170–174.

B. F. Latta, 1947, Kansas Geol. Survey Bull. 65, p. 86, 87. Not differentiated as stratigraphic unit. Included in Kiowa shale.

Named for Greenleaf Ranch, on upper Medicine River, 10 or 12 miles west of Belvidere, Kiowa County.

Green Lodge Formation[1]

Upper Cambrian: Eastern Massachusetts.

Original reference: E. J. Rhodes and W. H. Graves, Jr., 1931, Am. Jour. Sci., 5th, v. 22, p. 364–372.

Occurs at Green Lodge, Dedham quadrangle.

†Green Mountain Beds[1]

Green Mountain Conglomerate

Eocene: Central Colorado.

Original reference: G. L. Cannon, Jr., 1893, Colorado Sci. Soc. Proc., v. 4, p. 253.

L. W. LeRoy, 1946, Colorado School Mines Quart., v. 41, no. 2, p. 111–113. Sediments herein designated as Green Mountain conglomerate were assigned to division "D" of Denver formation (Cross, 1896, U.S. Geol. Survey Mon. 27). Hares (1926) suggested that these conglomerates be removed from Denver formation. Marr (1930, unpub. rept.) gave name Green Mountain conglomerate series to unit. In this report, name Green Mountain conglomerate is retained and unit is removed from Arapahoe-Denver formation. Thickness at least 600 feet.

S. O. Reichert, 1956, Geol. Soc. America Bull., v. 67, p. 111. Green Mountain conglomerate should be abandoned because it is a partial representative of Dawson formation as herein restricted.

Exposed on slopes of Green Mountain, Denver basin region.

Green Mountain Gneiss[1]

Green Mountain Series

Precambrian: Southwestern to northwestern Vermont.

Original reference: C. B. Adams, 1845, Vermont State Geologist 1st Ann. Rept., p. 60–61.

E. C. Jacobs, 1938, Vermont State Geologist 21st Rept. 1937–1938, p. 36–37. Age of Green Mountain series is Precambrian.

Green Mountains cross the State of Vermont.

Green Pond Conglomerate[1]

Silurian: Northern New Jersey and southeastern New York.

Original reference: H. D. Rogers, 1836, New Jersey Geol. Survey, p. 127.

P. K. Sims, 1958, U.S. Geol. Survey Prof. Paper 287, p. 42, pl. 1. Crops out on both Copperas and Green Pond Mountains in Dover district where it overlies Precambrian rocks. Silurian.

Named for Green Pond Mountains, N.J.

†Green Pond Quartzite[1]

Silurian: New Jersey.

Original references: N. H. Darton, 1894, New Jersey Geol. Survey Ann. Rept. State Geologist; H. B. Kummel and S. Weller, 1902, New Jersey Geol. Survey Ann. Rept. State Geologist.

†Green Pond Mountain Formation[1]

Silurian: New York.

Original reference: D. S. Martin, 1888, Geologic map of New York City and vicinity.

†Green Pond Mountain Group[1]

Devonian: New Jersey and New York.

Original reference: F. J. H. Merrill, 1887, New York Acad. Sci. Trans., v. 6, p. 59.

Extends from northern New Jersey through Orange County, N.Y., to Hudson River and for some distance beyond.

Green River Formation[1]

Eocene, lower and middle: Southwestern Wyoming, northwestern and central Colorado, and eastern Utah.

Original references: Henry Engelmann, 1859, Preliminary report on the geology of the country between Fort Bridger and Camp Floyd, Utah Territory, and southwest of the latter place, along Captain J. H. Simpson's routes, 1858; Appendix A *in* Report of the Secretary of War communicating, in compliance with a resolution of the Senate, Captain Simpson's report and map of wagon road routes in Utah Territory: U.S. 35th Cong. 2d sess., S. Ex. Doc. 40, p. 45–75; F. V. Hayden, 1869, U.S. Geol. Survey Terr. 3d Ann. Rept.

W. H. Bradley, 1931, U.S. Geol. Survey Prof. Paper 168, 58 p. Formation of Colorado and Utah is series of lake beds of middle Eocene age that occupy two broad, shallow, structural basins: the Piceance Creek in northwestern Colorado, and the Uinta in northeastern Utah. Average thickness about 2,000 feet; about 1,200 feet at north end of Piceance Creek basin, and about 2,800 feet in central part of basin; about 4,900 feet in western part of Uinta basin. In both basins, underlain by beds of sandy mudstone of Wasatch formation. In Piceance Creek basin, rocks of the Green River are youngest rocks exposed except in one area where they are overlain by 400 feet of sandy beds of fluviatile origin that appear to be lithologically and stratigraphically equivalent to basal beds of Bridger formation of Uinta basin. In Uinta basin, the Green River is conformably overlain by Bridger formation, and that, in turn, is subdivided into (ascending) Douglas Creek, Garden Gulch, Parachute Creek, and Evacuation Creek members (all new). West of Bitter Creek, Utah, formation is not divided into members. In at least two localities, it contains thick deltaic facies. In western part of Uinta basin, lower beds interfinger with Wasatch formation. Locally contact between Green River and overlying Bridger has been greatly distorted by differential compaction.

P. T. Walton, 1944, Geol. Soc. America Bull., v. 55, no. 1, p. 120–121. Most of southern part of Uinta basin consists of outcrops of Green River formation. Varies in thickness; along Indian Canyon, exceeds 5,000 feet; farther east at Duchesne County line, about 1,800 feet present; at Colorado border 2,000 feet. Along north of Uinta basin, lower boundary of Green River is surface of overlap. From Asphalt Ridge, eastward along Rim Rock, beds unconformably overlie Mesaverde group. Throughout this distance, base of Green River rises stratigraphically until, at Raven Ridge, the Wasatch is exposed. On south side of Uinta basin, Green River shale overlies and interfingers with Colton formation (new). It also concordantly overlies Flagstaff limestone at north end of Wasatch Plateau. Throughout south and middle parts of Uinta basin, Green River strata are conformably overlain by Uinta formation. Part of unit herein termed Uinta(?) may be facies change of Green River formation similar to Cathedral Bluff tongue of northwestern Colorado.

E. M. Spieker, 1946, U.S. Geol. Survey Prof. Paper 205-D, p. 122, 140, 141 (fig. 18). Formation, on northern and western borders of Wasatch Plateau, is about 5,000 feet thick. In eastern area, overlies Colton formation (formerly considered an upper member of Wasatch), and, in western area, overlies Flagstaff limestone (formerly considered member of Wasatch).

E. M. Spieker, 1949, Utah Geol. Soc. Guidebook 4, p. 13 (table), 35. Overlies Colton formation and locally Flagstaff formation and underlies Crazy Hollow formation (new) in Sanpete-Sevier district.

J. H. Donavan, 1950, Wyoming Geol. Assoc. Guidebook 5th Ann. Field Conf., p. 63. In Sublette and Lincoln Counties, Wyo., includes Fontenelle member (new). Fontenelle overlies Knight member of Wasatch. Middle Eocene.

J. R. Donnell, 1953, Rocky Mountain Assoc. Geologists Guidebook Field Conf. May 14–16, chart facing p. 17. Comprises (ascending) Anvil Points (new), Parachute Creek, and Evacuation Creek members in area between Rifle and De Beque Canyon, Colo. Overlies Wasatch formation. Thickness about 3,000 feet.

C. H. Dane, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 3, p. 405–425. Discussion of stratigraphic and facies relationships of upper part of Green River formation and lower part of Uinta formation in Duchesne, Uintah, and Wasatch Counties, Utah. Parachute Creek member of Green River is an approximate time-equivalent zone across Uinta basin, as shown by correlation of extensive thin tuff beds within the member. Top of overlying Evacuation Creek member is regarded as base of Uinta formation. This formation boundary rises stratigraphically toward center of basin, as also shown by correlation of tuff beds. Much of lower part of fluviatile beds of Uinta formation as exposed along Colorado-Utah line grades westward into beds that are in considerable part of lacustrine, playa, and mudflat origin in area of which Indian Canyon is center. These beds, formerly considered saline facies of Green River are here included as part of Uinta formation.

G. N. Pipiringos, 1955, Wyoming Geol. Assoc. Guidebook 10th Ann. Field Conf., p. 100–103. Discussion of central part of Great Divide basin, Sweetwater County, Wyo. The Green River comprises Luman tongue (new), Tipton tongue, Laney shale member, and Morrow Creek member, Intertongues with Wasatch formation. Battle Spring formation (new) intertongues with all parts of Wasatch and Green River formations except Laney shale member. In northern part of area, the Battle Spring replaces all parts of Wasatch and Green River formations except Morrow Creek member. Underlies Bridger formation.

W. H. Bradley, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 5, p. 1072–1075. Discussion of revision of stratigraphic nomenclature of Green River formation of Wyoming. In southwestern Wyoming, lacustrine Green River formation of early and middle Eocene age intertongues laterally with fluviatile deposits of Wasatch formation. For many years, the Green River has been subdivided into Tipton tongue (or Tipton shale member) as base, Laney shale member, and, at top, Morrow Creek member. East of eastern margin of Bridger basin, the Cathedral Bluffs tongue of the Wasatch separates Tipton tongue from Laney shale member. A comparable tongue of the Wasatch enters Green River formation along western margin of Bridger basin. Donavan (1950) named this tongue the New Fork tongue of Wasatch and named the basal unit of Green River in that area the Fontenelle member. Concluded from present study that what has until now been called Laney shale member of Green River in Bridger basin is older than type Laney and is time equivalent of Cathedral Bluffs and New Fork tongues of Wasatch formation. Beds in Bridger basin formerly thought to be Laney shale member of Schultz (1920) are herein named Wilkins Peak member of Green River. Morrow Creek member is equivalent to Schultz' type Laney shale member; term Morrow Creek is herein abandoned. Luman tongue of Green River continues upward into base of Tipton tongue. Laney shale is overlain by Bridger formation.

Type locality: At town of Green River, Sweetwater County, Wyo.

Greensburg or Flat Rock stone[1]

Silurian: Southeastern Indiana.

Original reference: E. T. Cox, 1879, Indiana Geol. Survey 8th, 9th, and 10th Ann. Repts., p. 57, 88–89.

Extensively quarried on Flat Rock Creek, near St. Paul, and near Greensburg, Decatur County.

Greenstone Flow[1] (in Portage Lake Lava Series)

Precambrian (Keweenawan): Northern Michigan.

Original reference: R. D. Irving, 1883, U.S. Geol. Survey Mon. 5, p. (see index), pls. 17 and 18.

H. R. Cornwall, 1951, Geol. Soc. America Bull., v. 62, no. 2, p. 164, 165. Southwest of Ahmeek, consists of ophitic basalt and columnar basalt topped by cellular amygdaloid. Contains amygdaloidal inclusions and streaks. Thickness at Quincy mine 55 feet; at Delaware 1,299 feet.

W. S. White, H. R. Cornwall, and R. W. Swanson, 1953, U.S. Geol. Survey Geol. Quad. Map GQ–27. Included in Portage Lake lava series.

So named because its great basal bed forms the well-known Greenstone Ridge, Keweenaw County.

Greenup cyclothem (in McLeansboro Group)

Greenup cyclothem (in Mattoon Formation)

Pennsylvanian: Southeastern Illinois.

W. A. Newton and J. M. Weller, 1937, Illinois Geol. Survey Rept. Inv. 45, p. 9, 26–27. Lies above Newton cyclothem (new) and below Gila cyclothem (new). Includes Greenup limestone.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 52 (table 2), pl. 1. In Mattoon formation (new). Above Bogota cyclothem and below Woodbury cyclothem. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type locality: Just north of town of Greenup, Cumberland County.

Greenup Limestone Member (of Mattoon Formation)

Greenup Limestone (in McLeansboro Group)

Pennsylvanian: South-central Illinois.

W. A. Newton and J. M. Weller, 1937, Illinois Geol. Survey Rept. Inv. 45, p. 26–27. Included in Greenup cyclothem, McLeansboro group. Commonly light-gray limestone; fossiliferous. Thickness 2½ to 3 feet. Overlies massive to thin-bedded sandstone that varies in thickness from few feet to more than 25 feet. Stratum above limestone may be thin-bedded to massive sandstone, or it may be poorly bedded slightly greenish shale which grades into basal member of Gila cyclothem above.

J. M. Weller, L. G. Henbest, and C. O. Dunbar, 1942, Illinois Geol. Survey Bull. 67, p. 19 (fig. 4), 28–29 [1943]. In Cumberland County, consists of about 4 feet of light-gray earthy limestone that is nodular in places; thins southward and in Jasper County is represented by 1 foot of hard brownish-gray limestone or more or less inconspicuous zone of limestone nodules. No coal or underclay is present beneath the Greenup, and locally it is in direct contact with underlying sandstone.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 40, 41, 51 (table 1), 79, pl. 1. Assigned to member status in Mattoon formation (new). Occurs below Gila limestone member and above Bogota limestone member. Thickness 3 feet at type outcrop. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality; Near center W½NE¼ sec. 3, T. 9 N., R. 9 E., Cumberland County.

Green Valley Formation

Pliocene, lower: Western California.

Carlton Condit, 1938, Carnegie Inst. Washington Pub. 476, p. 248. Name applied to formation consisting of interbedded brown sands and gray shales occurring in quarry on south side of Mount Diablo.

B. L. Clark, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 195. Series of continental beds (previously referred to as Orinda formation). Overlies marine beds of lower Pliocene age, locally known as Alamo formation; underlies lacustrine deposits locally known as Tassajara formation. Type section noted.

B. L. Clark, 1943, California Div. Mines Bull. 118, pt. 2, p. 189 (fig. 72), 191 [1941]. Above the Alamo are between 2,000 and 3,000 feet of continental beds, the Green Valley formation. Name Green Valley is used here for first time. It is equivalent to "Orinda formation," the name used by Clark (1935, Geol. Soc. America Bull., v. 46, no. 7) for continental deposits which immediately overlie the Alamo in section to west and southwest of Mount Diablo. Underlies Tassajara formation and separated from it by series of tuffaceous deposits, the "Moraga" tuff (Clark, 1935).

C. E. Weaver and others, 1944, Geol. Soc. America Bull., v. 55, no. 5, p. 585, chart 11. Heterogeneous series of continental deposits may be in part lacustral; thickness 300 feet. Shown on chart as overlying Diablo formation (new name for Alamo formation) and underlying Tassajara formation.

N. L. Taliaferro, 1951, California Div. Mines Bull. 154, p. 143–144. Diablo formation grades upward into at least 6,000 feet of nonmarine floodplain and lacustrine sediments to which name Green Valley has been given.

Type section: Immediately to west and southwest of Mount Diablo.

Green Valley Tonalite

Upper Cretaceous: Southern California.

F. S. Miller, 1937, Geol. Soc. America Bull., v. 48, no. 10, p. 1408–1409. Incidental mention in discussion of San Marcos gabbro.

E. S. Larsen, Jr., 1948, Geol. Soc. America Mem. 29, p. 53–57, pl. 1. Gray medium-grained tonalite; uniform in character; resembles Bonsall tonalite but lacks abundant streaked inclusions of that tonalite. Intrudes Triassic sedimentary, Jurassic volcanic rocks, and San Marcos gabbro; intruded by Woodson Mountain granodiorite.

D. L. Everhart, 1951, California Div. Mines Bull. 159, p. 74–78, pls. 2–5. Described in Cuyamaca Peak quadrangle. Older than Bonsall tonalite; younger than Cuyamaca gabbro. Age considered to be Upper Cretaceous.

Richard Merriam, 1958, California Div. Mines Bull. 177, p. 12–13, pl. 1. Limited to two small masses at west edge of Santa Ysabel quadrangle. In contact with younger Lake View Mountain tonalite. No other contacts exposed, but relations elsewhere show the Green Valley to be younger than San Marcos gabbro and older than Bonsall tonalite.

Named for its development in southeastern part of San Luis Rey quadrangle.

Green Valley Volcanic Series

Tertiary: Southwestern Texas.

S. S. Goldich and M. A. Elms, 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1197. Lake deposits, pyroclatics, and intercalated lava flows which rest on basement of Cretaceous strata. Lower 900 feet of series is named Pruett formation, and the upper 1,000 feet, the Duff tuff; these two formations are separated by basaltic lava flows up to 325 feet thick which are designated the Cottonwood Springs basalts. Duff tuff is overlain by Mitchell Mesa rhyolite (new) which is youngest rock of series.

Occurs in Green Valley on southern Davis Mountain from in Trans-Pecos Texas, in Buck Hill quadrangle, Brewster County.

Greenville Dolomite[1]

Upper Cambrian : Northeastern Tennessee.

Original references: E. O. Ulrich, 1924, Tennessee Dept. Education, Div. Geol. Bull. 28, p. 34 ; Bull. 31, p. 16.

C. E. Resser, 1938, Geol. Soc. America Spec. Paper 15, p. 4, 15. Abandoned. It is not clear whether name Greeneville limestone used by Ulrich was intended to represent a part of or a bed beneath the Copper Ridge.

Type locality not stated but understood to be Greenville, Greene County.

Greenville Shale (in Greenbrier Limestone[1] or Series)

Mississippian (Meramecian) : Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 449, 466.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey Greenbrier County, p. 267, 271–272; J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (columns 98, 99). Shale in Greenbrier series (Meramec). Underlies Alderson limestone ; overlies Union limestone.

Type locality: In road on north side of Indian Creek, 0.1 mile northwest of Hunter Spring School and 1.6 miles southeast of Greenville, Monroe County.

Greenwater volcanics[1]

Tertiary : California and Nevada.

Original reference : C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 52, 79.

Probably named for exposures at or near Greenwater, east of Death Valley, in Inyo County, Calif.

Greenwater Volcanics

Pliocene(?) : Southern California.

L. F. Noble, 1941, Geol. Soc. America Bull., v. 52, no. 7, 955, 966. Glassy andesitic and latitic lavas, tuffs, and breccias, which in Greenwater Canyon interfinger with pumiceous water-laid tuffs. Thickness 2,500 feet. Unconformably underlies Funeral fanglomerate (new) ; unconformably overlies Furnace Creek formation. Name credited to T. P. Thayer.

Typically exposed between Greenwater Canyon and Brown's Peak, in Greenwater Range, southern Death Valley region.

†Greenwich Formation[1]

Precambrian(?) : Southwestern Connecticut.

Original reference: J. G. Percival, 1842, Connecticut Geol. Survey Rept., p. 46, 49, 58, 63, 72, map.

Occurs in Stamford and Greenwich, Fairfield County, and extends along the Sound from east side of Stamford Harbour into New York State.

†Greenwich Formation[1]

Lower Cambriam : Eastern New York.

Original reference: T. N. Dale, 1904, U.S. Geol. Survey Bull. 242, p. 43, 50, pl. 1.

U.S. Geological Survey has abandoned the term Greenwich Formation on the basis that C. D. Walcott's manuscript [not Walcott, 1910, Smithsonian Misc. Colln., v. 53, no. 6] for which the name was approved was never published.

Occurs in Washington and Rensselaer Counties. Named for exposures at Greenwich, Washington County.

Greenwich Shale[1]

Cretaceous (?) : Southeastern Colorado.

Original reference: W. T. Lee, 1901, Jour. Geology, v. 9, p. 343–352.

In Purgatoire Canyon near mouth of Plum Canyon.

Greenwood Iron-Formation Member (of Michigamme Slate)

Greenwood Iron-Formation[1]

Precambrian (Animikie Series) : Northern Michigan.

Original reference: J. Zinn, 1933, Michigan Acad. Sci., Arts and Letters, v. 18, p. 442, 443, 451–454.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 36. Lower part of Michigamme slate in Marquette area includes Bijiki iron-formation, Clarksburg volcanics, and Greenwood iron-formation members.

Type locality and derivation of name not stated. Greenwood is in Marquette County.

Greenwood Sandstone[1]

Pennsylvanian: Western Arkansas and central eastern Oklahoma.

Original reference: A. Winslow, 1896, New York Acad. Sci. Trans., v. 15, p. 51.

Probably named for Greenwood, Sebastian County, Ark.

†Greer Formation[1]

Permian: Southwestern Oklahoma and central and northern Texas.

Original reference: C. N. Gould, 1902, Oklahoma Geol. Survey 2d Bienn. Rept., p. 42, 52.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 101. Abandoned by Oklahoma Geological Survey. Was named to designate rocks of the Blaine and rocks mistakenly thought to correlate with it.

Type locality: Butte known as Cedar Top in northwestern corner of Kiowa County, Okla. Named for Greer County, Okla.

Greggs Breccia[1]

Tertiary, upper; Northwestern Arizona.

Original reference: W. T. Lee, 1908, U.S. Geol. Survey Bull. 352, p. 17.

C. R. Longwell, 1936, Geol. Soc. America Bull., v. 47, no. 9, p. 1414. Pliocene (?).

Exposed south of Colorado River and east of Greggs Ferry and fills Grand Wash Trough [northwest corner of Mohave County].

Greggs Landing Marl Member (of Tuscahoma Sand)[1]

Eocene, lower: Southwestern Alabama.

Original reference: E. A. Smith, 1886, Alabama Geol. Survey Bull. 1, p. 12.

L. D. Toulmin, P. E. LaMoreaux, and C. R. Lanphere, 1951, Alabama Geol. Survey Spec. Rept. 21, p. 65, pl. 3. Described in Choctaw County where it lies about 25 feet below the Bells Landing marl member.

Named for exposures at Greggs Landing, on Alabama River, in northwestern part of Monroe County.

†Greggs Landing Series[1]

Eocene, lower: Alabama.

Original reference: W. H. Dall, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 2, p. 346.

Gregorian series[1]

Pleistocene: Iowa.

Original reference: C. R. Keyes, 1935, Pan-Am. Geologist, v. 63, no. 4, p. 281.

Derivation of name not stated.

Gregory Member (of Pierre Shale)

Gregory zone (in Sully Member of Pierre Formation)

Upper Cretaceous: Central South Dakota.

W. V. Searight, 1937, South Dakota Geol. Survey Rept. Inv. 27, p. 10–20, pls. 2, 3. Includes all beds from top of Niobrara to base of Oacoma zone of Sully member (new) south of the Great Bend and, northward from this locality, all beds lying below Agency shale zone of Sully. At and near type locality, divisible into two lithologically and faunally distinct subdivisions. Lower consists of dark bentonite-bearing bituminous shales which contain fish scales. Upper is thin zone of chalk, chalky shale, argillaceous chalk, or marl. From vicinity of mouth of White River, Lyman County, to northernmost exposures near DeGrey, Hughes County, lower and upper Gregory are separated by thin but persistent sandstone bed. Thickness 12 to 145 feet.

W. V. Searight, 1938, Iowa Acad. Sci. Proc., v. 45, p. 137. Microfaunal studies indicate that chalky beds of Gregory underlying Agency faunal zone of Sully member are closely related to the Sully and that beds previously described as upper Gregory should be included in Sully as lowermost zone of that member. Name Gregory [marl] is retained for this zone. Beds described as lower Gregory are contemporaneous with the Sharon Springs of Kansas and Colorado and the name [Sharon Springs] is adopted for beds between the Niobrara and Gregory zone of Sully as revised.

A. L. Moxon, O. E. Olson, and W. V. Searight, 1939, South Dakota State Coll. Agriculture and Mech. Arts Tech. Bull. 2, p. 20, 22. Gregory marl [zone] in Sully member consists of marl, shale, and chalky shale. Underlies Agency shale [zone].

J. P. Gries and E. P. Rothrock, 1941, South Dakota Geol. Survey Rept. Inv. 38, p. 8 (table 1), 11–14. Name Gregory resurrected and used to include all beds between base of Gregory marl and base of upper calcareous zone herein named Crow Creek zone of Sully member. These beds form distinct lithologic unit in type locality and as far north as Hughes County, where they pass beneath river level. Overlies Sharon Springs member; underlies Sully member.

D. R. Crandell, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 12, p. 2340 (table 1), 2346. Underlies Crow Creek herein given member status in Pierre; overlies Sharon Springs member. Thickness at type section 34 feet. Consists of beds of light-gray to buff-colored shale with concretions and calcareous layers, and locally, as in Gregory County, basal marl beds. Gregory member as here adopted is Gregory member of Gries and Rothrock (1941).

Type locality: Outcrops along Missouri River in eastern Gregory County. Well exposed in cut bank at south end of Rosebud Bridge, south of Wheeler. Also well exposed to east of Missouri River, especially south of U.S. Highway 18 in Charles Mix County.

Grenada Formation (in Wilcox Group)[1]

Eocene, lower: Mississippi, Kentucky, and western Tennessee.

Original reference: E. N. Lowe, 1913, Mississippi Geol. Survey Bull. 10, p. 23–25.

[Tom McGlothlin] 1940, Mississippi Geol. Soc. [Guidebook 2], p. 3, 4–5. At least upper part, and perhaps all of Grenada formation belongs in Tallahatta section.

Tom McGlothlin, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 1, p. 53. Suggested that term Grenada be abandoned.

G. F. Brown, 1947, Mississippi Geol. Survey Bull. 65, p. 34. Discussion of geology of alluvial plain of northwestern Mississippi. Outcrop beds earlier assigned to the Wilcox were divided into three formations: basal Ackerman, Holly Springs sand, and Grenada. Grenada is now known to be of Claiborne age, and outcrops of sand around Holly Springs are exposures of Meridian sand member of Tallahatta formation (basal Claiborne).

Benjamin Gildersleeve, 1953, Kentucky Geol. Survey Spec. Pub. 1, p. 18 (fig. 1). Generalized section—embayment region of Tennessee and Kentucky—shows Grenada formation above Holly Springs formation and below Jackson formation. Wilcox group. Lower Eocene.

Named for exposures at Grenada, Grenada County, Miss., especially on Yalobusha River, near Grenada.

Grenola cyclothem

Lower Permian (Wolfcamp): Eastern Kansas.

N. G. Lane, 1958, Kansas Geol. Survey Bull. 130, pt. 3, p. 150–156. Defined as beginning at base of unfossiliferous red and green shale in the Roca formation next below the Grenola.

Study was made at type area of Grenola formation in Elk and Cowley Counties.

Grenola Limestone (in Council Grove Group)

Grenola Formation[1]

Permian: Eastern Kansas, southeastern Nebraska, and northern Oklahoma.

Original reference: G. E. Condra and C. E. Busby, 1933, Nebraska Geol. Survey Paper 1.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 47–48. Grenola limestone in Council Grove group. Redefined in accordance with usage of Nebraska Geological Survey to include strata between base of Sallyards limestone and top of Neva limestone. As thus redefined, includes (ascending) Sallyards limestone, Legion shale, Burr limestone, Salem Point shale, and Neva limestone members. Underlies Eskridge shale; overlies Roca shale. Thickness 38 to 48 feet. Lower Permian, Wolfcamp series.

Type section: Ravines and creeks north and south of Highway 160, 4 to 5 miles west of Grenola, Elk County, Kans. All five members present in type section.

†Grenville Limestone[1]

Precambrian: Quebec, Canada, and northern New York.

Original references: W. E. Logan, 1859, Canada Geol. Survey Rept. Prog. 1858, p. 35–40; 1863, Canada Geol. Survey 15th Rept. Prog., p. 43–45; 1865, Canada Geol. Survey 16th Rept. Prog., p. 20, map.

Grenville Quartzite[1] or Amphibolite[1]

Precambrian: Northern New York.

Original reference: R. Balk, 1932, New York State Mus. Bull. 290, p. 14.

Grenville Series[1]

Precambrian: Ontario, Canada, and New York.

Original references: W. E. Logan, 1863, Canada Geol. Survey 15th Rept. Prog., p. 43–45; F. D. Adams, 1893, Jour. Geology, v. 1, p. 328–330.

K. E. Lowe, 1950, Geol. Soc. America Bull., v. 64, no. 5, p. 515. Term "Hudson Highlands complex" or "Highlands complex" includes entire sequence of crystalline rocks older than Storm King granite. Grenville sediments (quartzitic micaceous, and calacareous beds) comprise oldest formation in Hudson Highlands. The rocks are characteristically layered and have been intensely metamorphosed. At Bear Mountain, where Grenville series constitutes major part of Highlands complex, biotite, hornblende, epidote, and graphite schists and garnetiferous biotite gneiss are common. Pochuck diorite phase and Canada Hill granite phase associated with Grenville metamorphics.

R. J. Bean, 1953, Geol. Soc. America Bull., v. 64, no. 5, p. 515. Grenville formation mentioned in relation of gravity anomalies to geology of central Vermont and New Hampshire.

For detailed discussion of Grenville Series, see A. F. Buddington, 1939, Geol. Soc. America Mem. 7, 354 p. (Adirondack region), and J. E. Thomson, ed., 1956, The Grenville Problem: Toronto, Canada, Univ. Toronto Press and Royal Soc. of Canada, 119 p.

Name derived from Grenville Township, Argenteuil County, Ontario, Canada.

Greybull Sandstone Member (of Cloverly Formation)[1]

Lower Cretaceous: Central northern Wyoming and central southern Montana.

Original reference: F. F. Hintze, Jr., 1915, Wyoming Geologists Office Bull. 10.

P. W. Richards, 1955, U.S. Geol. Survey Bull. 1026, p. 44, 45. In upper part of Cloverly formation which is considered to be Lower Cretaceous in age. Underlies "rusty beds" here included in Cloverly.

D. L. Eicher, 1960, Yale Univ. Peabody Mus. Nat. History Bull. 15, p. 7–8, 15–16. Term Greybull sandstone member (Hewett and Lupton, 1917, U.S. Geol. Survey Bull. 656) has been applied to some sandstone beds in this general section. Inasmuch as type locality was not designated accurately, it is not now possible to ascertain whether term referred only to channel sandstones in upper part of Cloverly or to sandstone beds at base of rusty beds, or to some of each. Term Greybull should not be used beyond confines of Greybull oil field where originally it was informally applied to an oil sand.

Named for Greybull, Wyo.

Greyhorse Limestone (in Wabaunsee Group)[1]

Pennsylvanian: Oklahoma, northwestern Missouri, and southeastern Nebraska.

Original reference: G. E. Condra, 1935, Nebraska Geol. Survey Paper 8, p. 9.

Type locality: In NW¼ sec. 11, T. 24 N., R. 6 E., Osage Reservation, Okla. Correct spelling is Grayhorse.

†Greylock Limestone[1]

Silurian: Massachusetts.

Original reference: R. Pumpelly, 1894, U.S. Geol. Survey Mon. 23.

Greylock Mountain region.

Greylock Schist[1]

Middle Ordovician: Northwestern Massachusetts and southern Vermont.

Original reference: T. N. Dale, 1891, Am. Geologist, v. 8, p. 1–7.

Norman Herz, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–108. Described in Cheshire quadrangle where it crops out in vicinity of Saddle Ball Mountain. In this report, color was used as primary distinction between Berkshire schist below and Greylock: black for Berkshire, green or greenish blue for Greylock. Some rocks formerly mapped as Greylock are included in Berkshire schist of this report.

J. B. Thompson, Jr., 1959, New England Intercollegiate Geol. Assoc. Guidebook 51st Ann. Mtg., p. 72, 77, 86. Geographically extended into Vermont. Thickness about 1,000 feet. If Berkshire schist is equivalent to Ira formation, Greylock schist may represent rocks that overlie Ira unconformably. However, Greylock closely resembles Biddie Knob formation of Castleton area which is believed to underlie conformably fossiliferous Cambrian of Taconic slate belt. Age uncertain.

Named for exposures on Mount Greylock, Mass.

†Greylock Series[1]

Precambrian: Massachusetts.

Original references: W. H. Hobbs, 1892, Geol. Soc. America Bull., v. 3, p. 460; 1893, Jour. Geology, v. 1, p. 717–736.

Occurs in Mount Greylock region.

Greyson Shale (in Missoula Group)

Greyson Member (of Spokane Formation)

Greyson Shale[1] (in Piegan Group)

Precambrian (Belt Series): Western central Montana.

Original reference: C. D. Walcott, 1899, Geol. Soc. America Bull., v. 10, p. 199–215.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1898. Member of Spokane formation. Consists of thinly bedded gray and greenish-gray shales that weather olive brown; conglomerate, pinkish sandstone, and brown sandy lenses in lower portion. Thickness 2,300 to 3,000 feet. In little Belt Mountains, consists of about 1,000 feet of gray argillite. Underlies Prickly Pear member (new).

C. P. Ross, D. A. Andrews, and I. J. Witkind, 1955, Geologic map of Montana (1:500,000): U.S. Geol. Survey. Shale distinguished only in vicinity of Helena. In Piegan group.

U.S. Geological Survey currently classifies the Greyson Shale as a formation in the Missoula Group on the basis of a study now in progress.

Type locality: On side of ridge between Deep and Greyson Creeks in Belt Mountains, southeast of Townsend.

Gries Ranch Formation

Gries Formation

Gries Ranch horizon[1]

Oligocene, lower: Western Washington.

Original reference: W. L. Effinger, 1936, Geol. Soc. America Proc. 1935, p. 411.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 108–109. Term Gries Ranch zone was applied by Dickerson (1917, California Acad. Sci. Proc., 4th ser., v. 7, no. 6) to relatively thin section of brownish-gray sandstone and sandy shale exposed in south bank of Cowlitz River, in south part of sec. 24, and north part of sec. 25, T. 11 N., R. 2 W., Cowlitz County. Collection of fossils made by Anderson and Martin was described by Dickerson as representing a lower facies of the *Molopophorus lincolnensis* zone. Original description of type locality was designated by Martin as "Locality 181 on east bank of Cowlitz River, just back of Greece ranchhouse about 4 miles east of Vader. There appear to be two formations represented at this point. The fossils occur in a sandstone which is associated with a conglomerate composed of basalt pebbles and boulders. These two beds dip northwest at very small angle varying from 1° to 5°. A few yards to south a well-stratified coarse gray compact sandstone is exposed dipping south at angle of 10° and striking N. 70° E. This sandstone is probably Eocene. About 20 feet south of fossil beds a mass of coarse conglomerate is butting perpendicularly against sand to the south. This conglomerate appears to be same as that where the fossils occur." Term Grecco ranch is used in description given by Dickerson. As ascertained by present writer [Weaver], the name of people who originally owned this ranch was spelled Gries and this name should be used rather than Grecco. Several years ago the property was sold by Gries family who moved some distance up river. Because name Gries Ranch fauna has become familiar to investigators of marine Oligocene, it is herein suggested that small headland on river on property formerly owned by Gries family be named Gries Point and that beds exposed in river bank and west of the point be termed Gries formation. Strata of Gries formation are exposed in south bank of Cowlitz River for distance of about 1,200 feet where they occupy nose of shallow faulted syncline, which plunges toward north, and whose dips in either limb are under 4°. Formation is commonly regarded as lowermost Oligocene and is probably in part at least equivalent to Keasey formation in Oregon.

W. L. Effinger, 1938, Jour. Paleontology, v. 12, no. 4, p. 355–390. Description of Gries Ranch fauna. Measured section at Gries Ranch locality gives thickness of Gries Ranch beds as 106 feet. Seems likely that the Gries Ranch may be correlated with Willapa River shales of southwestern Washington and Keasey shales of Oregon, but their faunas are apparently of deeper water facies.

Type locality: Outcrop on southeast bank of Cowlitz River, in Lewis County, about 4 miles east of Vader, sec. 25, T. 11 N., R. 2 W. Named for Gries Ranch.

Griffin Bed[1]

Miocene, lower: Western Florida and southwestern Georgia.

Original reference: A. F. Foerste, 1894, Am. Jour. Sci., 3d, v. 48, p. 52–54.

Named for exposures on Griffins Creek, 4½ miles south of Bainbridge, Decatur County, Ga., and about one-half mile west of Griffin's House.

Griffin Sandstone Member (of Lake Murray Formation)

Pennsylvanian: Southern Oklahoma.

B. H. Harlton, 1956, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 1: Tulsa, Okla., Am. Assoc. Petroleum Geologists. p. 137 (fig. 2), 140, 141 (fig. 3). Middle member of Lake Murray formation (new). Overlies Bostwick member: underlies Frensley member.

Derivation of name not stated. Area of report is Harrisburg trough, Stephens and Carter Counties.

Griffith Beds

Cretaceous(?): Southern California.

G. J. Neuerburg, 1953, California Div. Mines Spec. Rept. 33, p. 7 (table 1), 18–19, pl. 1. Sandstone and fanglomerate about 2,500 feet thick. Separable into four units or members (unnamed): lowest, about 500 feet consists predominantly of thick-bedded medium-grained arkose with beds of silty clay shale, siltstone, and pebble conglomerate; second, about 150 feet, is thick beds of cobble conglomerate and arkose; third and fourth members are boulder conglomerate; third has about 20 percent arkose matrix as compared to 30 to 40 percent in the fourth member. Probably oldest sedimentary unit in area. Unconformably overlies pre-Cretaceous(?) basement rocks; underlies Cahuenga beds (new). Griffith beds occupy an isolated fault block; unit is in fault contact with sediments of Topanga formation and Hollycrest formation (new) on all sides.

Occurs in Griffith Park area, city of Los Angeles.

Grimes Siltstone Member (of West Falls Formation)

Grimes Sandstone[1]

Upper Devonian: Western and west-central New York.

Original reference: D. D. Luther, 1902, New York State Mus. Bull. 52, p. 616–629.

J. F. Pepper, Wallace de Witt, Jr., and G. W. Colton, 1956, U.S. Geol. Survey Oil and Gas Inv. Map OC–55. Unit termed Grimes sandstone by Luther is here designated as Grimes siltstone member of West Falls formation (new). Consists largely of light-greenish-gray and light-bluish-gray siltstone in lenticular beds 1 inch to 6 feet thick. Maximum thickness not more than 60 feet; 1 foot in west-central Livingston County; 15 feet near Dansville, Livingston County; about 50 feet in southern Ontario and western Yates Counties; 5 feet in Steuben County. Overlies Hatch shale member; underlies Gardeau shale member; both contacts gradational.

Named for exposures in Grimes Glen at Naples, Ontario County.

Grimes Canyon Sand and Gravel Member (of Santa Barbara Formation)

Pleistocene, lower: Southern California.

California State Water Resources Board, 1953 (revised 1956), California State Water Resources Board Bull. 12, v. 2, p. B–24, B–103–B–104, pls.

B-1C, B-2. Sand and gravel 100 to 1,000 feet thick near top of formation; rusty-brown color; slightly cemented. Underlies Fox Canyon member (new) of San Pedro formation.

T. L. Bailey, 1954, *in* Pacific Petroleum Geologist, v. 8, no. 9, p. 1; R. G. Thomas and others, 1954, California Div. Mines Bull. 170, chap. 6, p. 20, pls. 2, 6, 7. Marginal facies of formation. Grades from fine sand ranging from 20 feet thick in Las Posas Hills to 1,000 feet thick in southernmost part of Oxnard Plain.

Exposed in Grimes Canyon and southeastward, mostly on flank of Oak Ridge, Ventura County.

Grimsby Sandstone (in Albion Group)

Grimsby Sandstone[1] (in Medina Group)

Lower Silurian: Ontario, Canada, and New York.

Original reference: M. Y. Williams, 1914, Science, new ser., v. 39, p. 915–918.

Tracy Gillette, 1940, New York State Mus. Bull. 320, p. 21, 22 (fig. 6), 24–26. Top formation in Albion group, Medinan series. Oldest rock exposed in Clyde and Sodus Bay quadrangles. Underlies Thorold sandstone of Clinton group.

Tracy Gillette, 1947, New York State Mus. Bull. 347, p. 13 (fig. 2), 30, 31 (fig. 4). In area of Fulton, the Grimsby underlies Oneida conglomerate.

D. W. Fisher, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 9, p. 1982 (fig. 3), 1991–1993. Top formation in Medinan group. Correlation chart shows that Grimsby underlies Thorold sandstone and overlies Cabot Head shale in all areas except Lockport where it is unconformable below the Neagha and overlies Fish Creek shale (new). Thickness 3 to 70 feet.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. Term Medina group used in this report in preference to Medinan group. Term Rumsy Ridge replaces preoccupied name Fish Creek. Chart shows Grimsby overlies Rumsy Ridge in some areas.

Named for exposures along east side of Niagara Gorge at Grimsby, Ont.

Grindstaff cyclothem (in Abbott Formation)

Grindstaff cyclothem (in Tradewater Group)

Pennsylvanian: Southwestern and southeastern Illinois.

H. R. Wanless, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 9, p. 1764 (table 2). In list of cyclothems of southern Illinois, the Grindstaff occurs at base of Tradewater group and underlies Delwood cyclothem.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 5, 9, pl. 1. Includes (ascending) Grindstaff sandstone, Willis coal, and Boskydell marine horizon. Underlies Delwood cyclothem; overlies Pounds cyclothem of Caseyville group. Type locality given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 52 (table 2), pl. 1. In Abbott formation (new). Above Pounds cyclothem and below Delwood cyclothem. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type locality: NE¼ sec. 28, T. 10 S., R. 8 E., Gallatin County.

Grindstaff Sandstone Member (of Abbott Formation)

Grindstaff Sandstone Member (of Tradewater Formation)[1]

Grinsdtaff Sandstone (in Tradewater Group)

Middle Pennsylvanian: Southeastern Illinois and western Kentucky.

Original reference: C. Butts, 1925, Illinois Geol. Survey Bull. 47, p. 44.

J. M. Weller, 1940, Illinois Geol. Survey Rept. Inv. 71, p. 40. Rank raised to formation in Tradewater group. Underlies Delwood formation (new).

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 31, 44 (table 1), 62. Rank reduced to member in Abbott formation (new). Thickness about 50 feet in type section of Abbott. Occurs above Reynoldsburg coal member and below Willis coal member (both new). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

U.S. Geological Survey has discontinued use of the name Tradewater in Illinois.

Type locality: NE¼ cor. sec. 28, T. 10 S., R. 8 E., Gallatin County, Ill. Area is known as Grindstaff Hollow.

Grindstone Group

Upper Jurassic (Knoxville): Northern California.

F. M. Anderson, 1943, California Div. Mines Bull. 118, pt. 2, p. 184 (fig. 68) [preprint 1941]. Shown as middle group of Knoxville series. Underlies Newville group (new): overlies Elder Creek group (new).

F. M. Anderson, 1945, Geol. Soc. America Bull., v. 56, no. 10, p. 926–929. Begins with well-marked basal conglomerate; upper parts dark sandstone and black sandy shale. Thickness on Grindstone Creek between Chrome and Elk Creek village 5,400 feet; on Redbank Creek 2,800 feet—due to faulting; west of Bennett Creek and Toms Creek, 6,600 feet or more. In some areas, rests directly upon Klamath complex; in other areas, overlies Elder Creek group or overlies Paleozoic limestones. South of Cold Fork, conglomerates lie discordantly on Elder Creek group in disconformable overlap, and constitute a belt that stands out in relief along strike of beds. Derivation of name given.

Named from Grindstone Creek which crosses the group 1 to 2 miles west of road between Chrome and Elk Creek village, Glenn County. Well exposed in sec. 26, T. 28 N., R. 9 W., on northeast slope of Tedoc Peak, northwest Tehama County.

Grindstone Creek Formation (in Millsap Lake Group)

Grindstone Creek Member (of Millsap Lake Formation)[1]

Pennsylvanian: North-central Texas.

Original reference: E. H. Sellards, 1933, Texas Univ. Bull. 3232, p. 106, 107.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Rank raised to formation in Millsap Lake herein given group status. Includes (ascending) "Buck Creek sandstone", Santo limestone, Goen limestone-Ricker limestone. Underlies Garner formation; overlies Lazy Bend formation.

Leo Hendricks, 1957, Texas Univ. Bur. Econ. Geology Pub. 5724, p. 18–20, fig. 3, pl. 4. Chiefly a succession of shales, sandy shales, and sandstones occurring immediately above Brannon Bridge limestone. Thickness about

450 feet. In this report, includes Santo limestone bed about middle of formation and Goen limestone bed at top. Top of formation has been defined in Palo Pinto County (Plummer and Hornberger 1936, Texas Univ. Bull. 3232) as base of Thurber coal where present and top of Goen limestone where coal is missing. Thurber coal is missing in Parker County, and the Goen can be traced from Palo Pinto County only one-half mile eastward into Parker County; hence, in this report, boundary between Grindstone Creek and overlying Garner is mapped by projection of topographic and structural position of Goen limestone, but this method is considered unsatisfactory.

Type locality: West of Grindstone Creek, Parker County. Exposures occur in scarps and artificial cuts near Brazos River; lower shales are exposed in scarp north of U.S. Highway 80, east of river; middle part exposed in roadcut southeast of Bennett. Upper part composes scarp west of Bennett; type section includes these exposures and extends from top of Brannon Bridge limestone to top of easternmost Goen limestone on highland west of Bennett.

Grinnell Formation
Grinnell Argillite[1] } (in Ravalli Group)

Precambrian (Belt Series): Northwestern Montana, and southwestern Alberta and southeastern British Columbia, Canada.

Original reference: Bailey Willis, 1902, Geol. Soc. America Bull., v. 13, p. 316, 322.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1887–1888. Red or purplish argillites and white to light-green quartzites. Formation comprises three members (ascending): Rising Wolf, Red Gap, and Rising Bull. Thickness 1,500 to 3,500 feet. Overlies Appekunny formation; underlies Siyeh formation. Type locality restated.

C. P. Ross, 1950, U.S. Geol. Survey Bull. 974–E, p. 142, 144 (table), pl. 4. Argillite, in Ravalli group, underlies Wallace formation in Hamilton quadrangle, Montana.

C. P. Ross, 1959, U.S. Geol. Survey Prof. Paper 296, p. 19 (table), 27–33, pls. 1, 2. Grinnell argillite, in Flathead and Swan Ranges, crops out extensively with Appekunny argillite below and Siyeh limestone above, evidently in normal stratigraphic relations uncomplicated by deformation. Formation consists largely of pale- and grayish-blue-green, grayish-purple, and grayish-red-purple siliceous argillite, in part calcareous, and some quartzite. In Swan Range, lowest and thickest part of formation is dominantly pale- and grayish-red-purple argillite, nowhere well exposed. Above this is middle member in which proportion of red-purple beds decreases upwards, and much of rock is quarzitic argillite and argillaceous quartzite, with thin argillite partings, commonly rather dark-red-purple. Uppermost member commonly consists of grayish-blue-green calcareous argillite and argillaceous limestone, constituting transition zone below Siyeh limestone of Piegan group. Thickness 1,000 to 4,000 feet. Fenton and Fenton (1937) studied the Grinnell mainly in and north of northern part of Glacier National Park in localities not examined closely during present study. The members they proposed differ from those in Swan Range.

Type locality: Grinnell Point (Stark Point of some maps), at head of Swiftcurrent formerly McDermott Lake, Glacier National Park, Mont.

Griswold Conglomerate
Griswold Gap Conglomerate (in Pocono Formation)[1]
Griswolds Gap Conglomerate

Mississippian: Northeastern Pennsylvania.

Original reference: I. C. White, 1881, Pennsylvania 2d Geol. Survey Rept. G_5, p. 56, 57.

Bradford Willard, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 255, 279, 282. Griswold Gap conglomerate at base of Pocono. Above Mount Pleasant red shale.

Well exposed opposite Grisword's Gap, just east of Forest City, Susquehanna County.

Grizzly Formation

Precambrian: Southwestern South Dakota.

T. A. Dodge, 1942, Geol. Soc. America Bull., v. 53, no. 4, p. 563. Name appears on list of Precambrian rocks of area. Phyllite, about 3,000 feet thick. Overlies Flag Rock formation (new).

J. A. Noble and J. A. Harder, 1948, Geol. Soc. America Bull., v. 59, no. 9, p. 944 (fig. 1), 962. Consists almost wholly of fine-grained gray to dark-gray sericitic phyllite with no distinctive character and almost no bedding. Thickness about 3000 feet not allowing for possible duplication by undisclosed folding; probably thicker in vicinity of Deadwood. Top of formation not observed overlies Flag Rock formation.

Occurs at Homestake mine, in vicinity of Lead, Lawrence County.

Grizzly Formation[1]

Silurian(?) (may be Ordovician): Northern California.

Original reference: J. S. Diller, 1892, Geol. Soc. America Bull., v. 3, p. 370–394.

P. A. Lyndon, T. E. Gay, Jr., and C. W. Jennings, 1960, Geologic map of California Westwood sheet (1:250,000): California Div. Mines. Gray quartzite and slaty sandstone (pre-Permian). Mapped with Paleozoic marine sedimentary and metasedimentary rocks.

Named for exposures on east and northeast slopes of Grizzly Mountains, Plumas County.

Grizzly Creek Member (of Crack Canyon Formation)

Upper Jurassic[?] or Cretaceous[?]: Northern California.

J. E. Lawton, 1956, Dissert. Abs., v. 16, no. 10, p. 1885. Listed as upper member of formation. Overlies Blue Ridge member (new); underlies Leesville member of Little Valley formation (both new). Upper Jurassic and Cretaceous section, about 40,000 feet thick, consists of sequences of shale and silty shale which alternate with sequences of sandstone.

Occurs in Morgan-Wilbur area in Lake, Yolo, and Colusa Counties.

Grizzly Mountain Rhyolite[1]

Tertiary: Central Colorado.

Original reference: J. T. Stark and F. F. Barnes, 1935, Colorado Sci. Soc. Proc., v. 13, no. 8, p. 477, map.

Named for Grizzly Mountain Sawatch Range.

†Grizzly Peak Andesite[1]

Grizzly Peak Basalt

Pliocene: Western California.

Original reference: A. C. Lawson and C. Palache, 1902, California Univ. Pubs. Dept. Geol. Bull., v. 2, p. 379, map.

[O. P. Jenkins], 1949, *in* Mineral Inf. Service, v. 2, no. 2, p. 7, 14 (map). Described and mapped as Grizzly Peak basalt. Includes agglomerates, tuffs, and mud flows. Underlies Siesta formation; overlies Orinda formation.

D. E. Savage and O. E. Bowen, 1955, *in* Geol. Soc. America Cordilleran Sec. [Guidebook] Apr. 28–30, Trip 2, p. 2. Lower member of Moraga volcanic series is locally called Grizzly Peak basalt.

Forms Grizzly Peak, in Berkeley Hills, San Francisco region.

Grizzly Peak Rhyolite[1]

Tertiary: Central Colorado.

Original reference: J. V. Howell, 1919, Colorado Geol. Survey Bull. 17.

Occurs in Grizzly Peak, Chaffee County.

Groat Sandstone Bed (in Gammon Ferruginous Member of Pierre Shale)[1]

Upper Cretaceous: Southeastern Montana, western South Dakota, and northeastern Wyoming.

Original reference: W. W. Rubey, 1930, U.S. Geol. Survey Prof. Paper 165–A.

M. E. Wing, 1940, South Dakota Geol. Survey Rept. Inv. 35, p. 10, columnar section. Geographically extended into Belle Fourche district, South Dakota. Apparently not extensive in South Dakota.

Named for exposures along Groat Creek in T. 7 S., R. 56 E., Carter County, Mont.

Groesbeck Dolomite[1]

Permian: Central northern Texas and southwestern Oklahoma.

Original reference: F. W. Cragin, 1897, Am. Geologist, v. 19, p. 357.

Named for Groesbeck Creek, Hardeman County, Tex.

Groos Quarry Member (of Trenton Formation)

Middle Ordovician: Northern Michigan.

R. C. Hussey, 1952, Michigan Dept. Conserv., Geol. Survey Div. Pub. 46, Geol. Ser. 39, p. 13, 14, 33, 34. Middle member of formation. Underlies Haymeadow Creek member and overlies Chandler Falls member (both new). Forty feet of rock exposed in Groos quarry section; lower 6 feet consist of even-bedded dolomite that grades upward into irregularly bedded argillaceous limestone; parting lenses and thin layers of black shale present throughout section; disconformity about 12 feet above base.

Type locality: Abandoned Bichler quarry at Groos, sec. 1, 39 N., 3 W., Delta County, 5 miles north of Escanaba.

Gros Ventre Formation[1]

Gros Ventre Group

Gros Ventre Member (of Depass Formation)

Middle Cambrian: Northwestern Wyoming and central southern Montana.

Original reference: E. Blackwelder, 1918, Washington Acad. Sci. Jour., v. 8, p. 417.

B. M. Miller, 1936, Jour. Geology, v. 44, no. 2, p. 119–123, 129, 132, 134. Formation in northwestern Wyoming comprises lower shale division, Death Canyon member (new), and upper shale division. Thickness 675 feet. Overlies Flathead formation; underlies Gallatin formation.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1096–1098, 1101 (fig. 3), 1103. Rank reduced to member status in Depass formation (redefined). Overlies Flathead sandstone member. Underlies Maurice member of Boysen formation (new). Thickness 300 feet.

A. J. Bertagnolli, Jr., 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 9, p. 1732 (table 1), 1733. Restricted in La Barge region, Wyoming, to exclude Death Canyon limestone herein raised to formation rank. Thickness 450 to 800 feet. Consists of dark fissile shales with thin gray fossiliferous limestones. Underlies Gallatin formation.

A. B. Shaw and P. O. McGrew, 1954, Wyoming Geol. Assoc. Guidebook 9th Ann. Field Conf., chart 2. Rank raised to group in western Wyoming where it includes three mappable formations (ascending): Wolsey shale, Death Canyon limestone, and Park shale. Where Death Canyon limestone is missing, entire green shale sequence may be called Gros Ventre formation, but where these rocks are in a brown to red sand and siltstone facies, name Buck Spring formation (new) is applied. Overlies Flathead sandstone; underlies Gallatin group.

H. R. Wanless, R. L. Belknap, and Helen Foster, 1955, Geol. Soc. America Mem. 63, p. 11–13. Formation as used in this report includes Wolsey shale, Death Canyon limestone, and Park shale members. Overlies Flathead sandstone; underlies Boysen limestone.

First described in Gros Ventre Range, Wyo.

Groton Granite[1]

Devonian: Northeastern Vermont.

Original reference: E. J. Foyles and C. H. Richardson, 1929, Vermont State Geologist, 16th Rept., table opposite p. 288.

Quarried in southwestern part of Groton Township, Calendonia County.

Grouse Hill Dacite Flow, Lava

Pleistocene to Recent: Southwestern Oregon.

J. S. Diller and H. B. Patton, 1902, U.S. Geol. Survey Prof. Paper 3, p. 36, 111. Name given to dacite flow on Grouse Hill. About same relative age as Cloud Cap dacite flow (new). On inner slope, a layer of pumice beneath flow of Llao Rock overlaps Grouse Hill flow, showing that Grouse Hill flow is older than Llao Rock eruption. At south base of Grouse Hill, the dacite is regularly banded, and on hill next northeast of Llao Rock it is spherulitic. [See Sun Creek Dacite Flow.]

J. E. Allen, 1936, Jour. Geology, v. 44, no. 6, p. 737–739. Grouse Hill flow lies on fairly smooth surface which slopes northward about 250 feet to mile. Flow is almost 2 miles long, 1 mile wide, and averages 250 feet in thickness, rising to over 800 feet in center. This point of highest elevation probably indicates location of vent. Flow has suffered only minor amount of erosion.

Howel Williams, 1942, Carnegie Inst. Washington Pub. 540, p. 49–51, 137–138. Diller supposed that lava of Grouse Hill was older than Llao Rock flow because it seemed to have suffered more erosion and because it was partly overlain by same sheet of pumice that underlies dacite cliffs of Llao. First of these arguments is questionable, and second is invalid because pumice on top of Grouse Hill is part of same sheet that lies above Llao flow. There is no way of telling which of the two flows is the older. Probably they are about the same age. Dominant lava is pale-gray minutely vesicular and glassy dacite, richly charged with phenocrysts of plagioclase, pyroxene, and hornblende.

Grouse Hill is on north rim of Crater Lake.

Grove Limestone[1]

Lower Ordovician: Western Maryland

Original reference: G. W. Stose and A. I. Jonas, 1935, Washington Acad. Sci. Jour., v. 25, no. 12, p. 564–565.

A. J. Stose and G. W. Stose, 1946, Maryland Dept. Geology, Mines and Water Resources [Rept.] Carroll and Frederick Counties, p. 43, 47–52, 84. Thick-bedded high-calcium limestone with beds of massive dolomite in lower part and highly quartzose limestone at base. Thickness in quarry near LeGore, 590 feet. Overlies Frederick limestone; underlies New Oxford formation. Distribution noted.

Named from Grove Quarry and Grove Station, on Baltimore and Ohio Railroad, Frederick County. In middle of Frederick Valley, forms belt about 1 mile wide that extends from point south of Buckeystown northward to LeGore, where it is overlapped diagonally by Triassic sedimentary rocks; belt widens north of Fountain Rock, and at north end, west of Woodsboro, attains width of 2 miles; several narrower bands lie to west of main belt, and extend from south end of Chestnut Hill southwestward to U.S. Highway 40, west of Frederick.

Grove Creek Formation

Grove Creek Limestone (in Gallatin Group)

Grove Creek Member (of Boysen Formation and Snowy Range Formation)

Upper Cambrian: Southern Montana and northwestern Wyoming.

Erling Dorf and Christina Lochman, 1938, (abs.) Geol. Soc. America Proc. 1937, p. 276; 1940, Geol. Soc. America Bull., v. 51, no. 4, p. 543–545. Formation consists of glauconitic limestone rounded pebble conglomerates with patches of white crystalline limestone containing large star-shaped crinoid stem plates overlain by a series of intercalated yellow-green fissile shales, thin gray limestone, and thin-bedded buff to orange-red sandy dolomites. Average thickness 30 feet; at type locality 47 feet. Underlies Bighorn formation; overlies Snowy Range formation (new). Trempealeau equivalent. Term Gallatin formation not applicable in this area [southern Montana].

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1092–1093, 1101 (fig. 3), 1105. Rank reduced to member status in Boysen formation (new) in Wind River area, Wyoming. Uppermost member of formation; overlies Snowy Range member. Thickness 40 feet in type section of Boysen.

A. B. Shaw, 1954, Billings Geol. Soc. Guidebook 5th Ann. Field Conf., p. 32–34. Name Grove Creek limestone adopted here for capping limy unit in Gallatin group in both Pryor and Bighorn Mountains. Dorf and Lochman defined unit as Trempealeau equivalent, but name is used here in lithic sense, rather than time-rock, for these upper limestones regardless of their age, which is not exclusively Trempealeauan. There is a need for inclusive rock term for entire limy sequence (now called upper Gallatin limestone) above Dry Creek shale. Time-rock terms Grove Creek and Snowy Range of Dorf and Lochman are not legitimately usable where faunal evidence is lacking. Grove Creek of Pryor Mountains comprises 260 feet of predominantly green or gray-green massive flat-pebble conglomerate with thinner beds of fine-grained limestone; interbedded with limestones are green and gray-green arenacous and calcareous, apparently glauconitic shales. Thickness 160 feet in northern Bighorns, flat-pebble conglomerates predominating.

P. W. Richards, 1957, U.S. Geol. Survey Bull. 1021–L, p. 397, 400, 401. Formation described east and southeast of Livingston, Mont., where it is 50 feet thick and consists predominantly of conglomeratic limestone and shale with stringers of sandstone and siltstone. Overlies Snowy Range formation; underlies Bighorn dolomite.

W. G. Pierce, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 4, p. 611 (fig. 15), 612. In Heart Mountain thrust area, Wyoming, Grove Creek locally underlies Crandall conglomerate (new).

R. E. Grant, 1958, Dissert. Abs., v. 18, no. 6, p. 2107. Reallocated to member status in Snowy Range formation. Upper member of formation overlies Sage member; underlies Maywood formation. Thickness about 25 feet; member nowhere complete; upper part removed by erosion in some areas and by faulting in others. Report covers Horseshoe Hills and Bridger Mountains, Mont., and Yellowstone Park vicinity.

Type locality: South side of North Fork of Grove Creek, a tributary of Clark Fork of Yellowstone River, in Beartooth front, 5 miles southeast of Red Lodge, Carbon County, Mont. Section measured in N½NW¼ sec. 36, T. 8 S., R. 20 E.

†Groveland Formation[1]

Precambrian (upper Huronian): Northwestern Michigan.

Original reference: H. L. Smyth, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 3, p. 114–121, 137–139.

Well exposed in central part of sec. 31, T. 42 N., R. 29 W., in vicinity of abandoned Groveland mine, in Felch Mountain district.

Grover Gravel

Miocene(?): Eastern Missouri and western Illinois.

Leland Horberg, 1950, Illinois Acad. Sci. Trans., v. 43, p. 173. Incidental mention as Grover gravel of St. Louis region.

W. M. Rubey, 1952, U.S. Geol. Survey Prof. Paper 218, p. 12 (chart), 61–74. Name applied to thin layer of gravel that lies between highest Mississippian or Pennsylvanian formations and overlying Pleistocene deposits. Gravels formerly called "Lafayette." Throughout most of Hardin and Brussels quadrangles (this report), the Grover seems to be merely a thin veneer of pebbles, and in a number of places it is absent. In southern part of Brussels quadrangle, formation is commonly 2 to 5 feet and in a few places 10 feet thick. In parts of St. Louis County, Mo., thickness is slightly more than 30 feet.

Type locality: Uplands near Grover, St. Louis County, Mo. Occurs only on uplands where it caps the high narrow remnants of an old and once much more extensive upland surface.

Grundy Knob Limestone (in Lisman Formation)

Pennsylvanian: Northern Kentucky.

J. A. Culbertson, 1932, The paleontology and stratigraphy of the Pennsylvanian strata between Caseyville, Kentucky, and Vincennes, Indiana: Urbana, Ill., Univ. Illinois, Abs. Thesis, p. 8. Incidental mention; equivalent to New Haven limestone of Illinois.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 85. Marine limestone in Lisman formation. Locality noted. Formerly called Carthage limestone.

Exposed in Grundy Knob, Union County, Ky., 5 miles northeast of Shawneetown, Ill.

Guadalupan series

Late Carbonic: New Mexico.

C. R. Keyes, 1940, Pan-Am. Geologist, v. 74, nos. 2 and 3, p. 106, 136, 139. Guadalupan series, as shown on chart of geologic formations, spans interval between Mescaleran series below and Malagan (Pecosan) series above. Comprises Otero, Word, Capitan, and Chaves terranes.

Guadalupe Series

Guadalupe Group[1]

Lower and Upper Permian: Western Texas, southern Kansas, eastern New Mexico and Oklahoma.

Original reference: G. H. Girty, 1902, Am. Jour. Sci., 4th, v. 14, p. 363–368.

J. E. Adams and others, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 11, p. 1675–1676, 1678. Rank raised to series. Thickness 4,100 feet at type locality, south end of Gaudalupe Mountains; consists of 2,300 feet of sandstone overlain by 1,800 feet of (Capitan) limestone. Rests on Bone Spring limestone of Leonard age. Because of erosion, youngest beds of series missing from type section. Getty Oil Co.'s Dooley No. 7 in sec. 24, T. 20 S., R. 29 E., Eddy County, N. Mex., penetrated thickness of 5,250 feet. In Delaware basin, series represented by sandstone facies, Delaware Mountain sandstone, which is 3,000 to 3,500 feet thick at outcrop in Delaware Mountains and is there divided into three approximately equal formations. Series in and around Delaware basin subdivided into two paleontologic units. Lower unit, which includes lower and middle formation of Delaware Mountain sandstone, the equivalent Word formation, and certain limestones of the marginal belt, contains ammonoid *Waagenoceras* and is characterized by species of genus *Parafusulina* more advanced than primitive genus of same species found in underlying Leonard series. Upper unit, which includes upper formation of Delaware Mountain and equivalent Capitan limestone, characterized by fusulind genus *Polydiexodina*. Underlies Ochoa series (new). Includes Whitehorse group and equivalent beds in Texas, Oklahoma, and Kansas. Cimarron series of northern midcontinent region should be abandoned and its strata reclassified as belonging to Leonard series and Guadalupe series.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 575–608, 699–709. Series in Glass Mountains consists of Word formation below followed by a complex of deposits divided into Altuda formation, Capitan limestone, and Gilliam limestone. If this classification is correct, beds of upper Guadalupe age in eastern Glass Mountains are much more restricted than they were thought to be in 1931, when they were supposed to include Vidrio, Gilliam, and Tessey limestones. The Tessey has been shown to be younger (King, 1938), and it is suggested herein that the Vidrio is older. Rocks of Guadalupe series in Delaware basin constitute Delaware Mountain group, composed dominantly of sandstone and divided into (ascending) Brushy Canyon, Cherry Canyon, and Bell Canyon formations. Away from basin, the sandstones tend to disappear. Their lower part passes out by overlap, and higher part is replaced by thick reef masses, Goat Seep and Capitan limestones. In shelf area, the reef masses grade into a complex of limestone, sandstone, and evaporite that forms Carlsbad and Chalk Bluff formations.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 37. Rocks of Guadalupian series crop out in southern Kansas. They comprise unfossiliferous deposits that seem to have been laid down partly on land and partly in shallow basins occupied by strongly saline waters. Thickness of outcropping rocks of series about 290 feet. Subsurface thickness averages about 400 feet in southwestern part of state.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. As shown on correlation chart, Guadalupian stage is Middle Permian.

G. V. Cohee, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 9, p. 1578–1579. U.S. Geological Survey recognizes a two-fold subdivision of the Permian. Reference sequence for United States is designated as outcrops on northwestern Trans-Pecos Texas (Delaware Mountains, Guadalupe Mountains, and Sierra Diablo Mountains) where approximate faunal boundary is taken as that between Cherry Canyon and Bell Canyon formations which are encompassed by Guadalupe provincial series.

C. C. Branson, 1960, Oklahoma Geology Notes, v. 20, no. 9, p. 233 (table 1). In Oklahoma, series includes El Reno and Whitehorse groups.

Type locality: South end of Guadalupe Mountains. Named for Guadalupe Point, south end of Guadalupe Mountains, El Paso, Tex.

Guadalupe Mountain Quartz Diorite

[Jurassic]: Central California.

G. H. Curtis, J. F. Evernden, and J. Lipson, 1958, California Div. Mines Spec. Rept. 54, p. 6. Discussed in report dealing with potassium-argon age determinations. Age given as 142.9 million years.

Occurs in Guadalupe Mountain pluton which intrudes Mariposa formation and older rocks. Dated specimen collected from side of road through southern end of Guadalupe Mountains in Indian Gulch quadrangle, NE¼ sec. 24, T. 6 S., R. 17 E.

Guadalupian Series or Stage

See **Guadalupe Series.**

Guajataca Member (of Cibao Formation)

Oligocene: Puerto Rico.

A. D. Zapp, H. R. Bergquist, and C. R. Thomas, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 85. Introduced to designate sequence of gravels, sands, and shales with interfingering argillaceous limestone that occurs in upper part of Cibao marl. Gravel beds reach several meters in thickness and contain some cobbles up to 10 centimeters in diameter. Apparently reaches maximum thickness of 120 meters in area about 7 kilometers east of Moca; northwest and west of Moca, beyond point of disappearance of Lares limestone, apparently rests directly on San Sebastian sandstone; thins eastward from the Lago de Guajataca as clastic beds interfinger and intergrade with marls and limestones of the Cibao.

Named from exposures along escarpment east and west of the Lago de Guajataca in Quebradillas quadrangle.

Gualala Group

Gualala Series

Middle or Upper Cretaceous: Northwestern California.

Original references (Wallala beds): G. F. Becker, 1885, U.S. Geol. Survey Bull. 19, p. 7–17; (Wallala group): C. A. White, 1885, U.S. Geol. Survey Bull. 22, p. 8.

C. E. Weaver, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1959. Described as Gualala series. Consists predominantly of massive and stratified brownish-gray medium- to coarse-grained quartzose sandstones; conglomerate lenses common near base and middle of series; also thick layers of clay shale; interstratified shaly sandstones and sandy shales constitute 30 percent of stratigraphic section. Thickness approximately 20,000 feet. Beds lie in two major synclinal and two anticlinal folds whose axes trend diagonally to course of San Andreas fault.

C. E. Weaver, 1943, California Div. Mines Bull. 118, pt. 3, p. 628, 629, 630 (table), 631 (fig. 280). Stratigraphic table shows Gualala series as underlying Skooner Gulch basalt (new) and overlying Franciscan group (Franciscan absent west of San Andreas fault).

C. E. Weaver, 1944, Washington [State] Pubs. in Geology, v. 6, no. 1, p. 6–17. Referred to as Gualala group. Unconformably underlies Iversen basalt (new). Middle Cretaceous.

Occurs in Point Arena-Fort Ross region in Mendocino and Sonoma Counties. Named from town of Gualala at mouth of Gualala River, Mendocino County.

Guanajibo Formation

Miocene, upper, or Pliocene, lower (?): Puerto Rico (subsurface).

C. L. McGuinness, 1948, Ground-water resources of Puerto Rico: [San Juan?] Puerto Rico Aqueduct and Sewer Service, p. 226–227. Comprises series of light-yellow to gray limestones, sandy or earthy and ranging from soft to fairly hard and sands, silts, and clays. Deepest well to end in these sediments is well Mg36, 256 feet deep.

P. H. Mattson, 1960, Geol. Soc. America Bull., v. 71, no. 3, p. 347–348. Guanajibo formation was described in subsurface, but there are valid surface exposures on north side of Lajas Valley, about one-fourth mile east of western intersection of Routes 4 and 306.

Penetrated by wells at Mayagüez. Name derived from Guanajibo Channel.

Guayabal Group

Eocene, middle: Puerto Rico.

E. A. Pessagno, Jr., 1960, Caribbean Geol. Conf., 2d, Mayagüez, Puerto Rico, 1959, Trans., p. 83. Includes Naranjo and Augustinillo formations (both new). Intruded by Anon andesite-diorite (new). Footnote states group is currently called Jacaguas.

Occurs in Ponce-Coamo area, south-central part of island.

Guayabal Limestone[1]

Upper Cretaceous: Puerto Rico.

Original reference: G. J. Mitchell, 1922, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 1, pt. 3, p. 256.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 36 (table 2), 47, 48 (table 4). In Ponce district, underlies Ensenada shale; overlies Coamo tuff limestone. Thickness 400 feet. Heading on table 2 (stratigraphic table for Puerto Rico) reads Upper(?) Cretaceous, but text and other table headings do not qualify Upper Cretaceous.

Type locality: Vicinity of Guayabal Reservoir north of Juana Díaz, where rock makes conspicuous white hills to east and west, Ponce district.

Guayama Limestone

Guayama Series[1]

Upper Cretaceous: Puerto Rico.

Original reference: E. T. Hodge, 1920, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 1, pt. 2, p. 142.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 36 (table 2), 47, 48 (table 4), 51, 60 (table 7). Thickness of Guayama series 2,600 feet. Overlies Sierra de Cayey series. Term series taken from original surveys but is misnomer. Limestone lenses occurring mostly in upper part of Guayama series are here referred to as "Guayama limestone." Heading on table 2 (stratigraphic table for Puerto Rico) reads Upper(?) Cretaceous, but text and other table headings do not qualify Upper Cretaceous.

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm., and Princeton Univ. Dept. Geology, p. 24, 44. Toa Vaca formation (new) includes Río Jueyes and Guayama series of Hodge (1920). Ildefonso formation (new) also includes part of Hodge's Guayama series.

Named for city of Guayama located upon series in southeastern corner of Coama-Guayama district.

Guaynabo Formation[1]

Upper Cretaceous(?): Puerto Rico.

Original reference: H. A. Meyerhoff and I. F. Smith, 1931, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 2, pt. 3, p. 275.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 36 (table 2), 46, 60 (table 7). Thickness 850 feet. Underlies La Muda limestone; overlies Hato Puerco tuffs. Upper Cretaceous.

C. A. Kaye, 1959, U.S. Geol. Survey Prof. Paper 317–A, p. 7 (table), 9 (fig. 3), 10 (fig. 4), 12–13, pl. 2. Redefined as study indicates: (1) in several places, sediments sharply terminated by volcanic rocks—Tortugas andesite (new), (2) in several places La Muda limestone, as herein defined, rests either on this volcanic sequence or is separated from it by varied thickness of noncarbonate rocks—Frailes formation (new), and (3) beds cropping out in vicinity of Guaynabo do not include sedimentary rocks having stratigraphic position given by Meyerhoff and Smith. As thus redefined, includes only the section of noncarbonate sediments overlying Hato Puerco tuff and underlying Tortugas andesite, or, where latter horizon is missing, the Frailes formation. Consists of several thousand feet of stratified tuffaceous sandstone or graywacke, conglomerate or shale. May attain thickness of 4,500 feet in Barrio Cupey, although lower contact is an inferred fault. No identifiable fossils found. Since formation in places seems to be conformable with younger Frailes, which contains late Upper Cretaceous fauna, it is designated Late Cretaceous(?). Report discusses San Juan metropolitan area.

Named for occurrence near Guaynabo, Fajardo district. Town lies near southwestern edge of broad formational outcrop, which extends beyond limits of district to Bayamon, where sediments lose their identity in residual soils.

Guayo Conglomeratic Sandstone Member (of Naranjo Formation)

Eocene, middle: Puerto Rico.

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm. and Princeton Univ. Dept. Geology, p. 85–94; 1960, Caribbean Geol. Conf., 2d, Mayagüez, Puerto Rico, 1959, Trans., p. 84. Thickness 0 to 9,280 feet. Occurs in beds 2 to 20 feet thick. Contains boulders and pebbles of most Eocene rocks as well as many Cretaceous. Interfingers with Coamo Springs limestone and Río Descalabrado members of Naranjo and with Collores member of Augustinillo formation (new).

Type locality: In bed of Río Guayo, opposite kilometer post K2H1 on road to Collares, northeastern Ponce quadrangle.

Gubik Formation

Gubik Sand[1]

Pleistocene: Northern Alaska.

Original reference: F. C. Schrader, 1902, Geol. Soc. America Bull., v. 13, p. 233–252.

George Gryc, W. W. Patton, Jr., and T. G. Payne, 1951, Washington Acad. Sci. Jour., v. 41, no. 5, p. 160 (table 1), 167, fig. 2. Formation as redefined ranges in thickness from few feet to 150 feet, but in most exposures is 10 to 30 feet. Largely marine predominantly of loosely consolidated cross-bedded brown or buff gravel, sand, silt, and clay. Mantles much of Arctic Coastal Plain of northern Alaska. Unconformably overlies Sagavanirktok formation (new) [in some areas] and Colville group in other areas. Type locality designated.

F. S. MacNeil, 1957, U.S. Geol. Survey Prof. Paper 294–C, p. 100. Striking difference in fauna from different localities may suggest that Gubik is not one unit but consists of several thin units of slightly different age.

Type locality: Bluffs along west bank of Colville River from mouth of Anaktuvuk River to Ocean Point. Name is from Eskimo name of Colville River. Eskimo name for the lower river is Kupik or "big river." Gubik, now the accepted spelling, is misspelling of Kupik.

Guernsey Formation[1]

Devonian and Mississippian: Southeastern Wyoming.

Original reference: W. S. T. Smith and N. H. Darton, 1903, U.S. Geol. Survey Geol. Atlas, Folio 91.

J. D. Love, L. G. Henbest, and N. M. Denson, 1953, U.S. Geol. Survey Oil and Gas Inv. Chart OC–44. In Hartville area, formation divisible into two units, upper consists of limestone and dolomite of Mississippian age and lower consists of dolomite and sandstone of Devonian age. Thickness as much as 300 feet. Underlies Hartville; overlies Precambrian.

Mapped around town of Guernsey, Platte County.

Gueydan Ash Member (of Catahoula Formation)

†Gueydan Formation[1]

Oligocene or Miocene, lower: Southern Texas.

Original reference: T. L. Bailey, 1924, Science, new ser., v. 59, p. 299–300.

G. R. Pinkley, 1958, South Texas Geol. Soc. [Guidebook] Fall Field Trip, p. 35. Referred to as Gueydan ash basal member of Catahoula in discussion of Fashing field area, Atascosa County. Overlaps entire Frio to southwest and to north has covered Upper Jackson lying on beds of Manning (Hockley shales) around Falls City.

Named for exposures on Gueydan Ranch and survey, southeastern McMullen County.

Gueydan Group[1]

Oligocene and Miocene (?): Southern Texas.

Original reference: F. B. Plummer, 1933, Texas Univ. Bull. 3232, p. 530, 700–727.

Guffey Volcanics

Oligocene: Central Colorado.

J. E. Bever, 1954, Dissert. Abs., v. 14, no. 7, p. 1088. Oligocene extrusive rocks here named Guffey volcanics with upper section correlated with Thirty-nine Mile andesite series, and lower section here designated Chumway rhyolite. They covered most of area with flows and tuffs thousands of feet thick.

Guffey area [Park County].

Guilarte Limestone[1]

Upper Cretaceous: Puerto Rico.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 47, 48 (table 4). Distinctive blue-black limestone.

Occurs near Monte Guilarte, Ponce district.

Guilford Granite

Post-Glenarm: Central Maryland.

Ernst Cloos and C. H. Broedel, 1940, Geologic map of Howard County and adjacent parts of Montgomery and Baltimore Counties (1:62,500): Maryland Geol. Survey. Biotite-muscovite granite, structureless, closely associated with pegmatite. Named on map legend with units older than Glenarm series. Age of Glenarm series uncertain.

R. W. Chapman, 1942, Geol. Soc. America Bull., v. 53, no. 9, p. 1301, 1320–1321, pl. 1. Bounds Laurel granite on north.

Type locality and derivation of name not stated.

Guilford Slate[1]

Silurian (?): Southeastern Vermont.

Original reference: C. H. Hitchcock, 1912, Vermont State Geologist 8th Ann. Rept., p. 127.

Guilmette Formation[1]

Middle and Upper Devonian : Western Utah.

Original reference: T. B. Nolan, 1930, Washington Acad. Sci. Jour., v. 20, no. 17, p. 421–432.

C. W. Merriam, 1940, Geol. Soc. America Spec. Paper 25, p. 68–69. In Gold Hill region, varies in thickness from 1,400 feet to 890 feet within distance of 3 miles and is overlain either by Madison limestone of Lower Mississippian age or by Woodman formation of Upper Mississippian age. Overlies Simonson dolomite.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1763, chart 4. Shown on correlation chart as Middle and Upper Devonian.

G. S. Campbell, 1951, Utah Geol. Soc. Guidebook 6, p. 21 (fig. 4), 22. In Confusion and House Ranges, underlies Pilot shale and overlies Sevy(?) dolomite. Thickness 1,200 feet.

G. W. Crosby, 1959, Brigham Young Univ. Research Studies, Geology Ser., v. 6, no. 3, p. 19–20, 52, pl. 11. In south Pavant Range, conformably underlies Cove Fort quartzite (new); conformably overlies Simonson dolomite. Thickness 570 feet. Middle Devonian.

Named for exposures in Guilmette Gulch, Gold Hill region.

Guinda Formation

Upper Cretaceous (Chico Series) : Northern California.

J. M. Kirby, 1942, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 26, no. 5, p. 899. Listed as underlying Forbes formation and overlying Funks formation (new).

J. M. Kirby, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 3, p. 282, 283–284, 291, 293. Described as consisting primarily of massive- to well-bedded, fine- to medium-grained, gray- to buff-weathering concretionary sandstone. Thickness varies from 30 feet to 2,975 feet. Typical exposures noted.

Typically exposed in headwaters of Petroleum and Salt Creeks in central and northern parts of T. 12 N., R. 3 W., Yolo County and along faulted western slope of Rumsey Hills, between town of Rumsey on north and Tancred Siding (abandoned) on south.

†Gulf Group[1]

Tertiary : Gulf Coastal Plain.

Original reference : O. Meyer, 1888, Am. Geologist, v. 2, p. 88–89, 93–94.

Comprises states from Alabama to Texas.

Gulf Series[1]

Upper Cretaceous : Gulf Coast region.

Original reference : R. T. Hill, 1887, Am. Jour. Sci., 3d ser., v. 33, p. 298.

R. W. Imlay, 1944, Geol. Soc. America Bull., v. 55, no. 8, chart 10a. In terms of European equivalents, Gulf series includes upper Cenomanian, Turonian, Santonian, Campanian, and Maestrichtian stages. Overlies Comanche series which includes lower part of Cenomanian stage. Rock units included in standard section (ascending) : Woodbine, Eagle Ford, Austin, Taylor, and Navarro.

Named for extensive development along Coastal Plain of Gulf of Mexico.

Gulf Hammock Limestone

Eocene (Claiborne or Jackson) : Florida.

D. B. Ericson, 1945, Science, v. 102, no. 2644, p. 234. Proposed for surface exposures of limestone that correlates with subsurface Avon Park. Name Avon Park should be dropped.

R. O. Vernon, 1951, Florida Geol. Survey Bull. 33, p. 104. Gulf Hammock formation, as defined by Ericson, includes Inglis member (new) of Moodys Branch formation and upper part of Avon Park limestone as used in this report. Since Avon Park limestone is very thin in parts of outcrop area and since regional unconformity separates it from Moodys Branch formation, Ericson's correlation of Gulf Hammock formation with Avon Park is inexact, and use of term Gulf Hammock should be abandoned.

Named for exposures at Gulf Hammock, Levy County.

Gullette Bluff Beds (in Nanafalia Formation)

†Gullette Bluff Beds (in Wilcox Group)[1]

Eocene, lower : Southwestern Alabama.

Original reference: J. E. Brantly, 1920, Alabama Geol. Survey Bull. 22, p. 148–150.

L. D. Toulmin, Jr., 1940, Alabama Geol. Survey Bull. 46, p. 28. Nanafalia formation, as restricted by Cooke (1933, Am. Assoc. Petroleum Geologists Bull., v. 17, no. 2) is equivalent to Gullette Bluff beds of Brantly.

Lyman Toulmin, Jr., 1944, Alabama Acad. Sci. Jour. v. 16, p. 42. Listed as uppermost unit in Nanafalia formation. Overlies "Nanafalia Landing (*Ostrea thirsae*) marl".

P. E. LaMoreaux and L. D. Toulmin, 1959, Alabama Geol. Survey County Rept. 4, p. 96 (fig. 32), 97. Middle and upper divisions of Nanafalia of Smith and Johnson (1887) are equivalent to the "Gullette Bluff beds" of Brantly (1920), and in present report comprise middle and Grampian Hills members of Nanafalia.

Named for exposures at Gullette Bluff, Wilcox County.

Gum Sulphur Siltstone Member (of New Providence Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 77, 117–119. Brittle shelly roughly bedded siltstone up to 40 or more feet thick. Occurs in central part of Dicks River facies (new) of formation. Underlain by an argillaceous basal shale, up to 45 feet thick and overlain by clayey shale as much as 75 feet thick.

Named for village of Gum Sulphur, northwestern Rockcastle County, three-fourths mile east of Lincoln County line. Well exposed along valley sides across Dicks River to the north.

Gunflint Iron-Formation[1] (in Animikie Group)

Precambrian : Northeastern Minnesota.

Original reference: C. R. Van Hise and J. M. Clements, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 3, p. 401–409, map.

D. A. White, 1954, Minnesota Geol. Survey Bull. 38, p. 3 (table 1), 4. In Gunflint district, the three units of Animikie group corresponding to

Pokegama, Biwabik, and Virginia formations of Mesabi district are called, respectively, Kakabeka, Gunflint, and Rove formations.

Well developed on north shore of Gunflint Lake.

Gunn Member (of Mount Simon Formation)

Upper Cambrian: Northern Illinois (subsurface).

J. S. Templeton, Jr., 1950, Illinois Acad. Sci. Trans., v. 43, p. 153 (fig. 2), 154 (fig. 3), 155. Name applied to the relatively fine-grained unit overlying Lacey member (new). Type section extends from depths of 1,648 to 1,880 feet. Thickness 71 to 260 feet. Underlies Charter member (new).

Type well: McQueen No. 1 (well 6), in SW¼NE¼NE¼ sec. 27, T. 42 N., R. 3 E., Dekalb County. Name derived from Gunn School, 2¾ miles northwest of type well.

Gunners Cove Formation

Oligocene or Miocene: Alaska.

R. Q. Lewis, W. H. Nelson, and H. A. Powers, 1960, U.S. Geol. Survey Bull. 1028–Q, p. 560–561, pl. 70. Includes, in approximate order of decreasing abundance, tuffaceous conglomerate and sandstone, crystalvitric basaltic tuff, and thin flows of basaltic lava. Beds dip from 5° to 35° in diverse directions; structural details not determined; hence, no estimate of total thickness made. Inferred to be younger than Rat formation (new), but contact not exposed; trace of contact trends north-south across high crest of island and is probably high-angle normal fault. On basis of fauna, believed to be Oligocene or Miocene.

Makes up about two-thirds of Rat Island, which is on midpart of segment of Aleutian Ridge that includes Amchitka and southern Kiska Islands. Formation exposed from sea level to an altitude of about 1,050 feet. Named for Gunners Cove, a small embayment on north side of island.

†Gunnison Formation[1]

Upper Jurassic: Central western Colorado.

Original reference: G. H. Eldridge, 1894, U.S. Geol. Survey Geol. Atlas, Folio 9.

Named for exposures in canyon of Gunnison River, Delta and Mesa Counties.

Gunnison or Gunnisonian series

Upper Jurassic: Arizona, Colorado, New Mexico, and Utah.

C. R. Keyes, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 314; 1940, Pan-Am. Geologist, v. 74, no. 2, p. 106 (chart); no. 3, p. 252 (chart). Series in Upper Jurassic. Unconformable above Zunian series and below Morrisonian series. Includes McElmo shales.

Gunnison Tillite

Gunnison Volcanic Conglomerate

Miocene: West-central Colorado.

W. W. Atwood and W. R. Atwood, 1925, (abs.) Geol. Soc. America Bull., v. 36, no. 1, p. 168. Pre-Pleistocene tillite that probably correlates with Ridgway tillite.

W. W. Atwood and W. R. Atwood, 1926, Jour. Geology, v. 34, no. 7, pt. 1, p. 612–622. Light-buff-brown to light-gray tillite overlain by volcanic tuff. Probably mid-Eocene. Type locality stated.

F. B. Van Houten, 1957, Geol. Soc. America Bull., v. 68, no. 3, p. 383–385, 387 (table 1). Referred to as Gunnison volcanic conglomerate. Believed to be volcanic-rich mudflow and stream deposit that seemingly is basal part of Miocene San Juan tuff.

Type locality: Along State highway, 3 miles east of Gunnison, Gunnison County.

Gunnison River Series[1]

Precambrian: Colorado.

Original reference: T. S. Lovering and others, 1935, Geologic map of Colorado.

Series includes the following named units: Irving Greenstone, Dubois Greenstone, River Portal Mica Schist, Black Canyon Schist, and Swandyke Hornblende Gneiss.

Named for exposures in Black Canyon of Gunnison River.

Gunn Peak Formation[1]

Carboniferous(?): Central Washington.

Original reference: C. E. Weaver, 1912, Washington Geol. Survey Bull. 7, p. 34–50.

C. E. Weaver, 1937, Washington [State] Univ. Pub. in Geology, v. 4, p. 19. Intruded by Index granodiorite.

Named for Gunn Peak region, Snohomish County.

Gunpowder Granite[1]

Post-Glenarm: Northeastern Maryland.

Original reference: E. B. Knopf and A. I. Jonas, 1929, Maryland Geol. Survey Baltimore County, Rept., p. 104, 125.

U.S. Geological Survey currently considers the Glenarm Series to be Lower Paleozoic(?).

Named for outcrops along Gunpowder Falls, Baltimore County.

†Gunsight Formation (in Cisco Group)[1]

Pennsylvanian: Central northern Texas.

Original reference: F. B. Plummer, 1919, Am. Assoc. Petroleum Geologists Bull., v. 3, p. 133–145.

Named for Gunsight, Stephens County.

Gunsight Limestone Member (of Graham Formation)[1]

Gunsight Limestone (in Graham Group)

Upper Pennsylvanian: Central and central northern Texas.

Original reference: F. B. Plummer, 1919, Am. Assoc. Petroleum Geologists Bull., v. 3, p. 133–145.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Rank raised to formation in Graham group. Underlies Wayland shale; overlies units referred to as post-Bunger cycles 1 to 7. Cisco series.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 70, pl. 27. Member of Graham formation. Overlies Bluff Creek shale member; underlies Wayland shale member. Generally fine-grained and pale-brownish-yellow to gray fossiliferous limestone. Thickness about 17 feet along Colorado River to as much as 25 feet in north-central Brown County.

Member was called *Campophyllum* bed by Drake (1893, Texas Geol. Survey 4th Ann. Rept., pt. 1) ; Hudnall and Pirtle (1931, Geologic map of Brown County: Texas Univ. Bur. Econ. Geology) divided Gunsight limestone of Plummer into Upper Gunsight and Lower Gunsight limestones.

Named for Gunsight, Stephens County.

Gunstock Gneiss[1]

Age (?) : Eastern New Hampshire.

Original reference: L. V. Pirsson and H. S. Washington, 1906, Am. Jour. Sci., 4th, v. 22, p. 505.

Winnipesaukee quadrangle, Lake Winnipesaukee region. Probably named for Gunstock River.

Gunter Sandstone Member (of Van Buren Formation)[1]

Gunter Formation (in Prairie du Chien Group)

Gunter Member (of Gasconade Formation)

Lower Ordovician: Central and southern Missouri and northern Illinois.

Original reference: S. H. Ball and A. F. Smith, 1903, Missouri Bur. Geology and Mines, v. 1, 2d ser., p. 26.

R. D. Knight, 1954, Kansas Geol. Soc. Guidebook 17th Ann. Field Conf., p. 57–59. [Reprinted as Missouri Geol. Survey and Water Resources Rept. Inv. 17.] Member of Gasconade formation. Unconformably overlies Eminence formation; conformable with overlying nonsandy dolomites of Gasconade. Consists of sandstone and sandy dolomite. Average thickness 25 to 30 feet; maximum 50 feet in localized area. Missouri Geological Survey no longer uses Van Buren as formational name because unit is only locally distinctive. In parts of Kansas and Oklahoma, recognized in subsurface as member of Arbuckle group.

H. B. Willman and J. S. Templeton, 1951, Illinois Acad. Sci., v. 44, p. 111 (fig. 2), 116–117. Geographically extended into Illinois. Formation consists principally of argillaceous, silty, finely glauconitic greenish-gray to cream chalky dolomite which contains fine muscovite flakes and is slightly sandy in lower 2¾ feet. Thickness about 10¼ feet. Overlies Trempealeau; underlies Oneota. Lower Ordovician. Exposures confined to quarry near Rochelle, Lee County, and to prospect pit and ravine in Ogle County.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., fig. 3. Shown on chart as formation in Prairie du Chien group.

Type section: At Hahatonka [Gunter or Hahatonka Springs], Camden County, Mo. Named from now abandoned Gunter post office in Miller County.

Gunther dolomite (in Chuaran series)

Precambrian: Northern Arizona.

Charles Keyes, 1938, Pan-Am. Geologist, v. 70, no. 2, p. 107 (chart), 112. Mainly of massive dolomite; downward the section seems to merge into a calciferous sandstone. Constitutes prominent cliff-forming ledge. Thickness 150 feet. Underlies Jupiter shales (new) ; overlies Chiquito sandstone (new).

Name comes from Gunther Castle, opposite mouth of Little Colorado River. The "Castle" is mainly fashioned from this rock. Grand Canyon region.

Gurnee Formation (in Pottsville Formation)[1]

Pennsylvanian: Central northern Pennsylvania.

Original reference: G. H. Ashley and S. H. Cathcart, 1932, Pennsylvania Topog. and Geol. Survey Bull. 102A, p. 6.

Type locality: Vicinity of Gurnee, Tioga County.

Guthrie Dolomite[1] (in Double Mountain Group)

Guthrie Dolomite Member (of Dog Creek Formation)

Permian (Guadalupe Series): Central northern Texas.

Original reference: M. G. Cheney, 1929, Texas Univ. Bull. 2913, p. 26, pl. 1.

R. L. Clifton, 1942, Jour. Paleontology, v. 16, no. 6, p. 686 (table 1). In this report, classed as member of Dog Creek formation.

T. S. Jones, 1953, Stratigraphy of the Permian basin of West Texas: West Texas Geol. Soc., p. 30 (fig. 9). Shown on correlation chart as member of Dog Creek formation; occurs below Wagon Yard gypsum member and above Mangum dolomite member. Permian (Guadalupe).

Underlies town of Guthrie, King County. Crops out along South Wichita River east of town.

Guthrie Creek Member (of Harrodsburg Limestone)[1]

Guthrie Creek Member (of Warsaw Formation)

Lower Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1929, Indiana Acad. Sci. Proc., v. 38, p. 233–242.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 805. Reallocated to member status in Warsaw formation. Overlies Leesville member (reallocated); underlies massive regularly bedded limestone of upper part of formation.

Named for exposures along Guthrie Creek, in southeastern part of Lawrence County.

Guttenberg Limestone Member[1] (of Decorah Formation)

Guttenberg Limestone (in Galena Group)

Guttenberg Submember (of Decorah Shale Member of Galena Formation)

Middle Ordovician: Northeastern Iowa, northwestern Illinois, southeastern Minnesota, and southwestern Wisconsin.

Original reference: G. M. Kay, 1928, Science, new ser., v. 67, p. 16.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 9 (geol. column), 81, 83, 84, 86. Considered submember of Decorah shale member of Galena formation in Minnesota. Lies at base of restricted Decorah shale member and begins with pebbly corrosion zone at top of *Stictoporella* bed. Largely shale in St. Paul area where it is about 43 feet thick; to south limestone layers increase in importance; chiefly limestone at type locality. Underlies Ion submember.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., p. 6, fig. 3. Considered formation in Galena group in Dixon-Oregon area, Illinois. Thickness about 5 feet. Includes Garnavillo member below and Glenhaven (Garnet) member above (both new). Underlies Dunleith formation (new); unconformable above Quimbys Mill formation of Platteville group; Spechts Ferry formation absent in this area.

M. P. Weiss, 1955, Jour. Paleontology, v. 29, no. 5, p. 763. Members of Decorah formation (Spechts Ferry, Guttenberg, and Ion) not recognizable rock units in Minnesota.

A. F. Agnew and others, 1956, U.S. Geol. Survey Prof. Paper 274–K, p. 289–293; A. V. Heyl, Jr., 1959, U.S. Geol. Survey Prof. Paper 309, p. 16. Member commonly 12 to 14 feet thick; less than 2 feet near Rockford, Ill.; about 6½ feet near Blanchardville, Wis. Limestone, brown, fine-grained, thin-bedded, nodular conchoidal; dark-brown shale; some sections dolomitic; bentonite layer in shale seam near base at Spechts Ferry, Iowa, and northeast of Galena, Ill., also noted in drill holes in Grant County, Wis. Underlies Ion member and, in some areas, is poorly distinguished or indistinguishable from it; overlies Spechts Ferry member. Where Spechts Ferry member is absent, Guttenberg lies with slight regional disconformity on Quimbys Mill member of Platteville.

M. P. Weiss, 1957, Geol. Soc. America Bull., v. 68, no. 8, p. 1034. In this report [Fillmore County, Minn.], the unit of green calcareous shale between limestone and Platteville formation and limestone of Galena formation is called Decorah. Therefore Decorah formation of this report includes shaly upper part of Spechts Ferry, the Guttenberg, and, in places, the Ion of Stauffer and Thiel (1941).

Type section: In bluff of Mississippi River just northwest of Guttenberg, Clayton County, Iowa.

Guyandot Sandstones (in Sewell Formation)[1]

Guyandot Sandstones (in New River Group)

Pennsylvanian (Pottsville Series): Southern West Virginia.

Original reference: M. R. Campbell, 1902, U.S. Geol. Survey Geol. Atlas, Folio 77.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey Greenbrier County, p. 216, 227, 229. In Greenbrier County, Guyandot sandstone (Campbell, 1902) is massive, grayish white, and coarse grained; somewhat lenticular, its interval being occupied locally by sandy shale. Thickness 30 to 50 feet. Underlies Castle coal; overlies Skelt shale; locally apparently coalesces with stratigraphically higher Harvey sandstone. Lower Guyandot sandstone (Hennen and Gawthrop, 1915) is massive coarse grained and grayish white in northern part of county; in Meadow Bluff district, its position in column is, in whole or in part, occupied by sandy shale. Thickness 10 to 30 feet. Underlies Sewell "A" coal; overlies Hartridge shale. Both sandstones are included in New River group.

Named from exposures along Guyandot River from Pineville, Wyoming County to Gilbert, Mingo County.

Guye Formation[1]

Eocene: Central Washington.

Original reference: G. O. Smith and F. C. Calkins, 1906, U.S. Geol. Survey Geol. Atlas, Folio 139.

W. C. Warren, 1941, Jour. Geology, v. 49, no. 8, p. 810–811. Paleobotanical evidence indicates Eocene age.

R. J. Foster, 1960, Geol. Soc. America Bull., v. 71, no. 2, p. 101 (table 1), 111-113, pl. 1. Name was applied by Smith and Calkins to heterogeneous group of sedimentary and volcanic rocks whose structure was not clearly known. As a result, rocks of several ages were included in the formation. This composite unit erroneously dated Miocene from small collection of fossil leaves, although Smith and Calkins and most later workers realized that the rock types and structure resembled lower Tertiary rocks more closely than Miocene. Because the Guye was one of the few dated units in region, its age was used to date more widespread formations. Guye formation of Smith and Calkins here separated into four formations: Denny (new), Guye (restricted), Mount Catherine rhyolite (new), and Naches. Exposure south from Snoqualmie Pass is bounded on three sides by Mount Catherine rhyolite which dips away from the Guye on all sides and apparently unconformably overlies it. Structure interpreted as anticline in the rhyolite with homoclinal Guye exposed in core. On Denny Mountains, underlies Keechelus andesite, apparently unconformably. Locally intruded by Snoqualmie granodiorite. Formation is thick sequence of shale, sandstone, and conglomerate; fluviatile origin shown by lenses of conglomerate that are interbedded with sandstone and leaf-bearing shale. Conglomerate, sandstone, and shale are mixed in all proportions; beds or lenses range from thin to massive. Conglomerate, percentagewise is the least important rock type but is the most distinctive. Thickness about 5,000 feet. Paleobotanic evidence and stratigraphic relationships suggest an Eocene or Paleocene age. Type area designated.

Type area: Coal Creek and its tributaries, on east side of Snoqualmie Pass. Area almost parallels strike; hence, stratigraphic exposure is limited. Named from exposures on Guye Creek.

Guymard Quartzite

Lower to Middle Silurian: Eastern New York.

C. F. Kilfoyle, 1954, New York State Mus. Bull. 348, p. 499, 500, 591, 650. Incidental mention in faunal list.

Occurs at Otisville, Orange County.

Guzmán Formation[1]

Upper Cretaceous: Puerto Rico.

Original reference: H. A. Myerhoff, 1931, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 2, pt. 3, p. 267.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 36 (table 2), 41, 60 (table 7). Thickness about 750 feet. Underlies Hato Puerco tuffs. Heading on table 2 (stratigraphic table for Puerto Rico) reads Upper (?) Cretaceous, but text and other table headings do not qualify the Upper Cretaceous.

Named from occurrence in western part of Barrio Guzmán Abajo, where they crop out along Río Canovanas about 9 miles south of village of Canovanas.

Gwinn Series[1]

Precambrian (middle Huronian): Northwestern Michigan.

Original reference: R. C. Allen, 1914, Jour. Geology, v. 22, p. 567, 569.

Named for occurrence at and around Gwinn, Marquette County.

†Gwynedd Shale (in Newark Group)[1]

Upper Triassic: Southeastern Pennsylvania.

Original references: B. S. Lyman, 1893, Pennsylvania Geol. Survey geol. and topog. map of Bucks and Montgomery Counties; 1895, Pennsylvania 2d Geol. Survey Summ. Final Rept., v. 3, pt. 2, p. 2589–2638.

Exposed at Gwynedd Tunnel, Bucks and Montgomery Counties.

†Gym Limestone[1]

Permian: Southwestern New Mexico.

Original reference: N. H. Darton, 1916, U.S. Geol. Survey Bull. 618, p. 19, 35.

V. C. Kelley and L. E. Bogart, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 8, p. 1644–1648. Stratigraphic studies in Florida Mountains Luna County, have revealed that type locality of Gym limestone consists mostly of Fusselman dolomite of Silurian age. Preliminary examination of other principal localities [see this report for discussion] of supposed Gym limestone shows either similar misidentification or considerable dissimilarity. Until all localities of Gym can be restudied, it appears best to restrict term Gym to the small outcrops in southeastern part of Florida Mountains. Gym as originally described is in Luna County.

U.S. Geological Survey has abandoned the term Gym Limestone.

Type locality: Gym Peak and vicinity, Deming region, Luna County.

Gypsum Spring Formation

Gypsum Spring Member (of Twin Creek Limestone)

Gypsum Spring Formation (in Chugwater Group)

Gypsum Spring Member (of Chugwater Formation)

Middle Jurassic: Wyoming, Montana, and South Dakota.

J. D. Love, 1939, Geol. Soc. America Spec. Paper 20, p. 42–43, 45, 46. Uppermost member of Chugwater. Overlies Popo Agie member; underlies Sundance formation. Consists of sequence of limestone, shale, and gypsum. Thickness 181½ feet where exposed on Red Creek.

E. B. Branson and C. C. Branson, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 124 (table 1), 126 (fig. 2), 136. Rank raised to formation in Chugwater group. Uppermost formation of group; overlies Wyopo formation (new) and where Wyopo is absent rests on Popo Agie formation. Thickness 20 to 200 feet. Triassic.

J. D. Love and others, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 14. Classed as formation; all or parts of unit have been included in Chugwater by some geologists and in Sundance by others; it has been defined both as a formation and as a member of Chugwater. Consists of basal red blocky slightly sandy siltstone overlain by 50 to 125 feet of massive white gypsum on surface and white anhydrite in subsurface. Overlying the gypsum bed is alternating sequence of thin beds of gypsum, red shale, gray ribbon dolomites, and fine slabby limestone. Maximum thickness about 250 feet (northwestern part of Wind River Basin). Unconformable above Nugget sandstone; underlies unit referred to as lower Sundance. Contains marine Middle Jurassic fossils.

R. W. Imlay, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 2, p. 231 (table 1), 236–247, strat. sections. Term Gypsum Spring formation extended to include gypsiferous beds in northern Wyoming and Montana. In Black Hills area, rather thin beds directly below the Sundance are herein called Gypsum Spring formation because they occupy same stratigraphic position of formation in north-central Wyoming and southernmost Montana, directly beneath beds containing *Arcticoceras henryi* (Meek and Hayden), and because they show considerable lithologic resemblance to typical Gypsum Spring formation. If this correlation is correct, formation extends across Powder River Basin in subsurface, a distance slightly more than 100 miles. In Black Hills area, South Dakota and Wyoming, Gypsum Spring represents first widespread invasion and withdrawal of marine waters during Jurassic in Western Interior region; formation is Middle Jurassic in age and correlative with Gypsum Spring and Sawtooth formations farther west. Represents upper Bajocian and Bathonian stages and is separated from adjoining formations by disconformities. Beds herein included in Gypsum Spring comprise two laterally intergrading facies: one consists of gypsum commonly interbedded with soft maroon siltstone and shale, locally attains thickness of 45 feet, and extends roughly on the western side of Black Hills from Elk Mountain to Sundance and on the northeast side from about 10 miles south of Sturgis to vicinity of Spearfish; second facies consists of interbedded gray shale, limestone, and dolomite, occurs in northwestern end of Black Hills, attains at least 21 feet in thickness, and is well exposed on road from Hulett to Alva. Underlies Stockade Beaver shale member (new) of Sundance formation; underlies Canyon Springs sandstone member (new) of Sundance formation at type section of Canyon Springs. Overlies unit referred to as Nugget(?); locally overlies Spearfish formation.

R. W. Imlay and others, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 32. Basal part of Piper formation (new) locally includes equivalents of type Gypsum Spring of central Wyoming as defined by Love.

R. W. Imlay, 1952, Geol. Soc. America Bull., v. 63, no. 9, p. 967–968, chart 8C (columns 44, 45, 46, 50, 51, 53). Formation represents basal deposits of transgressive sea; may not be same age throughout its extent, and may represent much more time at one locality than at another. Imlay considers that rocks assigned to Gypsum Spring formation by U.S. Geological Survey parties in Big Horn Basin of Wyoming are identical with Piper formation of eastern Montana and that they include more than type Gypsum Spring as defined by Love (1939; 1945). This observation has been disputed for sections along west side of Big Horn Mountains. Piper formation was first identified by Imlay (1947) as Gypsum Spring, but later work demonstrated that Gypsum Spring of type area in central Wyoming represents only basal Middle Jurassic and correlates with lower member of Gypsum Spring, as employed by U.S. Geological Survey parties in Montana and in parts of Big Horn basin of Wyoming. This usage in Montana arose because it was practical in mapping and because Gypsum Spring was assumed to include all beds of Middle Jurassic older than type Sundance formation. Because beds equivalent to type Gypsum Spring in Montana are not mappable, name Piper is employed in that state for beds hitherto called Gypsum Spring.

T. P. Storey, 1958, Alberta Soc. Petroleum Geologists Jour., v. 6, no. 4, p. 90–104. Upper and Middle Jurassic of Williston Basin region comprises nine stratigraphic units or regional correlation intervals and two regional unconformities. On basis of faunal, environmental, and tectonic evidence, these units are grouped into four major depositional sequences or stagelike intervals which Imlay refers to as Gypsum Spring (or Piper), Sawtooth, Rierdon, and Swift formations. Miscorrelation of type section of these formations are result of variations in stratigraphic succession caused by sub-Swift and sub-Rierdon unconformities which correspond respectively to Arkell's (1956, Jurassic geology of the World: New York, Hafner Publishing Co.). Lower Callovian and uppermost Callovian to Lower Oxfordian marine transgressions. Recognition of regional extent and significance of these unconformities suggests that these are the following stratigraphic variations from those generally accepted: (1) the lower Swift (Stockade Beaver-Hulett of lower Sundance) is older than type Swift and younger than type Rierdon formations; and (2) Sawtooth is discrete stratigraphic unit which is younger than Piper or Gypsum Spring.

R. E. Skinner, 1960, Wyoming Geol. Assoc. Guidebook 15th Ann. Field Conf., p. 129–130. Stratigraphically extended below to include Kendall sandstone member (new).

U.S. Geological Survey currently classifies the Gypsum Spring as a member of Twin Creek Limestone in Lincoln County, Wyo., on the basis of a study now in progress.

Named for the gypsum spring on Red Creek, Fremont County, Wyo.

Gypsy Quartzite

Cambrian: Northeastern Washington.

C. F. Park, Jr., 1938, Econ. Geology., v. 33, no. 7, p. 713 (chart), 714. Named on stratigraphic chart and map. Thickness 5,300 to 8,500 feet. Underlies Maitlen phyllite (new); overlies Monk formation.

C. F. Park, Jr., and R. S. Cannon, Jr., 1943, U.S. Geol. Survey Prof. Paper 202, p. 6 (table), 13–15, pl. 1. Consists of alternating beds of quartzite and phyllite in nearly equal parts. Grades downward into Monk formation and upward into Maitlen phyllite; limits of quartzite placed where quartzite and grit beds predominate over beds of other types. Derivation of name given.

C. D. Campbell, 1947, Geol. Soc. America Bull., v. 58, no. 7, p. 602 (table 4), 608–609, 611, pl. 1. Remapping of northeastern Stevens County and discovery of Cambrian and Ordovician fossils are thought to justify adoption there of formation names established by Park and Cannon (1943) for Metaline quadrangle. New names replace those given by Weaver (1920). Correlative with Gypsy quartzite is a small part of Boundary argillite.

Named for exposures in high amphitheaters of Gypsy Ridge, Pend Oreille County.

Hackberry Shale[1]

Upper Devonian: Northeastern Iowa.

Original reference: C. L. Webster, 1889, Am. Nat., v. 23, p. 242, 243.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1737 (fig. 1), chart 4. Figure 1 A (attributed to Stainbrook) shows undifferentiated Hackberry below the Sheffield and above Shell Rock; figure 1 B (attributed to Cooper and Warthin) shows Hackberry including Juniper Hill, Cerro Gordo, and Owen; probable true position of Independence between Juniper Hill and Cerro Gordo.

M. A. Stainbrook, 1945, Am. Jour. Sci., v. 243, no. 2, p. 67. Hackberry formation of Webster and authors includes Cerro Gordo and Owen members of Lime Creek but not Juniper Hill shale. Column of Iowa Devonian ascribed by Cooper and others to present writer [Stainbrook] has Hackberry intercalated between Shellrock and Sheffield. Hackberry as an Iowa formational term is not recognized by Iowa Geological Survey and has never been used as equivalent to Lime Creek by present writer. Lime Creek, including Juniper Hill, Cerro Gordo, and Owen, is used in Iowa for interval between Sheffield and Shellrock.

Named for exposures at Hackberry Grove, Cerro Gordo County.

Hackberry Shale (in Cimarron Group)[1]

Permian: Central southern Kansas and northwestern Oklahoma.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 3, 46.

Named for Hackberry Creek, Clark County, Kans.

Hackett Sandstone (in Hinton Formation)[1]

Mississippian: Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 297, 353.

Type locality: On ridge road between Hackett and Island Creeks, 1.6 miles northeast of Pettry, Mercer County.

Hackett Shale (in Hinton Formation)[1]

Mississippian: Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 297, 354.

Type locality: On ridge road between Hackett and Island Creeks, 1.6 miles northeast of Pettry, Mercer County.

Haddam Granite Gneiss[1]

Haddam Tonalite

Paleozoic(?): South-central Connecticut.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 115, 143, 145, map.

W. G. Foye, 1949, Connecticut Geol. Nat. History Survey Bull. 74, p. 51, 52, 54, pl. 1. Referred to as orthogneiss and mapped as Monson orthogneiss.

E. N. Cameron and others, 1954, U.S. Geol. Survey Prof. Paper 255, p. 20, 21. Age unknown; possibly the same as Monson gneiss, here designated Devonian.

H. M. Mikami and R. E. Digman, 1957, Connecticut Geol. Nat. History Survey Bull. 86, p. 25–33, 51, pls. 1, 2. Haddam tonalite constitutes Killingworth dome which covers large part of Guilford quadrangle. Present study has shown that entire dome can be mapped as one tonalite mass with peripheral zone of mixed rocks. Entire formation is herein designated Haddam tonalite. Term Haddam preferred to Monson. No petrographic study of rocks between Haddam, Conn., and Monson, Mass., (type locality of Monson) has been made. Foye (1949) correlated Haddam, Eastford, and Glastonbury gneisses of Connecticut with Monson of Massachusetts, but verification awaits detailed study of very difficult region. Mamacoke gneiss shown by Gregory and Robinson (1907, Connecticut Geol. Nat. History Bull. 7) near Guilford village has been eliminated from present map as has Madison hornblende gneiss of Foye (1949). Former is a mixed facies zone of granite and Haddam tonalite, and latter a facies of the Haddam with a hornblende content above average. Haddam is in contact with Middletown gneiss throughout most of the area. Concordant relationship with Clinton granitic gneiss.

Typically exposed about Higganum, Haddam Township, on both sides of Connecticut River.

Hades quartzite[1]

Upper Devonian: Utah.

Original reference: C. R. Keyes, 1924, Pan.-Am. Geologist, v. 41, p. 37, 47–53, 281, 287, 290.

Well exposed in towering cliffs on the hot, gloomy, and inhospitable canyon on east side of Duchesne River.

Hagan Shale Member (of Clinch Sandstone)

Lower Silurian: Southwestern Virginia and northeastern Tennessee.

R. L. Miller and J. O. Fuller, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 76 (2 sheets); 1954, Virginia Geol. Survey Bull. 71, p. 141–143, 188; R. L. Miller and W. P. Brosgé, 1954, U.S. Geol. Survey Bull. 90, p. 76, 122, pl. 1. Consists of green shale, with interbeds of fine-grained sandstone and siliceous sandstone; massive sandstone 1 to 2 feet thick at base. Thickness 70 to 77 feet. Underlies Poor Valley Ridge member (new); overlies Sequatchie formation.

L. D. Harris and R. L. Miller, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–111. Lower Silurian.

Named for exposures along Louisville and Nashville Railroad cut in gap through Poor Ridge Valley near Hagan, Lee County, Va.

Hager Formation (in Plattin Group)

Middle Ordovician: Southeastern Missouri.

E. R. Larson, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 9, p. 2053–2058. Named as third of four formations in group. Generally fine-textured calcite rocks; shows three principal facies and their mutual gradations, major part of formation is slabby light-olive-gray calcite with buff-weathering partings; calcarenite and calcilutite constitute lesser part of formation; calcitite facies, principally developed in southern thicker sections, grades downward into calcarenite; calcilutite facies overlies the calcitite in type area but grades laterally into calcarenite in Ste. Genevieve County exposures. Thickness at type locality 66 feet; thickens southward and thins northward. Underlies Macy formation (new); overlies Beckett formation (new).

Type section: Near Hager School, in NW¼NW¼ sec. 29, T. 35 N., R. 12 E., Perry County.

†Hagerman Lake Beds[1]

Pliocene, upper: Southern Idaho.

Original references: H. T. Stearns, 1932, Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932; 1936, Jour. Geology, v. 44, no. 4, p. 434–439.

H. T. Stearns, Lynn Crandall, and W. G. Steward, 1938, U.S. Geol. Survey Water-Supply Paper 774, p. 31, 52–56, pl. 4. Thickness about 600 feet. Overlie Banbury volcanics. Upper Pliocene.

C. P. Ross and J. D. Forrester, 1958, Idaho Bur. Mines and Geology Bull. 15, p. 17. Term Hagerman lake beds is essentially synonymous with

Idaho formation for area in which it has been applied but has the advantage that it is tied to upper Pliocene fossils whose stratigraphic relations are known definitely. These show that Hagerman lake beds appear to be continuous with Idaho formation of areas farther west, but detailed relationships remain to be determined.

Type locality: Hagerman Valley, Gooding and Twin Falls Counties, where it forms prominent bluffs along Snake River.

Haggard Limestone (in Cumberland Sandstone)

Upper Ordovician: South-central Kentucky.

W. R. Jillson, 1953, The Haggard limestone: Frankfort, Ky., Roberts Printing Co., p. 9–12. Name applied to fossiliferous group of gray semicompact and crystalline limestones and shaly limestone beds at top of Cumberland sandstone. Thickness 35 feet. Stratigraphically above Burkesville limestone lentil; underlies Chattanooga shale.

Exposed on farm of B. P. Cary near headwaters of Haggard Branch, a south-flowing tributary of Cumberland River, near Burkesville, Cumberland County.

Hagman Formation

Hagman Andesite

Eocene, upper: Mariana Islands (Saipan).

Risaburo Tayama, 1938, Geomorphology, geology, and coral reefs of Saipan Island: Tropical Industry Inst., Palau, South Sea Islands, Bull. 1 [English translation in library of U.S. Geol. Survey, p. 50–51]. Hagman andesite consists of two-pyroxene andesite lava, agglomerate, and tuff. Lower part is mainly lava and agglomerate; upper part mainly agglomerate and tuff, which is locally arenaceous and shows crossbedding. Relationship to Sankakuyama liparite not clear because no contact observed, but Hagman is believed to be younger.

P. E. Cloud, Jr., R. G. Schmidt, and H. W. Burke, 1956, U.S. Geol. Survey Prof. Paper 280–A, p. 46–51, pl. 2, chart 2. Formation includes andesitic pyroclastic rocks, lava flows, and water-laid volcanic sediments, some of which contain late Eocene fossils. Its three principal facies comprise occurrences of andesite flow rock 30 feet or more thick, breccias and tuffs, and conglomerate and tuffaceous sandstone. Differs from Sankakuyama formation below in being dominantly andesitic, and from Densinyama formation mainly above in generally lacking quartz and quartz-bearing rocks. Thickness as much as 1,100 feet.

S. Hanzawa *in* Jacques Avias and others, 1956, Lexique, Strat. Internat., v. 6, Océanie, fasc. 2, p. 37. Age of Hagman andesite given as lower Oligocene-Eocene.

Type section: Exposures at Point Hagman (Puntan Hagman).

Hague Gneiss[1]

Precambrian (Grenville): Northern New York.

Original reference: H. L. Alling, 1918, New York State Mus. Bull. 199.

E. N. Cameron and P. L. Weis, 1960, U.S. Geol. Survey Bull. 1082–E, p. 289 (fig. 28), 290. Mentioned in report on strategic graphite. Occurs above Trumbull gneiss and below Dixon schist.

Type locality: Lakeside mine, at Hague, Warren County.

Haigler Formation

Precambrian: East-central Arizona.

Gordon Gastil, 1958, Geol. Soc. America Bull., v. 69, no. 12, pt. 1, p. 1498 (table 1), 1504–1506, pl. 1. Much of the rock is rhyolite, but formation believed to include thick sections of basic extrusive rock and volcanic sedimentary rock. Lower member mapped as five submembers (sequence not stated): gray to black albite porphyry rhyolite; black or brown rhyolite with vitreous luster; tuff breccia of coarse, irregular volcanic or accidental ejecta in matrix of tuff; and two separate conglomerates composed of rock types that underlie them—rocks subrounded and well sorted. Stratigraphic continuity of members overlying lower member not established, and therefore type section not described for them. Lower member tentatively believed to be overlain in succession by at least 1,450 feet of rhyolite, 1,000 feet of basic and intermediate volcanic and sedimentary rocks, at least 1,100 feet of rhyolite, largely tuff, and 1,600 feet of sedimentary and pyroclastic rocks. Underlies Oxbow Mountain rhyolite (new); overlies Board Cabin formation (new).

Type section of lower member begins at upper contact of Board Cabin formation just east of Board Cabin Draw in hillside southwest of abandoned "Hot Shot" mine and extends northeast to east fork of Board Cabin Draw, Diamond Butte quadrangle. Name derived from Haigler Creek, in northeastern part of quadrangle.

Haiku Volcanics[1] (in Honolulu Volcanic Series)

Pleistocene, upper: Oahu Island, Hawaii.

Original reference: H. T. Stearns, 1935, Hawaii Div. Hydrography Bull. 1.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 84–85. Lava flows of nepheline basalt containing pegmatoid veinlets and segregations, and associated cinder and palagonite tuff, containing fragments of Koolau lavas. Pyroclastic rocks more than 30 feet thick in places, and lava flow more than 20 feet. Unconformably overlies Koolau volcanic series and underlies noncalcareous nonmarine and marine sediments. Probably erupted during plus 95-foot (Kaena) stand of sea. Pleistocene.

Named for Haiku Stream along which it is exposed.

Hailey Conglomerate Member (of Wood River Formation)

Pennsylvanian (Morrowan through Derryan): Central and eastern Idaho.

M. R. Thomasson, 1959, Dissert. Abs., v. 20, no. 3, p. 999. Comprises gradation upward from immature graywackes to supermature orthoquartzites. Thickness, 1,900 feet. Late Morrowan where it interfingers with limestones east of Muldoon trough; in the west, upper boundary is Desmoinesian. Older than Slate Creek member (new); overlies Muldoon formation (new).

H. J. Bissell, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 8, p. 1427 (fig. 3). Correlation chart shows the Hailey at base of Wood River formation in Bellevue area. Underlies unnamed lower sandy limestones of formation; unconformable above Milligen formation.

Deposited in Muldoon trough, aligned N. 30° W., Bellevue area.

Hailey Shale[1]

Upper Cretaceous: Central Wyoming.

Original reference: S. W. Williston, 1905, Science, new ser., v. 22, p. 504.

Probably named for town of Hailey, eastern Fremont County.

Haines Granite[1]

Post-Triassic and pre-Tertiary: Northeastern Oregon.

Original reference: U. S. Grant and G. H. Cady, 1914, Oregon Bur. Min. and Geol. Min. Resources Oregon, v. 1, no. 6, p. 133–144.

Named for town in Baker district.

Hakatai Shale (in Unkar Group)[1]

Precambrian (Grand Canyon Series): Northern Arizona.

Original reference: L. F. Noble, 1914, U.S. Geol. Survey Bull. 549.

J. H. Maxson, 1949, (Abs.) Geol. Soc. America Bull., v. 60, no. 12, pt. 2, p. 1963. Thickness 600 feet in Bright Angel quadrangle. Includes diabase sills. Overlies Bass limestone; underlies Shinumo quartzite.

Named for Hakatai Canyon, where typically exposed, Grand Canyon region.

Halcyon Lake Formation

Lower Ordovician: Southeastern New York.

E. B. Knopf, 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1212; 1956, (abs.) Geol. Soc. America Bull., v. 67, no. 12, pt. 2, p. 1817. Consists of sandstones, dolomites, and calc-dolomites; estimated thickness 350 feet. Conformably underlies Rochdale limestone; younger than Briarcliff dolomite (new).

Described in area of Stissing Mountain, Dutchess County.

Haldeman Siltstone Member (of Brodhead Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 76, 180, 184, pl. 16. Included in Morehead facies of Brodhead formation (new). Thickness 32 to 70 feet. Underlies Indian Fort shale (new), Irvine facies, and Perry Branch siltstone (new), Morehead facies; overlies Frenchburg siltstone (new). Persistent for many miles away from type locality.

Type area: Vicinity of Haldeman, 7½ miles northeast of Morehead, Rowan County.

Hale Formation[1]

Hale Sandstone Member (of Morrow Formation)[1]

Lower Pennsylvanian (Morrow Series): Northern Arkansas, southern Missouri, and northeastern Oklahoma.

Original reference: G. I. Adams and E. O. Ulrich, 1905, U.S. Geol. Survey. Geol. Atlas, Folio 119.

E. B. Branson, 1944, Missouri Univ. Studies, v. 19, no. 3, p. 295. Geographically extended into Barry County, Mo., where it is composed of yellowish-brown massive crossbedded sandstone. Unconformably overlies Fayetteville and, in some places, the Keokuk and Reeds Spring.

L. G. Henbest, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 8, p. 1936–1938. In type area, formation is divided into two members: Cane Hill below and Prairie Grove above.

G. G. Huffman and others, 1958, Oklahoma Geol. Survey Bull. 77, p. 75–80. Described in northeastern Oklahoma on the flanks of the Ozark uplift where it ranges in thickness from zero in portions of Mayes and Craig Counties to 136 feet on Ross Mountain. Rests with pronounced unconformity upon Pitkin and older strata; grades upward into Bloyd formation; contact is typically placed at base of first prominent shale above the massive Hale limestone. It is basal part of Morrow series of the midcontinent section.

Named for Hale Mountain, Washington County, Ark.

Hales Limestone[1]

Cambrian: Central Nevada.

Original reference: H. G. Ferguson, 1933, Nevada Univ. Bull., v. 27, no. 3, p. 15.

Named for Hales shaft of Tybo mine, northern Nye County.

Half Dome Quartz Monzonite[1] (in Tuolumne Intrusive Series)

Cretaceous: East-central California.

Original reference: F. C. Calkins, 1930, U.S. Geol. Survey Prof. Paper 160, p. 126, map.

J. F. Evernden, G. H. Curtis, and J. Lipson, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 9, p. 2121, 2122, 2123 (fig. 1). Discussed in paper dealing with potassium-argon dating of igneous rocks. Age given as 84.1 millions of years. Younger than Sentinel granodiorite and older than Cathedral Peak granite.

Named for fact that it composes Half Dome in Yosemite National Park.

Halfway horizon (in Duchesne River Formation)[1]

Eocene (Duchesnean): Eastern Utah.

Original reference: J. L. Kay, 1934, Carnegie Mus. Annals, v. 23, p. 357–359.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 21, pl. 1. Overlies Randlett horizon; underlies Lapoint horizon. Eocene (Duchesnean).

Well exposed along Halfway Hollow, basin which drains that district in Tps. 4 and 5 S., Rs. 19 and 20 E. Salt Lake meridian, Uintah County.

Halgaito Tongue or Member (of Cutler Formation)[1]

Halgaito Formation (in Cutler Group)

Permian: Northeastern Arizona and southeastern Utah.

Original reference: A. A. Baker and J. B. Reeside, Jr., 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, no. 11, p. 1420, 1423, 1424, 1441, 1443, 1446.

S. A. Wengerd and M. L. Matheny, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 9, p. 2054, cross secs. Chart of new terminology shows Halgaito formation in Cutler group; underlies Cedar Mesa formation; overlies Rico transition facies. Pennsylvanian and Permian.

Well exposed near Halgaito Spring, southwest of Mexican Hat (Bluff post office), Utah, but between Lees Ferry and Kayenta, Ariz.

Halifax Chlorite Schist[1]

Upper Cambrian(?) : Southeastern Vermont.

Original reference: George D. Hubbard, 1924, Vermont State Geologist 14th Rept., p. 288–291, map.

Probably named for development in Halifax Township, Windham County.

Hall cyclothem (in McLeansboro Group)

Hall cyclothem (in Modesto-Bond Formation)

Pennsylvanian: Northern Illinois.

C. L. Cooper, 1946, Illinois Geol. Survey Bull. 70, p. 12, 16 (fig. 2). Pennsylvanian succession between the Gimlet and La Salle cyclothems, exposed in upper Illinois valley, contains several prominent but thin limestones which are basis for recognition of incomplete cyclothems to which the names (ascending) Turner, Hicks, and Hall have been applied by H. B. Willman.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 12, pl. 1. Includes Hall limestone. Type locality given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 52 (table 2), pl. 1. In Modesto-Bond formations (both new). Above Hicks cyclothem. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification independent of rock-stratigraphic classification.

Type locality: NW¼SW¼ sec. 33, T. 16 N., R. 11 E., Bureau County.

Hall Limestone Member (of Bond Formation)

Hall Limestone (in McLeansboro Formation)

Hall Limestone (in McLeansboro Group)

Pennsylvanian: Northern Illinois.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (col. 29). Shown on correlation chart as limestone in McLeansboro formation. Occurs below La Salle limestone and above Hicks limestone (new).

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 12, pl. 1. Shown on correlation chart as limestone in McLeansboro group. Included in Hall cyclothem. Type locality given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 39, 50 (table 1). Reallocated to member status in Bond formation (new). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: NW¼SW¼ sec. 33, T. 16 N., R. 11 E., Bureau County.

Hall Canyon Formation[1]

Pleistocene, lower: Southwestern California.

Original reference: J. E. Eaton, 1928, Am. Assoc. Petroleum Geologists Bull., v. 12, no. 2, p. 111–151.

J. E. Eaton, 1943, California Div. Mines Bull. 118, pt. 2, p. 204, 205 (fig. 86) [preprint 1941]. Shown as unconformably overlying Barlow Ranch [beds].

T. L. Bailey, 1943, Geol. Soc. America Bull., v. 54, no. 10, p. 1557. Name abandoned in Hall Canyon, the type section of the Pleistocene of Ventura Basin.

Best exposed in Hall Canyon, Ventura Basin.

Hall Canyon Member (of Oquirrh Formation)

Pennsylvanian (Morrowan) : Utah.

H. J. Bissell, 1959, Utah Geol. Soc. Guidebook 14, p. 94–100, pls. 1, 2. Consists essentially of 915 feet of bioclastic and crystalline limestones which are black, dark gray, and medium brown gray; a massive, in part cherty, crystalline, and bioclastic limestone bed that is commonly 40 to 50 feet thick comprises uppermost unit of member. Conformably underlies Meadow Canyon member (new) ; overlies Manning Canyon shale; contact commonly transitional.

Type locality: Eastern ½ sec. 19, T. 5 S., R. 3 W., Tooele County. Named for outcrops in Hall Canyon.

Hall City Limestone[1]

Carboniferous: Northern California.

Original reference: J. S. Diller, 1903, Am. Jour. Sci., 4th, v. 15, p. 342–362.

Hall City mines, Klamath Mountains.

Hallett Formation or Shale (in Wabaunsee Group)

Pennsylvanian (Virgil Series) : Northeastern Oklahoma.

C. C. Branson, 1956, Oklahoma Geology Notes, v. 16, no. 11, p. 122–125. Name given to predominantly shale sequence from top of Bird Creek limestone to base of Wakarusa limestone. Thickness about 105 feet. Name credited to P. B. Greig (unpub. thesis).

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 50–53, pl. 1. Thickness 105 to 110 feet. Overlies Bird Creek limestone; underlies Wakarusa limestone. Equivalent section in Kansas contains nine subdivisions, none of which can be identified in Pawnee County. In Wabaunsee group.

Type section: Exposed south of village of Hallett, Pawnee County.

Hallian Stage

Pleistocene: Southern California.

Manley Natland, 1953, Pacific Petroleum Geologist, v. 7, no. 2, p. 2. Uppermost of four stages, based on foraminiferal assemblages, in Pliocene and Pleistocene of southern California. Occurs above Wheelerian stage; division between the two is within the upper Pico or "Mud Pit shale". Upper Hallian is marine part of series of coarse sediments sometimes referred to as the Saugus in the Ventura area. [Saugus is considered Pliocene and Pleistocene.] Chart shows Hallian as wholly Pleistocene.

Hall Lake Member (of McRae Formation)

Upper Cretaceous and Tertiary (?) : Southwestern New Mexico.

H. P. Bushnell, 1955, Compass, v. 33, no. 1, p. 11 (table), 14–16. Mainly purple, maroon, and chocolate-brown shales among which are interspersed purple, maroon, olive, buff, or gray sandstone and a few purple conglomerate beds. Occasional nodular limestone beds distributed through section. Shale units generally thick and make up as much as 80 percent of section at type locality. A few conglomerate beds scattered throughout member. Total thickness measured at type locality is 1,660 feet where an additional estimated 1,200 feet of section are covered by water of the lake. Conformably overlies Jose Creek member (new).

Type locality: On east shore of Hall Lake, northeast of Elephant Butte and south of McRae Canyon, Sierra County. Named from Hall Lake, which is formal name of lake backed up by Elephant Butte Dam. Crops out widely in McRae Canyon area and in Jornada del Muerto.

Halloran Complex

Precambrian: Southern California.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 499–500. Includes, in order of age, metasediments, variable altered and granitized diorite, and variably altered granite.

Named for exposures in the area of about 40 square miles of small mountains extending from vicinity of Halloran Spring westward to north of Silver Lake village, San Bernardino County. Best and most typical exposures occur in vicinity of Silver Lake; complex might better be named for that locality, but name is preoccupied.

Halloran Spring Complex

See Halloran Complex.

Hallowell Member (of Cobourg Formation)

Middle Ordovician (Mohawkian): Southern Ontario, Canada, and northern New York.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 278–280, pl. 4. Lower Cobourg limestone of earlier reports. Lower part lithologically similar to underlying Sherman Falls formation. Upper part composed of gray medium- to coarse-textured massive limestone with very few intercalated shales; contrasts with more argillaceous Hillier member (new) above. Thickness about 100 feet.

Type section: At Picton, Hallowell Township, Prince Edward County, Ontario.

Halls Diorite Porphyry

Miocene, middle or upper: Northwestern Oregon.

T. P. Thayer, 1939, Oregon Dept. Geology and Mineral Industries Bull. 15, p. 10. Varies from fine-grained purple-gray porphyry at the contact to a medium-grained almost white porphyry containing hornblende and plagioclase phenocrysts. Intrudes Sardine lavas.

Exposed in a roughly rectangular area of about 1 square mile in North Santiam River gorge; southeastern contact is approximately 1,000 feet east of Halls siding, Marion County.

Hall Summit Formation

Paleocene (Midway): Northwestern Louisiana and northeastern Texas.

Grover Murray, Jr., 1941, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 25, no. 5, p. 941–942. Youngest of three named divisions of Midway sediments that crop out in northwestern Louisiana and outline the highest structural portion of Sabine uplift. Consists of basal sand member, middle lignitic shale member, and upper calcareous member. Overlies Logansport formation (new).

D. P. Meagher and L. C. Aycock, 1942, Louisiana Dept. Conserv. Geol. Pamph. 3, p. 13. Includes (ascending) Loggy Bayou, Grand Bayou, and Bistineau members (all new).

G. E. Murray, Jr., and E. P. Thomas, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 1, p. 48 (fig. 2), 58–60; G. E. Murray, 1948, Louisiana Dept. Conserv. Geol. Bull. 25, p. 127–129, pl. 10. Maximum thickness more than 300 feet in northern Sabine Parish; thins to north and west to an estimated 150 feet in Shelby County, Tex. Underlies Marthaville formation; overlies Logansport formation; both contacts gradational. Paleocene. Type locality designated.

Type locality: Exposures in vicinity of village of Hall Summit in T. 14 N., R. 9 W., Red River Parish, La.

Hamakua Volcanic Series

Tertiary, upper(?) and Quaternary: Hawaii Island, Hawaii.

G. A. Macdonald, 1945, Am. Jour. Sci., v. 243, pt. 1, no. 4, p. 211–217. Chiefly olivine basalts with a few intercalated thin ash beds. Greatest exposed thickness 650 feet. Unconformably underlies Laupahoehoe volcanic series (new).

H. T. Stearns and G. A. Macdonald, 1946, Hawaii Div. Hydrography Bull. 9, p. 152–157, 195. Separated into two members: Lower consists largely of olivine with abundant primitive picrite-basalt; upper largely olivine basalt but associated with it are andesites and picrite-basalts of augite-rich type. Underlies Pahala ash. Type section described in detail.

D. A. Davis and G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 85. Late Tertiary(?) and Quaternary.

Type section: Southern wall of Laupahoehoe Gulch. Named for exposures along Hamakua coast, northwest of Hilo, where it is well exposed in sea cliffs and in walls of large gulches.

†Hambergian series[1] or Hamburgian[1]

Upper Cambrian: Nevada.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 51, 53, 79.

Hambre Sandstone (in Monterey Group)[1]

Miocene, middle: Western California.

Original reference: A. C. Lawson, 1914, U.S. Geol. Survey Geol. Atlas, Folio 193.

C. A. Hall, Jr., 1958, California Univ. Pub. Geol. Sci., v. 34, no. 1, p. 20, fig. 2, geol. map. Thickness about 500 feet in Pleasanton area. Conformably overlies Tice shale; conformably underlies Briones formation with contact gradational in most places. In Concord quadrangle, separated from Briones by Rodeo shale. In Pleasanton area, lower member of Briones is generally interbedded with brown silty shale layers ranging from 10 to 20 feet in thickness. It is possible that, from Concord quadrangle, the Rodeo grades laterally into interbedded sandstone and shale of Hambre and Briones in Pleasanton area. Upper Miocene. Term Monterey group not considered appropriate in this area.

Named for exposures along Arroyo del Hambre, Concord quadrangle, Contra Costa County.

†Hamburg Beds[1] or Clays[1]

Upper Cretaceous: Western South Carolina.

Original reference: E. Sloan, 1904, South Carolina Geol. Survey, ser. 4, Bull. 1, p. 68, 72–75.

Named for exposures at Hamburg, Aiken County.

Hamburg Limestone[1] or **Dolomite**

Middle and Upper Cambrian: Eastern Nevada.

Original reference: Arnold Hague, 1883, U.S. Geol. Survey 3d Ann. Rept., p. 253, 255–259.

H. E. Wheeler and D. M. Lemmon, 1939, Nevada Univ. Bull., Geol. and Mining Ser., no. 31, p. 25–26, 30, fig. 3. Referred to as Hamburg dolomite. Composed of light-gray coarsely crystalline limestone, dolomitic limestone, and dolomite that has been badly shattered and filled with calcite stringers. Thickness 900 to 1,225 feet. Underlies Dunderberg shale; overlies Secret Canyon shale. Locally in fault contact with Eldorado formation. Upper Cambrian.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 15 (fig. 2), 16–18. Hamburg dolomite described in vicinity of Eureka. Overlies Clarks Spring member (new) of Secret Canyon shale; underlies Dunderberg shale. Middle and Upper Cambrian. Type locality noted.

Type locality: At Hamburg mine in southern branch of New York Canyon, Eureka district.

Hamburg Member (of Hannibal Formation)

†Hamburg Oolite (in Kinderhook Group)[1]

Mississippian: Southwestern Illinois.

Original reference: S. Weller, 1906, St. Louis Acad. Sci. Trans., v. 16, p. 464–467.

J. R. Ball, 1952, Illinois Geol. Survey Bull. 77, p. 15. In Carlinville quadrangle, Hannibal formation consists of Hamburg and Maple Mill members. Hamburg member is 72 to 87 feet thick. Conformably underlies Maple Mill member; separated from underlying Louisiana limestone by sharp unconformity.

Named for occurrence at Hamburg, Calhoun County.

†Hamburg Shale[1]

Upper Cambrian: Eastern Nevada.

Original reference: A. Hague, 1883, U.S. Geol. Survey 3d Ann. Rept., p. 253, 255–256.

Well exposed opposite Hamburg and Dunderberg mines and in ravine north of Adams Hill, Eureka district.

Hamburg Slate[1]

Precambrian (middle Huronian): Central northern Wisconsin.

Original reference: S. Weldman, 1907, Wisconsin Nat. History Survey Bull. 16, p. 61.

In Berlin and Hamburg Townships, Marathon County.

†Hamburg Mountain Gneiss[1]

Hamburgh Mountain Gneiss Series

Precambrian: Northern New Jersey.

Original reference: J. E. Wolff and A. H. Brooks, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 2, p. 439.

J. M. Hague and others, 1956, Geol. Soc. America Bull., v. 67, no. 4, p. 468. Hamburgh Mountain gneiss series is oldest in sequence of metasedimentary and metavolcanic rocks in Franklin-Sterling area. Thickness unknown because of intrusion by Byram gneiss; probably more than 2,000 feet. Older than Franklin marble.

Type locality not given but town of Hamburg is in Sussex County.

Hamden Limestone or Member (of Allegheny Formation)[1]

Hamden limestone member

Pennsylvanian (Allegheny Series): Southeastern Ohio.

Original reference: Wilber Stout, 1918, Ohio Geol. Survey, 4th ser., Bull. 21, p. 173.

R. C. Moore and others, 944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 10). Shown on correlation chart as limestone in Allegheny series.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 46, 47, table 1. Hamden limestone included in Lower Kittanning cyclothem, Allegheny series, although not well represented in Perry County.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 48 (table 7), 66. Hamden limestone member of Strasburg cyclothem in report on Athens County. Stout and others (1923, Ohio Geol. Survey, 4th ser., Bull. 26) described in Oak Hill underclay a carbonate zone consisting of limestone, ferruginous limestone, and (or) ironstone. Restudy of type Hamden has revealed that the member is nonmarine and not marine limestone as Stout (1918) intimated and that it belongs to Oak Hill underclay and not to marine shale and limestone overlying Lower Kittanning coal. In this report, name Hamden is restricted to limestone and ironstone member associated with Oak Hill underclay. Thickness about 2 feet. Allegheny series.

Named for its occurrence at stratigraphic horizon of Hamden iron ore of southern Vinton and northern Jackson Counties.

Hamilton Group[1] or Formation

Hamilton Member (of Romney Shale)

Middle Devonian: New York, Indiana, Maryland, New Jersey, Pennsylvania, Virginia, and West Virginia.

Original reference: L. Vanuxem, 1840, New York Geol. Survey 4th Rept., p. 380.

Bradford Willard, 1937, Am. Jour. Sci., 5th, v. 33, no. 196, p. 264–278. Term Hamilton group is here expanded to include all of the Middle Devonian, that is, all beds from subjacent Oriskany formation to superjacent Portage group. This use makes Hamilton synonymous with Middle Devonian. Although number of subdivisions recognized increases from Maryland to New York, three important divisions are almost everywhere present. At base is Onondaga, above is Marcellus, and upper part is Mahantango or its equivalent, the "Hamilton" of Maryland Survey and earlier writers. Group is discussed in New York, New Jersey, Pennsylvania, and Maryland.

Bradford Willard, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G-19, p. 132-136, 161-200. Term Hamilton group has been used as synonymous with Middle Devonian. Validity of this usage is questioned. Group is restricted at base to exclude Onondaga group. In Pennsylvania, group includes Marcellus formation below and Mahantango formation above. New York terms Skaneateles, Ludlowville, and Moscow are retained as facies of Mahantango formations. Erian stage.

Guy Campbell, 1942, Geol. Soc. America Bull., v. 53, no. 7, p. 1055-1072. Hamilton group in Indiana comprises (ascending) Speeds, Deputy, Silver Creek, Swanville, and Beechwood formations. Overlies Jeffersonville formation of Onondaga; underlies New Albany shale. Terms Sellersberg and Sellersberg beds, as they have been used, are each equivalent to term Hamilton group as used in this paper.

Winifred Goldring, 1943, New York State Mus. Bull. 332, p. 42, 235-279. Hamilton beds (in Coxsackie quadrangle) include (ascending) Bakoven shale (Marcellus "black shale"), Mount Marion beds, Ashokan shales and flags, and Kiskatom beds.

H. P. Woodward, 1943, West Virginia Geol. Survey, v. 15, p. 308-311. In West Virginia, it is not advisable to differentiate members within what has been previously called Hamilton and what, therefore, corresponds to post-Marcellus Hamilton of New York and Pennsylvania. Hamilton can be used in either, but not both, of two ways. It can be retained in its original West Virginia use, which is for interval between Marcellus shale and Tully limestone, in which case it is not available for group name to include the Marcellus. If used as a group name, it would be necessary to have a new name for post-Marcellus, pre-Tully beds. Name Erie (Erian) group is used for Marcellus-Hamilton group of this report.

Theodore Arnow, 1949, New York State Water Power and Control Comm. Bull. GW-20, p. 8 (table 1). Group in Albany County comprises (ascending) Bakoven shale, Mount Marion formation, Ashokan formation, and Kiskatom formation. Underlies Onteora formation; overlies Onondaga limestone.

A. J. Mozola, 1951, New York State Water Power and Control Comm. Bull. GW-26, p. 10 (table 3). Group in Seneca County comprises (ascending) Marcellus, Skaneateles, Ludlowville, and Moscow shale. Underlies Tully limestone; overlies Onondaga limestone.

Ernst Cloos, 1951, Maryland Dept. Geology, Mines and Water Resources [Rept. 14] Washington County, p. 88. Member of Romney shale in Maryland. Overlies Marcellus shale member; underlies Jennings formation.

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 3-4. Group, in east-central Pennsylvania, includes Montebello and Sherman Ridge (new) formations. Mahantango formation embraces that part of Hamilton group above Marcellus formation and below Susquehanna group in west-central Pennsylvania.

Named for Hamilton, Madison County, N.Y.

Hamlin Shale[1] Member (of Janesville Shale)

Hamlin Shale (in Admire Group)

Permian: Southeastern Nebraska and eastern Kansas.

Original references: R. C. Moore, M. K. Elias, and N. D. Newell, 1934, Stratigraphic sections of Pennsylvanian and "Permian" rocks of Kansas River valley: Kansas Geol. Survey, issued Dec.; R. C. Moore, 1935, Rock formations of Kansas *in* Kansas Geol. Soc. [Am. Assoc. Petroleum Geologists 20th Ann. Mtg.] March 21–23: Wichita; G. E. Condra, 1935, Nebraska Geol. Survey Paper 8, p. 8–9.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2273, 2274 (fig. 1). Rank reduced to member of Janesville shale (new). Locally contains Houchen Creek limestone bed [also Oaks shale bed and Stine shale bed]. Uppermost member of Janesville; overlies Five Point limestone member. Wolfcamp series.

M. R. Mudge and R. H. Burton, 1959, U.S. Geol. Survey Bull. 1068, p. 14 (table 2), 51–52, pl. 2. Hamlin shale member described in Wabaunsee County, Kans. Strata now known as Hamlin shale member was included in West Branch shale by Condra (1927) in his reclassification of Admire shale of Adams (1903). Moore, Elias, and Newell (1934) included Stine shale, Houchen Creek limestone, and Oaks shale as members of Hamlin shale. Moore and Mudge (1956) reduced Hamlin to rank of member. Herein suggested that Houchen Creek limestone bed be used as formal name. Recent field work has shown that this bed of Hamlin shale could not be correlated south of Pottawatomie County. Hamlin consists of silty to clayey shales, beds of sandy shale and sandstone, and beds of siltstone, limestone, and conglomerate. Thickness 35 to 45 feet. Overlies Five Point limestone member; underlies Americus limestone member of Foraker limestone.

Type locality and derivation of name not given; Hamlin was included in section from Forest City, Mo., to Dubois, Nebr.

Hammar Bluff Formation[1]

See **Hammer Bluff Formation,** correct spelling.

Hammer Bluff Formation

Miocene: Western Washington.

Original reference: S. L. Glover, 1936, Pan-Am. Geologist, v. 65, no. 1, p. 77–78

D. R. Mullineaux, L. M. Gard, and D. R. Crandell, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 3, pt. 1, p. 692–694. Crops out in both valley walls of Green River. On south side of river, consists of about 100 feet of brown to greenish-gray sandy montmorillonitic and kaolinitic clay and clayey sand; near base of section is about 20 feet of cross-bedded pebble gravel underlain by 7 feet of gray kaolinitic quartz sand. Logs as large as 1½ feet in diameter and 15 feet long are scattered throughout the sand and gravel. On north side of river, formation consists of more than 25 feet of quartz sand and kaolinitic plastic clay which contains a layer of woody lignite 2 to 3 feet thick; sand and gravel are overlain by more than 30 feet of brown to greenish-brown sand and pebble gravel. Unconformably overlies sandstone of Puget group; unconformably underlies glacial drift of Orting(?) age. Miocene. Name has been spelled Hammar Bluff.

Named for occurrence near Hammer Bluff, a few miles east of Auburn, King County.

Hammett Shale

Lower Cretaceous: Southeastern Texas (subsurface and surface).

F. E. Lozo and F. L. Stricklin, Jr., 1956, Gulf Coast Assoc. Geol. Soc. Trans., v. 6, p. 69; J. R. Sandige, chm., 1956, Gulf Coast Assoc. Geol. Soc. Guide Book Ann. Mtg. Field Trip, p. 12–13, fig. 5. Name applied to unit between Sycamore sands below and Cow Creek limestone above. Where exposed, lower 20 feet consists of buff-colored shales, dark when fresh, with thin fossiliferous limestone at base. Remaining 40 to 45 feet, as revealed in cored section, is largely shale with fine sand streaks in base and middle, latter associated with a bed of small clams; uppermost part contains fossiliferous dolomitic limestones. Cow Creek boundary is transitional, arbitrarily determined at base of lowermost well-developed limestone; lower contact is surface of disconformity marked sporadically by pebble and boulder layer immediately above top of Sycamore.

Type section: Completely cored section at Hamilton Pool core holes 1 and 2. Name derived from Hammett Crossing, about 1 mile west of Hamilton Pool in western Travis County.

Hammond Fire Clay (in Kanawha Formation)[1]

Hammond Fire Clay (in Kanawha Member of Pottsville Formation)

Pennsylvanian: Northeastern West Virginia.

Original reference: R. V. Hennen and D. B. Reger, 1913, West Virginia Geol. Survey Rept. Marion, Monongalia, and Taylor Counties, p. 369.

J. B. McCue and others, 1948, West Virginia Geol. Survey [Rept.], v. 18, p. 18. Hammond clay occurs about 90 feet below top of Pottsville.

R. L. Nace and P. P. Bieber, 1958, West Virginia Geol. Survey Bull. 14, p. 23 (table 6). Listed as clay in Kanawha member of Pottsville.

W. A. Tallon, 1959, West Virginia Geol. and Econ. Survey Rept. Inv. 17, p. 17. Hammond clay grades downward into horizon here named Bessemer clay.

Named for Hammond, Marion County.

Hammondville Gneiss[1]

Precambrian: Eastern New York.

Original reference: D. H. Newland, 1908, New York State Mus. Bull. 119, p. 43–50.

Occurs at Hammondville mines, Crown Point Township, Essex County.

Hampden Basalt (in Newark Group)

Hampden Diabase (in Newark Group)[1]

Hampden Lava Member (of Meriden Formation)

Upper Triassic: Central Massachusetts and central Connecticut.

Original reference: B. K. Emerson, 1898, U.S. Geol. Survey Geol. Atlas, Folio 50.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Rank reduced to member status in Meriden formation. Greenish-black rock, weathering bright orange, grading from basalt near contacts to coarse dolerite in interiors. Interior parts are massive and commonly show good columnar jointing; upper parts are commonly vesicular, and upper and lower parts may show flow brecciation. Separated from underlying Holyoke lava member by unnamed upper sedimentary member; underlies Portland arkose.

Robert Balk, 1957, Geol. Soc. America Bull., v. 68, no. 4, p. 495. Diabase is included in Granby tuff and mapped as an unnamed unit.

E. P. Lehmann, 1959, Connecticut Geol. and Nat. History Survey Quad. Rept. 8, p. 6–25 pl. 1. Term Meriden formation not used in this report [Middleton quadrangle]; rock units involved are given formational status. Newark group comprises (ascending) New Haven arkose, Talcott basalt, Shuttle Meadow formation (new), Holyoke basalt, East Berlin formation (new), Hampden basalt, and Portland arkose. Hampden basalt is exposed in series of low ridges trending generally north across center of quadrangle and in northwest corner. Belt of outcrop has been offset and repeated by faulting. Width of outcrop belt is variable, ranging from 600 feet in northwest corner of quadrangle where dip of basalt is at maximum (17° to 20°) to about 3,500 feet in Miramichi area west of Middleton where low dip (7° to 8°) of Hampden and topography combine to widen belt.

R. W. Schnabel, 1960, U.S. Geol. Survey Geol. Quad. Map GQ–134. Described in Avon quadrangle, Connecticut, where it is probably 150 to 200 feet thick, neither upper or lower contact exposed.

Crops out across Hampden County, Mass.

Hampshire Formation[1]

Upper Devonian: Eastern West Virginia, western Maryland, Pennsylvania, and western Virginia.

Original reference: N. H. Darton, 1892, Am. Geologist, v. 10, p. 13, 17, 18.

P. H. Price and H. P. Woodward, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 11, p. 1993–1994; H. P. Woodward, 1943, West Virginia Geol. Survey, v. 15, p. 497–529. Inasmuch as redbeds of Catskill Mountains of New York have been determined to be of Portage and Hamilton age, it seems unwise further to apply name "Catskill" in Appalachian region to redbeds that are post-Chemung. Name Hampshire formation, applied by Darton to exposure of this series in Hampshire County, is here revived for rocks previously called "Catskill" in West Virginia. Term also applies to unit previously called "Catskill formation" by Maryland Geological Survey. Formation is well developed along the Potomac where it attains maximum thickness of about 3,000 feet in Morgan and Hampshire Counties; thins westward and southward. Includes red and green sandstones and shales which overlie Chemung formation and occur below beds of "Pocono" facies, either highest Devonian or lowest Mississippian.

Charles Butts, 1945, U.S. Geol. Survey Geol. Atlas, Folio 227. Described in Hollidaysburg and Huntingdon quadrangles, Pennsylvania. Thickness 2,000 to 2,500 feet. Overlies Chemung formation; underlies Pocono formation.

Named for Hampshire County, W. Va.

†Hampton Clays[1]

Pleistocene: Coastal Plain of South Carolina.

Original references: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, advance copies; published in 1908, in South Carolina Geol. Survey, ser. 4, Bull. 2; 1907, Summary of mineral resources of South Carolina, p. 12, 20.

Probably named for development in Hampton County.

Hampton Formation[1]

Mississippian (Kinderhook): Central northern and southeastern Iowa.

Original reference: L. R. Laudon, 1930, Geol. Soc. America Bull., v. 41, p. 174.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (columns 68, 69). Correlation chart shows Hampton formation including (ascending) Chapin beds, Maynes Creek limestone, Eagle City beds, and Iowa Falls members in north-central Iowa where it underlies Gilmore City limestone and overlies English River sandstone. In southeastern Iowa, includes North Hill beds below and Wassonville limestone. Underlies Burlington limestone and overlies English River sandstone. Kinderhook. [Laudon, 1935, restricted Hampton by excluding North Hill member and part of Chapin beds.]

Named for exposures at Hampton, Franklin County.

Hampton Granodiorite[1]

Devonian(?): Southeastern New Hampshire.

Original reference: A. Wandke, 1922, Am. Jour. Sci., 5th, v. 4, p. 148, 149.

Probably named for exposures at Hampton or in Hampton Township, Rockingham County.

Hampton Shale[1] or **Formation** (in Chilhowee Group)

Lower Cambrian(?): Eastern Tennessee, western North Carolina, and southwestern Virginia.

Original reference: M. R. Campbell, 1899, U.S. Geol. Survey Geol. Atlas, Folio 59, p. 3.

P. B. King and others, 1944, Tennessee Div. Geology Bull. 52, p. 35–37, pls. Consists of beds between Erwin above and Unicoi below. Composed of alternating beds of clay shale, siltstone, vitreous quartzite, and arkosic quartzite. Thickness commonly 1,200 to 1,400 feet. On Embreeville Mountains, formation may be as much as 2,500 feet thick. In sections southeast of Hampton, about 500 feet thick. No consistent sequence of members present. Amount of shale varies from place to place, and few shale bodies are consistent. No part of section can be set off as unit to be designated "Hampton shale." No specific type section was designated, but formation crops out along Doe River both northwest and southeast of Hampton. Sections at the two places are of unlike character. That to northwest is on Shady Valley thrust sheet and is typical of formation in much of region. That to southeast is in Mountain City window and is thinner than elsewhere and less characteristic.

S. S. Oriel, 1950, North Carolina Div. Mineral Resources Bull. 60, p. 16–18, pl. 1. In Hot Springs area, formation is subdivided into three members: upper shale, middle quartzite, and lower shale. Contacts are readily mappable, and Keith (1904, U.S. Geol. Survey Geol. Atlas, Folio 116) used same horizons as formational boundaries between Murray slate and Nebo quartzite and between Nebo and underlying Nichols slate. Thickness 910 to 1,430 feet. Overlies Unicoi formation; underlies Erwin formation. Two sets of names for Lower Cambrian clastic rocks are in use in eastern Tennessee and western North Carolina. Northeast Tennessee names, Unicoi, Hampton, and Erwin, are used for same rocks which Keith (1904) and Stose and Stose (1947, Am. Jour. Sci., v. 245, no. 10) named Cochran, Nichols, Nebo, Murray, and Hesse, all defined by Keith (1895) in Chilhowee Mountain area, Blount and Sevier Counties, Tenn.

W. B. Brent, 1960, Virginia Div. Mineral Resources Bull. 76, p. 19, pl. 1. In this report [Rockingham County], term Hampton formation used in preference to Harpers shale. Estimated thickness 800 to 2,750 feet. Overlies Weverton formation; underlies Erwin (Antietam) quartzite. Cambrian.

P. B. King and H. W. Ferguson, 1960, U.S. Geol. Survey Prof. Paper 311, p. 28, 32, 40–41, pls. 1, 12. Formation described in northeasternmost Tennessee where it crops out along Doe River both northwest and southeast of Hampton, the two sections being unlike and lying in different structural blocks. Section to northwest is herein designated type locality. Consists of interbedded layers of clay, shale, siltstone, arkosic sandstone, and vitreous quartzite. Keith (1907, U.S. Geol. Survey Geol. Atlas, Folio 151) believed that strata between underlying Unicoi and overlying Erwin was single shale unit 100 to 300 feet thick; in many places, he invoked complex faulting to explain wide band of outcrop and apparent repetition of shaly layers within it. As now defined, the Hampton is 1,200 to 1,400 feet thick in area of Holston Mountain and Iron Mountains; appears to thicken to nearly 2,000 feet immediately south of Tennessee-Virginia State line; 500 feet or less in Doe ridges. Nowhere Ridge, and on Doe River southeast of Hampton. In southwestern part of Iron Mountains and Holston Mountain, includes Cardens Bluff shale member (new) at base Chilhowee group. Lower Cambrian.

Type locality: Section to northwest of Hampton, Carter County, Tenn.

Hana Volcanic Series

Pleistocene and Recent: Maui Island, Hawaii.

H. T. Stearns *in* H. T. Stearns and G. A. Macdonald, 1942, Hawaii Div. Hydrography Bull. 7, p. 63, 65 (table), 66 (table), 90–102, pl. 1. Comprises all volcanics laid down since the great valleys reached their maximum size. In Nahiku area, includes (ascending) Big Falls picritic basalts. Makapipi basalt, Waiaaka basaltic andesite, Kapaula basaltic andesite, Makaino basaltic andesite, Mossman picritic basalt, Kuhiwa basaltic andesite, Paakea basalt, and Hanawi basaltic andesite; in Keanae area (ascending). Pauwalu basalt, Wailuanui basalt, Ohia basalt, Piinaau basalt, Waiokamilo basalt, and Keanae basalt; in Kipahulu Valley, Kipahulu member. Commonly separated from Kula lavas (new) by erosional unconformity; in deep valley where Kula lavas were probably removed by erosion, Hana lavas lie either on alluvium or on Honomanu basalts (new).

G. A. Macdonald *in* H. T. Stearns and G. A. Macdonald, 1942, Hawaii Div. Hydrography Bull. 7, p. 238–254, 292–302. Described in Nahiku area. Petrography discussed.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat, Internat., v. 6, Océanie, fasc. 2, p. 86. Pleistocene and Recent. Includes Kaupo mudflow.

Named for village of Hana where typical lavas and cones of series are exposed. Covers three areas: east end, southwest end, and summit depression of Haleakola (East Maui) volcano.

Hanaupah Formation[1] (in Telescope Group)

Precambrian: Southeastern California.

Original reference: F. M. Murphy, 1933, California Div. Mines Rept. 28 of State Mineralogist, July-Oct. 1932, p. 329–356.

B. K. Johnson, 1957, California Univ. Pubs. Geol. Sci., v. 30, no. 5, p. 355, 378 (fig. 7). This study [Manly Peak quadrangle] has made possible the correlation of formations defined by Murphy (1930, 1932 [1933]) in Telescope Peak quadrangle with formations now commonly used in Death Valley region. Hanaupah formation is correlated with upper part of Johnnie formation here assigned to Precambrian as defined in this report.

Name probably derived from proximity to Hanaupah Canyon, in southern part of Panamint Range.

Hanawi Basaltic Andesite (in Hana Volcanic Series)

Pleistocene (?) : Maui Island, Hawaii.

G. A. Macdonald *in* H. T. Stearns and G. A. Macdonald, 1942, Hawaii Div. Hydrography Bull. 7, p. 230 (table), 253–254, pl. 1. Aa lava; vertical jointing prominent but not regular enough to be columnar. At highway, visible thickness 30 feet with base not exposed; remnant of Hanawi north of Big Spring is about 100 feet thick, which is probably close to original thickness. Relative ages of Hanawi, Kuhiwa, and Paakea lavas not accurately determined; they are nowhere in contact; their topographic position and degree of erosion are similar, and they are regarded as approximately contemporaneous.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 86. Forms single band along Hanawi Gulch. Completely filled valley south of Koolau ditch but only partly filled it farther north where valley was deeper; Haleakala (East Maui) volcano. Pleistocene (?).

†Hanbury Slate[1]

Precambrian: Northwestern Michigan.

Original reference: C. R. Van Hise and W. S. Bayley, 1900, U.S. Geol. Survey Geol. Atlas, Folio 62.

C. A. Lamey and C. E. Dutton, 1941, Michigan Dept. Conserv., Geol. Survey Div. Prog. Rept. 6, p. 10–13. Type locality restudied in 1940. Term Hanbury rejected because of lack of definite age relations at type locality and because of possibility that Hanbury of type locality is a complex of several formations.

Type locality: Hanbury Hill, south of Hanbury Lake, Menominee district.

Hance Formation (in Breathitt Group)

Hance Formation (in Pottsville Group)[1]

Pennsylvanian: Southeastern Kentucky and northeastern Pennsylvania.

Original reference: G. H. Ashley and L. C. Glenn, 1906, U.S. Geol. Survey Prof. Paper 49, p. 33, 37, 207 pl. 40A.

H. R. Wanless, 1946, Geol. Soc. America Mem. 13, p. 55, 57, 65–68, 141. Includes strata below Lower Hance coal (Mingo formation) and above Naese sandstone (Lee formation); approximately correlated wih Briceville formation (Tennessee).

U.S. Geological Survey currently classifies the Hance as a formation in the Breathitt Group on the basis of a study now in progress. U.S. Geological Survey does not use the term Pottsville Group in Kentucky.

Named for Hance Ridge, Bell County, Ky.

Hancock Amygdaloid[1] (in Ashbed Group)

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Named for its occurrence in old Hancock mine, Houghton County.

Hancock Conglomerate[1] (in Portage Lake Lava Series)

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

W. S. White, H. R. Cornwall, and R. W. Swanson, 1953, U.S. Geol. Survey Geol. Quad. Map GQ–27. Included in Portage Lake lava series.

Named for exposures in a ravine just east of Hancock mine, Houghton County.

Hancock Flow [1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Probably named for its occurrence in old Hancock mine, Houghton County.

Hancock Limestone[1] or **Dolomite**

Upper Silurian or Silurian and Devonian: Northeastern Tennessee and western Virginia.

Original reference: A. Keith, 1896, U.S. Geol. Survey Geol. Atlas, Folio 27, p. 3.

R. L. Miller and W. P. Brosgé, 1950, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 104, sheet 2; 1954, U.S. Geol. Survey Bull. 990, p. 83–86. Hancock dolomite described in Jonesville district, Lee County, Va. Consists of basal pebbly sandstone, overlain by bluish-gray ribbon limestone or mottled limestone; upper part is massive-bedded gray fine-grained dolomite. Formation becomes dominantly limestone at east edge of district. Thickness 168 to 188 feet. As used here, formation includes only beds of Cayugan age. Disconformably overlies Clinton shale; unconformably overlain by Upper Devonian shale.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, p. 103. Hancock limestone in eastern Tennessee consists chiefly of fairly thick-bedded limestone and dolomite, many layers being sandy and a few cherty; some layers, especially at base or where formation is thin, contain so much sand as to grade into calcareous or dolomitic sandstone; some sand carries Lower Devonian fossils. May be more than 300 feet thick locally in belt on south side of Powell Mountain, but elsewhere is thinner. Occurs above Rockwood formation.

Named for Hancock County, Tenn.

Hancock Member (of Pinney Hollow Formation)

Lower Cambrian: West-central Vermont.

P. H. Osberg, 1952, Vermont Geol. Survey Bull. 5, p. 55, 57–58, 59. Dark-green albite-epidote-calcite-chlorite schist occurring in middle of Pinney Hollow formation. West of Hancock, thin beds of white quartz-tremolite-calcite granulite are interstratified with schist; locally, thin discontinuous beds of buff-weathering dolomitic marble are present. Thickness approximately 500 feet in vicinity of Rochester and Hancock; thins to about 200 feet toward northern border of Rochester quadrangle.

Named from exposures in Hancock Tunnel. Crops out in Rochester-East Middlebury area.

Hancock West Conglomerate[1] (in Ashbed Group)

Precambrian (Keweenawan): Northern Michigan.

Original reference: A. R. Marvine, 1873, Michigan Geol. Survey, v. 1, pt. 2, p. 77, 83, chart.

Probably named for old Hancock mine, Houghton County.

Haney Limestone Member (of Golconda Formation)

Haney Limestone

Mississippian (Chester Series): Southeastern Illinois, southwestern Indiana, and northeastern Kentucky.

A. C. McFarlan and others, 1955, Kentucky Geol. Survey, ser. 9, Bull. 16, p. 18, 19. New name is needed for the "Golconda" as recognized east of Todd County, Ky., and north into Indiana. Haney limestone is proposed for upper "Golconda." At type section, consists of 12½ feet of moderate-light-gray, yellowish-gray, and light-brownish-gray limestone with oolite near base; 11 feet of shale and limestone; and 7 feet of light-gray to light-olive-gray coarsely crystalline fossiliferous slightly crossbedded limestone. Unit somewhat thin at this outcrop; upper shale reaches maximum of 30 to 40 feet but occurs only as sporadic remnants beneath pre-Hardinsburg unconformity; main Haney limestone is typically 40 to 50 feet thick, with extremes of 20 to 70 feet along south-central border of Illinois basin; oolite increases westward from type section, and an oolite zone has been named Marigold member [oolite] in western Illinois (Sutton, 1934). Underlies Hardinsburg sandstone; overlies Fraileys shale (new) or Big Clifty sandstone.

U.S. Geological Survey currently classifies the Haney Limestone as a member of the Golconda Formation on the basis of a study now in progress.

Type locality: Easternmost exposure of the Golconda in Illinois, on south slope of hill along west edge of NE¼SE¼ sec. 9, T. 12 S., R. 10 E., Cave in Rock quadrangle, Hardin County, Ill. Outcrop faces Ohio River, 4 miles upstream from Cave in Rock, through a gap in bluff made by branch of Honey Creek (not named on topographic map) but locally known as Haney Creek.

†Hanging Rock Limestone (in Allegheny Formation)[1]

Pennsylvanian: Southeastern Ohio.

Original reference: E. Orton, 1878, Ohio Geol. Survey, v. 3, p. 888, 892–895, pls. opposite p. 889, 900, 912, 921.

Named for Hanging Rock district.

Hanging Rock Sandstone[1]

Pennsylvanian: Southeastern Illinois.

Original reference: F. H. Bradley, 1869, Indiana Geol. Survey 1st Ann. Rept., p. 157.

Named for Hanging Rock, on Big Vermilion River, Vermilion County.

Hanging Rock Sandstone[1]

Pennsylvanian: Central western Indiana.

Original reference: A. H. Worthen, 1875, Illinois Geol. Survey, v. 6, p. 51–60.

Hanging Rock bluff, 3 miles northeast of Mount Carmel, Wabash County.

Hanley Sandstone (in Cattaraugus Formation)

Devonian: Northwestern Pennsylvania.

C. R. Fettke, 1938, Pennsylvania Geol. Survey, 4th ser., Bull. M–21, p. 36, 37–38. Name given to fine- to medium-grained dark-reddish- to purplish-gray very fossiliferous sandstone in lower part of formation. Discoidal quartz pebbles sparingly distributed through upper part. Thickness 14 feet. Occurs approximately half way between Salamanca and Wolf Creek horizons. Apparently a local development.

Exposed in shale quarry at Hanley Co. plant, Lewis Run, McKean County.

Hanna Formation[1]

Eocene: Central southern Wyoming.

Original reference: C. F. Bowen, 1918, U.S. Geol. Survey Prof. Paper 108, p. 228, 231.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 21. Supposedly Paleocene and Wasatchian (Eocene).

Well exposed north and west of town of Hanna, Carbon County.

Hannah Formation

Miocene, lower: Central California.

Martin Van Couvering and H. B. Allen, 1943, California Div. Mines Bull. 118, pt. 3, p. 496–500. Divisible into three shaly members separated by two sandstones. Thickness about 2,180 feet. Unconformably underlies Escudo sandstone (new); unconformably overlies Wagonwheel formation.

Occurs in Devils Den oil field district in northwestern Kern County, adjacent to Kings County line, about 40 miles east of Paso Robles and about 60 miles northwest of Bakersfield.

†Hannan Limestone or Formation

Mississippian: Northwestern Montana.

Charles Deiss, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1896. One of nine sedimentary formations identified in Sawtooth Range.

Charles Deiss, 1943, Geol. Soc. America Bull., v. 54, no. 2, p. 212 (table 1), 228–231. Name Hannan limestone proposed for all strata which lie between Devonian and Jurassic rocks in Saypo quadrangle. Basal limestone-breccia overlain by gray limestone and alternating units of shaly-bedded argillaceous limestone which grades upward into hard tan- and pale-gray crystalline fossiliferous limestone. Contains much pale-gray chert in nodules and beds as much as 7 inches thick. Upper 200 feet consists of white-gray finely crystalline thin- and thick-bedded dolomite. Thickness 1,370 feet. Disconformably underlies Ellis formation.

W. A. Cobban, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 9, p. 1294, 1296. In Swift Reservoir and Sun River sections, unconformably underlies Sawtooth formation (new).

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, pl. 2 (column 38). Correlation chart shows Hannan limestone to include (ascending) Saypo limestone, Dean Lake chert, Rooney chert, and Monitor Mountain limestone. Kinderhookian, Osagean, and Meramecian.

J. M. Andrichuk, 1955, Billings Geol. Soc. Guidebook 6th Ann. Field Conf., p. 85. Assignment of group status to the Madison of northwestern Montana by U.S. Geological Survey precludes any need for term Hannan.

Name taken from Hannan Gulch where Mississippian rocks form crest of both sides of gulch [Teton County]. Almost the complete section of the Hannan is exposed on north side of Sun River Canyon at south end of Castle Reef, which forms east side of Hannan Gulch.

Hanna Valley Bed (in Strawn Formation)[1]

Pennsylvanian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 374, 383.

D. A. Zimmerman and G. D. Glover, 1956, Soc. Econ. Paleontologists and Mineralogists Permian Basin Sec. [Guidebook] Spring Mtg., p. 74. Clay, about 200 feet thick. Overlies Cottonwood Creek bed; underlies Rough Creek bed. Strawn series.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 58, pl. 27. Drake (1893) separated rocks of Strawn group [division] into 20 units of alternating sandstone and shale beds. He gave local names to these units or "beds" as he termed them, and numbered them from bottom to top, 4 to 23. Only Drake's name for upper unit, the Ricker, is in common use today, and that name has been restricted to the base of Drake's Ricker bed.

Hannegan Volcanics

Tertiary, middle: Northwestern Washington.

Peter Misch, 1952, The Mountaineer, v. 45, no. 13, p. 4 (geol. map), 18. The flat-lying Hannegan volcanics are later than any of the folding of the Northern Cascades.

Prominently exposed around Hannegan Pass, Whatcom County.

Hannibal Shale[1]

Hannibal Group

Hannibal Shale (in Easley Group)

Lower Mississippian: Northeastern Missouri, western Illinois and southeastern Iowa.

Original reference: C. R. Keyes, 1892, Geol. Soc. America Bull., v. 3, p. 289.

J. M. Weller, 1948, (abs.) Am. Jour. Sci., v. 246, no. 3, p. 150. In type area in Mississippi Valley, Easley group (new) consists of Hannibal shale and Chouteau limestone and related groups or formations.

L. A. Thomas, 1949, Geol. Soc. America Bull., v. 60, no. 3, p. 410. Lateral tracing by means of well cores and similarity of conodont assemblages indicates that Hannibal formation grades laterally into English River and Prospect Hill siltstones of Iowa. Term Hannibal has priority over English River; therefore English River and Prospect Hill are considered members of Hannibal formation.

M. A. Stainbrook, 1950, Am. Jour. Sci., v. 248, no. 3, p. 209, 210. English River siltstone and Maple Mill shale are not considered members of Hannibal shale.

L. E. Workman and Tracey [Tracy] Gillette, 1956, Illinois Geol. Survey Rept. Inv. 189, p. 8 (fig. 1), 20–28. Rank raised to group. Includes formations that lie above Louisiana limestone and beneath the Chouteau. Comprises (ascending) Glen Park siltstone, Maple Mill shale, and English River siltstone. Where the Louisiana is absent, group rests on the Saverton, and where Saverton is absent it lies on Grassy Creek shale. In small area in westernmost Illinois, McCraney formation of North Hill group overlies the Hannibal and where neither the Chouteau nor McCraney is present, the Hannibal is overlain by Osage strata.

T. J. Laswell, 1957, Missouri Geol. Survey and Water Resources Rept. Inv. 22, p. 9 (fig. 2), 34–39, pl. 1. Formation described in Bowling Green quadrangle where it is 90 to 121 feet thick. Composed of two lithologies: upper siltstone to fine-grained sandstone and lower silty shale. Unconformably overlies Louisiana wherever latter is present; where Louisiana is absent, formation lies unconformably on Saverton. Underlies Chouteau formation; where Chouteau is absent, underlies Burlington formation.

M. G. Mehl, 1960, Denison Univ. Jour. Sci. Lab., v. 45, art. 5, p. 98, 99. Unconformably overlies Cuivre shale (new) in Pike County, Mo.

Named for exposures at Hannibal, Marion County, Mo.

Hanover Diorite Porphyry

Hanover Granodiorite Porphyry

Upper Cretaceous or younger: Southwestern New Mexico.

Harrison Schmitt, 1939, Geol. Soc. America Bull., v. 50, no. 5, p. 780, 782, 784. Incidental mention as diorite porphyry sill. Sills. sheets, and laccoliths of quartz diorite porphyry intruded Colorado shale but are truncated by prominent widespread angular unconformity probably representing early Tertiary (Eocene?) erosion.

P. F. Kerr and others, 1950, Geol. Soc. America Bull., v. 61, no. 4, p. 287–288, fig. 3. Granodiorite porphyry is body (stock) of relatively unaltered rock in region of intense mineralization. Generally coarsely crystalline showing prominent phenocrysts of plagioclase, hornblende, and biotite, ranging from porphyritic to granular. Ground mass dense and gray to buff.

Sill in Pewabic mine area, in Central Mining district, near Hanover, Grant County. Stock [approximately 1 mile northwest of Santa Rita in southeast corner of Santa Rita quadrangle].

Hanover Limestone[1]

Hanover Limestone (in Lake Valley Limestone)

Lower Mississippian: Southwestern New Mexico.

Original reference: Harrison Schmitt, 1933, Am. Inst. Mining Metall. Engineers Contr. 39.

Harrison Schmitt, 1939, Geol. Soc. America Bull., v. 50, no. 5, p. 780–781, pl. 2. Underlies Parting shale (new) in Pewabic mine area, Hanover.

L. R. Laudon and A. L. Bowsher, 1949, Geol. Soc. America Bull., v. 60, no. 1, p. 7. Appears that Hanover as originally defined included both Kelly and top part of Lake Valley formation.

P. F. Kerr and others, 1950, Geol. Soc. America Bull., v. 61, no. 4, p. 283 (fig. 5), 284. Lake Valley limestone divided into lower blue limestone and overlying crinoidal or Hanover limestone.

H. L. Jicha, Jr., and Christina Lochman-Balk, 1958, New Mexico Bur. Mines Mineral Resources Bull. 61, p. 59. New Mexico Bureau of Mines and Mineral Resources recommends suppression of the name Hanover limestone.

In vicinity of Hanover, in Central Mining district or Santa Rita-Hanover-Fierro district, Grant County.

Hanover Limestone (in Carbondale Group)

Hanover Limestone Member (of Carbondale Formation)

Pennsylvanian: West-central and southern Illinois.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 22, 85. In type area, irregularly laminated light-gray fairly pure limestone with knobby upper surface; overlies soft dark-gray shale. In Knox County, thinner than in type area and quite glauconitic and sandy with scattered pebbles of dark-gray phosphatic limestone.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 101, 190, 195, 196, 204. Most persistent near Pleasantview, Beardstown quadrangle, where limestone is conglomerate with dark-blue-gray limestone masses in matrix of light-gray limestone. Commonly massive, but in thickest exposures shows rude bedding. Thickness 1 to 4 feet near Pleasantview but 6 inches or less elsewhere. In most exposures, unconformably underlies St. David underclay and underclay limestone. Included in Summum cyclothem. Name credited to J. R. Pelt (1928, Illinois Geol. Survey field notes).

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 34, 35, 47 (table 1), 66, pl. 1. Rank reduced to member status in Carbondale formation (redefined). Occurs above Summum (No. 4) coal member and below Harrisburg (No. 5) coal member. Thickness 10 feet. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: NE¼SW¼ sec. 27, T. 10 N., R. 11 W., Greene County.

†Hanover Pebble Bed (in Cuyahoga Formation)

Mississippian: South-central Ohio.

J. E. Hyde 1953, Ohio Geol. Survey Bull. 51, p. 98. Name applied by Hyde in 1910 manuscript to unit now termed Berne member of Cuyahoga formation. Described as thin pebble bed capping massive conglomerates of Toboso conglomerate province of the Cuyahoga. In Licking County, can be traced westward to beyond Newark where it overlies Cuyahoga shales of Granville province. Bed cannot be traced from outcrop to outcrop in Hocking Valley area.

Named from exposures near Hanover, Licking County.

Hanover Shale Member (of Java Formation)

Hanover Shale[1]

Hanover Shale Member (of Chemung Formation)

Upper Devonian: Western and west-central New York.

Original references: C. A. Hartnagel, 1912, New York State Mus. Handb. 19, p. 76; G. H. Chadwick, 1933, Pan-Am. Geologist, v. 60, p. 96, 98, 193, 198, 199, 357.

J. F. Pepper and Wallace de Witt, Jr., 1950, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 37. In western and central New York, includes Pipe Creek shale member at base. Eastward, intertongues with siltstone of Wiscoy sandstone. Underlies Dunkirk shale; overlies Angola shale in west and Nunda sandstone in east.

J. F. Pepper and Wallace de Witt, Jr., 1951, U.S. Geol. Survey Oil and Gas Inv. Chart OC-45. In area between Dunkirk, Chautauqua County, and Franklin Gulf, Erie County, Hanover shale underlies Dunkirk, member of Perrysburg formation (new).

I. H. Tesmer, 1955, New York State Mus. Sci. Service Circ. 42, p. 10 (fig. 1). Considered member of Chemung formation.

J. F. Pepper, Wallace de Witt, Jr., and G. W. Colton, 1956, U.S. Geol. Survey Oil and Gas Inv. Chart OC-55. Overlies Angola shale member of West Falls formation (new).

Wallace de Witt, Jr., 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 12, p. 1934, 1935 (fig. 2). Redefined as member of Java formation (new). Consists largely of medium to medium-greenish-gray slightly calcareous shale and blocky weathering mudrock. East of central Wyoming County, Wiscoy sandstone member of Java separates Hanover member from Dunkirk shale member of Perrysburg.

Type exposure on Silver Creek, Hanover Township, Chautauqua County.

Hanoverian series[1]

Cambrian: Iowa.

Original reference: C. R. Keyes, 1936, Pan-Am. Geologist, v. 65, no. 4, p. 315.

Named for township in Allamakee County.

Hans Lollik Formation (in Virgin Island Group)

Upper Cretaceous: Virgin Islands.

T. W. Donnelly, 1960, Dissert. Abs., v. 20, no. 7, p. 2756; 1960, Caribbean 2d Geol. Conf. Trans., Mayagüez, Puerto Rico, p. 153. Minimum thickness 10,000 feet. Poorly exposed either the youngest unit present or equivalent to Louisenhoj formation (new), which it resembles lithologically, and faulted into place. Virgin Island group considered of Cenomanian age.

Report discusses geology of St. Thomas and St. John Islands.

Hanson Beds

Silurian: Subsurface in northwestern North Dakota and northeastern Montana, and surface and subsurface in southern Manitoba, Canada.

Saskatchewan Geological Survey, 1958. Report of the Lower Paleozoic names and correlations committee: Saskatchewan Geol. Soc., p. 14, 15, charts A and B. Uniformly pale-colored microcrystalline and lithographic dolomites with interbedded porous dolomitized fossiliferous-fragmental and ostracodal limestones. Occasional dark-colored argillaceous dolomites and shale seams. Basal anhydrite in central part of Williston Basin. Depositional thickness ranges from 300 to 365 feet. Underlies Risser beds (new) with possible unconformity; variably truncated by pre-Middle Devonian unconformity beyond edge of Risser beds.

Type locality: Amerada No. 3-C. Hanson (center SW¼NW¼ sec. 18, T. 158 N., R. 94 W., Montrail County, N. D.) between 11,825 and 12,165 feet; Williston Basin, N. Dak.

Hansonburg Group

Pennsylvanian (Missouri Series): Central New Mexico.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 27 (table 2), 63–65. Proposed for group of rocks in upper part of Missouri series between top of Veredas group (new) and base of Keller group (new) of Virgil series above. Includes Burrego (base) and Story formations (both new). Thickness ranges from 115 feet at type locality to more than 200 feet in Mocking Bird Gap. With the exception of interval of red shale, sandstone, and gray shale from 38 to 57½ feet below top, type section consists entirely of light-gray to purple massive to nodular limestones.

Type locality: On northeast side of Oscura Mountains, on north bluff of large arroyo that drains northwest past Julian Tank, in and near east part of SE¼ sec. 31, T. 5 S., R. 6 E., Socorro County. Name derived from Hansonburg, headquarters of Bursum Ranch, about 5 miles east of north end of Oscura Mountains.

Hanson Creek Formation

Middle(?) and Upper Ordovician: Central Nevada.

C. W. Merriam, 1940, Geol. Soc. America Spec. Paper 25, p. 8 (table 1), 10–11, pl. 1; C. W. Merriam and C. A. Anderson, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1681 (table 1), 1685–1686. Lowest calcareous member of formation is dark-gray to blackish medium-grained poorly stratified dolomitic limestone containing small crinoid stems and irregular calcite veins—about 40 feet thick at type section; grades upward into very fine-textured poorly bedded noncrinoidal medium- to dark-gray limestone with many calcite veinlets and small black chert nodules—about 45 feet; above is 140 feet of thin-bedded slabby and shaly very fossiliferous limestone; succeeding 140 feet is dark-gray poorly stratified limestone; upper 180 feet is massive dark-gray fine-grained limestone. Thickness at type locality 560 feet. Overlies Eureka quartzite with probable unconformity; underlies Roberts Mountains formation (new). Formerly included in lower part of Lone Mountain limestone.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 32–34. In sections east of Eureka, Roberts Mountains formation appears to be absent, and interval between Hanson Creek and strata of Devonian age is occupied by thick-bedded poorly fossiliferous dolomites that have been included within Lone Mountain dolomite. Thickness 318 feet at Lone Mountain; 300 feet in Antelope Valley.

Type section: Northwest side of Roberts Creek Mountain and crosses east fork of Pete Hanson Creek, about 24 miles northwest of Eureka and 20 miles north of Lone Mountain.

Happy Hollow Limestone Member (of Scranton Shale)[1]

Happy Hollow Limestone (in Wabaunsee Group)

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, southeastern Nebraska, and northeastern Oklahoma.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, p. 40, 58.

R. C. Moore, 1936, Kansas Geol. Survey Bull. 22, p. 49 (fig. 11), 211–212. Rank raised to formation in Wabaunsee group. Term Scranton abandoned. Overlies White Cloud shale; underlies Cedar Vale shale. Thickness 1 to 8 feet.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1), 2277. Rank reduced to member of Scranton shale here reintroduced a formation with stratigraphic span as assigned to it by Haworth and Bennett (1908). Overlies White Cloud shale member; underlies Cedar Vale shale member.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 14, fig. 5. Formation in Wabaunsee group. Poorly exposed in Iowa. In limited exposure in Adams County, a fine-grained sandy limestone that weathers yellowish is tentatively identified as Happy Hollow. In drill hole near Coin, unit is about 2 feet thick. Underlies Cedar Vale shale; overlies White Cloud shale.

Type locality: Vicinity of Happy Hollow ravine, below mouth of Big Nemaha River, southeast of Rulo, Richardson County, Nebr. Moore (1936) gave type locality as Happy Hollow Creek, northeastern Doniphan County, Kans.

Haragan Shale[1] **or Limestone** (in Hunton Group)

Haragan Formation (in Kite Group)

Lower Devonian: Central southern Oklahoma.

Original reference: C. A. Reeds, 1911, Am. Jour. Sci., 4th, v. 32, p. 256–258.

R. A. Maxwell, 1936, Northwestern Univ. Summ. Doctoral Dissert., v. 4, p. 132–134. Basal formation in Kite group (new). Underlies Cravatt limestone (new); overlies Henryhouse formation. Helderbergian.

T. W. Amsden, 1947, Oklahoma Geol. Survey Circ. 44, p. 6 (fig. 3), 7, 35–38. Formation (in Hunton group) is fossiliferous, argillaceous, and silty calcilutite which is here called marlstone. It is thin bedded, the beds ranging up to 3 or 4 inches in thickness and commonly weathering with irregular, nodular appearance. Maximum thickness is in vicinity of old Hunton townsite where there is 230 feet of strata between Chimneyhill and Bois d'Arc formations; however, this includes a 100-foot covered interval just above Clarita member (new) of Chimneyhill formation and this could be in part Henryhouse. Thins to north, and on Lawrence uplift is only a few feet thick; in area of Wapanucka, largely replaced by Bois d'Arc cherty beds; in belt extending west to Reagan, the Haragan is thin or absent; thickness about 50 feet in most westerly area studied. Variation in thickness is probably result of its facies relationship with Bois d'Arc formation. Henryhouse and Haragan have been studied at numerous places, and no reliable field criterion, other than fauna, has been found for separating the two and in this report they are grouped under term Hunton marlstone. Reeds named Haragan from small creek in SW¼ sec. 17, T. 2 S., R. 3 E., short distance northwest of White Mound. This is good type area because formation is well exposed and is about 100 feet thick. Type section designated.

T. W. Amsden, 1958, Oklahoma Geol. Survey Bull. 82, p. 7–13. Stratigraphic and faunal evidence indicate that entire Bois d'Arc formation is facies of Haragan formation. Base of Bois d'Arc formation arbitrarily placed at base of lowest cherty bed of any appreciable thickness. Defined in this manner, the Haragan is almost chert free.

T. W. Amsden, 1958, Oklahoma Geol. Survey Bull. 78, p. 9–144. Formation conformably overlain by Cravatt member of Bois d'Arc formation, which is lithologically much like Haragan, being thin-bedded yellowish-gray argillaceous calcilutite. Cravatt carries varying amounts of chert, and on this basis Bois d'Arc is distinguished from Haragan. Formation carries prolific and well-preserved Lower Devonian fauna. Present report is study of Haragan articulate brachiopods.

Type section: SE¼NE¼ sec. 20, T. 2 S., R. 3 E., Carter County. Named for exposures on Haragan Creek.

Harbison Meta-Granodiorite

Age not stated: Northern South Carolina.

S. D. Heron and J. W. Clarke, 1958, South Carolina Div. Geology Mineral Industries Lab. Bull. 2, no. 10, p. 69–75. Medium-gray meta-granodiorite characterized by small phenocrysts of feldspar embedded in fine-grained ground mass. Surrounding rocks are felsic varieties of Carolina slate.

Occurs in small pluton, mostly in Irmo quadrangle, near Columbia. Named for occurrence in Harbison State Forest.

Harbison Quartz Diorite[1]

Late Mesozoic: Southern California.

Original reference: W. J. Miller, 1935, Calif. Jour. Mines and Geology, v. 31, no. 2, p. 115–141, map.

W. J. Miller, 1946, Geol. Soc. America Bull., no. 5, table 4. Shown in plutonic sequence as younger than Alpine quartz diorite and older than Descanso granodiorites.

Type is in north part of Harbison Canyon, Peninsular Range, San Diego and Imperial Counties.

Harbor Hill Stade, Drift

Harbor Hill Substage[1]

Pleistocene (Wisconsin): Southeastern New York.

Original reference: J. B. Woodworth, 1901, New York State Mus. Bull. 48, pl. 1, map.

U.S. Geological Survey currently recognizes the term Harbor Hill Drift for till and associated outwash from Harbor Hill moraine.

Named for the fact that gravels occur at Harborhill, near Roslyn, Long Island.

Hardesty Shale[1]

Pennsylvanian: Eastern Kansas, northwestern Missouri, and southeastern Nebraska.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. 6th Ann. Field Conf. Guidebook, p. 93, 97.

Derivation of name not stated.

Hardgrave Sandstone[1]

Lower Jurassic: Northern California.

Original reference: J. S. Diller, 1892, Geol. Soc. America Bull., v. 3, p. 370–394.

E. D. McKee and others, 1956, U.S. Geol. Survey Misc. Geol. Inv. Map 1–175. Age shown as Lower Jurassic.

Named for exposures on Hardgrave's Ranch, near Taylorsville, Plumas County.

Hardgrave Tuff[1]

Middle Jurassic: Northern California.

Original reference: C. H. Crickmay, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 81.

Mount Jura.

Hardin Sandstone Member (of Chattanooga Shale)[1]

Hardin Sandstone Member (of Dowelltown Formation)

Upper Devonian: Western Tennessee and northern Alabama.

Original reference: J. M. Safford and J. B. Killebrew, 1900, Elements of geology of Tennessee, p. 104, 136, 137.

Guy Campbell, 1946, Geol. Soc. America Bull., v. 57, no. 9, p. 881, 891, 892, 894. Basal member of Dowelltown formation (new). Fine-grained gray to black sandstone that weathers yellow or brown. Reaches maximum thickness of 16 feet in vicinity of Olive Hill and from there thins in all directions; 2 feet at Iron City, southwest Lawrence County; 1 to 3 feet in southern Hardin County; 1½ to 3 feet along Tennessee River; 7 to 10 feet northward from Olive Hill to near Wayne-Perry County line and eastward to Forty Eight Creek. Where the Hardin has been certainly identified, a conglomeratic base has never been mentioned.

W. H. Hass, 1956, U.S. Geol. Survey Prof. Paper 286, p. 15–16. Basal member of Chattanooga shale; underlies Dowelltown member. As much as 16 feet thick and consists chiefly of siliceous fine-grained sand and silt. Early Late Devonian although some part may be slightly older. Geographic extent and good exposures noted. Ulrich and Bassler (1926, U.S. Natl. Mus. Proc., v. 68, art. 12) considered Hardin to be widespread deposit of Mississippian age. They described conodonts collected from sandstone at Mount Pleasant, Tenn., and identified bed as Hardin sandstone. Believed now that sandstone bed from which Ulrich and Bassler's (1926) conodont fauna came is neither same age as Hardin sandstone member of present report nor of early Mississippian age.

Named for Hardin County, Tenn. Part of widespread basal sandstone of Chattanooga and restricted to vicinity of Wayne, Perry, Lawrence, and Hardin Counties, Tenn., and adjoining part of Alabama. Well exposed along secondary road by stone church, 0.15 mile south of U.S. Highway 64 at Olive Hill, Hardin County, Tenn.

Harding Sandstone[1] or **Quartzite**

Harding Formation

Middle Ordovician: Central Colorado.

Original reference: C. D. Walcott, 1892, Geol. Soc. America Bull., v. 3, p. 154–167.

Ogden Tweto, 1949, Colorado Soc. Proc., v. 15, no. 4, p. 152 (table 1), 166–169. Harding quartzite, in Pando area, unconformably overlies Peerless formation and unconformably underlies Parting quartzite member of Chaffee formation. Tan, white, and greenish quartzite and some greenish sandstone.

W. C. Sweet, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 2, p. 284–305. Referred to as formation, dominantly fine-grained sandstone.

Thickness in Harding quarry section 120 feet; in Priest Canyon section 157 feet; maximum thickness 186 feet, 2½ miles north of Cotopaxi in Fremont County. On regional basis, overlies Manitou dolomite, but, in all sections south of Priest Canyon, rests directly on Precambrian; in Harding quarry section, overlies Precambrian Idaho Springs. Underlies Fremont formation.

M. G. Dings and C. S. Robinson, 1957, U.S. Geol. Survey Prof. Paper 289, p. 12–13. In Garfield quadrangle, 10 to 38 feet thick and extends entire length of belt of Paleozoic rocks. Almost entirely quartzite, white, pink, brown, gray, or bluish black. Unconformably overlies Manitou dolomite and unconformably underlies Fremont dolomite.

Named for exposures in Harding quarry, 1 mile northwest of State Penitentiary, at Canon City, Fremont County. Quarry now one of several pits operated under name of Bernite Gannister Quarries.

Hardinsburg Sandstone[1]

Hardinsburg Formation (in Stephensport Group)

Hardinsburg Sandstone (in Homberg Group)

Upper Mississippian (Chester Series): Western Kentucky, southern Illinois, southern Indiana, and northern Tennessee.

Original reference: A. D. Brokaw, 1916, Illinois Geol. Survey Extr. for Bull. 35; 1917, Illinois Geol. Survey Bull. 35.

J. M. Weller, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 131, 135, 136; J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 766 (fig. 1), 831–832. Assigned to Homberg group (new). Underlies Glen Dean limestone; unconformably overlies Golconda limestone. Absent from Chester section in Missouri.

A. C. McFarlan and others, 1955, Kentucky Geol. Survey, ser. 9, Bull. 16, p. 19. Overlies Haney (upper Golconda) limestone (new).

T. G. Perry and N. M. Smith, 1958, Indiana Geol. Survey Bull. 12, p. 26–27, pl. 1. Described in Indiana where it commonly consists of thin-bedded ripple-marked sandstone, shaly sandstone, and interbedded drab shale. Locally massive and crossbedded. Thickness 25 to 45 feet; complete sections rare. Underlies Glen Dean limestone; overlies Golconda formation. Term Homberg group not applied in Indiana.

H. H. Gray, R. D. Jenkins, and R. M. Weidman, 1960, Indiana Geol. Survey Bull. 20, p. 36 (table 5), 39, pl. 1. Formation included in Stephensport group (redefined). Consists mostly of gray shales, siltstones, and mudstones and in places includes thin-bedded fine-grained sandstones, some of which are ledge forming. Thickness ranges from 62 feet in area where Hardinsburg is mostly sandstone to 43 feet in drill hole in which formation is mostly shale. Overlies Golconda limestone (restricted) with transitional contact; underlies Glen Dean limestone.

Named for Hardinsburg, Breckinridge County, Ky.

Hardin School Limestone (in Wichita Group) [1]

Permian: Central Texas.

Original reference: F. M. Bullard and R. H. Cuyler, 1935, Texas Univ. Bull. 3501, p. 254–255.

Well exposed on hills just north and west of Hardin School, in southwestern part of Coleman County.

†Hardiston[1] or Hardistonville Quartzite[1]

Lower Cambrian: Northern New Jersey and northeastern Pennsylvania.

Original references: J. E. Wolff and A. H. Brooks, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 2, p. 442–443, 454–456; H. B. Kummel and S. Weller, 1901, Geol. Soc. America Bull., v. 12, p. 149–150.

Exposed at brook section in Hardistonville, Sussex County, N.J., and on hill 1 mile south of Hardistonville.

Hardman Fire Clay (in Allegheny Formation)[1]

Pennsylvanian: Northern West Virginia, western Maryland, and southwestern Pennsylvania.

Original reference: R. V. Hennen and D. B. Reger, 1913, West Virginia Geol. Survey Rept. Marion, Monongalia, and Taylor Counties, p. 347.

J. B. McCune and others, 1948, West Virginia Geol. Survey [Repts.], v. 18, p. 16. Hardman clay (Allegheny series) occurs few feet below Upper Kittanning underclay.

Henry Leighton, 1941, Pennsylvania Geol. Survey, 4th ser., Bull. M–23, p. 210. Noted in Somerset County.

First described near Hardman, Preston County, W. Va.

Hardscrabble Limestone

Mississippian: Eastern Colorado.

J. C. Maher, 1950, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 39; 1951, World Oil, v. 133 (Oct.), p. 89–91. Lower part of beds previously called Madison limestone along Front Range form lithologic unit bounded by unconformities. This unit here named Hardscrabble limestone. Characterized by light-buff to dark-brown, finely crystalline to dense limestone, upper layers of which contain red to orange dense chert and abundant medium-sized oolites. In Williams Canyon and Missouri Gulch, lower part of formation includes several beds of pink-gray-white dolomite and dolomitic limestone; tan to brown chert sparingly present locally; base marked by thin bed of conglomeratic limestone at South Hardscrabble and Beulah localities; spirifers common. Thickness at type locality 124 feet; 100 feet above Cave of the Winds; 41 feet in Missouri Gulch. Overlies Williams Canyon limestone; underlies Beulah limestone. Meramec(?).

Type locality: Almost vertical exposure on thrust block southwest of Wetmore on South Hardscrabble Creek about one-half mile west of North Creek Bridge in S½ sec. 11, T. 22 S., R. 69 W., Custer County.

Hardwick Granite[1]

Devonian: Northeastern Vermont.

Original reference: E. J. Foyles and C. H. Richardson, 1929, Vermont State Geologist 16th Rept., table opposite p. 288.

Quarried west of Hardwick, in Hardwick Township, Caledonia County.

Hardwick Granite[1]

Late Carboniferous or post-Carboniferous: Central Massachusetts and southwestern New Hampshire.

Original reference: B. K. Emerson, 1898, U.S. Geol. Survey Mon. 29, p. 239–241, 317–318, pl. 34.

Named for occurrence at and around Hardwick, Worcester County, Mass.

Hardwood Gneiss

Precambrian: Northern Michigan.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 27, 30 (table 1), 32. Dark medium-grained gneiss composed of hornblende, plagioclase, and pyroxene, which is interlayered with dark fine-grained gneiss, beds of light-colored gneiss with light and dark laminae, garnet-quartz-mica schist, and light-colored rock that resembles quartzite. Layers are a fraction of an inch to a few feet in thickness; layering in general dips easterly at angles less than 40°. Known thickness, including metagabbro sills, possibly no more than several hundred feet. Separated by covered interval from strata of Dickinson group (new); may be equivalent to or part of group but exposures are inadequate to establish relationship.

Exposed principally in secs. 5 and 8, T. 41 N., R. 27 W., Dickinson County, a short distance west of Harwood for which unit is named.

Hardwood Point Shales and Flags (in Lower Marshall Sandstone)

Mississippian (Kinderhook): Southern Michigan.

Shown on map legend: H. M. Martin, 1936, The centennial geologic map of the southern peninsula of Michigan (1:500,000): Michigan Geol. Survey Div. Pub. 39, Geol. Ser. 33.

Hardy Creek Limestone

Hardy Creek Limestone Member (of Moccasin Formation)

Middle Ordovician: Southwestern Virginia.

R. L. Miller and J. O. Fuller, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map. 76 (2 sheets); R. L. Miller and J. O. Fuller, 1954, Virginia Geol. Survey Bull. 71, p. 104–106. Hardy Creek limestone member proposed for upper part of Moccasin limestone. Consists of even-bedded limestone and siliceous limestone, with abundant oval chert nodules in some beds. Thickness 141 to 154 feet. Overlies lower unnamed member consisting of buff-weathering highly fossiliferous argillaceous and shaly limestone 138 to 143 feet thick. Underlies Eggleston limestone.

R. L. Miller and W. P. Brosgé, 1950, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 104 (2 sheets). Rank raised to formation. Overlies Ben Hur limestone (new).

R. L. Miller and W. P. Brosgé, 1954, U.S. Geol. Survey Bull. 990, p. 32 (table 1), 33–34, 58–61, 121–122, pl. 1. Further described and type section given. Discussion of correlation problems and summarizes nomenclature of Middle Ordovician formations in Lee and Tazewell Counties.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 65–66. Underlies Cane Creek limestone (new).

Type section: In cut of a spur of Louisville and Nashville Railroad along headquarters of Hardy Creek near Hagan, Lee County.

Hardy Hill Quartzite Member (of Orfordville Formation)

Middle Ordovician(?): Western New Hampshire and eastern Vermont.

C. A. Chapman and others, 1938, Geologic map and structure sections of the Mascoma quadrangle, New Hampshire (1:62,500); J. B. Hadley and others, 1938, Geologic map and structure sections of the New Hampshire portion of the Mount Cube quadrangle (1:62,500): New Hampshire Highway Dept. Consists of gray to white quartzite and quartz conglomerate with some quartz-mica schist and mica schist. Outcrops are discontinuous. Middle member of formation. Occurs above Post-Pond volcanic member and below Sunday Mountain volcanic member (both new). Middle Ordovician(?).

C. A. Chapman, 1939, Geol. Soc. America Bull., v. 50, no. 1, p. 132–133. Occurs in middle of black schists near top of Orfordville formation. Maximum thickness 250 feet.

J. B. Hadley, 1950, Vermont Geol. Survey Bull. 1, p. 12, 15. Geographically extended to Vermont. Ordovician.

J. B. Lyons, 1955, Geol. Soc. America Bull., v. 66, no. 1, p. 112, 114, 116, pl. 1. Assigned stratigraphically lower position in Orfordville formation; placed below Post Pond volcanic member.

Mapped in several narrow belts in vicinity of Hardy Hill Brook in northwestern corner of Mascoma quadrangle, New Hampshire.

Hardyston Quartzite[1]

Hardyston Formation

Lower Cambrian: Northern New Jersey and northeastern Pennsylvania.

Original reference: J. E. Wolff and A. H. Brooks, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 2, p. 442–443, 454–456.

B. L. Miller and P. B. Myers *in* B. L. Miller, D. M. Fraser, and R. L. Miller, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. C–48, p. 206–223, 227, pl. 1. In Northampton County, overlies Precambrian crystalline formations and underlies Tomstown formation (extended into this area as substitute for Leithsville).

B. F. Howell, Henry Roberts, and Bradford Willard, 1950, Geol. Soc. America Bull., v. 61, no. 12, p. 1361. Chickies quartzite used rather than Hardyston in Buckingham area, Pennsylvania. Hardyston reserved for those areas where Lower Cambrian quartzite can be closely correlated with type formation in New Jersey.

M. E. Johnson, 1950, Geologic map of New Jersey (1:250,000) : New Jersey Dept. Conserv. Econ. Devel. As mapped, underlies Cambro-Ordovician Kittattiny limestone.

Bradford Willard, 1955, Geol. Soc. America Bull., v. 66, no. 7, p. 821, 824–825, 826–827, 832. Base of Cambrian in eastern Pennsylvania. Thickness 25 to 300 feet. Underlies Leithsville formation with contact conformable at all but one locality where there is local disconformity; overlies Precambrian, contact changes from place to place but always nonconformable.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000) : Pennsylvania Geol. Survey, 4th ser. Mapped as Hardyston formation.

Named for exposures at Hardistonville (now Hardyston), Sussex County, N.J.

Harebell Formation

Upper Cretaceous; Northwestern Wyoming.

J. D. Love, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 8, p. 1899, 1900–1904. Succession of olive-drab to gray sandstone, conglomerate, claystone, and shale. Three facies present. In type area, lenses of quartzite pebble conglomerate present throughout sequence; in Blackrock Creek area quartzite pebble conglomerate lenses are in upper part; and in southernmost outcrops, conglomerate lenses are composed of rock fragments of Paleozoic and Mesozoic ages with lesser amounts of quartzite. Thickness about 5,000 feet in type area. Unconformable contacts with overlying Pinyon conglomerate and underlying Bacon Ridge sandstone.

Type locality: Extends from head of Snake River gorge southward over Big Game Ridge, about 2 miles east of Mount Hancock, and on across Wolverine Creek to north base of Pinyon Peak. Name derived from Harebell Creek, westward-flowing stream in Snake River drainage system along south margin of Yellowstone National Park. In Jackson Hole, Teton County.

Hares Valley Limestone and Shale Member (of Newton Hamilton Formation)

Middle Devonian: Central Pennsylvania.

F. M. Swain, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2860 (fig. 2), 2864 (fig. 3), 2865, 2867–2868. Interbedded shale and argillaceous limestone with limestone generally increasing upward in section. Thickness about 21 feet. Overlies Beaverdam Run shale member (new); underlies Marcellus black shale. Willard (1939) applied name Selinsgrove to upper noncherty "Onondaga" limestones of central Pennsylvania, but without specific statement as to type locality or typical section. I. C. White (1883) used name Selinsgrove for five different subdivisions of Middle Devonian. Name seems too indefinite to be used in Mount Union quadrangle. Name Hares Valley applied to upper shale and limestone of Newton Hamilton formation where it occurs north of mouth of Hares Valley at Mapleton.

Type section: In Dowell sand pit 1½ miles north of Mapleton, Mount Union quadrangle, Huntingdon County.

Harg Shale Member or facies (of Portwood Formation)

Upper Devonian: Eastern Kentucky.

Guy Campbell, 1946, Geol. Soc. America Bull., v. 57, no. 9, p. 862–863, 866. Proposed for the tripartite facies of Portwood (new) in area between Berea and Olympia. Lower division of Harg is greenish, gray, or bluish-black argillaceous shale, 2½ feet thick and associated with layers of limestone at Harg, but typically represented with thickness of 10 feet at Witt Schoolhouse; middle division is carbonaceous-calcareous shale, 9½ feet thick at Harg, 23 feet at Witt Schoolhouse, and 13 feet at Rice Station; upper division is stony light-gray argillaceous shale, its layers varying in hardness, 3 feet thick at Harg, 5½ feet at Rice Station. The three divisions seldom have same relative representation at any two localities. Different levels of Harg rest on the Hamilton and commonly a layer of limestone belonging to the Harg is basal layer of the New Albany. Considered coeval facies with Duffin dolomite, and Ravenna shale facies (new). Replaces the Duffin dolomite in area where former appears and is transitional between the Duffin and Ravenna. Underlies Trousdale shale.

Type section: In cut on Louisville and Nashville Railroad, one-half mile north of Harg, 6 miles northwest of Irvine, Estill County. Lower and middle division typically represented at Witt Schoolhouse; upper division well exposed at Rice Station; all three divisions occur together at Harg.

Hargett Sandstone (in Chester Group)[1]

Hargett Sandstone or Shale Member (of Alsobrook Formation)

Mississippian (Chester Series): Northeastern Mississippi.

Original reference: W. C. Morse, 1935, Mississippi Geol. Survey Bull. 26, p. 9, 10.

W.C. Morse, 1936, Mississippi Geol. Survey Bull. 32, p. 11. Listed as middle member of Alsobrook formation. Overlies unnamed limestone; underlies Cripple Deer sandstone or shale member. Chester series.

Occurs in Tishomingo County.

Harkers Fanglomerate (in Salt Lake Group)

Pliocene: Central northern Utah.

L. W. Slentz, 1955, Utah Geol. Soc. Guidebook 10, p. 23, 24 (fig. 6), 28–30. Salt Lake group, in Lower Jordan Valley, divided into (ascending) Traverse volcanics, Jordan Narrows unit, Camp Williams unit, Harkers fanglomerate, and Travertine unit. Fanglomerate, tan to gray, poorly consolidated; occasional channels and lenses of reddish silts; torrential bedding and cut and fill structure common. Thickness at least 300 feet. Within Jordan Narrows proper, fanglomerate is in fault contact with Camp Williams unit or overlies it unconformably. Exact relationship to Travertine unit unknown; may be contemporaneous.

A. J. Eardley, 1955. Utah Geol. Soc. Guidebook 10, fig. 9. Contemporaneous with Huntsville fanglomerate in Morgan Valley and Mink Creek conglomerate in Cache Valley.

Type locality: Harkers Canyon, which cuts through northern part of Oquirrh foothills just south of Bacchus, Salt Lake County. Lower Jordan Valley is defined as that part of Jordan Valley northward from Traverse Mountains to great Salt Lake.

Harkness Lavas, Basalts, Flows.

Cenozoic: Northern California.

Howel Williams, 1932, California Univ. Pub., Bull. Dept. Geol. Sci., v. 21, no. 8, p. 272–280. Earliest Harkness lavas are generally pale-gray massive andesitic basalts that weather to whitish crust and are rich in conspicuous phenocrysts of bright-yellowish-green augite. Nearer the vent, the later lavas usually darker, often purplish, weathering to pinkish crusts, and more vesicular, whereas in the crater rim the flows are almost black. Cinders forming summit cone are black and scoriaceous. Younger than flat-lying Saddle Mountain lavas (new).

Mount Harkness is in Plumas County in southeastern part of Lassen Volcanic National Park.

Harlan Sandstone

Harlan Formation

Harlan Sandstone (in Pottsville Group)[1]

Pennsylvanian: Southeastern Kentucky and southwestern Virginia.

Original reference: M. R. Campbell, 1893, U.S. Geol. Survey Bull. 111, p. 28, 31.

H. R. Wanless, 1946, Geol. Soc. America Mem. 13, p. 114–118, 142. Harlan sandstone (or formation) is uppermost division of Pennsylvanian in Black Mountains, Harlan and Letcher Counties, Ky., and Wise and Lee Counties, Va. Overlies Wise formation. Includes massive cliff-forming conglomeratic sandstone at base (probably Campbell's original Harlan sandstone). Base commonly stated to be 5 to 50 feet above High Splint coal. Although it contains shales and coals, the formation has commonly been called Harlan sandstone. May be lower Allegheny in age.

Named for Harlan County, Ky.

Harlem Clay (in Conemaugh Formation)[1]

Harlem clay or underclay member

Pennsylvanian (Conemaugh Series) : Eastern Ohio.

[Original reference] : Wilber Stout and others, 1923, Ohio Geol. Survey, 4th ser., Bull. 26, p. 458.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 71. Harlem clay included in Harlem cyclothem, Conemaugh series. Not recognized with certainty in area of report [Perry County]. Within the cyclothem, position of clay is below Harlem coal and above unit termed Harlem shale and (or) sandstone.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 95 (table 11), 133. Underclay member of Harlem cyclothem in report on Athens County. Average thickness 2¼ feet. Above Rock Riffle limestone member (new).

Named for association with Harlem coal.

Harlem cyclothem

Pennsylvanian (Conemaugh Series) : Southeastern Ohio.

N. K. Flint, 1949, Ohio Acad. Sci. [Guidebook] 24th Ann. Field Conf., p. 15. Incidental mention in road log.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 71–72, table 1, geol. map. Includes (ascending) Harlem shale and (or) sandstone, 25 feet; Harlem clay and coal (not recognized with certainty in Perry County) ; unnamed shale; and Ames limestone, 1 to 2½ feet. Occurs above Barton cyclothem and below an unnamed cyclothem. In area of this report, Conemaugh series is described on cyclothemic basis; seven cyclothems named. [For sequence see Mahoning cyclothem.]

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 95 (table 11), 129–134. In Athens County, comprises (ascending) Saltsburg, Round Knob, Rock Riffle, and Harlem members. In sequence, occurs above Upper Bakerstown cyclothem and below Ames cyclothem. In this report Conemaugh series described on cyclothemic basis; 15 cyclothems named, [For sequence see Mahoning cyclothem.]

Harlem Gneiss[1]

Precambrian : Southeastern New York.

Original reference : R. P. Stevens, 1867, New York Lyc. Nat. History Annals, v. 8, p. 116–120.

Along southern shore of Spuyten-Duyvel Creek and Harlem River, Manhattan Island.

Harlem shale and (or) sandstone member

See Harlem cyclothem.

Harlow Bridge Quartzite Member (of Cram Hill Formation)

Middle Ordovician : Central Vermont.

L. W. Currier and R. H. Jahns, 1941, Geol. Soc. America Bull., v. 52, no. 9, p. 1493, 1495. Buff to pale-green platy to massive quartzite beds with intercalated siliceous schists. Basal member of formation. Thickness approximately 300 to 800 feet. Overlies unnamed Ordovician (?) schists.

Type locality : Vicinity of large railroad bridge (Harlow Bridge) 2.4 miles south-southwest of Northfield, Barre quadrangle.

Harmon Formation (in Maysville Group)[1]

Upper Ordovician: Southeastern Indiana.

Original reference: E. R. Cumings and J. J. Galloway, 1913, Indiana Dept. Geology and Nat. Resources 37th Ann. Rept. p. 359.

Probably named from Harmon's Station, Dearborn County.

Harmon Hill Gneiss[1]

Precambrian: Southwestern Vermont.

Original reference: C. E. Gordon, 1914, Vermont State Geologist 9th Rept. p. 345, 349.

In vicinity of Bennington, Bennington region, Vermont.

Harmony Formation

Upper Cambrian: North-central Nevada.

R. J. Roberts, 1951, Geology of the Antler Peak quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–10]. Described as chiefly greenish-brown sandstone, arkose, grit, and green, red, or black shale, calcareous shale, and limestone. Lower beds interbedded sandstone, arkose, grit, and shale. Upper beds principally sandstone, shale, limy shale, and thin limestone beds. Thickness estimated to exceed 3,000 feet. In thrust contact with Scott Canyon, Comus, and Valmy formations; overlain unconformably by Battle formation. Mississippian(?).

H. G. Ferguson, S. W. Muller, and R. J. Roberts, 1951, Geology of the Winnemucca quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–11]. Thickness at type locality may exceed 5,000 feet.

R. J. Roberts and others, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2827–2828. Harmony formation, previously regarded as Mississippian(?) now known to be of latest Cambrian age. Determination based on trilobites.

Type locality: Harmony Canyon, Sonoma Range, Winnemucca quadrangle.

Harmony Hill Formation (in Ancell Group)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., p. 21, figs. 3, 12. Consists of green platy shale about 6 feet thick. Shown on columnar section as uppermost formation of Ancell group (new). Underlies Hennepin member (new) of Pecatonica formation; overlies Loughridge formation (new).

Occurs in Dixon-Oregon area.

Harmony Hills Tuff Member (of Quichapa Formation)

Oligocene: Southwestern Utah and eastern Nevada.

J. H. Mackin, 1960, Am. Jour. Sci., v. 258, no. 2, p. 90, 92 (fig. 2), 94–95. Uppermost member of formation. At type locality, overlies Bauers tuff member (new); underlies Rencher formation; elsewhere lava flows or other volcanic rocks, local in origin and extent, at contacts. Characteristically tan to light red brown. Only moderately indurated, but does not show signs of welding. May be an ignimbrite or may be an airfall tuff. Thickness 300 to 350 feet. Zircon age of Leach Canyon tuff member is 28 million years; this suggests that Quichapa formation is Oligocene. Discussion of ignimbrites of area.

E. F. Cook 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 138 (fig. 3). Geographically extended into eastern Nevada.

Type locality: Harmony Hills specifically south side of Right Quichapa Canyon, Mount Stoddard quadrangle, Iron Springs district, Utah.

Harney Formation[1]

Pliocene(?) : Southeastern Oregon.

A. M. Piper, 1936, Geol. Soc. Oregon County News Letter, v. 2, no. 8, p. 10. Includes massive basaltic tuff and breccia, sandstone and siltstone, and some incoherent gravel. Thickness about 750 feet. Overlies Danforth formation (new) with angular and erosional nonconformity; underlies an extensive plain of intermediate altitude in west-central part of Harney Basin. Outliers occur along all margins of central district except northern Pliocene(?).

A. M. Piper, T. W. Robinson, and C. F. Park, Jr., 1939, U.S. Geol. Survey Water-Supply Paper 841, p. 38–41, pl. 2. Detailed description. Thickness 468 feet at type section herein designated. [This is reference cited in Wilmarth Lexicon as "in press"].

W. D. Wilkinson, [1939], Geologic map of Round Mountain quadrangle, Oregon (1:96,000): Oregon Dept. Geology and Mineral Industries. Mapped in Round Mountain quadrangle, Crook County.

Type section: East face of Dog Mountain, along boundary between secs. 20 and 28, T. 25 S., R. 30 E., Harney County.

†Harney Granite[1]

Precambrian: Southwestern South Dakota.

Original reference: H. G. Ferguson and F. N. Turgeon, 1908, Harvard Coll. Mus. Comp. Zoology Bull., v. 49, p. 273–281.

Occurs in northern Black Hills.

Harney Peak Granite[1]

Precambrian: Southwestern South Dakota.

Original reference: C. R. Van Hise, 1898, Geol. Soc. America Bull., v. 9, p. 311.

G. L. Taylor, 1935, Am. Jour. Sci., 5th ser., v. 29, no. 171, p. 281. Dikes of Harney Peak fine-grained granite cut Game Lodge granite (new).

L. R. Page and others, 1953, U.S. Geol. Survey Prof. Paper 247, p. 6–7. Discussed in pegmatite investigations in Black Hills 1942–1945.

Present in Black Hills region.

Haro Formation[1]

Upper Triassic: Northwestern Washington.

Original reference: R. D. McLellan, 1927, Washington Univ. Pub. in Geology, v. 2, p. 93, 112–113.

Composes peninsula known as Davidson Head at northern extremity of San Juan Island.

Harold Formation

Pleistocene upper (?) : Southern California.

L. F. Noble, 1953, Geology of the Pearland quadrangle, California: U.S. Geol. Survey Geol. Quad. Map [GQ–24]. Well-stratified variable sequence of interbedded deposits; gravel, coarse arkosic sand with pink feldspar, in part lime-cemented and resembling travertine; buff sand and silt; whitish nodular marly clay in lower part of formation; brown gypsiferous clay beds locally at base of formation wherever it overlies gypsiferous Anaverde formation. Thickness generally 100 feet or less, 200 feet in some areas, but top is eroded. In some areas not easily differentiated from Nadeau gravel (new).

L. F. Noble, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–50. Described in Valyermo quadrangle where it underlies Shoemaker gravel (new). Formation gently folded; most dips less than 20°.

Type locality: Hills one-half mile southwest of San Andreas fault and 1 mile southeast of Harold Siding on Southern Pacific Railroad.

Harper Siltstone (in Nippewalla Group)

Harper Sandstone (in Cimarron Group)[1]

Harper Sandstone (in Nippewalla Group)

Permian: Central southern Kansas and northern Oklahoma.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 3, 18–20.

G. H. Norton, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 12, p. 1557. Includes (ascending) Ninnescah shale (new), Stone Corral, Chikaskia sandstone (new), and Kingman sandstone (new) members.

W. A. Ver Wiebe, 1937, Wichita Municipal Univ. Bull., v. 12, no. 5, p. 11. Typical Harper redbeds overlie Afton limestone member (new) of Wellington formation.

G. H. Norton, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 12, p. 1782–1786. Assigned to Nippewalla group (new) and restricted below to exclude Ninnescah shale and Stone Corral formations.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 159. Includes (ascending) Chikaskia member and Kingman sandstone member. Thickness about 220 feet. Overlies Stone Corral dolomite of Sumner group; underlies Salt Plain formation; northward is overlapped by Cenozoic rocks. Outcrops are in Harper, Kingman, Reno, and Rice Counties. Included in Nippewalla group, Leonard series.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Harper siltstone comprises (ascending) Chikaskia siltstone and Kingman siltstone members. Overlies Stone Corral formation; underlies Salt Plain siltstone. Nippewalla group.

Named for exposures in Harper County, Kans.

Harpers Shale[1] **Schist,**[1] **Slate,**[1] **Phyllite,**[1] **or Formation** (in Chilhowee Group)

Lower Cambrian(?): West Virginia, Maryland, southeastern Pennsylvania, and Virginia.

Original references: A. Keith, 1893, as reported by G. H. Williams and W. B. Clark, in Maryland, its resources, industries, and institutions, chap. 3, p. 68; 1894, U.S. Geol. Survey 14th Ann. Rept., pt. 2, p. 333–335, pls. 22–23.

G. W. Stose, 1906, Jour. Geology, v. 14, p. 207. In southern Pennsylvania, Harpers schist includes Montalto quartzite member (new).

P. B. King, 1950, U.S. Geol. Survey Prof. Paper 230, p. 15 (fig. 5), 19–20, pl. 1. Formation in Chilhowee group. In Elkton area, Virginia [this report], shale constitutes only small part of unit, remainder being largely siltstone and fine-grained sandstone; hence, unit designated as formation.

Thickness about 900 feet. Overlies Weverton formation; underlies Antietam quartzite.

D. M. Scotford, 1951, Geol. Soc. America Bull., v. 62, no. 1, p. 49–51, pl. 1. Discussion of structure of Sugarloaf Mountain area, Maryland. Phyllites of area, which have been considered volcanic members of Glenarm series (Stose and Stose, 1946) are Harpers phyllite. This conclusion based on structural evidence that local stratigraphic section is reverse of that previously reported—that is, anticlinal not synclinal. Stose and Stose divided this phyllite into Ijamsville and Urbana phyllites largely on basis of color and lack of calcareous bands in the Ijamsville. Although this division may be valid, it is difficult to map the contacts accurately and the Ijamsville and Urbana are herein considered part of the Harpers. Lower Cambrian age of Harpers is based on its position conformably below Antietam quartzite on Catoctin Mountain west of Sugarloaf area. Overlies Weverton quartzite.

A. J. Stose and G. W. Stose, 1951, Geol. Soc. America Bull., v. 62, no. 6, p. 697–699. Discussion of Scotford article. Stose and Stose reiterate their conclusions that Sugarloaf Mountain quartzite is synclinal and not anticlinal; the phyllites that surround the quartzite are not Harpers but phyllites of an eastern shale sequence containing volcanic flows and tuffs, which are Urbana and Ijamsville phyllites.

J. C. Whitaker, 1955, Geol. Soc. America Bull. v. 66, no. 4, p. 445–446. Studies indicate that Catoctin Mountain is not a syncline as previously interpreted but a tightly folded eastward-dipping sequence which forms upper and east limb of South Mountain anticlinorium. Strata formerly mapped as Loudoun along eastern border of Catoctin Mountain constitute a zone including upper Weverton quartzite and basal Harpers phyllite. The Harpers overlies Weverton quartzite in normal sequence along eastern slopes of Catoctin Mountain. Formation extends from northern end of area southward to 3 miles north of Leesburg, Va., where it is cut off by Triassic border fault. Underlies Antietam quartzite throughout most of area; between Thurmont and Mount St. Marys in northern Maryland, underlies Frederick limestone; just north of Potomac River, underlies Tomstown dolomite.

R. O. Bloomer and H. J. Wheeler, 1955, Geol. Soc. America Bull., v. 66, no. 5, p. 595–597, pl. 1. In Blue Ridge region, central Virginia, formation includes Snowden member (new). Transitional between Unicoi formation below and Antietam quartzite above. Thickness 800 to 1,200 feet.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Mapped as formation including Montalto member.

Named for exposures in gorges of Potomac and Shenandoah Rivers at Harpers Ferry, W. Va.

†Harpersville Formation (in Cisco Group)[1]

Pennsylvanian: Central and northern Texas.

Original reference: F. B. Plummer and R. C. Moore, 1921, Texas Univ. Bull. 2132; 1922, Jour. Geology, v. 30, p. 24, 31, 39.

Wallace Lee and others, 1938, Texas Univ. Bur. Econ. Geology Pub. 3801, p. 61–74, 128–132. In Brazos River valley, extends from top of Breckenridge limestone member of Thrifty formation to base of Pueblo formation, an interval of 233 feet. It is part of a chaotic series of thin limestones, relatively thin lenticular sandstone, variegated sandy and clay shales, and thin coals. This complex series of beds, interrupted by unconformities expressed in large and small channels, extends with progressive changes upward beyond limits of Harpersville to middle of Moran formation. Formation comprises (ascending) unnamed limestone and shale interval, Crystal Falls limestone, unnamed shale interval. "Upper Crystal Falls limestone," unnamed shale and limestone interval, Belknap limestone, unnamed interval, and Saddle Creek limestone. In Colorado River valley, includes Waldrip bed of Drake and Saddle Creek limestone member. Thickness 238 feet. Overlies Thrifty formation; underlies Pueblo formation.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 91. Term abandoned. Pennsylvanian-Permian boundary is placed at disconformity in Harpersville formation. This boundary is 40 to 150 feet below Saddle Creek limestone. Harpersville beds below boundary are assigned to Obregon (new) and Chaffin formation of Thrifty group; those above the systemic boundary to Saddle Creek formation of expanded Pueblo group.

F. B. Plummer and H. B. Bradley, 1949, Texas Univ. Bur. Econ. Geology Pub. 4915, p. 5–23. Three clays, Quinn, Curry, and Craddock, named in this report. The Quinn is described as next to lowest clay in the Harpersville as defined in report and map by Plummer and Moore (1921). Curry clay occurs between upper and lower layers of Crystal Falls limestone.

L. F. Brown, Jr., 1960, Texas Univ. Bur. Econ. Geology Rept. Inv. 41, p. 21–26, pl. 1. Discussion of lower part of Harpersville formation in Stephens County. Here includes (ascending) Quinn clay, Crystal Falls limestone, and Curry clay members.

Named for Harpersville, 10 miles south of Breckenridge, Stephens County.

†Harpeth Shale[1]

Mississippian: Central Tennessee.

Original reference: P. M. Jones, 1892, Geology of Nashville and immediate vicinity; Nashville, Tenn., Univ. Press, June 1892, p. 14.

Named from fine presentation in picturesque bluffs, along Big Harpeth River, in Cheatham County.

†Harpeth and Tennessee River Group[1]

Silurian and Devonian: Western Tennessee.

Original reference: J. M. Safford, 1851, Am. Jour. Sci., 2d, v. 12, p. 353, 357–358.

Named for Harpeth River, Cheatham and Dickson Counties.

Harpole Mesa Formation

Pleistocene: Southeastern Utah.

G. M. Richmond, 1956, Dissert. Abs., v. 16, no. 6, p. 1127–1128. Consists of three unnamed members, lower two of which comprise till, alluvial gravel, and eolian deposits. Upper member comprises eight lithofacies, including till and several kinds of alluvial, colluvial, and eolian deposits. Tills form sheetlike deposits on high interfluves and broad valley surfaces. Alluvial gravel of lower member trends across present canyons. Similar very strongly developed soils occur on each member. Rarely distinguishable, they are jointly called the Spring Draw soil. Older than Placer Creek formation (new).

Located in La Sal Mountains area.

Harrell Shale (in Susquehanna Group)

Harrell Shale (in Portage Group)[1]

Harrell Member (of Fort Littleton Formation)

Upper Devonian: Central Pennsylvania and West Virginia.

Original reference: C. Butts, 1918, Am. Jour. Sci., 4th ser., v. 46, p. 523, 532, 536.

Bradford Willard, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 201, 217–218. Restricted at base to exclude Burket black shale and rank reduced to member status in Fort Littleton formation. Underlies Brallier member of Fort Littleton.

H. P. Woodward, 1943, West Virginia Geol. Survey, v. 15, p. 390–412. Rock previously called "Genesee black shale" by Maryland and West Virginia Geological Surveys appears to be continuous extension of Harrell shale of Pennsylvania. Believed that Pennsylvania name appropriate for outcrops in West Virginia. Shale thinnest in Eastern Panhandle, where it is 5 to 20 feet thick, and wholly absent from easternmost sections. Thickens westward, being about 300 feet along U.S. Highway 50 near Hampshire-Mineral County boundary. Overlies Hamilton formation; underlies Brallier shale.

U.S. Geological Survey currently classifies the Harrell Shale as a formation in the Susquehanna Group on basis of a study now in progress.

Named for exposures at Harrell, Blair County, Pa.

Harriett Formation

Silurian: Western Ohio.

Wilber Stout, 1941, Ohio Geol. Survey, ser. 4, Bull. 42, p. 90–91. Name tentatively applied to a limestone 21 feet thick that occurs below Cedarville dolomite and above Lilley dolomite.

Occurs in Harlan Skeen quarry located on Sinking Spring-Hillsboro Road (Route 124), three-fourths of mile northeast of Harriett, 2 miles south of Marshall, Highland County.

Harriman Chert[1]

Harriman Formation

Lower Devonian: Western and central Tennessee.

Original reference: C. O. Dunbar, 1918, Am. Jour. Sci., 4th, v. 46, p. 747.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Age shown on correlation chart as Lower or Middle Devonian.

C. W. Wilson, Jr., Tennessee Div. Geology Bull. 56, p. 306–309, fig. 88. Harriman formation, locally referred to as Harriman limestone or Harriman chert depending upon phase represented, used to include both Dunbar's "Harriman novaculite and Quall limestone." The Quall considered unweathered phase of the Harriman. Formation consists of two contemporaneous lithologic phases of limestone and chert. Thickness 37 to 55 feet. Unconformably overlies Flat Gap limestone where present; elsewhere unconformably overlies either Ross limestone member or Birdsong shale member of Ross formation (new). Unconformably underlies Chattanooga shale, or, as in Decatur and Benton Counties, Camden formation.

Named for Harriman Creek, Decatur County. [Harriman Creek is called Herron Creek on Jeanette planimetric quadrangle, Tennessee Valley Authority, Wilson, p. 307.]

Harriman Shale Member (of Lykins Formation)

Permian: North-central Colorado.

L. W. LeRoy, 1946, Colorado School Mines Quart., v. 41, no. 2, p. 31–33. Name proposed to represent lowermost unit of Lykins formation. In Glennon Canyon, member consists primarily of red arenaceous thin-bedded shales and mudstones containing several thin layers of white massive fine to medium crystalline limestone in lower third. Limestone layers rarely exceed 6 inches in thickness and contain black brittle bituminous material along fractures and in minute vugs, Bituminous material also occurs sporadically throughout lower half of shale in thin discontinuous streaks along and transverse to bedding planes. Shales immediately adjacent to bituminous material are of bluish-green tints. Thickness 58 to 92 feet in area. Underlies Falcon limestone member (new); rests sharply on conglomeratic phase of Lyons formation.

Type section: In west tributary of Glennon Canyon, Golden-Morrison area, Jefferson County, where typically developed and well exposed. Named from Harriman irrigation canal, which receives water from Bear Creek at town of Morrison.

Harrington Formation[1]

Lower Triassic: Southwestern Utah.

Original reference: B. S. Butler, 1913, U.S. Geol. Survey Prof. Paper 80.

Type locality: Harrington-Hickory mine, southeast of Frisco district.

Harris Formation[1]

Miocene or Pliocene: Southern California.

C. F. Tolman, 1927, Econ. Geology, v. 22, no. 5, p. 459. Named in stratigraphic column. Described as massive diatomite 2,000 feet thick. Underlies Foxen formation and overlies Monterey formation.

W. P. Woodring and M. N. Bramlette, 1950, U.S. Geol. Survey Prof. Paper 222, p. 36. Harris formation is Sisquoc formation of current usage.

Occurs in Santa Maria district.

Harrisburg Coal Member (of Carbondale Formation)

Pennsylvanian: Southern and eastern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 34, 36, 47 (table 1), pl. 1. Assigned member status in Carbondale formation (redefined). In southern area, occurs above Hanover limestone member and below St. David limestone member; in eastern area, occurs above Summum coal (No. 4) member and below Herrin (No. 6) coal member. Coal named by Shaw and Savage (1912, U.S. Geol. Survey Geol. Atlas, Folio 185). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: In coal mines in vicinity of Harrisburg, Saline County.

Harrisburg Gypsiferous Member (of Kaibab Limestone)[1]

Permian: Southwestern Utah and northwestern Arizona.

Original reference: H. Bassler and J. B. Reeside, Jr., 1921, U.S. Geol. Survey Bull. 726–C, p. 90–92.

E. D. McKee, 1938, Carnegie Inst. Washington Pub. 492, p. 35. The α, or uppermost member of Kaibab, as described herein, has been referred to variously as the A member, the Super Aubrey, Bellerophon limestone, and Harrisburg gypsiferous member.

Named for occurrence in Harrisburg dome, 8 miles east of St. George, Washington County, Utah.

Harrisite Dolomite

Middle Silurian: Northwestern Utah.

F. W. Osterwald, 1953, U.S. Geol. Survey Trace Elements Inv. Rept. TEI-330, p. 105; M. H. Staatz and F. W. Osterwald, 1959, U.S. Geol. Survey Bull. 1069, p. 19 (fig. 2), 25–26, pl. 1. Massive dark-gray to black locally banded dolomite, containing as much as 20 percent black chert chiefly as nodules and discontinuous layers along the bedding; lower 10 feet has mottled appearance and is commonly limy. Thickness 110 to 174 feet. Overlies Bell Hill dolomite and underlies Lost Sheep dolomite (both new).

Type section: Steep west side of canyon 2,000 feet northeast of Harrisite mine, sec. 10, T. 13 S., R. 12 W., Juab County. Named for exposures that cap hill a short distance east of Harrisite mine.

Harrison Diorite[1]

Harrison Gneiss

Pre-Triassic: Southwestern Connecticut and southeastern New York.

Original reference: F. J. H. Merrill, 1898, New York State Mus. 15th Ann. Rept., v. 1, p. 30.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Redescribed as a dark-gray to greenish gneiss; composed of andesine, quartz, hornblende, and biotite. Augen structure locally present. Pre-Triassic.

Crops out extensively in town of Harrison, Westchester County, N.Y.

Harrison Formation

Harrison Member (of Pottsville Formation)[1]

Pennsylvanian: Southeastern Ohio.

Original references: W. Stout, 1916, Ohio Geol. Survey, 4th ser., Bull. 20, p. 481; 1927, Ohio Geol. Survey, 4th ser., Bull. 31, p. 67, 68.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 20–21, table 1. Rank raised to formation in Pottsville series. Harrison formation conforms with contour of post-Mississippian-pre-Pottsville erosion surface. Formation overlapped by various strata of lower Pottsville age from Anthony shale up to Massillon sandstone.

Named for deposits in Scioto County. Formerly worked for iron smelting at Harrison Furnace.

Harrison Sandstone (in Arikaree Group)

†Harrison Beds[1]

Harrison Formation (in Arikaree Group)

Harrison Member (of Arikaree Formation)

Miocene, lower: Western Nebraska, southern South Dakota, and eastern Wyoming.

Original reference: J. B. Hatcher, 1902, Am. Philos. Soc. Proc., v. 41, p. 117.

C. B. Schultz, 1938, Am. Jour. Sci., 5th ser., v. 35, no. 210, p. 442–443, 444. Formation considered uppermost unit in Arikaree group. Overlies Monroe Creek formation; underlies Marsland formation (new). Harrison used here as defined by Hatcher. Peterson (1906, Annals Carnegie Mus., v. 4) applied term "Lower Harrison" to the whole of the already named Harrison beds of Hatcher, and "Upper Harrison" was used for the overlying buff-colored deposits which Hatcher miscalled the Nebraska beds of Scott. This has resulted in much confusion of what constitutes the Harrison. "Upper Harrison" beds here named Marsland formation.

A. L. Lugn, 1938, Am. Jour. Sci., 5th ser., v. 36, no. 213, p. 226, 227; 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1252, 1253–1254. Thickness of formation 200 feet. Harrison here used as defined by Hatcher. Overlying Marsland formation not included in Harrison of Hatcher. Application of name "Upper Harrison" to these beds by Peterson and others in recent years is unfortunate as these beds (Marsland) have no close stratigraphic or faunal relation to true Harrison (in Hatcher sense) and are separated from underlying Harrison by most significant and important structural and erosional unconformity in western Nebraska.

H. J. Cook and J. T. Gregory, 1941, Jour. Paleontology, v. 15, no. 5, p. 549–552. Described fauna from "Upper Harrison." States that Marsland as defined by Schultz includes two separable formations—"Upper Harrison" and higher previously unnamed deposits. Marsland is restricted to deposits at type locality and, as thus restricted, is equivalent to unnamed beds between "Upper Harrison" and the Sheep Creek as shown in columnar section of region by Cook and Cook (1953, Nebraska Geol. Survey Paper 5). New name is not proposed for "Upper Harrison".

R. C. Cady and O. J. Scherer, 1946, U.S. Geol. Survey Water-Supply Paper 969, p. 22–26, pls. 1, 7. Described as sandstone in Box Butte County where it is 85 to 130 feet thick. Unconformably overlies Monroe Creek sandstone and underlies Marsland formation.

S. G. Collins, 1959, Geology of the Martin quadrangle, South Dakota (1:62,500): South Dakota Geol. Survey. Considered member of Arikaree formation in South Dakota. Consists of light-pink to brown or grayish-buff poorly consolidated mostly calcareous very fine sand and silt with discontinuous zones of calcareous concretionary nodules increasing in abundance upward; upper part contains thin zones of white limy sandstone and local lenses of garnetiferous sandstone. Thickness as much as 150 feet. Overlies Monroe Creek member; contact gradational and difficult to locate precisely. Underlies Valentine formation.

J. C. Harksen, 1960, Geology of the Sharps Corner quadrangle, South Dakota (1:62,500): South Dakota Geol. Survey. Formation in Arikaree group. Consists of up to 125 feet of massive gray, partly crossbedded, poorly consolidated fine to very fine sands. Includes "Rosebud" facies. Overlies Monroe Creek formation.

S. G. Collins, 1960, Geology of the Patricia quadrangle, South Dakota (1:62,500): South Dakota Geol. Survey. Formation in Arikaree group. Maximum thickness estimated to be 60 to 80 feet. Overlies Monroe Creek formation. On regional scale, the Harrison and Monroe Creek become less distinct as separable units eastward from source area; believed that there is little practical value in attempting to map them separately eastward from Patricia and Martin quadrangles. Underlies Ogallala group (Valentine formation).

Well exposed in bluffs of all small streams that head near summit of Pine Ridge in vicinity of Harrison, Sioux County, Nebr. Named from exposures in vicinity of Harrison, Sioux County, Nebr.

†Harrison Series[1]

Precambrian: Southern Idaho and northwestern Utah.

Original reference: A. L. Anderson, 1931, Idaho Bur. Mines and Geology Bull. 14, p. 24.

V. E. Peterson, 1942, Econ. Geology, v. 37, no. 6, p. 470, 471 (table 1). Geographically extended to Ashbrook mining district, Utah. Generalized stratigraphic section of Ashbrook district shows Harrison series below Cambrian(?) Sentinell quartzite.

Best exposed on flanks of Mount Harrison, Cassia County, Idaho.

Harrodsburg Formation or Limestone

†Harrodsburg Limestone (in Meramec Group)[1]

Lower Mississippian: Indiana and northern Kentucky.

Original reference: T. C. Hopkins and C. E. Siebenthal, 1897, Indiana Dept. Geology and Nat. Resources 21st Ann. Rept., p. 296.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 72–73, 75, 224, pl. 25. Harrodsburg limestone has become well established formation in Indiana since its introduction in 1897. Stockdale (1929, Indiana Acad. Sci. Proc., v. 38) divided unit into Upper Harrodsburg limestone and Lower Harrodsburg limestone consisting of (descending) Guthrie Creek, Leesville limestone, and Ramp Creek members. In Indiana from south side of Floyd County northward, there is lithologic contrast between top of Borden group and overlying Ramp Creek member; southward from Floyd County into Kentucky, cherty, impure limestone appears at successively lower horizons beneath upper boundary of Borden group until more than entire topmost Borden unit (Edwardsville of Indiana) is of siliceous calcareous facies identical with Ramp Creek member to north. Distinctive Warsaw fauna is feature of Upper Harrodsburg, which is pure limestone in most of southern Indiana. Hence basal Harrodsburg beds are placed with Borden group as part of uppermost unit herein named Muldraugh formation. "Upper" division referred to as Harrodsburg (restricted) formation in this report.

W. N. Melhorn and N. M. Smith, 1959, Indiana Geol. Survey Rept. Prog. 16, p. 8 (table 1), 14. Harrodsburg limestone, in Mount Carmel fault area, is 80 to 90 feet, and is divided into upper and lower units. Gradational into underlying Edwardsville formation through series of thin-bedded argillaceous limestones interbedded with layers of brown to blue-gray massive coarse-grained crinoidal limestone. Underlies Salem limestone.

Named for Harrodsburg, Monroe County, Ind.

Harshberger Limestone (in Conemaugh Formation)[1]

Pennsylvanian: Southwestern Pennsylvania.

Original reference: F. and W. G. Platt, 1877, Pennsylvania 2d Geol. Survey Rept. H_3, p. 222, 223, pl. 13.

Named for Harshberger quarries at Forwardstown, Somerset County.

Hart Limestone Member (of Stratford Formation[1] and Wichita Formation)

Permian: South-central Oklahoma.

Original reference: G. D. Morgan, 1924, [Oklahoma] Bur. Geology Bull. 2, p. 137–140.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Hart limestone is at base of Wichita formation in southwest and central southern part of state; is member of Stratford formation of Pontotoc group in Pontotoc, Garvin, and Murray Counties.

Named for typical development near village of Hart, western part of Pontotoc County.

Harter Shale Member (of Frankfort Formation)

Upper Ordovician (Cincinnatian): Central New York.

G. M. Kay, 1943, Am. Jour. Sci., v. 241, no. 10, p. 601 (fig. 3). Name appears on stratigraphic diagram. Overlies Utica formation.

Marshall Kay, 1953, New York State Mus. Bull. 347, p. 64–66. Lowest member of Frankfort formation. Consists of greenish-gray laminated claystone grading imperceptibly into black shale of underlying Utica formation with which it has been mapped. Shale weathers into small conchoidally fractured chips in contrast to more platy, larger fragments of the weathered Utica. Thin cross-laminated siltstones or fine quartz sandstones, similar to sandstones in Moyer member (new), present locally near top. Thickness about 100 feet. Underlies Hasenclever member (new) with sharply defined contact useful as a mapping horizon. Typical exposures described and derivation of name stated.

Typical exposures in ravine south of Harter Hill, located along east-central border of Utica quadrangle.

Hartford Clay[1]

Pleistocene, upper: Central Connecticut.

Original reference: R. F. Flint, 1933, Geol. Soc. America Bull., v. 44, no. 5, p. 965–987.

W. D. Urry, 1948, Am. Jour. Sci., v. 246, no. 11, p. 689–700. Age about 18,000 years. Determination made on basis of study of radium content in varved clays.

Occurs in vicinity of Hartford, Hartford County.

Hartford Limestone[1]

Pennsylvanian: Western-central Kentucky.

Original reference: C. J. Norwood, 1884, Kentucky Geol. Survey Repts. on western coal field, Ohio County, p. 174.

Probably named for Hartford, Ohio County.

Hartford Limestone Member (of Topeka Limestone)

†Hartford Limestone (in Shawnee Formation)[1]

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, and northwestern Missouri.

Original reference: M. Z. Kirk, 1896, Kansas Univ. Geol. Survey, v. 1, p. 80.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2035 (fig. 5); 1949, Kansas Geol. Survey Bull. 83, p. 142 (fig. 29), 162; F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 18. Hartford limestone member of Topeka formation. Underlies Iowa Point shale member, overlies Calhoun formation. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 21. Condra and Reed (1937, Nebraska Geol. Survey Bull. 11, 2d ser.) were uncertain regarding relation of the Hartford of southern Kansas to lower member of the Topeka in northeastern Kansas, southeastern Nebraska, northwestern Missouri, and southwestern Iowa so proposed name Wolf River for basal member of Topeka in this area. Nebraska Survey will drop name Wolf River if it proves to be correlative with the Hartford, which was loosely defined by Kirk (1896) and may have priority if it does not include beds of Du Bois, Iowa Point, and Wolf River age. Type locality stated.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 16–17, fig. 5. Commonly one bed of light- to blue-gray massive limestone; locally contains thin shale bed. Thickness 1 foot near Thurman, Fremont County; 0.5 foot near Howe, Adair County. Basal member of Topeka limestone; underlies Iowa Point shale member; overlies Calhoun shale. Called Wolf River in Nebraska.

H. G. O'Connor, 1960, Kansas Geol. Survey Bull. 148, pl. 1. In Douglas County, member is 6 to 8 feet thick and consists of two limestone beds separated by thin shale bed just below middle of member. Underlies Iowa Point Shale member; overlies Calhoun shale.

Type locality: Where member passes under Neosho River at Hartford, Coffee County, Kans. Well exposed just north of Hartford.

Hartford Hill Rhyolite Tuff

Oligocene(?): Western Nevada.

V. P. Gianella, 1934, Mining and Metallurgy, v. 15, no. 331, p. 299 (table 1). Name Hartford Hill rhyolite appears only on table. Miocene(?). Thickness 400 feet.

V. P. Gianella, 1936, Nevada Univ. Bull. 30, no. 9, p. 35 (table), 45–52. Described as biotite rhyolite with some quartz latite; occasional underlying lenses of dacite; in places rhyolite overlies fanglomerate or auriferous gravels. Exposures commonly buff to reddish-brown, although some dense glassy facies are lavender; usually light colored, commonly almost white on fresh surfaces. Attains thickness of 450 feet.

G. A. Thompson, 1956, U.S. Geol. Survey Bull. 1042–C, p. 50, pl. 3. Redescribed as light-pink to dull-purple vitric-crystal tuff, tuff-breccia, and welded tuff. Includes a few feet of conglomerate at its base on south slopes of Hartford Hill. Fragments of granitic and metamorphic rocks are common and, in a few places, constitute as much as 10 percent of the rock. Thickness at type locality about 1,000 feet. Some interbedding with overlying Alta formation. Type locality and geographic extent indicated.

Type locality: Hartford Hill, near Silver City. Extensively exposed in Comstock Lode district and south and southwest of Virginia City quadrangle.

Hartgrove Limestone Member (of Talpa Formation)[1]

Permian: Central Texas.

Original reference: W. Kramer, 1934, Am. Assoc. Petroleum Geologists Bull., v. 18, no. 12, p. 1579, 1582.

Named from exposure on Mack Hartgrove's Ranch, where it crops out 0.4 mile south of and 37 feet lower than the ground at Eugene Mays well, about 4.5 miles southeast of Paint Rock, Concho County.

Hartland Formation

Hartland Schist[1]

Paleozoic: Western Connecticut.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 96–100, map.

R. M. Gates, 1952, *in* R. M. Gates and W. C. Bradley, Connecticut Geol. Nat. History Survey Misc. Ser. 5. Termed a formation. Includes variety of rock types from mica quartzites to mica-quartz schists which are interlayered on scale of inches and feet. Locally characterized by crystals of garnet, staurolite, and kyanite. Color varies from metallic silvery gray to dark brownish black. Fine to coarse grained; very schistose to nearly massive. Individual beds few inches to 100 feet thick. Intruded by Mount Tom hornblende gneiss. Cambro-Ordovician.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Subdivided to include the Straits schist member. Age changed to pre-Triassic.

R. M. Gates, 1959, U.S. Geol. Survey Geol. Quad. Map GQ–121. Formation described and mapped in Roxbury quadrangle. Rock types in Hartland separated into three groups: group A, rocks composed of muscovite, biotite, quartz and feldspar without—or with subordinate—garnet staurolite, or kyanite; group B, rocks composed of micas, quartz, and feldspar with prominent garnet, staurolite, and kyanite; group C, various minor types. Intruded by Mount Tom hornblende gneiss. Stratigraphic position of Hartland uncertain. In the north, the Hartland forms east flank of Berkshire Hills, which are considered part of Precambrian core of Green Mountain anticlinorium, and must be Paleozoic in age. From Berkshire Hills southward, the Hartland separated from known Precambrian rocks to west by belt of marble or gneiss, or both, of unknown age—the Woodville marble of Rodgers and others (1956), and Waramung formation of Gates and Bradley (1952) respectively. Paleozoic.

M. H. Carr, 1960, Connecticut Geol. Nat. History Survey Quad. Rept. 9, p. 6–12, pl. 1. Described in Naugatuck quadrangle where it is divided into three parts arranged in probable order decreasing as follows: (1) The Straits schist member (2) undifferentiated Hartland (3) quartzitic member. In most places, intruded and interbanded with granites and granite gneisses of varied compositions. Occurs in belt west and south of Waterbury gneiss. Area here mapped as undifferentiated Hartland was formerly mapped as part of Prospect gneiss (Rice and Gregory, 1906). Prospect gneiss here restricted to dark-gray biotite augen gneiss and excludes interbanded schists which are considered to be part of undifferentiated Hartland. Prospect gneiss occurs between The Straits schist member and quartzitic member of Hartland. Orange phyllite is mapped to east of Hartland. Undifferentiated Hartland intruded by Ansonia granite. Pre-Triassic.

Named for development in Hartland [Township], Hartford County.

Hartland Shale Member (of Greenhorn Limestone)[1]

Upper Cretaceous: Western Kansas and southeastern Colorado.

Original reference: N. W. Bass, 1926, Kansas Geol. Survey Bull. 11, p. 33.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 25. Chalky shale, a few thin beds of chalky limestone and bentonite. Thickness 23 feet in Kearny County to 35 feet in Ellis County. Underlies Jetmore chalk member; overlies Lincoln limestone member.

T. G. McLaughlin, 1954, U.S. Geol. Survey Water-Supply Paper 1256, p. 115–116, 117 (fig. 42). In Baca County, Colo., consists almost entirely of light-gray chalky shale; locally contains one or more thin beds of dense chalky limestone and a few thin layers of bentonite. Thickness about 30 feet. Underlies Bridge Creek limestone member; overlies Lincoln limestone member.

Named for exposures along Arkansas River from a short distance west of Hartland, Kearney County, to Kendall, Hamilton County, Kans.

Hartley Augen Gneiss[1]

Precambrian: Northern Maryland and southeastern Pennsylvania.

Original reference: E. B. Knopf and A. I. Jonas, 1923, Am. Jour. Sci., 5th ser., v. 5, p. 43, 44.

Ernst Cloos, 1937, Maryland Geol. Survey [Rept.], v. 13, pt. 1, p. 80. Underlies and does not transgress Setters formation.

Named from outcrops at Hartley Mill on Long Green Creek, eastern Baltimore County, Md.

Hartley Shale and Sandstone (in Chinle Formation)

Upper Triassic: Southwestern Utah.

P. D. Proctor, 1953, Utah Geol. and Mineralog. Survey Bull. 44, p. 19, pl. 2. Predominantly deep red shales and lesser fine-grained sandstone beds mainly only a few inches in thickness. Towards top of section, small slumped areas in the red shales are indicative of salt which has been dissolved away. Minor gypsum also occurs in section. Thickness 280 feet. Prominent cliff-forming bed of arkosic sandstone at top of Hartley beds is 5–15 feet thick and weathers light brown to white. Underlies Fire Clay Hill bentonitic shale (new); overlies Shinarump formation.

Named from exposures measured northwest of Leeds Cemetery, Silver Reef (Harrisburg) Mining District, Washington County.

Hartline Chert

Upper Mississippian: Southern Illinois.

J. M. Weller, 1944, Illinois Geol. Survey Bull. 68, p. 99. Incidental mention.

J. M. Weller *in* J. M. Weller and G. E. Ekblaw, 1940, Illinois Geol. Survey Rept. Inv. 70, p. 7, 19–20. In Dongola quadrangle, consists of about 50 feet of massive gray novaculitic chert in well-defined beds 1 foot or more thick; chert appears to thin and change in character northwestward. Appears to unconformably overlie Springville shale; relation of Hartline to overlying beds not known because contact was not observed; general succession of strata in outcrops along bluff west of Ullin suggests that Hartline grades upward into cherty Osage limestone.

Well exposed in face of bluff west of Ullin in sec. 21, T. 14 S., R. 1 W., Dongola quadrangle, Union County.

Hartmann Limestone[1]

Hartmann Group

Middle Cambrian: Central northern Utah.

Original reference: James Gilluly, 1932, U.S. Geol. Survey Prof. Paper 173.

J. K. Rigby, 1959, Utah Geol. Soc. Guidebook 14, p. 14 (table 1), 17–21. Rank raised to group. In southern Oquirrh Mountain area, includes Teutonic limestone below, and Herkimer limestone above. Dagmar dolomite, which normally separates the Teutonic and Herkimer, not recognized in area. Constant difference in lithology used as contact. Overlies Ophir group; underlies Bowman limestone.

Named from exposures on western side of Hartmann Gulch (sometimes called Graveyard Gulch), just north of Ophir, Tooele County.

Hartridge Shale (in New River Group)

Hartridge Shale (in Pottsville Group)[1]

Pennsylvanian (Pottsville Series): Northern West Virginia.

Original reference: D. B. Reger, 1918, West Virginia Geol. Survey Rept. Barbour and Upshur Counties, p. 288.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey Greenbrier County, p. 216, 229. Dark to black argillaceous laminated shale containing plant fossils. Thickness as much as 5 feet. Underlies lower Guyandot sandstone; separated from underlying Welch sandstone by Sewell coal and unnamed shale interval. Included in New River group, Pottsville series.

Exposed at Hartridge, Randolph County.

Hart School Bed (in Moran Formation)[1]

Permian: Central northern Texas.

Original reference: F. B. Plummer and R. C. Moore, 1922, Texas Univ. Bull. 2132, p. 179, 180.

Crops out on road at Hart School, sec. 2969, T. E. and L. survey, 6 miles north of Putnam, Callahan County.

Hartselle Sandstone[1]

Upper Mississippian: Northern, central, and eastern Alabama.

Original reference: E. A. Smith, 1894, Alabama Geol. Survey geol. map of Alabama with explanatory chart.

S. W. Welch, 1958, U.S. Geol. Survey Oil and Gas Inv. Chart OC–58. In northwestern Alabama, overlies Green Hill member of Pride Mountain formation (both new); underlies Bangor limestone. Thickness about 140 feet in central Colbert County; thins eastward to 10 feet at Monte Sano, Madison County. Consists chiefly of fine-grained sandstone; a few beds of siltstone and shale present at most localities; asphaltic at many places. Contains marine fossils and plant fossils.

Named for exposures at Hartselle, Morgan County.

Hartshorne Sandstone[1] (in Krebs Group)

Pennsylvanian (Des Moines Series): Eastern Oklahoma and western Arkansas.

Original reference: J. A. Taff, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 3, p. 436.

M. C. Oakes and M. M. Knechtel, 1948, Oklahoma Geol. Survey Bull. 67, p. 21–26. Described in Haskell County where it is 100 to 200 feet thick, overlies Atoka formation and underlies McAlester formation. Two coal beds, Upper and Lower Hartshorne coals, associated with the sandstone. Common usage has placed upper boundary of formation at top of first sandstone below Upper Hartshorne coal. Hitherto unrecognized coalescence of the two coals, in northwestern Le Flore and Haskell Counties, requires redefinition of upper boundary of the Hartshorne; proposed here to include both coals in Hartshorne sandstone. Underlies McAlester formation; overlies Atoka formation.

M. C. Oakes, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 6, p. 1523, 1524. Basal formation in Krebs group (new).

E. W. Reed, S. L. Schoff, and C. C. Branson, 1955, Oklahoma Geol. Survey Bull. 72, p. 63–65. Described in Ottawa County. Proposed that name Hartshorne be that of the formation which embraces rocks from top of Atoka to top of Upper Hartshorne coal. At type locality, formation consists of Upper Hartshorne coal, "Hartshorne sandstone", Lower Hartshorne coal and underclay, and shale tongues locally developed between those members. Specific sandstone bed called Hartshorne is given its older but seldom used name, Tobusky sandstone (Chance, 1890). In Ottawa County, formation consists of rocks from top of Mississippian to top of Riverton coal, or where coal is absent, to base of Warner sandstone member of McAlester formation.

J. A. Reinemund and Walter Danilchik, 1957, U.S. Geol. Survey Oil and Gas Inv. Map OM–192. Described and mapped in Waldron quadrangle, Arkansas. As much as 270 feet thick. Consists dominantly of sandstone in lenticular beds that collectively form first continuous sandstone unit below Lower Hartshorne coal bed. Stratigraphic equivalence of Hartshorne in Waldron quadrangle with Hartshorne in Fort Smith district and western Oklahoma is in doubt. It is possible that the true Hartshorne is absent in Waldron quadrangle and that unit herein called Hartshorne is facies of sandstone elsewhere identified as upper part of Atoka. Overlies Atoka formation; underlies McAlester formation.

Named for exposures near Hartshorne, Pittsburg County, Okla.

Hartsville Limestone[1]

Silurian (Niagaran): Southeastern Indiana.

Original reference: J. A. Price, 1900, Indiana Dept. Geol. and Nat. Res. 24th Ann. Rept., p. 84–85.

Charles Schuchert, 1943, Stratigraphy of the eastern and central United States: New York, John Wiley & Sons, Inc., p. 582. Abandoned.

Named for Hartsville, Bartholomew County.

Hartville Formation[1]

Mississippian(?), Pennsylvanian, and Permian: Southwestern Wyoming.

Original reference: W. S. T. Smith and N. H. Darton, 1903, U.S. Geol. Survey Geol. Atlas, Folio 91.

G. E. Condra, E. C. Reed, and O. J. Scherer, 1940, Nebraska Geol. Survey Bull. 13, p. 2–5. Condra and Reed (1935, Nebraska Geol. Survey Paper No. 9) subdivided the Hartville into six divisions (I–VI, descending). These divisions are herein named: Fairbank formation (VI), Reclamation group (V), Roundtop group (IV), Hayden group (III), Meek group and Wendover group (II), Broom Creek group and Cassa group (I). Nomenclature problems of Hartville uplift discussed. Term Minnelusa has priority over Hartville.

R. L. Bates, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 10, p. 1986–1990. Smith (1903) applied name Hartville to rocks between Guernsey limestone below and Opeche shale above. Hartville as used in this report is restricted to exclude unit named Fairbank formation by Condra, Reed, and Scherer (1940). Thickness 1,123 feet in Sand Canyon, Platte County, Wyo. Early Permian (Wolfcamp), Pennsylvanian, and possibly Late Mississippian.

First described and mapped in area around Hartville.

Hartwell Sandstone[1]

Mississippian: Southern West Virginia.

Original reference: R. V. Hennen and R. M. Gawthrop, 1915, West Virginia Geol. Survey Rept. Wyoming and McDowell Counties, p. 244.

Exposed at Hartwell, McDowell County, and quarried one-half mile southeast of Hartwell.

Hartwell Sandstone[1]

Pennsylvanian: Western Arkansas.

Original reference: A. Winslow, 1896, New York Acad. Sci. Trans., v. 15, p. 51.

Derivation of name not known, but probably named for town of Hartwell, Madison County.

Hartwick dolomite[1]

Silurian (Niagaran): Central eastern Iowa.

Original reference: C. R. Keyes, 1912, Iowa Acad. Sci. Proc., v. 19, p. 149, 150.

Named for Hartwick, Poweshiek County.

Harvard Conglomerate Lentil (of Worcester Formation)[1]

Carboniferous: Eastern Massachusetts.

Original reference: W. O. Crosby, 1876, Rept. on geologic map of Massachusetts.

W. R. Hansen, 1956, U.S. Geol. Survey Bull. 1038, p. 1, 20–23, pl. 1. Reassigned to redefined Worcester formation. Lies at base of formation; underlies Vaughn Hills member (new). States type locality as designated by Emerson (1917).

Type locality: Pin Hill in town of Harvard, Worcester County.

†Harvard Granite[1]

Late Carboniferous: Massachusetts.

Original reference: B. K. Emerson, 1889, Geol. Soc. America Bull., v. 1, p. 560.

Harvest Home shale member[1]

Mississippian: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 134, table opposite p. 61.

Well exposed along Rock Creek, Greenwood Township, Crawford County, especially at Peterson's Falls on edge of which is located the Harvest Home Grove.

Harvey Conglomerate Lentil (in Sewell Formation)[1]

Harvey Sandstone (in New River Group)

Pennsylvanian (Pottsville Series): Southern West Virginia.

Original reference: M. R. Campbell, 1902, U.S. Geol. Survey Geol. Atlas, Folio 77.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey Greenbrier County, p. 216, 226. Harvey (conglomerate) sandstone 20 to 60 feet thick; medium to coarse grained grayish white or light brown; lenticular, its interval locally occupied in part or entirely by sandy shale. Underlies Iaeger sandstone; locally apparently coalesces with Guyandot sandstone, cutting out intervening Sandy Huff shale and Castle coal.

Named for exposure at village of Harvey (now Bolt post office) on headwaters of Marsh Fork of Coal River, Raleigh County.

Harveyville Shale Member (of Emporia Limestone)

Harveyville Shale (in Wabaunsee Group)[1]

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, southeastern Nebraska, and northern Oklahoma.

Original reference: G. E. Condra, 1935, Nebraska Geol. Survey Paper 8, p. 10.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1), 2276. Rank reduced to member status in Emporia limestone (redefined). Overlies Reading limestone member; underlies Elmont limestone member.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 57–58. Described in Pawnee County where it is 35 to 53 feet thick. Overlies Reading limestone member; underlies Elmont limestone member. Extends southward across Pawnee County into Payne County; southern extent not known.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 13, fig. 5. Geographically extended into southwestern Iowa where it is classified as formation in Wabaunsee group. Where exposed in Fremont County consists of gray shale in lower part, limy nodules near center, and brown shale in upper part. Thickness 3 feet. Underlies Elmont limestone; overlies Reading limestone.

Type locality: Near Harveyville, southeastern Wabaunsee County, Kans.; well exposed in sec. 25, T. 15 S., R. 13 E.

Hasenclever Sandstone Member (of Frankfort Formation)

Upper Ordovician (Cincinnatian): Central New York.

Marshall Kay, 1953, New York State Mus. Bull. 347, p. 64, 66. Name proposed for middle member of formation. Composed of finely cross-laminated buff-weathering thin-bedded fine sandstones and interbedded greenish shales. Shale occurring in beds a few inches to 1 foot or more thick normally comprises one-third to one-half of unit's total thickness of 40 feet. Sandstones similar to those in overlying Moyer member (new). Overlies Harter shale member (new) with sharply defined contact.

Typically exposed south of Harter Hill, located near east-central border of Utica quadrangle. Also occurs on Hasenclever Hill about 2 miles southwest of Harter Hill.

Haskell Limestone Member (of Stranger Formation)[1]

Haskell Limestone Member (of Cass Formation)

Pennsylvanian (Virgil Series): Eastern Kansas, northwestern Missouri, and southeastern Nebraska.

Original reference: R. C. Moore, 1931, Kansas Geol. Soc. 5th Ann. Field Conf. Guidebook, correlation chart.

R. C. Moore, 1949, Kansas Geol. Survey Bull. 83, p. 130 (fig. 24), 135. In Kansas, commonly 2 to 4 feet thick. Underlies Robbins shale member; overlies Vinland shale member.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. vii (fig. 3), 16, 17. In Missouri, overlies Vinland shale member and underlies Lawrence formation.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 29. In Nebraska, uppermost member of Cass formation. Overlies Little Pawnee shale member (new); underlies Robbins shale. Thickness 12 to 15 feet.

Type locality: On 15th St., NE¼ sec. 5, T. 13 S., R. 20 E., at eastern edge of Lawrence, Douglas County, Kans. Named from Haskell Institute.

Haskew Gypsum Member (of Blaine Formation)[1]

Permian (Leonard Series): Northwestern Oklahoma and southern Kansas.

Original reference: N. Evans, 1931, Am. Assoc. Petroleum Geologists Bull., v. 15, no. 4, p. 402–432.

G. H. Norton, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 12, p. 1798. Geographically extended into southern Kansas where it is about 1 foot thick and is exposed about 5 feet above Shimer gypsum member, red shales separating the beds.

A. J. Myers, 1959, Oklahoma Geol. Survey Bull. 80, p. 31–33. Uppermost member of Blaine. In Harper County, consists of 4 feet of gypsum underlain by 4 feet of brownish-red shale. Overlies Shimer member.

Named for exposures near old store known as Haskew Store, NE cor. sec. 2, T. 25 N., R. 19 W., Woodward County, Okla.

Hasmark Formation[1] or Dolomite

Upper Cambrian: Western Montana.

Original reference: F. C. Calkins and W. H. Emmons, 1913, U.S. Geol. Survey Prof. Paper 78.

Christina Lochman and Donald Duncan, 1944, Geol. Soc. America Spec. Paper 54, p. 13–14. Upper Cambrian section at Philipsburg correlated with section at Mount Helena and name Hasmark extended into area. Thickness about 500 feet. Underlies unit correlated with Red Lion formation.

W. T. Holser, 1950, Geol. Soc. America Bull., v. 61, no. 10, p. 1058 (table 1), 1061. Hasmark dolomite, in Philipsburg region, consists of limestone, light blue-gray to white weathering buff to white, aphanitic to fine-grained, massive; dolomitic. Average thickness about 900 feet, but thinning to 350 feet near intrusives. Overlies Silver Hill formation; underlies Red Lion formation.

L. L. Sloss and C. A. Moritz, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 10, p. 2140 (fig. 5), 2144–2145. Formation described in extreme southwestern Montana. Name has priority over term Maurice which is considered equivalent. Unit is as much as 242 feet thick. Underlies Red Lion formation and is transitional into underlying Park shale.

Named for abandoned settlement southeast of Philipsburg, Granite County.

Hastings Creek Formation[1] or Limestone

Lower Ordovician: Northwestern Vermont, and southeastern Quebec, Canada.

Original reference: H. W. McGerrigle, [1931], Vermont State Geologist 17th Rept., p. 182, 184, 185.

J. A. Dresser and T. C. Denis, 1944, Quebec Dept. Mines Geol. Rept. 20, v. 2, p. 396, 398–399. Overlies Morgan Corner[s] dolomite; underlies Naylor Ledge limestone. Thickness 315 feet. Phillipsburg series. Beekmantown.

Exposed from northern part of St. Albans quadrangle, Vermont, across the international border for about 20 miles into Quebec.

†Hatbox Tongue (of Chandler Formation)

Lower Cretaceous: Northern Alaska.

George Gryc, W. W. Patton, Jr., and T. G. Payne, 1951, Washington Acad. Sci. Jour., v. 41, no. 5, p. 164, figs. 2, 3. Lower part of nonmarine Chandler formation (new) and lies between marine Tuktu and Topagoruk members (new) of Umiat formation (new). Approximately 3,000 feet thick at type locality and wedges out northward.

R. L. Detterman *in* George Gryc and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 2, p. 237, fig. 4. Renamed the Killik tongue (new), and type locality changed because sequence is better exposed along Killik River than at Hatbox Mesa.

Type locality: Hatbox Mesa in Chandler River drainage, in northern Foothills section of Arctic Foothills province.

Hatch Shale Member (of West Falls Formation)

Hatch Formation (in Naples Group)

Hatch Shale[1]

Upper Devonian: Western and west-central New York.

Original reference: J. M. Clarke and D. D. Luther, 1903, New York State Mus. Bull. 69, p. 1005, map.

J. F. Pepper, Wallace de Witt, Jr., and G. W. Colton, 1956, U.S. Geol. Survey Oil and Gas Inv. Map OC–55. Luther (1903) applied name Hatch flags and shales to sequence of rocks below his Grimes sandstone and above his Rhinestreet shale. The sequence of rocks is here designated Hatch shale member of West Falls formation (new). Composed of medium-dark-gray and dark-gray silty shale containing many layers of even-bedded to crossbedded siltstones, ranging from laminae to beds 1½ feet thick, and some layers of black shale. Muddy limestone concretions and calcareous siltstone concretions present, mainly in lower part of member. Thickness about 160 feet at Calabogue Gulf; 342 feet in Conklin Gully on Hatch Hill; 370 feet in Big Gully; 400 feet in Urbana Glen. Underlies Grimes siltstone member; where Grimes is absent, Hatch cannot be distinguished from Gardeau shale member; overlies Rhinestreet shale member.

Wallace de Witt, Jr., and G. W. Colton, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2826. Hatch shale member can be traced from type exposures near Naples at south end of Canandaigua Lake eastward to vicinity of Van Etten, south of Cayuga Lake. Hatch constitutes much of lower part of Cayuta shale member of Chemung formation (Williams, 1906) in area around Van Etten.

R. G. Sutton, 1960, New York State Mus. Bull. 380, p. 11, 19–20. Uppermost formation in Naples group. Overlies Rhinestreet black shale; underlies Grimes sandstone.

Named for Hatch Hill, at Naples, Ontario County.

Hatchetigbee Formation (in Wilcox Group)[1]

Eocene, lower: Southern Alabama and eastern Mississippi.

Original reference: E. A. Smith and L. C. Johnson, 1887, U.S. Geol. Survey Bull. 43, p. 39–43.

M. V. Foster, 1940, Mississippi Geol. Survey Bull. 41, p. 14, 61–66. Lowe (1933, Mississippi Geol. Survey Bull. 25) described unconformity between lignitic sands and clay-shales of typical Hatchetigbee and thick red sand which immediately underlies the claystone in Mississippi and limited formation to that section lying between basal Claiborne sands and the Bashi. It is in latter sense that term has since been used in Mississippi. In Lauderdale County, composed of lignitic sands, sandy silts, and silty or sandy clays interbedded one with the other. Commonly, basal part of formation is more sandy than upper part. In some areas, separable into two members: an upper composed of clay-shale, including one well-developed lignite bed 1 to 2½ feet thick, and a lower member composed of relatively fine- or medium-grained sand locally grading down into coarse grit-bearing sand. Thickness 75 to 150 feet. Overlies Bashi formation; underlies Meridian formation.

F. S. MacNeil, 1944, Southeastern Geol. Soc. [Guidebook] 2d Field Trip, p. 27–28. Proposed that Hatchetigbee be expanded to include Bashi marl at base.

F. S. MacNeil, 1946, U.S. Geol. Survey Strategic Minerals Inv. Prelim. Rept. 3–195, p. 21–22. Uppermost formation of Wilcox group in Alabama. At type locality is a fossiliferous exposure at crest of Hatchetigbee anticline, downdip from main outcrop. Unfossiliferous along main outcrop above Bashi marl member (restricted to exclude sands, shales, and lignites included in Tuscahoma sand). Thickness about 150 feet in western Alabama; thins to east to less than 15 feet at Chattahoochee River. Overlies Tuscahoma sand.

R. J. Hughes, Jr., 1958, Mississippi Geol. Survey Bull. 84, p. 178–188, pls. 1, 5. Described in Kemper County, where it consists of fine-grained gray and olive sands and brown or chocolate-colored carbonaceous clays more or less interbedded and containing lignite seams. Bashi marl member is primarily a glauconitic sand containing fossil prints. Thickness about 100 feet. Overlies Tuscahoma sand. Wilcox group. Historical summary of usage of name.

P. E. LaMoreaux and L. D. Toulmin, 1959, Alabama Geol. Survey County Rept. 4, p. 19–22, 141–145, pls. Described in Wilcox County, Ala., where it is about 250 feet thick. Includes Bashi marl member at base. Overlies Tuscahoma sand; underlies Tallahatta formation.

Named for exposures at Hatchetigbee Bluff, on Tombigbee River, in sec. 16, T. 18 N., R. 1 W., Washington County, Ala.

Hatchet Mountain Formation

Eocene, upper: Southwestern Washington.

M. H. Pease, Jr., and Linn Hoover, 1957, U.S. Geol. Survey Oil and Gas Inv. Map OM–188. Named on correlation chart. Overlies Cowlitz formation; underlies Toutle formation (new). Name credited to A. E. Roberts (in press).

A. E. Roberts, 1958, U.S. Geol. Survey Bull. 1062, p. 12 (chart), 19–24, pl. 1. Consists of lava flows, flow breccias, pyroclastic rocks, and tuffaceous sedimentary rocks. Thickness more than 2,750 feet. Overlies Cowlitz formation; unconformably underlies Toutle formation.

Typically exposed in vicinity of Hatchet Mountain in secs. 30 and 31, T. 11 N., R. 2 E., and secs. 25 and 26, T. 11 N., R. 1 E., Toledo-Castle Rock district. Exposed along both flanks of Napavine syncline.

Hatch Hill Formation

Upper Cambrian: Eastern New York.

George Theokritoff, 1959, New England Intercollegiate Geol. Conf. Guidebook 51st Ann. Mtg., p. 53, 55. Applied to unit consisting of sooty-black pyritic rusty-weathering shales interbedded with rotten-weathering bluish dolomitic sandstones. Locally crossbedded and characteristically traversed by numerous quartz veins. Overlies West Castleton formation; underlies Lower Ordovician Poultney formation. Contains graptolite fauna considered to be Upper Cambrian.

Type locality: Western flank of Hatch Hill in Thorn Hill quadrangle, Washington County.

Hat Creek Basalt

Recent: Northern California.

C. A. Anderson, 1940, Am. Jour. Sci., v. 238, no. 7, p. 477–492. Name applied to basalt erupted along a line of north-south fissures north of Lassen Peak.

Occurs in Hat Creek valley about 10 miles north-northeast of Lassen Peak.

Hat Creek Beds[1]

Oligocene, middle: Wyoming.

Original reference: H. F. Osborn, 1918, Am. Mus. Nat. History Mem., new ser., v. 2, pt. 1, p. 11.

Hathaway Formation

Middle Ordovician: Northwestern Vermont.

David Hawley, 1957, Geol. Soc. America Bull., v. 68, no. 1, p. 58, 68–77. Includes argillite and bedded radiolarian cherts, commonly intensely deformed, with included small fragments to large blocks of quartz sandstone, coarse graywacke, dolomite, limestone, and chert. Considered a submarine slide breccia. Thickness more than 100 feet. Overlies Iberville formation.

Named for Hathaway Point on southeastern St. Albans Point, St. Albans quadrangle. Also exposed on several nearby islands in Lake Champlain.

Hathaway Formation[1]

Pliocene, lower(?): Southern California.

Original reference: F. E. Vaughan, 1922, California Univ. Pubs., Dept. Geol. Sci., v. 13, no. 9, p. 344, 375, 376–378, 384, map.

C. R. Allen, 1957, Geol. Soc. America Bull., v. 68, no. 3, p. 324 (fig. 2), 325 (table 1), 326–327, pls. 2, 3. Redefined and restricted to exclude sedimentary rocks north of Banning (included by Vaughan in original description). Paleontological evidence shows these rocks to be much younger than type Hathaway in Lion Canyon, and they are assigned tentatively to San Timoteo formation. As redefined, consists of two unnamed members: a lower, 1,100 feet thick, consisting of tan to light-gray arkosic sandstone with subordinate siltstone and lenticular beds of conglomerate; and an upper, 650 feet thick, consisting of massive conglomerate and breccia. Conformably underlies Imperial formation; map shows Hathaway in fault contact with San Gorgonio igneous-metamorphic complex. Type section designated.

Type section: In main branch of Lion Canyon, north of Cabazon, Riverside County. Named for Hathaway Creek, on and near which it is exposed.

Hato Puerco Tuff[1]

Upper Cretaceous(?): Puerto Rico.

Original reference: H. A. Meyerhoff and I. F. Smith, 1931, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 2, pt. 3, p. 272.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 36 (table 2), 40, 60 (table 7). Thickness 4,000 feet. Underlies Guaynabo formation; overlies Guzman formation. In some areas, the tuffs are in juxtaposition with Lower Cretaceous Río de la Plata series.

C. A. Kaye, 1959, U.S. Geol. Survey Prof. Paper 317–A, p. 7 (table), 9 (fig. 3), 10 (fig. 4), 11–12, pl. 2. Recognized in San Juan area, although Guzman formation does not outcrop, and Guaynabo is herein redefined. Consists characteristically of massive pyroclastic rocks with thick sections of flow rocks; some well-bedded to obscurely bedded tuffs, prevailingly green to dark blue. Shows somewhat higher degree of regional metamorphism than later rocks. No estimate of thickness made owing to massiveness of formation. Unit probably formed main mass of volcanic cone or complex. No fossils found. Meyerhoff and Smith thought entire older complex of Puerto Rico to be within Upper Cretaceous. Recent work has revealed that Paleocene or early Eocene faunas, as well as Late Cretaceous faunas occur in older complex (Kay, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 1). At present time, age of Hato Puerco is designated Late Cretaceous(?).

Named for Barrio Hato Puerco situated on Río Canovanillas midway between Barrio Guzman Abajo and Trujillo Bajo, Fajardo district.

Hatter Limestone, Formation, Group

Middle Ordovician: Central Pennsylvania.

L. C. Craig, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1964. In Cumberland Valley, Mercersburg limestone (new) is separated from Shippensburg limestone (new) by Hatter limestone and Snyder member of Benner limestone.

G. M. Kay, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1969. Dark siliceous limestone, 96 feet at type section. Underlies Loysburg formation. "Carlim group", Chazyan(?) series.

G. M. Kay, 1943, Econ. Geology, v. 38, no. 3, p. 191 (fig. 2), 193; 1944; Jour. Geology, v. 52, no. 1, p. 3 (fig. 2), 6–14. Subdivided into (ascending) Eyer, Grazier, and Hostler members (all new). Thickness 102 feet at Union Furnace. Overlies Clover member of Loysburg formation; underlies Snyder member of Benner limestone. Chazyan.

Marshall Kay, 1947, (abs.) Geol. Soc. America Bull., v. 58, no. 12, pt. 2, p. 1198–1199. Hatterian, lower part of Bolarian series (new), comprises in Virginia: Ward Cove, Peery, and Benbolt limestones; and in Pennsylvania: Eyer, Grazier, and Hostler limestones. In New York and Ontario, the Pamelia is thought to be facies of the higher Hatterian. Upper Bolarian is Hunterian (new).

Marshall Kay, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1406–1407. Rocks between Lincolnshire limestone, or in its absence, the Five Oaks or Clover calcilutite and top of Hostler, or correlated Benbolt limestone, form rather constant time-stratigraphic unit that loses older beds northward along east side of Allegheny synclinorium. Name Hatter was applied to rocks in this sequence in Pennsylvania as formational name. Subsequently the Hatter was divided into three members: Eyer, Grazier, and Hostler; these can be classed as formations in a group. About the same time, Ward Cove, Peery, and Benbolt formations were described in Tazewell County, Va., the first two assigned to Cliffield group. Relations of the two sequences were not considered; the three Virginia units were thought to be represented in the Hatter, though the lower incomplete. Proposed that Hatter be considered a group or subseries comprising rocks younger than post-Lincolnshire regional unconformity, and older than top of Hostler and Benbolt formations, though essentially synchronous. The Hatterian forms lower and older part of Bolarian series-epoch. Older than Hunterian group or subseries.

Marshall Kay, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 82. Name Hatter formation can be applied in Pendleton County, W. Va., to rocks between Lincolnshire and McGlone limestone (new) where it is not possible to recognize Ward Cove, Peery, and Benbolt formations; also referred to Hatterian stage. Bolarian series.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 7. Name Bolarian includes two divisions—Hatterian and Hunterian. These terms are unsatisfactory to show relationships as understood in this report. Hatter formation, whose time designation is Hatterian, appears to be same as Hunterian if, as shown in this report, the Hatter is equivalent to Ridley formation.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Mapped as Hatter formation.

Type section: Hatter Creek, north of Roaring Spring, Blair County, Pa.

Hatterian Subseries or Stage

See Hatter Limestone or Group.

Hattiesburg Clay[1]

Miocene, lower and middle: Coastal Plain of Alabama, Mississippi, Louisiana, and Texas.

Original reference: L. C. Johnson, 1893, Science, v. 21, p. 90–91.

F. S. MacNeil, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 29. Correlation chart of outcropping Tertiary formations of eastern Gulf region shows Hattiesburg clay above Catahoula sandstone and below Pascagoula clay. Exact equivalence of the Pascagoula and Hattiesburg clays with any of named formations of Florida has not been demonstrated.

Named for exposures at Hattiesburg, Forrest County, Miss.

Hatton Tuff Lentil (of Stanley Shale)[1]

Mississippian (Meramec): Southwestern Arkansas and southeastern Oklahoma.

Original reference: H. D. Miser, 1920, Geol. Soc. America Bull., v. 31, p. 125.

W. H. Hass, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 7, p. 1582. Paleontological evidence suggests that Hatton tuff is Meramec in age.

Well exposed in cut of Kansas City Southern Railway half a mile south of Hatton, Polk County, Ark.

Hauns Bridge Group[1]

Upper Devonian: Central Pennsylvania.

Original reference: I. C. White, 1885, Pennsylvania 2d Geol. Survey Rept. T_3, p. 92.

Named for 1,000-foot exposure at Hauns' Bridge in Juniata Township, Huntingdon County.

Haupu Formation (in Waimea Canyon Volcanic Series)

Haupu Volcanic Series

Pliocene(?): Kauai Island, Hawaii.

H. T. Stearns, 1946, Hawaii Div. Hydrography Bull. 8, p. 85 (table), 87. Composed of an extra-caldera or lower member of thin-bedded primitive-type olivine basalts dipping 8° to 15° away from central vent and an upper member of horizontal massive basalts filling a caldera 1½ miles across. Upper and lower members separated by partly exhumed fault scarp and talus breccia. Series is remains of independent volcano about 2,300 feet high on side of ancient Waimea volcano. Separated from underlying Waimea volcanic series by zone of weathering and from overlying Koloa series by angular erosional unconformity.

G. A. Macdonald, D. A. Davis, and D. C. Cox, 1954. Volcano Letter 526, p. 2; D. A. Davis and G. A. Macdonald in Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 87. Included in Waimea Canyon series. Caldera member designated Haupu formation; extra-caldera member unnamed. Maximum thickness formation 1,850 feet; base not exposed. Approximately coeval with Olokele formation (new) and later than most of Napali formation (new). Pliocene(?).

G. A. Macdonald, D. A. Davis, and D. C. Cox, 1960, Hawaii Div. Hydrography Bull. 13, p. 40–42, table facing p. 20, pl. 1. Haupu volcanic series (Stearns, 1946) herein restricted to rocks occupying small filled caldera in Haupu Ridge and named Haupu formation of Waimea Canyon volcanic series. Rocks of formation surrounded by lavas of Napali formation, and separated from them by buried caldera walls. Base not exposed; maximum exposed thickness 1,850 feet. Formation and filling of Haupu caldera believed to have taken place contemporaneously with eruption of upper portion of Napali formation, or Olokele formation. Probably Pliocene.

Type locality: Southern side of Haupu Ridge, between Haupu Peak and a point 0.3 mile east of Kamaulele Peak.

Havallah Formation

Pennsylvanian and Permian: North-central Nevada.

S. W. Muller, H. G. Ferguson, and R. J. Roberts, 1951, Geology of the Mount Tobin quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–7]; 1952, Geology of the Golconda quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–15]. Intertonguing chert, slate, and quartzite with some limestone lenses and quartzose grit; rare greenstone near base. Quartzite, light-brown, very fine and even-grained; locally crossbedded and conglomeratic near base. Limestone grades into calcareous slate or into coarse sandstone with calcareous matrix. Chert is evenly bedded, mostly light colored. Incomplete section at type locality exceeds 10,000 feet. Underlies Koipato formation with major angular unconformity and overlies Pumpernickel formation (new) with contact gradational. Permian(?) (Wolfcamp and possibly Leonard).

R. J. Roberts and others, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2824 (fig. 5), 2847–2848. Pennsylvanian and Permian.

Type locality: On ridge south of Hoffman Canyon in Tobin Range, Golconda quadrangle. Named for Havallah Range which is Indian name for Tobin Range (40th Parallel Atlas).

Havasu Member (of Muav Formation)

Lower and (or) Middle Cambrian: Northwestern Arizona.

E. D. McKee, 1945, Carnegie Inst. Washington Pub. 563, p. 14 (fig. 1), 29, 109–110. Variable in lithology, consisting of mottled, aphanitic limestone in places, and mottled, fine-grained dolomite elsewhere. In general, limestone forms lower beds and dolomite forms upper, but relative positions and amount of each type not constant. Much of the dolomite is red or pink, mottled with tan. Upper limit marked by group of thin carbonate beds. At type locality, forms sheer cliff overlying narrow bench marked by flat-pebble conglomerate. Thickness throughout most of Grand Canyon about 100 feet but in extreme western part averages closer to 120 feet. Top member of formation in Grand Canyon area; younger than Gateway Canyon member (new).

Type locality: Near mouth of Havasu Canyon, in Grand Canyon.

Havasupai sandstones (in Aubreyan series)[1]

Carbonic: Northern Arizona.

Original reference: C. [R.] Keyes, 1922, Pan-Am. Geologist, v. 38, p. 251, 336.

Charles Keyes, 1936, Pan-Am. Geologist, v. 66, no. 3, p. 215 (chart), 223. Overlies Huethawali limestone. Carbonic age.

Probably named for Havasupai Point. Best exposed in rim wall near Bass Camp, west of El Tovar, Grand Canyon.

Havensville Shale Member (of Wreford Limestone)[1]

Permian: Eastern Kansas and southeastern Nebraska.

Original reference: G. E. Condra and J. E. Upp, 1931, Nebraska Geol. Survey Bull. 6, 2d ser., p. 32.

D. E. Hattin, 1957, Kansas Geol. Survey Bull. 124, p. 39–43. Middle member of formation; overlies Threemile limestone member; underlies Schroyer limestone member. Condra and Upp (1931) state that thickness of Havensville at type locality is 18 to 19 feet, but 5 feet of shale and limestone at base is not definitely assigned to either the Threemile or the Havensville. These questioned beds are here included in Havensville. Also, at type locality, a limestone bed and overlying shale unit, both included as lower 3 feet of Schroyer limestone by Condra and Upp, are lithologically and paleontologically part of the Havensville. Thus, thickness of Havensville at type locality is 27 feet. Thickness varies from north to south across State; minimum thickness 1½ feet in Chase County.

Type locality: In cuts on Highway 63 about 2 miles south of Havensville, Pottawatomie County, Kans.

Haverhill Granodiorite

Upper Devonian(?): West-central New Hampshire.

J. B. Hadley and others, 1938, Geologic map and structure sections of the New Hampshire portion of the Mount Cube quadrangle (1:62,500): New Hampshire Highway Dept. Described as medium-grained white or gray granodiorite, locally weakly foliated. Included in New Hampshire magma series.

J. B. Hadley, 1942, Geol. Soc. America Bull., v. 53, no. 1, p. 143, 148, pl. 1. Consists of two small stocklike masses of biotite granodiorite in Mount Cube area. Slightly finer grained aplite dikes are associated with northern body. Represents latest intrusions of New Hampshire magma series in this area. Structurally and petrographically similar to larger body south of town of Haverhill in Woodsville quadrangle.

Exposed in western part of Orford Township, Grafton County.

Hawaiiloa Volcanics[1] (in Honolulu Volcanic Series)

Pleistocene, upper: Oahu Island, Hawaii.

Original reference: H. T. Stearns, 1935, Hawaii Div. Hydrography Bull. 1.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6. Océanie, fasc. 2. p. 87–88. Cinder cone and lava flow of melilite-nepheline basalt; lava appears to be subaerial. Flow more than 100 feet thick; cone 337 feet high above sea level, base not exposed. Unconformably underlies Ulupau tuff. Extent noted.

Named for Puu Hawaiiloa, cinder cone at source of flow. Covers about 0.75 square mile on western part of Mokapu Peninsula, on northeast coast of Oahu about 13 miles northwest of Makapuu Head.

Hawarden shale[1]

Upper Cretaceous: Northwestern Iowa.

Original reference: C. R. Keyes, 1912, Iowa Acad. Sci. Proc., v. 19, p. 148.

Probably named for Hawarden, Sioux County.

Hawi Volcanic Series

Pleistocene: Hawaii Island, Hawaii.

H. T. Stearns and G. A. Macdonald, 1946, Hawaii Div. Hydrography Bull. 9, p. 173 (table), 178–180; D. A. Davis and G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 88. Lavas chiefly oligoclase andesites with several flows of trachyte and one of andesine andesite. Flows 10 to 150 feet thick and average about 40 feet. Total thickness about 500 feet. Separated from underlying Pololu volcanic series (new) by erosional unconformity. Overlain by Pahala ash and overlapped by lavas of Hamakua volcanic series.

Type locality: Kohala Sugar Co. quarry at 400 feet altitude in Kumakua Gulch, near Hawi, on north slope of Kohala Mountains. Covers summit area and part of slopes of Kohala Mountains. Name derived from Hawi, main town on mountain.

Hawkeye Granite Gneiss

Hawkeye Granite[1]

Precambrian: Northern New York.

Original reference: W. J. Miller, 1919, Jour. Geology, v. 27, p. 29; 1919, Econ. Geology, v. 14, p. 512.

A. W. Postel, 1952, U.S. Geol. Survey Prof. Paper 237, p. 8–10, 37 (table), pl. 1. Termed granite gneiss. Has pronounced phacoidal texture; strongly foliated. Miller described Hawkeye granite as facies of his Lyon Mountain granite, but it is here considered to be an older separate unit. Interpreted as having been intruded into original Grenville series.

A. W. Postel, C. L. Dodson, and L. D. Carswell, 1956, U.S. Geol. Survey Geol. Quad Map GQ–63. Granite gneiss described and mapped in Loon Lake quadrangle. Commonly a dark-greenish coarse well-foliated phacoidal-textured rock composed of quartz and feldspar, with lesser amounts of pyroxene, hornblende, and biotite. In some areas, lacks planar foliation and is rod or pencil gneiss. Locally fresh rock is pink instead of greenish.

Named for exposures just east of Hawkeye post office. Clinton County. Forms major anticlinal bodies in Lyon Mountain quadrangle.

Hawkhill Formation

Eocene, middle: Northern California.

Ralph Stewart, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 34. Consists of four members: lower siltstone 110 feet thick, lower sandstone 160 feet thick, upper siltstone 650 feet thick, and upper concretionary fine sandstone 270 feet thick. Disconformable with underlying Cretaceous strata and with overlying Eocene strata referred to Domengine formation.

Type section: Exposed in roadcuts near Hawkhill in Mount Diablo Park on south side of Mount Diablo.

Hawkins Formation[1]

Pre-Jurassic(?): Central Washington.

Original reference: G. O. Smith, 1903, U.S. Geol. Survey Prof. Paper 19.

C. A. Lamey and P. E. Hotz, 1952, U.S. Geol. Survey Bull. 978–B, p. 30, pl. 9. Dark greenish-gray altered rock resembling greenstone. Pre-Jurassic(?).

R. C. Ellis, 1959, Dissert. Abs., v. 20, no. 3, p. 990. Rocks of Mount Stuart block, Dutch Miller Gap area, are exposed along east margin of map area and consist of Hawkins greenstone, Ingalls peridotite (new), and Mount Stuart granodiorite.

Makes up Hawkins Mountain, Mount Stuart quadrangle.

Hawkins limestone[1]

Cambrian: Southwestern New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257–259; 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 4, 8.

Exposed in Grant County.

Hawkins Limestone Member (of Chimneyhill Limestone)

Lower Silurian: South-central Oklahoma.

R. A. Maxwell, 1936, Northwestern Univ. Summ. of Doctoral Dissert., v. 4, p. 132, 133. Basal member of formation. Thin-bedded brown limestone as much as 9 feet thick. Underlies Keel limestone member (new); unconformably overlies Sylvan shale.

T. W. Amsden, 1957, Oklahoma Geol. Survey Circ. 44, p. 9. Replaced by name Ideal Quarry member; name Hawkins preoccupied. States Maxwell's type locality for Hawkins.

Type locality: NE¼ sec. 8, T. 2 N., R. 6 E., about one-fourth mile southeast of Chimneyhill Creek, Pontotoc County.

Hawkins Creek Member (of Modin Formation)

Upper Triassic: Northern California.

A. F. Sanborn, [1953], Stanford Univ. Abs. Dissert., v. 27, p. 436. Lowest member of formation. Underlies Devils Canyon member (new); overlies Brock shale.

A. F. Sanborn, 1960, California Div. Mines Spec. Rept. 63, p. 6, 9–10, pl. 1. Formal proposal of name. Consists of series of beds of volcanic material in form of conglomerate, agglomerate, volcanic breccia, and tuff. Maximum thickness about 900 feet. Underlies Devils Canyon member: overlies Brock shale.

Type area: Section in Devils Canyon beginning at contact with overlying Devils Canyon member about 1 mile west of confluence of Devils Canyon and Alder Creek, extending west along Devils Canyon to contact with Brock shale, Big Bend quadrangle. Shasta County. Named from exposures near head of Hawkins Creek in vicinity of Little Meadows.

Hawkins Point Clays[1]

Lower Cretaceous: Northeastern Maryland.

Original reference: L. F. Ward, 1895, U.S. Geol. Survey 15th Ann. Rept., p. 334.

Occur at Hawkins Point on lower Patapsco, where they form extensive cliff 40 feet high, with width along shore of nearly one-half mile toward Swan Creek, Anne Arundel County.

Hawley Schist[1]

Ordovician: Northwestern Massachusetts and southeastern Vermont.

Original references: B. K. Emerson, 1898, U.S. Geol. Survey Geol. Atlas, Folio 50; 1898, U.S. Geol. Survey Mon. 29, p. 163–171, pl. 34, map.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, pl. 2. Shown on correlation chart of east Vermont above Savoy formation and below Shaw Mountain formation.

Named for exposures in Hawley Township, Franklin County, Mass.

Hawleyville Granite Gneiss[1]

Precambrian (?): Western Connecticut.

Original reference: W. M. Agar, 1934, Am. Jour. Sci., 5th, v. 27, p. 355.

Northwest of Hawleyville, Fairfield County.

Hawpatch (glacial) Gravel and Sand[1]

Pleistocene: Southeastern Indiana.

Original reference: M. N. Elrod, 1882, Indiana Dept. Geol. and Nat. History 11th Ann. Rept., p. 156–158.

Occurs in Bartholomew County from Flat Rock River on northwest and Haw Creek on southeast, and reaches from White River bottoms to Shelby County.

Hawthorn Formation (in Alum Bluff Group)[1]

Hawthorn facies (of Alum Bluff Stage)

Miocene, lower and middle: Central northern, northern, and southern Florida, southern and southeastern Georgia, and South Carolina.

Original reference: W. H. Dall, 1892, U.S. Geol. Survey Bull. 84, p. 81–82, 107–112, 157, 158, 326.

C. W. Cooke, 1943, U.S. Geol. Survey Bull. 941, p. 89–98, pl. 1. Name Hawthorn here applied to widespread formation, to different part of which Veatch and Stephenson (1911, Georgia Geol. Survey Bull. 26) applied names Alum Bluff formation, Marks Head marl, and Altamaha (Lafayette) formation (part). Thickness about 300 feet; thickest near Florida line, from which it extends northward as thinning sheet. Supposed to lie conformably on Tampa limestone, but overlaps beyond the Tampa on Suwannee limestone, Flint River formation, Cooper marl, and Barnwell formation.

C. W. Cooke, 1945, Florida Geol. Survey Bull. 29, p. 144–161. Formation, in northern Florida, consists chiefly of gray phosphatic sand and lenses of green or gray fuller's earth. Probably lies conformably on Tampa limestone and unconformably on older formations. Merges westward into Chipola formation and probably includes equivalents of Shoal River formation; unconformably underlies Duplin marl.

H. S. Puri, 1953, Florida Geol. Survey Bull. 36, p. 39, 45. Considered lithofacies of Alum Bluff stage.

M. H. Bergendahl, 1956, U.S. Geol. Survey Bull. 1030–B, p. 69–73, pl. 1. Formation, as used in this report [De Soto and Hardee Counties], includes all marine rocks in central and southern peninsular Florida that are younger than Tampa limestone, of early Miocene age, but older than lowermost sediments of late Miocene age. Lower and middle Miocene.

C. W. Hendry, Jr., and J. E. Yon, Jr., 1958, Florida Geol. Survey Rept. Inv. 16, p. 29, 31–32, 34. Hawthorn referred to as a formation and as a facies of Alum Bluff stage. Facies overlies Chattahoochee facies of Tampa stage.

K. B. Ketner and L. J. McGreevy, 1959, U.S. Geol. Survey Bull. 1074–C, p. 65–71. Hawthorn of this report [area between Hernando and Hardee Counties] includes formation as described by Cooke (1945), middle Miocene rocks in hard-rock phosphate belt including those generally assigned to Alachua formation, and middle Miocene rocks in land-pebble phosphate district including noncalcareous rocks which have not always been distinguished from Bone Valley formation. Middle Miocene.

Named for exposures at Hawthorn, Alachua County, Fla.

†Hawthorne Formation[1]

See **Hawthorn Formation,** the approved spelling.

Hawxby Shale Member (of Onaga Shale)

Hawxby Shale[1] (in Admire Group)

Hawxby Shale Member (of Chicago Mound Formation)

Permian: Southeastern Nebraska and northeastern Kansas.

Original reference: R. C. Moore and G. E. Condra, 1932, Kansas Geol. Soc. 6th Ann. Field Conf., classification chart.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 37. Member of Chicago Mound formation (new). Underlies Falls City member; overlies Aspinwall member. Thickness 10 to 12 feet.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2273, 2274 (fig. 1). Reallocated to member status in Onaga shale (new). Overlies Aspinwall limestone member; underlies Falls City limestone.

Type locality: Hawxby Farm, SE¼ sec. 7, T. 4 N., R. 15 E., about 5 miles west of Nemaha, Nemaha County, Nebr.

†Haybro Formation (in Mesaverde Group)[1]

Upper Cretaceous: Northwestern Colorado.

Original reference: M. R. Campbell, 1931, Tentative correlation of named geologic units of Colorado, compiled by M. G. Wilmarth, U.S. Geol. Survey, separate chart.

Campbell report was not published. Name Haybro Formation appeared in bold face in Wilmarth Lexicon on basis of Wilmarth's correlation chart. Cobban and Reeside (1952, Geol. Soc. America Bull., v. 63, no. 10) used name Haybro Formation on Cretaceous correlation chart and cited Wilmarth Lexicon. U.S. Geological Survey has abandoned the name Haybro Formation.

Named for exposures at coal-mining village of Haybro, in Yampa coal field.

Hay Creek Formation[1]

Lower Cretaceous: Western South Dakota and northeastern Wyoming.

Original reference: W. P. Jenney, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 2, p. 593, fig. 122, map.

Probably named for Hay Creek, Crook County, Wyo., and Butte County, S. Dak.

Hayden Group

Pennsylvanian (Des Moines): Eastern Wyoming and southwestern South Dakota.

G. E. Condra, E. C. Reed, and O. J. Scherer, 1940, Nebraska Geol. Survey Bull. 13, p. 2 (fig. 2), 3, 22, 45, fig. 10. Consists mostly of dark-gray to black sandstones, shales, and dolomites. Some red sandstone. Comprises Division III of Hartville "formation" (Condra and Reed, 1935). Thickness 120 feet. Underlies Meek group (new); overlies Roundtop group (new).

Type locality: Hayden Cliff, sec. 22, T. 27 N., R. 66 W., Platte County, Wyo.

Hayden Branch Formation

Upper Pennsylvanian: Southwestern Indiana and southeastern Illinois.

C. A. Malott *in* K. A. Payne, 1937, Jour. Paleontology, v. 11, no. 4, p. 276, 277, 279. At type locality, includes 6 inches of underclay, 1 inch of coal, 1 inch of very fossiliferous soft gray shale containing ostracodes, and 6 inches of dark fossiliferous limestone with black phosphatic concretions that weather white. Separated from overlying Merom sandstone by an interval of shales and sandstones; separated from underlying Murphys Bluff sandstone (new) by 4 feet of gray shale.

Type locality: In north-central part of sec. 10, T. 8 N., R. 10 W., Turman Township, Sullivan County, Ind. Crops out in bed of Hayden Branch about 100 yards south of section-line road which crosses Hayden Branch about three-fourths mile east of town of Dodds Bridge.

†Hayden Gulch Sandstone Member (of Haybro Formation)[1]

Upper Cretaceous: Northwestern Colorado.

Original reference: M. R. Campbell, 1931, Tentative correlation of named geologic units of Colorado, compiled by M. G. Wilmarth, U.S. Geol. Survey, separate chart.

Campbell report was not published. Name Hayden Gulch Member appeared in bold face in Wilmarth Lexicon on basis of Wilmarth's correlation chart. Cobban and Reeside (1952, Geol. Soc. America Bull., v. 63, no. 10) used name Hayden Gulch on Cretaceous correlation chart, and cited Wilmarth Lexicon. U.S. Geological Survey has abandoned the terms Haybro Formation and Hayden Gulch Sandstone Member.

Named for exposures in Hayden Gulch, Yampa coal field.

Hayden Peak Latite[1]

Tertiary: Southern Colorado.

Original reference: H. B. Patton, 1916, Colorado Geol. Survey Bull. 9, p. 21–63.

J. W. Gabelman, 1953, Econ. Geology, v. 48, no. 3, p. 195, 196. In Greater Bonanza district, the volcanics in order of succession are Rawley andesite, Bonanza latite, Squirrel Gulch latite, Porphyry Peak rhyolite, and Bremer [Brewer] Creek latite. In South Bonanza district, the volcanic sequence is roughly the same except Porphyry Peak rhyolite is missing and Bonanza latite is replaced by Hayden Peak latite.

Occurs on summit of Hayden's Peak and North Hayden's Peak, Saguache County.

Hayes Canyon Member (of Devils Gate Limestone)

Middle and Upper Devonian: Central Nevada.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 49–50, 51, pl. 2. Made up mostly of thick-bedded limestones containing biostromes of corals. Basal bed is dark-gray oolitic argillaceous ostracod bearing limestone that in most places weathers to shades of pink. Upper 150 feet or so consist of limestone beds that average about a foot in thickness, many of which contain stringers or lenses of dark chert. Thickness 780 feet in northern part of Newark Mountain. Contact with underlying Meister member (new) marked by basal oolitic limestone bed. Boundary with overlying Pilot shale is sharp, but no evidence of unconformity at contact.

Well exposed along crest of Newark Mountain and named from Hayes Canyon, which drains west slope of Mountain, vicinity of Eureka, White Pine County.

Hayes River Beds[1]

Tertiary: Southern Alaska.

Original reference: J. E. Spurr, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 7, p. 172–173, 184.

Named for exposures along Hayes River near junction with Skwenta.

Hayfield Limestone[1]

Devonian or Carboniferous: Northwestern Pennsylvania.

Original reference: G. H. Chadwick, 1925, Geol. Soc. America Bull., v. 36, p. 463, 464.

Type locality: Hayfield Township, Crawford County.

Hayfield monothem[1]

Devonian or Carboniferous: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Palentology, v. 21, no. 71, p. 103, 116–119.

Hayfield Shale[1]

Devonian or Carboniferous: Northwestern Pennsylvania.

Original reference: G. H. Chadwick, 1923, Geol. Soc. America Bull., v. 34, p. 69.

Wallace de Witt, Jr., 1946, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 21. Name invalid because unit is found to be Bedford shale in present investigation; name Bedford has priority. Validity of included Littles Corners [Littles Corner] limestone as a unit questioned.

Type locality: In Hayfield Township, Crawford County.

Hay Flat Limestone (in Bisbee group)

Cretaceous (Albian): Southeastern Arizona.

A. A. Stoyanow, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 296, 297 (table). Consists of massive limestone. Younger than Mural limestone; older than Molly Gibson formation (new).

Hay Fork Beds[1]

Miocene: Northwestern California.

Original reference: J. S. Diller, 1902, U.S. Geol. Survey Bull. 196, p. 43–44.

Occurs near town of Hay Fork, Trinity County.

Hay Hollow Sandstone Lentil (in Tallant Formation)

Hay Hollow Sandstone Member (of Nelagoney Formation)[1]

Pennsylvanian (Missouri Series): Northeastern Oklahoma.

Original reference: M. I. Goldman and H. M. Robinson, 1920, U.S. Geol. Survey Bull. 686–Y, p. 362–363.

W. F. Tanner, 1956, Oklahoma Geol. Survey Circ. 40, p. 39. Reallocated to Tallant Formation. Described as a lens of little lateral extent near top of formation.

Named for occurrences along upper part of Hay Hollow in secs. 25 and 36, T. 28 N., R. 11 E., Osage County.

Haymaker Beds[1]

Upper Devonian: Western New York.

Original reference: G. H. Chadwick, 1934, Geol. Soc. America, Prel. list of titles and abstracts of papers to be offered at 47th Ann. Meeting, Rochester, N. Y., Dec. 27–29, 1934, p. 12.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown as uppermost unit in Chadakoin formation. Underlies Panama conglomerate; overlies Tanner Hill [Tanners Hill].

Occurs on Genesee-Olean meridian in Genesee River region.

Haymeadow Creek Member (of Trenton Formation)

Middle Ordovician: Northern Michigan.

R. C. Hussey, 1952, Michigan Dept. Conserv. Geol. Survey Div. Pub. 46, Geol. Ser. 39, p. 13, 14. Uppermost member of formation. Overlies Groos Quarry member (new) although actual contact not observed. Underlies Bills Creek beds and formerly considered basal part of them. Consists of shale that differs from typical Bills Creek shale in that it is darker and does not weather with light-gray surface.

Probably named for exposures along Haymeadow Creek, near Rapid River, Delta County.

Haymond Formation[1]

Lower Pennsylvanian: Western Texas.

Original reference: J. A. Udden, C. L. Baker, and E. Böse, 1916, Texas Univ. Bur. Econ. Geology and Tech. Bull. 44, p. 46.

P. B. King, 1937, U.S. Geol. Survey Prof. Paper 187, p. 64–73, pls. 10, 15, 16, 23, 24. Consists mostly of layers of sandstone and carbonaceous shale a fraction of an inch to several inches thick, in regular rhythmic alternation; there are a few thicker sandstone beds at long intervals, and near base some thick bodies of shale. Upper part contains thick layers of massive arkose, and in syncline east of Haymond station are several members of boulder-bearing mudstone as much as 150 feet thick. Thickness locally exceeds 3,000 feet. Overlies Dimple limestone; underlies Gaptank formation. No exposure known where there is complete and uninterrupted sequence from base to top.

R. C. Moore and M. L. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 3, p. 289 (fig. 1). Chart shows Haymond formation in Atokan or Derryan stage.

Named for exposures northwest and southeast of Haymond, Brewster County. Exposed in two synclines; both are broad and open but overturned and faulted on southeast.

Haynesville Formation

Upper Jurassic: Subsurface in Louisiana, Alabama, Arkansas, Mississippi, and Texas.

T. H. Philpott and R. T. Hazzard, 1949, *in* Shreveport Geol. Soc. Guidebook 17th Ann. Field Trip. fig. 5 (correlation chart). Shown on chart with basal Buckner member. Unconformable below Bossier formation; overlies Smackover formation.

L. A. Goebel, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 10, p. 1978–1979. Name proposed for red sands, shales, and anhydrite formerly included in basal part of Cotton Valley formation but separated from gray sands, silts, and variegated shales in upper part of that formation by major unconformity. Thickness varies from 400 feet in some wells to more than 2,000 feet as in Hunt Oil Co. No. 1, sec. 3, T. 23 N., R. 7 W., Claiborne Parish, La.

Type area; Wells in Haynesville oil field, northern Louisiana.

Haynies Limestone[1] Member (of Deer Creek Limestone)

Pennsylvanian (Virgil Series): Southwestern Iowa and southeastern Nebraska.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 40, 43, 49, 50.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 22. Underlies Burroak shale member; overlies Larsh shale member. [Not treated as a subdivision of Deer Creek by Kansas Geological Survey].

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 18. In Missouri, uppermost limestone of Deer Creek may include Haynies limestone member.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 17–18, fig. 5. Well exposed in outcrops and quarries near Pacific Junction, Mills County, where it is a single massive bed, dark-gray, argillaceous, and fossiliferous. Thickness 1 foot or less. Underlies Burroak shale; overlies Larsh shale. Where Haynies is absent Burroak and Larsh shales coalesce and are difficult to differentiate.

Type locality: In Missouri River bluffs southeast of Haynies Station, Mills County, Iowa.

Hay Ranch Formation

Pliocene, middle, to Pleistocene, middle: Northeastern Nevada.

Jerome Regnier, 1960, Geol. Soc. America Bull., v. 71, no. 8, p. 1191, 1199–1203. Consists of lake deposits of clay, vitric tuffs (mostly altered to zeolites), limestone, and tan tuffaceous siltstones and sandstones, which interfinger with conglomerates and fanglomerates. Except for northern part of valley, where it dips about 15° E., formation is essentially undisturbed. Overlain by extensive deeply dissected pediment Structural evidence indicates formation is thick. By correlating outcrops in southern part of area, a 420-foot section was measured. Overlies Carlin formation (new).

Named for Hay Ranch in NW¼ T. 29 N., R. 52 E., vicinity of Carlin. Covers most of floor of Pine Valley.

†Hays Limestone Member (of Niobrara Formation)[1]

Upper Cretaceous: Western Kansas and eastern Colorado.

Original reference: S. W. Williston, 1893, Kansas Acad. Sci. Trans., v. 13, p. 108–109.

Named for old Fort Hays, a well-known landmark in western Kansas.

Haystack Gypsum Member (of Blaine Gypsum)[1]

Permian: Southwestern Oklahoma.

Original reference: C. N. Gould, 1902, Oklahoma Geol. Survey 2d Bien. Rept., p. 42, 55.

G. L. Scott, Jr., and W. E. Ham, 1957, Oklahoma Geol. Survey Circ. 42, p. 17 (fig. 3), 21–22, pls. 1, 2. Described in Carter area where it is the lowermost gypsum member of the Blaine. Separated from overlying Cedartop gypsum member by shale unit; overlies unnamed shale unit at top of Flowerpot shale; this shale unit overlies Kiser gypsum which is here removed from the Blaine and reallocated to Flowerpot shale. Type locality noted.

Type locality: Haystack Butte, in sec. 23, T. 7 N., R. 23 W., about 6 miles west of Moravia, Greer County.

Haystack Rhyolite[1]

Devonian(?): Northeastern Maine.

Original reference: H. E. Gregory, 1900, U.S. Geol. Survey Bull. 165, p. 107–109, 153–156.

Probably named for Haystack Mountain, Aroostook County.

Hayward sandstone member[1]

Permian: Central northern Oklahoma.

Original reference: F. L. Aurin, H. G. Officer, and C. N. Gould, 1926, Am. Assoc. Petroleum Geoligists Bull., v. 10, p. 786–799.

Named for exposures at Hayward, Garfield County.

Hazel Sandstone[1] or Formation

Precambrian: Western Texas.

Original reference: E. T. Dumble, 1902, Texas Acad. Sci. Trans., v. 4, pt. 2, no. 6, p. 1–3.

P. B. King, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 144 (fig. 1), 145 (table), 148, 149–150. Restored to formal nomenclature. Millican formation (Richardson, 1914), divided into two formations and term Millican abandoned. Dumble's term Hazel sandstone is applied to upper of the two formations and Allamoore limestone is proposed for lower formation. Consists of conglomerate which passes upward into red sandstone. Thicknesses of conglomerate and sandstone not measured but estimated to be thousands of feet. At many places where conglomerate stands vertically it forms belts of outcrop nearly a mile wide (may be some duplication by folding). North of Hazel mine on Sierra Diablo escarpment exposed thickness of red sandstone is at least 2,000 feet, neither base nor top exposed. Succeeded by Van Horn sandstone.

P. B. King and P. T. Flawn, 1953, Texas Univ. Bur. Econ. Geology Pub. 5301, p. 23, 84–89. As used by Dumble, term Hazel was applied only to red sandstones, but since these are linked with conglomerate of almost equal volume term was extended to include conglomerate also. In this report, unit designated formation.

Named for Hazel mine, Diablo Mountains, El Paso County.

Hazel Slate (in Chilhowee Group)[1]

Precambrian: Western North Carolina and eastern Tennessee.

Original reference: Arthur Keith, 1895, U.S. Geol. Survey Geol. Atlas, Folio 16, p. 3.

P. B. King and others, 1958, Geol. Soc. America Bull., v. 69, no. 8, p. 958. Keith originally placed upper part of sequence here termed Great Smoky group in Hazel slate and Clingman conglomerate; these names now abandoned. Keith (1907, U.S. Geol. Survey Geol. Atlas, Folio 143) connected Hazel outcrops with those of Nantahala slate and assumed they were correlative. As mapped by Keith in northern Great Smoky Mountains, the Hazel corresponds to argillaceous rocks that are now placed in Anakeesta formation (new).

Named for outcrops on Hazel Creek, Swain County, N.C., on southern slope of Great Smoky Mountains.

Hazel Green Member (of Quimbys Mill Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., figs. 3, 9, 15C. Consists of massive whitish-weathering dolomite about 1 to 3 feet thick. Shown on columnar section as basal member of Quimbys Mill formation. Underlies Shullsburg member (new); overlies Everett member (new) of Nachusa formation (new).

Occurs in Dixon-Oregon area.

Hazelhurst [Formation]

Pleistocene: South Carolina and Middle Atlantic Coast.

G. E. Siple, 1957, Carolina Geol. Soc. Guidebook for South Carolina Coastal Plain Field Trip, Nov. 16–17, table 1, following p. 1. Name appears in list of Pleistocene formations. Occurs below Coharie formation.

Hazelton Group[1]

Jurassic(?): Southeastern Alaska, and British Columbia, Canada.

Original reference: W. W. Leach, 1910, Canada Geol. Survey Summ. Rept. 1909, p. 64.

F. M. Byers, Jr., and C. L. Sainsbury, 1956, U.S. Geol. Survey Bull. 1024–F, p. 126, pl. 13. Mapped in part of Hyder district.

Named for town of Hazelton, British Columbia. In Hyder district, Alaska.

Hazelton Bridge Formation

See Hazleton Bridge Formation.

Hazelwood Member (of Mifflin Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., figs. 3, 10, 16. Limestone, thick-bedded; dolomite, pure, nonshaly, medium-bedded. Thickness 5 to 7 feet. Shown on columnar section as underlying Briton member (new) and overlying Establishment member (new).

Occurs in Dixon-Oregon area.

†Hazlet Sands[1]

Upper Cretaceous: New Jersey.

Original reference: W. B. Clark, R. M. Bagg, and G. B. Shattuck, 1897, Geol. Soc. America Bull., v. 8, p. 315, 329.

Named for Hazlet, Monmouth County.

Hazleton Group[1]

Jurassic(?): Southeastern Alaska, and British Columbia, Canada.

See **Hazelton Group,** the correct spelling.

Hazleton Bridge Formation

Upper Pennsylvanian: Southwestern Indiana.

C. A. Malott, 1939, (abs.) Indiana Acad. Sci. Proc., v. 48, p. 114; 1947, v. 57, p. 130, 134, 135, 136 [1948]. Consists of 20 to 25 feet shale, locally containing one or more thin coals, a thin limestone, and black shale; locally fossiliferous. Underlies Dicksburg Hills sandstone (new); overlies Merom or Inglefield sandstone.

Type locality: At road level in White River bluff just south of White River bridge west of Hazleton on U. S. Highway, northern Gibson County.

Head Member (of Day Point Formation)

Middle Ordovician (Chazyan): Northwestern Vermont and northeastern New York.

Philip Oxley and Marshall Kay, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 4, p. 821, 824 (fig. 3), 825 (fig. 4), 826 (fig. 5), 844–845, geol. sections. Defined as 16 feet of dark-gray, greenish-tinged dense fine calcareous quartz sandstone to siltstone and interbedded silty argillite that disconformably overlies Bridport dolomite south of Scott Point, Isle La Motte; proportion of shaly argillite varies and is locally dominant. Thickness on Valcour Island 15 feet; on South Hero 11 feet. Near Vergennes, brown-weathering dolomite interbeds near base contrast with finer textured Bridport. Along Otter Creek 3 miles west of Ferrisburg, 3 feet of calcareous coarse quartz sandstone lies on an erosion surface on *Isoteloides*-bearing Bridport dolomite. Underlies Scott member (new).

Type locality: The Head, a bluff at south end of Isle La Motte, Vt.

Headquarters Granite[1]

Precambrian: Southwestern Oklahoma.

Original reference: C. H. Taylor, 1915, Oklahoma Geol. Survey Bull. 20.

C. A. Merritt, 1958, Oklahoma Geol. Survey Bull. 76, p. 28–33, pl. 1. Described in Lake Altus area as brownish-red finely crystalline granite containing local porphyritic phases. Geographically restricted to western part of Headquarters Mountain and to small hills north of mountain.

Probably named for occurrences near Headquarters Mountain, near Granite, Greer County.

Headquarters Schist[1] (in Snowy Range Series)

Precambrian: Southeastern Wyoming.

Original reference: E. Blackwelder, 1926, Geol. Soc. America Bull., v. 37, p. 620, 623, 627.

J. J. Runner, 1928, (abs.) Geol. Soc. America Bull., v. 39, no. 1, p. 202. Included in Snowy Range series (new).

R. S. Agatston, 1951, Wyoming Geol. Assoc. Guidebook 6th Ann. Field Conf., p. 130. Precambrian metamorphics consist of Anderson phyllite, Deep Lake metaquartzite, French slate, Heart metagraywacke, Headquarters schist. Nash marble series, Seminoe formation, and Towner greenstone.

Present in Medicine Bow Mountains, Headquarters Park located on outcrop.

Healing Springs Sandstone Member (of New Scotland Limestone)[1]

Healing Springs Sandstone

Lower Devonian: Central western Virginia and West Virginia.

Original reference: F. M. Swartz, 1930, U.S. Geol. Survey Prof. Paper 158–C.

P. H. Price and H. P. Woodward, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 11, p. 1986. South of latitude of Monterey, Va., the cherty New Scotland limestone apparently gives way to calcareous Healing Springs sandstone, which is well developed in Browns Mountain anticlinal area of Greenbrier County.

H. P. Woodward, 1943, West Virginia Geol. Survey [Rept.], v. 15, p. 89, pls. 10, 11. Healing Springs sandstone attains maximum thickness of 33 feet along Knapp Creek near Alvon, Greenbrier County. Because of general stratigraphic location the Healing Springs can be confused with Ridgeley sandstone of later age, or the older Clifton Forge member of the Keysers.

F. G. Lesure, 1957, Virginia Polytech. Inst. Bull., Engineering Expt. Sta. Ser. 118, p. 20 (table 2), 47–48. In Clifton Forge district overlies Coeymans limestone and underlies Licking Creek limestone, geographically extended into area to replace New Scotland and Becraft limestones as used by Butts (1940). Thickness as much as 25 feet.

Named for exposures in gap west of Healing Springs, Bath County, Va.

Healy Glaciation

Pleistocene: Central southern Alaska.

Clyde Wahrhaftig, 1953, *in* T. L. Péwé and others, U.S. Geol. Survey Circ. 289, p. 8, 13 (table 1); 1958, U. S. Geol. Survey Prof. Paper 293–A, p. 17–18, 32–33, pls. 2, 3, 5. Four distinct glacial advances separated by marked ice withdrawals recognized along Nenana River. Healy succeeded Dry Creek glaciation (new); preceded Riley Creek glaciation (new).

End moraine is prominent curved compound till-ridge. Modified lateral moraine ridges and patches of till, preserved on gentle sloping topography, identify position of upper surface of glacier. Outwash terrace about 470 feet above Nenana River near end moraine.

Moraine on terrace about 450 feet above Nenana River, 2 miles northeast of Healy, Nenana River valley area. Ice occupied U-shaped gorge between Healy and McKinley Park Railroad Station.

Heart Metagraywacke[1] (in Snowy Range Series)

Precambrian : Southeastern Wyoming.

Original reference: E. Blackwelder, 1926, Geol. Soc. America Bull., v. 37, p. 620, 623, 631.

J. J. Runner, 1928, (abs.) Geol. Soc. America Bull., v. 39, no. 1, p. 202. Included in Snowy Range series (new).

R. S. Agatston, 1951, Wyoming Geol. Assoc. Guidebook 6th Ann. Field Conf., p. 130. Precambrian metamorphics consist of Anderson phyllite, Deep Lake metaquartzite, French slate, Heart metagraywacke, Headquarters schist, Nash marble series, Seminoe formation, and Towner greenstone.

Present in Medicine Bow Mountains. Heart Lake is located on outcrop.

Heartwellville Schist[1]

Upper Cambrian(?) : Southwestern Vermont.

Original reference: G. D. Hubbard, 1924, Vermont State Geologist 14th Rept., p. 278–283, 291, 293, 315, map.

Named for fact that town of Heartwellville, Bennington quadrangle, lies on large area of the schist.

Heath Formation[1] **or Shale** (in Big Snowy Group)

Upper Mississippian : Central northern Montana.

Original reference : H. W. Scott, 1935, Geol. Soc. America Proc. 1934, p. 367.

E. S. Perry, 1937, Montana Bur. Mines and Geology Mem. 3, p. 16. In type locality, Big Snowy group comprises (ascending) Kibbey, Otter, and Heath formations. Consists of 450 feet of black petroliferous shale with sandstone lenses.

P. A. Mundt, 1956, Billings Geol. Soc. Guidebook 7th Ann. Field Conf., p. 46, 47; 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 8, p. 1918 (fig. 2), 1919–1920, 1923 (fig. 4). Upper limit of Heath formation as defined by Scott is not acceptable. Upper part of Scott's Heath includes prolific oil sands (Tyler sandstone), and unit is separated from lower nonsandy part of Heath by angular unconformity. Thus, Heath formation should be restricted to beds below the unconformity, and beds above, which were formerly included in the Heath, should be designated as separate unit and name Tyler (Freeman, 1922) is herein applied to this formation.

H. D. Hadley and P. J. Lewis, 1956, Billings Geol. Soc. Guidebook 7th Ann. Field Conf., p. 142. Underlies Cameron Creek formation (new).

L. S. Gardner, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 2, p. 333 (fig. 2), 334 (fig. 3), 335, 340–341, 346–347. In revision of Big Snowy group, Heath formation overlies the Otter and underlies Cameron Creek formation. Thickness, at composite standard section of revised Big

Snowy group, 423 feet. Reasons presented for not using Tyler formation in this classification.

R. P. Willis, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 1942 (fig. 2), 1943–1948. In this report, Heath considered uppermost formation in Big Snowy group. Overlies Otter formation and underlies Tyler formation. Faunal data indicate a late Mississippian (probably Chester) age.

Type section: On north flank of Big Snowy Mountains, in sec. 6, T. 12 N., R. 20 E.

Heber limestone[1]

Carboniferous: Utah.

Original reference: C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 37.

Derivation of name not stated.

Hebron Formation

Hebron Gneiss[1]

Hebron Quartz Schist

Pre-Pennsylvanian: Eastern Connecticut.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 115, 121, 122, 140, 142, map.

W. G. Foye, 1949, Connecticut Geol. Nat. History Survey Bull. 74, p. 73–76, pl. 1. Referred to as a quartz schist; discussed under heading of Hebron, or Paxton quartz schist. Was earlier mapped in part as Woodstock quartz schist. Age designated Precambrian or early Paleozoic.

E. N. Cameron and others, 1954, U.S. Geol. Survey Prof. Paper 255, p. 20, 21. Paleozoic(?).

J. W. Aitken, 1955, Connecticut Geol. Nat. History Survey Quad. Rept. 6, p. 9–10, 18–20. Termed a formation. Epidote amphibolite gneiss and skarn occurring along Hebron-Bolton boundary in Rockville quadrangle are here transferred from the Bolton to the Hebron.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Gneiss redefined to include following geographic phases: Hebron gneiss of original definition, Scotland schist, Woodstock quartz schist, and Pomfret phyllite. Derivation of name given.

Frederick Stugard, Jr., 1958, U.S. Geol. Survey Bull. 1042–Q, p. 619. East of Middle Haddam, has indefinite contact with Monson gneiss.

Named for town of Hebron, Tolland County.

Hecla Sandstone (in Allegheny Fomation)[1]

Pennsylvanian: Southeastern Ohio.

Original reference: E. Orton, 1884, Ohio Geol. Survey, v. 5, p. 96, 124, 128, 1025, 1026.

Probably named for Hecla, Lawrence County.

Hedgehog Trachyte[1]

Devonian(?): Northeastern Maine.

Original reference: H. E. Gregory, 1900, U.S. Geol. Survey Bull. 165, p. 109–110, 161–162.

Forms Hedgehog Mountain, Aroostook County.

Hedges Shale (in Pocono Group)[1]

Lower Mississippian: Northeastern West Virginia and western Maryland.

Original reference: G. W. Stose and C. K. Swartz, 1912, U.S. Geol. Survey Geol. Atlas, Folio 179.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (column 101). Shown on correlation chart as shale in Pocono group. Underlies Myers shale; overlies Purslane sandstone. Kinderhookian series.

C. B. Read, 1955, U.S. Geol. Survey Prof. Paper 263, p. 1. In Meadow Branch syncline, Maryland and West Virginia, the Pocono includes only Rockwell formation, Purslane sandstone, and Hedges shale.

Named for occurrence on Hedges Mountain, Berkeley County, W. Va.

Hedwig Breccia Member (of Esmeralda Formation)[1]

Miocene, upper: Central Nevada.

Original reference: H. G. Ferguson, 1924, U.S. Geol. Survey Bull. 723.

Crops out in vicinity of Hedwig claim, Manhattan district.

Heebner Shale Member (of Oread Limestone)[1]

Pennsylvanian (Virgil Series): Southeastern Nebraska, southwestern Iowa, eastern Kansas, and northwestern Missouri.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 32, 33, 37.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2035 (fig. 5); 1949, Kansas Geol. Survey Bull. 83, p. 126 (fig. 22), 148–149. Heebner shale member of Oread formation; underlies Plattsmouth member; overlies Leavenworth limestone member. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

T. L. Welp, L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 64, p. 418 (fig. 1), 419. Thickness about 3 feet in section measured near Winterset, Madison County.

H. G. O'Connor, 1960, Kansas Geol. Survey Bull. 148, p. 40–41, pl. 1. Thickness 5 to 8 feet in central and northern Douglas County; 14 to 18 feet in south-central part of county, south of Worden fault.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 22, fig. 5. Characteristically olive clay shale split near base by black fissile shale. Thickness 2½ feet in Cass County; 3 feet in Adair County; 5 feet in Montgomery County. Overlies Leavenworth limestone member; underlies Plattsmouth limestone member.

Type locality: Two and one-half miles west and 1½ miles north of Nehawka, Cass County, Nebr. Named for Heebner Farm and Creek.

Hefty Formation[1]

Precambrian: Northwestern Montana, and southern British Columbia, Canada.

Original reference: R. A. Daly, 1912, Canada Geol. Survey, Dept. Mines Mem. 38, map 2.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1881. Correlates with Singleshot member of Appekunny formation.

Mapped just west of Mount Hefty, Mont.

Heglar Canyon Member (of Wells Formation)

Pennsylvanian (Derryan) : Idaho.

H. J. Bissell, 1960. Am. Assoc. Petroleum Geologists Bull., v. 44, no. 8, p. 1427 (chart). Name appears on correlation chart accompanying preliminary statement on eastern Great Basin Permo-Pennsylvanian strata. Underlies Sublett member (new) ; overlies Calder Creek member (new).

Present in Sublett Mountains area.

Hegler Limestone Member (of Bell Canyon Formation)

Upper Permian (Guadalupe Series) : Western Texas and southern New Mexico.

P. B. King *in* A. K. Miller and W. M. Furnish, 1940, Geol. Soc. America Spec. Paper 26, p. 9. Incidental mention.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 582, 585 (fig. 7), pl. 2. Along foot of reef escarpment is a dark-gray lumpy, slabby limestone about 15 feet thick. In Delaware Mountains, straight-bedded, platy limestones occupy same position. Lies below Pinery limestone member; base of the Hegler marks lower boundary of formation; it is oldest bed to grade northwestward into the Capitan limestone. Overlies Manzanita limestone member of Cherry Canyon formation.

P. B. King, 1948, U.S. Geol. Survey Prof. Paper 215, p. 54–55, pl. 3 [1949]. In southeast part of southern Guadalupe Mountains, consists of 30 to 40 feet of dark-gray fine-grained limestone in beds a few inches thick, interbedded with platy sandstone. Mapped in New Mexico.

Named for Hegler Ranch, 6 miles east-northeast of Guadalupe Peak, near foot of Reef escarpment, Culberson County, Tex.

Heidlersburg Sandstone Member (of Gettysburg Shale)

Heidlersburg Member (of Gettysburg Shale)[1]

Upper Triassic: South-central Pennsylvania.

Original reference: G. W. Stose, 1929, U.S. Geol. Survey Geol. Atlas, Folio 225.

G. W. Stose and A. I. Jonas, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. C–67, p. 115–118. Gettysburg shale, in York County, comprises red shale and sandstone with (1) thick, lenticular zone in which are numerous beds of hard red pebbly arkosic sandstone and conglomerate, called Conewago conglomerate member, near base, (2) a zone in which hard gray and red sandstones and coarse conglomerate predominate, called Heidlersburg member, near middle, and (3) quartzose fanglomerate and limestone conglomerate at top. In type area, Adams County, the Gettysburg is predominantly red shale and sandstone with interbedded hard gray to white sandstones in Heidlersburg member and coarse fanglomerate. called Arendtsville fanglomerate lentil at top. Thickness of Heidlersburg 3,000 to 4,800 feet.

Named for exposures in vicinity of Heidlersburg, Adams County.

Heights Fanglomerate[1]

Quaternary : Southern California.

Original reference: F. E. Vaughan, 1922, Calif. Univ. Pub., Geol. Sci. Bull., v. 13, no. 9, p. 344, 392–393, map.

C. R. Allen, 1957, Geol. Soc. America Bull., v. 68, no. 3, p. 324 (fig. 2), 325 (table 1), 331–332, pl. 1, 2, 3. Described in western San Gorgonio Pass area as tan to dark-brown ill-sorted conglomerate, dominantly dark clasts of gneissic rock. Maximum thickness 500 feet. Unconformably overlies Cabezon fanglomerate.

Best exposures are on west wall of San Gorgonio Canyon. Named for Banning Heights, Riverside County.

Heiskell Shale[1]

Lower Ordovician: Northeastern Tennessee and southwestern Virginia.

Original reference: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, pl. 27.

C. E. Prouty, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 7, p. 1165. Type "Heiskell" appears to be part Benbolt and part Wardell. Ulrich did not define the Heiskell, and upper and lower limits cannot be definitely drawn. His application of the Heiskell at Speers Ferry, Va., indicates lower limit to be the "Holston" at Speers Ferry and upper limit to be the Bays (Moccasin). Because Bowen formation contains red claystone, like Moccasin claystone, Ulrich's basal Moccasin was most likely drawn below the Bowen which would then make the "Heiskell" equivalent to all the Benbolt, Gratton, and Wardell.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 66. Abandoned. Ulrich's (1911) reference is apparently only use of name. Shaly beds exposed in center of village of Heiskell contain fossils of the Benbolt formation; beds beneath are limestones and red beds. Thus, only rocks answering lithologically to Heiskell are Benbolt shales [of Middle Ordovician age]. Since name Heiskell was never established by definition or designation of type section, it cannot replace well-established and validly proposed name Benbolt.

Probably named for Heiskell, Knox County, Tenn.

Helderberg Group[1] or Limestone[1]

Lower Devonian: New York, western Maryland, New Jersey, eastern Pennsylvania, Virginia, and northern West Virginia.

Original reference: T. A. Conrad, 1839, New York Geol. Survey, v. 3, p. 62.

F. M. Swartz, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 29–91. Keyser limestone removed from group and assigned to Silurian. Units included in group: Coeymans limestone, New Scotland limestone, Mandata shale (new), Becraft limestone, and Port Ewen shale.

H. P. Woodward, 1943, West Virginia Geol. Survey, v. 15, p. 32–127. Group comprises (ascending) Keyser limestone, Coeymans limestone, New Scotland limestone, Port Ewen chert and shale, and Port Jervis limestone.

Ernst Cloos, 1951, Maryland Dept. Geology, Mines and Water Resources Washington County [Rept. 14], p. 81–85. In Maryland, Helderberg limestone comprises (ascending) Coeymans, New Scotland, and Becraft members. Overlies Keyser limestone; underlies Oriskany formation. Thickness 290 to 350 feet.

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 4, 13. Helderberg formation comprises (ascending) Mandata shale, New Scotland limestone, and Coeymans limestone members. Member units separable on faunal basis but not defined clearly enough for mapping purposes. Thickness 50 to 180 feet. Overlies Keyser formation; underlies Oriskany formation.

K. F. Bick, 1960, Virginia Div. Mineral Resources Rept. Inv. 1, p. 20–21, pl. 1. In Lexington quadrangle, group conformably overlies Keyser limestone and is conformably overlain by Ridgeley sandstone. Comprises (ascending) Coeymans, New Scotland, and Licking Creek limestones. Thickness 100 to 150 feet. Early Devonian (Ulsterian).

U.S. Geological Survey includes the following units in Helderberg Group: Alsen, Becraft, Coeymans, Kalkberg, Manlius, New Scotland, and Port Ewen.

Named for the fact that deposits form basal part of Helderberg Mountains in Albany County, N.Y.

Helderberg Stage

Lower Devonian: North America.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1732–1733, chart 4. Devonian is subdivided into nine stages. Group term Helderberg is elevated to stage rank. Helderberg is lowermost stage and is succeeded by Deerpark stage (new). Ulsterian series.

Helderbergian Series

Helderbergian[1] Period or Group

Lower Devonian: New York and adjacent areas.

[Original reference]: J. M. Clarke and Charles Schuchert, 1899, Science, new ser., v. 10, no. 259, p. 876, 877.

L. V. Rickard, 1955, New York State Geol. Assoc. Guidebook 21st Ann. Mtg., p. 7–8. Helderbergian series consists of nine formations, five of which are in central New York: Cobleskill, Rondout, Manlius, Coeymans, and Kalkberg. New Scotland (restricted), Becraft, Alsen, and Port Ewen not present in central New York.

L. V. Rickard, 1956, Dissert. Abs., v. 16, no. 1, p. 102. Base of Devonian system in New York apparently not at base of Coeymans limestone of eastern New York where it has been placed for many years. Proposed that term Helderberg be elevated to series rank. Revised Helderbergian series would include all Lower Devonian strata from base of Cobleskill to top of Port Ewen.

Helena Dolomite (in Missoula Group)

Helena Limestone[1] (in Piegan Group)

Precambrian (Belt Series): West-central Montana.

Original reference: C. D. Walcott, 1899, Geol. Soc. America Bull., v. 10, p. 199–215.

C. E. Erdmann, 1944, U.S. Geol. Survey Water-Supply Paper 866–B, p. 48. Upper member of Siyeh limestone known as Helena limestone in some localities.

D. A. Andrews, G. S. Lambert, and G. W. Stose, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 25, sheet 1. Limestone shown on map legend as part of Siyeh group.

C. P. Ross, 1949, (abs.) Washington Acad. Sci. Jour., v. 39, no. 3, p. 112. Where limestone is recognizable, which at present is only in vicinity of Helena, it is regarded as upper formation of Piegan group.

Adolph Knopf, 1950, Am. Mineralogist, v. 35, nos. 9–10, p. 837–838. Marysville stock surrounded by late Precambrian rocks of Belt series (ascending): Empire formation; Helena limestone, here renamed Helena dolomite; Marsh formation; and Greenhorn Mountain quartzite (new). Helena consists largely of buff-weathering aphanitic dolomite. Thickness about 4,000 feet. This buff-weathering feature has been mentioned as being typical of the formation by investigators since Walcott, but no one has mentioned its dolomitic composition. Formation contains subordinate limestone, which weathers gray or "bluish" gray, some siliceous limestone oolite, and beds of edgewise conglomerate up to 2 feet thick. Contains *Collenia* biostromes, up to 10 feet thick, that occur at intervals from top to bottom of formation.

C. P. Ross, D. A. Andrews, and I. J. Witkind, 1955, Geologic map of Montana (1:500,000) : U.S. Geol. Survey. Shown on map legend as limestone at top of Piegan group.

U.S. Geological Survey currently classifies the Helena as a formation in Missoula Group on the basis of a study now in progress.

Exposed in upper part of city of Helena and on hill slopes to the east.

Helenan series[1]

Precambrian: Montana.

Original reference: C. R. Keyes, 1925, Pan-Am. Geologist, v. 44, p. 215, 217.

Helenmode Formation (in Chilhowee Group)

Helenmode Member (of Erwin Formation)

Helenmode Member (of Hesse Sandstone)

Lower Cambrian: Eastern Tennessee and western North Carolina.

P. B. King and others, 1944, Tennessee Div. Geology Bull. 52, p. 31–32, 33, fig. 6, pls. 3, 5, 6. Helenmode member of Erwin formation consists of so-called "transition beds" of earlier reports. They embrace yellow finely laminated clays, which evidently were originally calcareous shale, and soft mealy arkosic sandstones, some stained red and purple with iron, others of a greenish color, due to contained glauconite grains. At top are coarse grits of rounded quartz grains, from which the former calcareous cement has been dissolved leaving a porous layer or loosely coherent mass, in many places stained with manganese oxide or rusty with iron oxide. Thickness about 100 feet near Helenmode mine; elsewhere thinner; 67 feet on U.S. Highway 19E between Valley Forge and Hampton. Overlies unit termed upper quartzite member; underlies Shady dolomite.

S. S. Oriel, 1950, North Carolina Div. Mineral Resources Bull. 60, p. 15–16. Geographically extended into Madison County. N.C., where it is considered member of Erwin formation.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, p. 35 (table 3). Shown on table as member at top of Hesse sandstone and as member at top of Erwin formation. Cambrian.

P. B. King and others, 1958, Geol. Soc. America Bull., v. 69, no. 8, p. 964. Rank raised to formation at top of Chilhowee group. Cambrian.

P. B. King and H. W. Ferguson, 1960, U.S. Geol. Survey Prof. Paper 311, p. 28 (table), 43–44. In northeasternmost Tennessee, considered uppermost member of Erwin formation. Overlies Hesse quartzite member; underlies Shady dolomite. Unit mapped around whole periphery of Shady Valley and Stony Creek Valley where it has thickness of 100 feet or a little less; 67 feet thick in section on U.S. Highway 19E, south of Valley Forge. Coarse sandstone bed here placed at top of Helenmode has been variously classified; in southwest Virginia, a similar layer has been called initial deposit of Shady dolomite. Lower Cambrian.

R. B. Neuman and R. L. Wilson, 1960, U.S. Geol. Survey Geol. Quad. Map GQ–131. Formation described in Blockhouse quadrangle, Tennessee, where it is 100 feet thick. Overlies Hesse quartzite; underlies Shady dolomite. Most of Chilhowee group is questionably assigned to Early Cambrian because recoverable fossils of Early Cambrian age are confined to Helenmode, youngest formation of group.

Named for Helenmode pyrite mine near Sadie in Stony Creek district, Carter County, Tenn.

Hellam Conglomerate Member (of Chickies Quartzite)[1]

Lower Cambrian: Southeastern Pennsylvania.

Original reference: G. W. Stose and A. I. Jonas, 1922, Washington Acad. Sci. Jour., v. 12, p. 360–362.

B. F. Howell, Henry Roberts, and Bradford Willard, 1950, Geol. Soc. America Bull., v. 61, no. 12, pt. 1, p. 1361. Chickies quartzite is used rather than Hardyston in Buckingham area, Bucks County. In Buckingham Valley, the quartzite carries a basal conglomerate believed to be the Hellam.

Bradford Willard and others, 1959, Pennsylvania Geol. Survey, 4th ser., Bull. C–9, p. 10, 38, 40, pl. 2. There is confusion as to use of Hellam conglomerate as separate unit or member of Chickies quartzite. Latter use is followed in this report [Bucks County] as serving to distinguish Chickies quartzite from Hardyston quartzite. Thickness about 300 feet.

Named for exposures in Hellam Hills, 3 miles west of Chickies Rock, York County.

Hellam Quartzite[1]

Lower Cambrian: Southeastern Pennsylvania.

Original reference: P. Frazer, 1886, Am. Philos. Soc. Proc., v. 23, p. 396, 398–400.

Named for exposures in Hellam Township, York County.

Hell Creek Formation[1]

Hell Creek Member (of Lance Formation)

Upper Cretaceous: Eastern Montana, northwestern North Dakota, northwestern and northern South Dakota, and northeastern Wyoming.

Original reference: B. Brown, 1907, Am. Mus. Nat. History Bull., v. 23, art. 33, p. 829–835.

E. P. Rothrock, 1937, South Dakota Geol. Survey Rept. Inv. 28, p. 7, 10–11. In Harding County, Hell Creek member of Lance formation includes Bull Creek sand (new). Underlies Ludlow member.

G. G. Simpson, 1937, U.S. Natl. Mus. Bull. 169, p. 15 (table), 16–20. For purposes of present report [Fort Union of Crazy Mountain field. Montana], it is assumed that beds up to and including the true dinosaur-bearing Lance and Hell Creek and their equivalents belong to the Cretaceous and that overlying beds without dinosaurs (except by redeposition) and with mammals of Tertiary type (including carnivores, condylarths, and others) from the Puerco and its equivalents upward, are to be placed in the Tertiary. It is also assumed that Paleocene is accepted as separate epoch. Hell Creek formation underlies Bear formation (new).

A. J. Collier and M. M. Knechtel, 1939, U.S. Geol. Survey Bull. 905, p. 10–11, pls. 1, 3. In McCone County, Mont., Hell Creek beds, mapped as member of Lance formation, overlie Colgate sandstone member of Fox Hills formation and underlie Tullock member of Lance. Thickness about 135 feet. Footnote (p. 10) states that since the present report was written, Hell Creek and Tullock members have been raisd to rank of formations in official classification of the U.S. Geological Survey; Hell Creek is assigned to the Cretaceous and the Tullock to Cretaceous or Eocene. Lance of the present report is placed in Eocene(?).

Erling Dorf, 1940, Geol. Soc. America Bull., v. 51, no. 2, p. 213–236. Discussion of relationship between floras of type Lance and Fort Union formations. Lance formation (equivalent to Hell Creek formation) is placed in Upper Cretaceous; Tullock formation (equivalent to Ludlow formation and Cannonball marine member) is placed at base of Paleocene Fort Union group.

W. M. Laird and R. H. Mitchell, 1942, North Dakota Geol. Survey Bull. 14, p. 9–15. Described in Morton County where it is about 250 feet thick in complete exposures. Includes Breien member (new). Overlies Fox Hills formation; underlies Ludlow formation of Fort Union group.

O. A. Seager and others, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 8, p. 1415, 1418. Youngest Cretaceous formation known in North Dakota. Consists largely of gray bentonitic sands and shales with which are lenticular beds of lavender-brown lignitic shale and rusty-brown to purplish-black ferruginous concretions. Thickness varies from 575 feet near Marmarth to less than 100 feet in Souris River area. Underlies Cannonball member-Ludlow member of Fort Union.

R. W. Brown, 1943, Geol. Soc. America Bull., v. 54, no. 1, p. 81. Laramie formation (redefined) is equivalent to the Lance, and thus becomes equivalent to the Hell Creek.

S. P. Fisher, 1952, North Dakota Geol. Survey Bull. 26, p. 17–20. Described in Emmons County where it is about 270 feet thick. Overlies Fox Hills formation and underlies Cannonball formation.

R. E. Curtiss, 1952, Areal geology of the Isabel quadrangle (1:62,500); 1954, Areal geology of the Firesteel Creek quadrangle (1:62,500): South Dakota Geol. Survey. Overlies Colgate sandstone member of Fox Hills. Thickness about 230 feet. Contains Isabel-Firesteel coal member [facies], 0 to 6 feet thick.

J. D. Love, J. L. Weitz, and R. K. Hose, 1955, Geologic map of Wyoming (1:500,000): U.S. Geol. Survey. Mapped in northeastern Wyoming. Consists of brown and gray sandstone and shale, thin coal, and carbonaceous shale beds.

W. J. McMannis, 1955, Geol. Soc. America Bull., v. 66, no. 11, pl. 7. Plate 7 shows that Livingston formation intertongues with Claggett, Judith River, Bearpaw, Lennep, Hell Creek, Tullock, and Lebo formations.

R. E. Stevenson, 1957, Geology of the McIntosh quadrangle (1:62,500): South Dakota Geol. Survey. Comprises a lower unit about 60 feet thick, at top of which is Isabel-Firesteel facies, and upper unit about 80 feet thick. Interfingers with overlying Ludlow formation; overlies Colgate member of Fox Hills formation.

Typically exposed on Hell Creek, north of Jordan, Garfield County, Mont., and nearby tributaries of Missouri River.

Heller Dacite[1]

Tertiary (may be upper Miocene): Central Nevada.

Original reference: J. E. Spurr, 1905, U.S. Geol. Survey Prof. Paper 42, p. 37.

Composes Heller Butte, near town of Tonopah, Tonopah district.

Hell Gate Dolomite

Early Paleozoic: Southeastern New York.

T. W. Fluhr, 1939, Municipal Engineers Jour., v. 25, p. 24, 25 (map), 29 (geol. profile). Named in list of formations in area of Triborough Bridge project. Occurs between Inwood limestone and Fordham gneiss.

T. W. Fluhr, 1957, Geol. Soc. America Eng. Case Histories No. 1, p. 2. Some workers regard this as one of larger interbedded limestone members in Fordham series, but it is herein interpreted as an infolded and infaulted belt of the Inwood, from which it is lithologically and chemically indistinguishable. Early Paleozoic. Discussion of geology of Queens midtown tunnel.

Derivation of name not given.

Hell Gate Glacial Substage

Pleistocene (Mankato): West-central Colorado.

R. L. Nelson, 1954, Jour. Geology, v. 62, no. 4, p. 333, fig. 2, table 4. Time of Wisconsin glaciation in Frying Pan Valley during which outwash deposits and Hell Gate moraines were deposited. Older than Chapman Gulch glaciation (new); younger than Ivanhoe glacial substage (new).

Type locality for deposits of Hell Gate advance is on Ivanhoe Creek, 1 mile above precipitous Hell Gate gorge. In Frying Pan River drainage just west of Continental Divide in Sawatch Range.

Hell Gate Porphyry[1]

Precambrian: Central Colorado.

Original reference: J. T. Stark and F. F. Barnes, 1932, Am. Jour. Sci., 5th, v. 24, p. 474.

Well exposed at Hell Gate Narrows, 5 miles west of divide on Lake Fork-Ivanhoe section, Lake Fork-Ivanhoe region.

Hellgate Quartzite Member (of Miller Peak Argillite)

Hellgate Formation[1]

Hellgate Quartzite (in Missoula Group)

Precambrian (Belt Series): Central western Montana.

Original reference: C. H. Clapp and C. F. Deiss, 1931, Geol. Soc. America Bull., v. 42, p. 679, figs. 2, 3.

F. S. Honkala, 1958, Soc. Vertebrate Paleontology Guidebook 8th Field Conf., p. 22. Hellgate quartzite is pink, weathers brown, massive. In Missoula group.

W. H. Nelson and J. P. Dobell, 1959, U.S. Geol. Survey Misc. Geol. Inv. Map I–296. Rank reduced to member status in Miller Peak argillite.

Type section: On north side of Mount Sentinel, in south wall of Hellgate Canyon, Missoula-Helena region.

Hell Inlet Glacial Stage

Pleistocene: North-central Colorado.

R. L. Ives, 1942, Geog. Rev., v. 32, no. 3, p. 450 (table 1). Name appears only on table giving late Pleistocene chronology of Monarch Valley. Older than Walden Hollow glacial stage (new).

Monarch Valley, Grand County.

Hell Roaring Formation

Paleocene-Eocene: Southwestern Montana and northwestern Wyoming.

C. W. Brown, 1958, Dissert. Abs., v. 18, no. 1, p. 194. Incidental mention.

In Yellowstone National Park.

Hell Roaring Member (of Altyn Formation)

Precambrian (Belt Series): Southern Alberta, Canada, and northwestern Montana.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc. America Bull., v. 48, no. 12, p. 1882–1883, fig. 2. Dolomite and dolomitic limestones, variably siliceous; blue gray to greenish gray, weathering to gray, buff, or cream; beds 2 to 24 inches thick. Many beds show laminae of limestone and dolomite and dolomite nodules. Thickness 1,200 to 1,300 feet. Underlies Carthew member (new); overlies Waterton member, contact gradational. This is "lower member" of Willis' Altyn descriptions.

Richard Rezak, 1957, U.S. Geol. Survey Prof. Paper 294–D, p. 137. Discussion of stromatolites of Belt series. Hell Roaring member of Fenton and Fenton is represented by *Collenia frequens* zone of Altyn limestone.

Type locality: Hell Roaring Falls, Waterton Lakes Park, Alberta. Well exposed on eastern slope of Mount Carthew.

Hells Canyon Formation (in Durst Group)

Hells Canyon Member (of Morgan Formation)

Pennsylvanian: Northwestern Colorado and northeastern Utah.

M. L. Thompson, 1945, Kansas Geol. Survey Bull. 60, pt. 2, p. 29, 31–34, geol. sections. Proposed for lithologic and faunal unit above Belden formation and below Youghall formation (new). About 294 feet thick at type locality where it is composed of highly fossiliferous limestones and gray shales, red to purplish shales, gray fissile shales, purplish siltstones, and thin beds of gray to red fine-grained sandstones.

Walter Sadlick, 1957, Intermountain Assoc. Petroleum Geologists Guidebook 8th Ann. Field Conf., p. 70, 71–75. Formation included in Durst group (new).

D. O. Peterson, 1960, Dissert. Abs., v. 20, no. 7, p. 2757. Rank reduced to member status in Morgan formation.

Type locality: In Hells Canyon, west bluff Hells Canyon, sec. 31, T. 6 N., R. 102 W., a tributary canyon of Yampa River in Moffat County, Colo.

Hells Gate Rhyolite

Precambrian: East-central Arizona.

Gordon Gastil, 1958, Geol. Soc. America Bull., v. 69, no. 12, pt. 1, p. 1498 (table 1), 1506. Recrystallized rhyolite tuff. Some of rock is intrusive, as for example south of Tonto Creek it intrudes Houden formation (new) on large scale. But large parts, as northwest of Hell's Gate, display columnar structure, and some specimens display pyroclastic texture. Thickness more than 10,000 feet. No direct evidence for stratigraphic position of columnar rhyolite, but it probably belongs high in stratigraphic column of Precambrian rocks. Name given on table as Hells Gate rhyolite but unit described in text as rhyolite of the Hell's Gate area.

Covers area 25 to 50 miles square between Lost Camp Mountain and granite of the Payson area. Exposed northeast of Hell's Gate, Diamond Butte quadrangle.

Hells Mesa Member (of Datil Formation)

(?)Miocene, upper: Southwestern New Mexico.

W. H. Tonking, 1954, Dissert. Abs., v. 14, no. 2, p. 340. Welded and "semi-welded" rhyolite tuff. Underlies La Jara Peak member (new); overlies Spears member (new).

W. H. Tonking, 1957, New Mexico Bur. Mines Mineral Resources Bull. 41, p. 26, 29–30, fig. 2, 1 [preprint? 1954?]. Color of basal half of section in eastern and northern Bear Mountains ranges from pink below to white or light gray higher in section. Upper half of member is white to light gray, capped by about 25 feet of pink tuff. Thickness about 250 feet in northern Bear Mountains, approximately twice as thick southward along eastern mountain front, and may be more than 2,000 feet in Gallinas Mountains. Source of name given.

D. B. Givens, 1957, New Mexico Bur. Mines Mineral Resources Bull. 58. p. 15–18, pl. 1. Further described from Gallinas Mountains.

Named for conspicuous peak in secs. 17 and 20, T. 1 N., R. 4 W., popularly called Hells Mesa, Puertecito quadrangle, Socorro County.

Hell To Finish Formation

Age unknown: Southwestern New Mexico.

R. A. Zeller, Jr., 1958, Roswell Geol. Soc. Guidebook 11th Field Conf., p. 10 (chart). Name appears on chart only. Consists of red beds, including red shale, siltstone, sandstone, gypsum, and andesite. Thickness between 1,000 and 2,000 feet. Underlies U Bar formation (new) of Lower Cretaceous age and overlies rocks of Permian age—Concha limestone(?) of Naco group.

R. H. Weber and F. E. Kottlowski, 1959, New Mexico Bur. Mines Mineral Resources Bull. 68, p. 13. In Big Hatchet Mountains, several thick beds of gypsum occur in lower part of Lower Cretaceous strata. Gypsum beds are at top of red-bed sequence, Hell To Finish formation, and just below massive- to thin-bedded limestone of U. Bar formation.

In Big Hatchet Peak quadrangle, Hidalgo County.

Helmet Fanglomerate

Miocene, lower(?): Southwestern Arizona.

J. R. Cooper, 1960, U.S. Geol. Survey Bull. 1112–C, p. 77, 89, pl. 1. Deformed postmineralization formation. Predominantly coarse ill-sorted and ill-bedded conglomerate characterized by angular pebbles, cobbles, and boulders in silty matrix. Intercalated are lava flows of porphyritic andesites, thin beds of rhyolitic tuff and tuffaceous sediments, and lentils and tongues of monolithographic breccia. Thickness at least 10,000 feet. Along northwest side, in depositional contact on rhyolitic tuff and probably Cretaceous(?) rocks; to northeast, extends beneath Quaternary alluvium; other boundaries are fault contacts with Precambrian granite, Paleozoic sedimentary rocks, and granodiorite. No fossils; tentative correlations suggest that fanglomerate may be of early Miocene age.

No type section designated. Most continuous exposures are along north-trending line from point three-fourths mile southeast of Helmet Peak to point 1¼ miles north-northwest of Twin Buttes village, Pima mining district, Pima County.

Helmick Formation

Eocene: Northwestern Oregon.

J. A. Cushman, R. E. Stewart, and K. C. Stewart, 1947, Oregon Dept. Geology and Mineral Industries Bull. 36, pt. 5, p. 95–96. Term Helmick formation used in this paper for unit described as Helmick beds by M. J. Mundorff (unpub. thesis). Consists chiefly of micaceous sandstone with some clay shales and an occasional concretionary lens firmly cemented with calcite. Sandstones are typically medium-grained thin-bedded friable bluish-gray rocks which weather buff or brown. Concretions commonly contain organic material. Uppermost part of unit is clay shale of which at least 40 feet or more are exposed along river north of Buena Vista.

Typically exposed in highway roadcut at Helmick Hill and along Willamette River at Buena Vista, Polk County.

Helms Formation[1]

Mississippian: Western Texas and southeastern New Mexico.

Original reference: J. W. Beede, 1921, Texas Univ. Bull. 1852, p. 8, 30, 36.

L. R. Laudon and A. L. Bowsher, 1949, Geol. Soc. America Bull., v. 60 no. 1, p. 8–9, 16–17, 19–20, 23, 32, 35, 39. Beede designated all rocks between Silurian and Pennsylvanian systems in Hueco Mountains as Helms. Name here restricted to upper part of these strata. As thus restricted, consists of green shale, shaly sandstone, and impure limestone beds, containing Chester fossils. In type area, unconformably overlies Rancheria formation (new) and unconformably underlies Pennsylvanian rocks. Thickness 98 feet in Franklin Mountains, N. Mex.

Well exposed about 1 mile south of Helms Peak, Hueco Mountains, Hudspeth County, Tex.

Hely Member (of Grand Detour Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., fig. 3. Shown on columnar section as underlying Victory member (new) and overlying Clement member (new).

Occurs in Dixon-Oregon area.

Hemingford Group

Miocene: Nebraska and Wyoming.

A. L. Lugn, 1938, Am. Jour. Sci., 5th ser., v. 36, no. 213, p. 226, 227; 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1253–1254. Includes Marsland below and Sheep Creek formations. Thickness 250 to 350 feet. Unconformable above Arikaree group (redefined) and below Ogallala group (redefined). Name suggested by C. B. Schultz.

Town of Hemingford is in Box Butte County, Nebr.

Hemingfordian Age

Miocene: North America.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 12, pl. 1. Provincial time term, based on the Hemingford group, including the Marsland and, especially, the limited or lower Sheep Creek fauna (Cook and Cook, 1933), and not on the formation limits as extended upward (Lugn, 1939). Covers interval between Arikareean and Barstovian ages. Report defines 18 provincial time terms, based on mammal-bearing units, for North American continental Tertiary. [For sequence see under Puercan.]

Hemlock Formation (in Baraga Group)

Hemlock Greenstone[1]

Precambrian (Animikie Series): Northern Michigan.

Original reference: J. M. Clements, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 3, p. 45–63, pl. 9.

J. E. Gair and K. L. Wier, 1956, U.S. Geol. Survey Bull. 1044, p. 14 (table 2), 41–51, pl. 1. Name Hemlock formation reinstated because term greenstone is too restricted to include all its units. Mainly greenstone; predominantly metabasalt in southwestern part, basic schist in northeastern part, and metarhyolite (including sericite slate) in southeastern part of Kiernan quadrangle. Formation completely surrounds Amasa oval (uplift). Thickness ranges from about 2,300 feet on east side of oval to about 20,000 feet on west side of oval (in region including type locality). Underlies Fence River formation; overlies Goodrich quartzite.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 36. Includes Mansfield iron-bearing slate member near base and newly defined Bird iron-bearing member about 1,300 feet below top. Assigned to newly defined Baraga group.

Occurs in Crystal Falls district, Iron County. Named for the fact that Hemlock River flows through formation for a number of miles.

Hempfield shale member[1] (of Shenango monothem)

Mississippian: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 141.

R. E. Sherrill and L. S. Matteson, 1939, Pennsylvania Geol. Survey Bull. 122, p. 7. In Hillards quadrangle, a shale unit, 75 to 100 feet thick, underlying the Burgoon sandstone is referred to as Hempfield (Shenango) shale member. Occupies stratigraphic position of Shenango shale, renamed Hempfield shale by Caster, of Crawford County.

First described in vicinity of Greenville, Hempfield Township, Mercer County.

Hemphill Beds[1]

Pliocene, lower: Northwestern Texas.

Original reference: L. C. Reed and O. M. Longnecker, Jr., 1932, Texas Univ. Bull. 3231, p. 16–43, 70–83, map.

Hemphill County.

Hemphillian Age

Pliocene: North America.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 12, pl. 1. Provincial time term, based on Hemphill member of Ogallala, which includes both Hemphill local fauna from the Coffee Ranch Quarry and the Higgins local fauna, Hemphill County, Texas. Covers interval between the Oligocene Clarendonian (older) and Blancan ages. Report defines 18 provincial time terms, based on mammal-bearing units, for North American continental Tertiary. [For sequence see under Puercan.]

Hempstead Gravel Member (of Manhasset Formation)[1]

Pleistocene: Southeastern New York and islands of southern New England.

Original reference: M. L. Fuller, 1914, U.S. Geol. Survey Prof. Paper 82.

Lawrence Weiss, 1954, U.S. Geol. Survey Prof. Paper 254–G, p. 146. Top member of Manhasset; overlies Montauk member. Manhasset is considered to be of Wisconsin age.

Named for exposures in upper part of many large gravel pits along west side of Hempstead Harbor, Long Island. Present on Marthas Vineyard, Block Island, No Mans Land, and probably Nantucket Island and Cape Cod.

Henderson Gneiss

Henderson Granite[1] or Granite Gneiss

Ordovician to Devonian: Western North Carolina and northwestern South Carolina.

Original reference: A. Keith, 1905, U.S. Geol. Survey Geol. Atlas, Folio 124, p. 4.

G. W. Crickmay, 1952, Georgia Geol. Survey Bull. 58, p. 26. Intrudes Brevard schist.

J. L. Stuckey and S. G. Conrad, 1958, North Carolina Div. Mineral Resources Bull. 71, p. 16–17; J. L. Stuckey, 1958, Geologic map of North Carolina (1:500,000): North Carolina Div. Mineral Resources. As mapped, Henderson granite gneiss unit is essentially Henderson granite as named and described by Keith (1905) and further described by Keith (1907, U.S. Geol. Survey Geol. Atlas, Folio 143). Recently the Henderson has been mapped to near Linville Falls, McDowell County, where it makes contact with what is considered southern extension of Cranberry granite. Both units are considered to be metasedimentary in origin and stratigraphically equivalent. Henderson composed essentially of rocks with pronounced gneissoid structure. Mapped as Precambrian(?).

H. W. Jaffe and others, 1959, U.S. Geol. Survey Bull. 1097–B, p. 115. Paleozoic on basis of Lead-alpha age determination.

U.S. Geological Survey currently designates the age of the Henderson Gneiss as Ordovician to Devonian on the basis of a study now in progress.

Named for extensive exposures in Henderson County, N.C.

Hendricks Dolomite (in Burnt Bluff Group)

Hendricks Member (of Burnt Bluff Formation)

Hendricks Series[1]

Middle Silurian (Niagaran): Northern Michigan and eastern Wisconsin.

Original reference: R. A. Smith, 1916, Michigan Geol. Survey Pub. 21, p. 155.

C. K. Swartz, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Burnt Bluff group in Michigan and Wisconsin includes Byron dolomite below and Hendricks dolomite above

G. M. Ehlers and R. V. Kesling, 1957, Michigan Geol. Soc. [Guidebook] Ann. Geol. Excursion, p. 2 (table), 11, 15–19. Hendricks dolomite, in type area, includes Fibron limestone member. Thickness about 60 feet. Overlies Byron dolomite; underlies Schoolcraft dolomite of Manistique group; contact marked by disconformity.

Type section: Abandoned Hendricks quarry, NW¼ sec. 6, T. 44 N., R. 8 W., and NE¼ sec. 1, T. 44 N., R. 9 W., Mackinac County, Mich.

Hendricks Sandstone[1]

Upper Devonian: Northern West Virginia.

Original reference: D. B. Reger and W. A. Price, 1923, West Virginia Geol. Survey Rept. Tucker County, p. 103, 240, 241, 245–254.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey [Rept.] Greenbrier County, p. 303. Comprises upper member of Chemung series and marks lower limit of Catskill series in Greenbrier County. Commonly grayish brown to reddish brown, massive, and contains numerous flattened quartz pebbles. Thickness 10 to 50 feet.

Named for exposure 1 mile northeast of Hendricks, Tucker County, in Black Fork district.

Hendry Ranch Member (of Tepee Trail Formation)

Eocene, upper: Northwestern Wyoming.

H. A. Tourtelot, 1957, Smithsonian Misc. Colln., v. 134, pt. 1, p. 11–14, fig. 2. Name applied to gray and greenish-gray claystone and siltstone and tan siltstone rich in volcanic material that forms upper part of Tepee Trail formation in five areas along northern margin of Wind River basin. Maximum thickness about 550 feet. Overlies lower part of formation referred to as green and brown member.

Type section: Composite including three localities, all in Natrona County: NE¼ sec. 31, T. 39 N., R. 88 W., which includes contact with green and brown member; SW¼ sec. 14, T. 39 N., R. 89 W., which displays exposures of fossiliferous gray and greenish-gray rocks; NE¼ sec. 23, T. 39 N., R. 89 W., which contains tan siltstone that makes up upper part of member.

Henefer Formation

Upper Cretaceous: Northeastern Utah.

A. J. Eardley, 1944, Geol. Soc. America Bull., v. 55, no. 7, p. 824 (table 1), 840–842, 845, pl. 1. Red, pink, purple, and light-gray shales; red and gray sandstones with numerous lenses of pea and pebble conglomerate; gray, tan, brown, and red pebble and boulder conglomerate; 200-foot bed of volcanic tuff near base. Thickness 1,250 feet at Echo Dam; 10,000 feet in Harris Creek Canyon. Overlies Frontier formation; underlies Pulpit conglomerate [member] (new) of Almy conglomerate. Norwood tuff (new) is inlaid in the Henefer in Little East Canyon. Lower Paleocene, post-Montana or upper Montana. Probably equivalent to all or part of the Hilliard, Adaville, and Evanston.

A. J. Eardley, 1951, (abs.) Geol. Soc. America Bull., v. 62, no. 12, pt. 2, p. 1435. Henefer conformably underlies beds considered Almy, and is probably a lower member of the Almy.

L. A. Hale, 1960, Wyoming Geol. Assoc. Guidebook 15th Ann. Field Conf., p. 136 (chart 1), 142. Frontier formation redefined. Name Henefer as originally defined is preferred to term Wanship of Williams and Madsen (1959) in restricted sense. This opinion is based on premise that upper boundary of Frontier should be placed on basis of gross lithologic character. The Henefer would then be defined as lying between the highest white sandstone of the Frontier (Upton member, new) and Echo Canyon (formerly Pulpit) conglomerate.

Named for exposures in Harris Creek Canyon northeast of Henefer, Summit County. From Franklin County westward, forms both sides of Henefer Valley to marrows of upper Weber Canyon.

Henley Beds[1]

Cretaceous: Oregon.

Original reference: F. M. Anderson, 1902, California Acad. Sci. Proc., 3d ser., v. 2, p. 1–62.

In southern part of Oregon Basin.

Henley Shale Member (of Cuyahoga Formation)[1]

Henley Shale Member (of New Providence Formation)

Henley shale facies (of Cuyahoga Formation)

Mississippian (Kinderhook): Southern Ohio and northern Kentucky.

Original reference: J. E. Hyde, 1915, Jour. Geology, v. 23, p. 656, 657, 758, 760, 762, 769.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 129, 130. Geographically extended into northern Kentucky where it is classed as member at base of New Providence formation; underlies Farmers siltstone member (new). In area of Bledstone facies, as much as 12 feet thick.

F. T. Holden, 1941, Illinois Acad. Sci. Trans., v. 34, no. 2, p. 172; 1942, Jour. Geology, v. 50, no. 1, p. 45. Henley shale facies includes Henley shale member.

Named for Henley, Scioto County, Ohio.

Hennepin Member (of Pecatonica Formation)

Middle Ordovician: Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., figs. 3, 12. Dolomite, argillaceous, silty, thin-bedded. Shown on columnar section as underlying Chana member (new) and overlying Harmony Hill formation (new).

Occurs in Dixon-Oregon area.

Hennessey Shale[1]

Permian: Central and southwestern Oklahoma.

Original reference: F. L. Aurin, H. G. Officer, and C. N. Gould, 1926, Am. Assoc. Petroleum Geologists Bull., v. 10, p. 786–799.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped with Cedar Hills sandstone member in upper part.

G. L. Scott, Jr., and W. E. Ham, 1957, Oklahoma Geol. Survey Circ. 42, p. 11–12, pl. 1. In southwestern Oklahoma overlies Wichita formation and underlies Duncan sandstone, or Flowerpot shale, where the Duncan is absent. Thickness in central Oklahoma 300 to 600 feet. In Carter area (this report), where only uppermost 40 to 50 feet is exposed, predominantly yellowish-gray to buff unfossiliferous shale; a few thin gray, blue-gray, or buff silty fine-grained calcareous sandstone stringers occur in the section as well as thin beds of bright red, brown, maroon, orange, yellow, and blue shales.

Named for exposures at Hennessey, Kingfisher County.

Hennessey Bayou Member (of Bucatunna Marl and Clay)

Oligocene (Vicksburg) : Central western Mississippi.

E. C. Tonti, 1955, Dissert. Abs., v. 15, no. 8, p. 1372. Proposed for lower Bucatunna transgressive unit heretofore included in Byram formation. Bentonite deposits occur in Bucatunna clays immediately above the marine Hennessey Bayou unit.

Typically exposed on Hennessey Bayou, 3 miles south of Vicksburg.

†Henrietta Formation[1] or Group[1]

Pennsylvanian (Des Moines Series) : Western Missouri, southern Iowa, and eastern Kansas.

Original reference: C. R. Keyes, 1897, Iowa Acad. Sci. Proc., v. 4, p. 23–24, 25.

L. M. Cline, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 26–27 (fig. 2). Columnar section shows group includes (ascending) Fort Scott limestone, Labette shale, Pawnee limestone, Bandera shale, Altamont limestone, and Nowata shale. Overlies Cherokee group; underlies Pleasanton group.

H. S. McQueen, 1943, Missouri Geol. Survey and Water Resources, v. 28, 2d ser., p. 95, 96. A sandstone (Squirrel) commonly included in Cherokee group here included at base of Henrietta group in Fort Scott formation.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2027; F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 5; G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 43. Abandoned in favor of Marmaton.

Named for Henrietta escarpment, near Henrietta, Johnson County, Mo.

Henryhouse Shale,[1] **Limestone, or Formation** (in Hunton Group)

Silurian: Central southern Oklahoma.

Original reference: C. A. Reeds, 1911, Am. Jour. Sci., 4th, v. 32, p. 256–268.

R. A. Maxwell, 1936, Northwestern Univ. Summ. Doctoral Dissert., v. 4, p. 132, 134. Underlies Haragan formation in Kite group (new).

T. W. Amsden, 1957, Oklahoma Geol. Survey Circ. 44, p. 6 (fig. 3), 7, 26–35. Typical lithology is fossiliferous argillaceous and silty calcilutite, commonly referred to as marlstone. Thinly bedded, beds ranging up to 3 inches and commonly weathering with irregular or nodular appearance. Chert absent or extremely rare. Maximum thickness about 230 feet on Lawrence uplift; thins rapidly to south; absent at Coal Creek; about 180 feet at Henryhouse Creek. Overlies Chimneyhill formation. No reliable field evidence, other than fauna, has been found for separating Henryhouse from overlying Haragan formation. These two formations are here grouped under term Hunton marlstone. Included in Hunton group. Silurian fauna appears to be closely related in age to the Brownsport of Tennessee but its position in terms of eastern Silurian faunas is in question.

Named for Henryhouse Creek, Carter County, which crosses the outcrop about 3 miles east of Woodford (SE¼ sec. 30, T. 2 S., R. 1 E.).

Henrys Chapel Ball Clay (in Wilcox Group)

Eocene, lower: Eastern Texas.

H. B. Stenzel, 1950, Texas Univ. Bur. Econ. Geology Pub. 5019, p. 15 (fig. 4). Shown on stratigraphic section as occurring at top of Wilcox group (undivided) in Troup district, Smith County.

H. B. Stenzel, 1953, Texas Univ. Bur. Econ. Geology Pub. 5305, p. 10 (fig. 3), 14–17, 30. Gray and black ball clay. Thickness 20.1 feet. Overlies silty clays of undifferentiated Wilcox group; underlies shaly silts of Carrizo formation, contact sharply defined.

Named for occurrences in Reliance Brick Co. quarry near Henrys Chapel, Smith County.

†Henrys Fork Group[1]

Upper Jurassic and Upper Cretaceous: Northeastern Utah and northwestern Colorado.

Original reference: J. W. Powell, 1876, Geology of eastern portion of Uinta Mountains, p. 40, 50, 153.

Type locality: South side of Henry's Fork, Uintah County, Utah, at and above where it unites with Green River.

Henryville Formation (in New Albany Shale)

Henryville Member (of New Albany Shale)

Mississippian (Kinderhookian): Southeastern Indiana.

Guy Campbell, 1946, Geol. Soc. America Bull., v. 57, no. 9, p. 835, 837, 851. Summit bed of New Albany formation. Overlies Falling Run member of Sanderson formation (both new), or Underwood formation (new) where it is present; underlies Jacobs Chapel shale (new). Consists of black fissile shale never more than 1 to 2 feet thick. Cannot be distinguished from Sanderson shale except by presence of Falling Run or Underwood between the two.

H. H. Murray and others, 1955, Indiana Geol. Survey Field Conf. Guidebook 8, p. 43, pl. 1. Mississippian part of New Albany has been divided into (ascending) Sanderson, Underwood, and Henryville "formations". Indiana Geological Survey uses these terms with rank of member.

Type section: On Caney Fork Creek, in Clark Grant 252, 1½ miles southwest of Henryville, Clark County.

Hensell Sand Member (of Travis Peak Formation)

Hensell Shale Member (of Pearsall Formation)

Hensell Sand (in Travis Peak Formation[1] or Glen Rose Formation)

Hensell Sand Member (of Shingle Hills Formation)

Lower Cretaceous (Comanche Series): Central Texas.

Original reference: R. T. Hill, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 7, p. 141–144, 152.

R. H. Cuyler, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 5, p. 633–635. Referred to as member of Travis Peak; sand in lower part; conglomerate, sandstone, sandy limestone, and sandy shale in upper part. Thickness 40 to 183 feet. Overlies Cow Creek member.

R. W. Imlay, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 3. Hensell shale is uppermost member of Pearsall formation (new) in subsurface. At type section of Pearsall, the Hensell is about 340 feet thick, and consists of calcareous black shale interbedded with considerable black to dark-gray shaly limestone and hard dense partly fossiliferous, black to light-brown limestone, or, less commonly, light-gray to white chalky limestone. Overlies Cow Creek limestone member. Occupies same stratigraphic position as Hensell sand member of Travis Peak.

V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Rept. Inv. 2, p. 6, 6–7 (fig. 1), 8. Reallocated to member status in Shingle Hills formation (new). Underlies Glen Rose limestone member.

F. E. Lozo and F. L. Stricklin, Jr., 1956, Gulf Coast Assoc. Geol. Soc. Trans., v. 6, p. 68, 69, 70, figs. Referred to as Hensel sand. Overlies Cow Creek formation. Hensel considered correct spelling.

J. M. Forgotson, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 10, p. 2336, figs. Hensell sand considered basal member of Glen Rose.

Named for Mr. Hensell's place, at Travis Peak post office, Burnet County.

Henshaw Formation[1]

Upper Pennsylvanian: Northwestern Kentucky.

Original reference: Wallace Lee, 1916, Geology of Kentucky part of Shawneetown quadrangle: Kentucky Geol. Survey.

Named for Henshaw, Union County.

Henson Formation (in Silverton Volcanic Group)

Henson Tuff (in Silverton Volcanic Series)[1]

Tertiary, middle and upper: Southwestern Colorado.

Original reference: W. Cross and E. Howe, 1907, U.S. Geol. Survey Geol. Atlas, Folio 153.

E. S. Larsen, Jr., and Whitman Cross, 1956, U.S. Geol. Survey Prof. Paper 258, p. 13, 80–81. Youngest member of Silverton volcanic series. Pyroclastic formation consisting chiefly of well-bedded fine-grained greenish- or brownish-gray sandy tuff composed of dark quartz latitic material. Thickness 100 feet. Older than lavas of Potosi volcanic series.

U.S. Geological Survey currently classifies the Henson as a formation in the Silverton Volcanic Group and designates the age as middle and late Tertiary on the basis of a study now in progress.

Named for exposures on Hensen Creek, Ouray quadrangle. Also exposed in parts of Silverton and Lake City quadrangles.

Hepler Sandstone (in Bourbon Group)

Hepler Sandstone (in Pleasanton Group)

Pennsylvanian (Missouri Series): Eastern Kansas and western Missouri.

J. M. Jewett, 1940, Kansas Geol. Survey Bull. 30, p. 8–9, fig. 2. A persistent sandstone, at base of Bourbon group generally not more than 3 or 4 feet thick but as much as 20 feet thick north of Pleasanton, Linn County, Kans., where it is asphalt bearing. Conformably underlies gray, yellow, and black shale; disconformably overlies upper layers of Marmaton group. Columnar section shows the Hepler overlying Memorial shale.

R. C. Moore, 1949, Kansas Geol. Survey Bull. 83, p. 73; R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 91. Reallocated to Pleasanton group which replaces Bourbon group (suppressed).

Type exposure is in center sec. 14, T. 27 S., R. 22 E., 1½ miles north of Hepler, Bourbon County, Kans.

Heppsie Andesite

Miocene(?) : Southwestern Oregon.

F. G. Wells, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–89. Name applied to andesitic flows that are generally thick-bedded, massive though locally slightly platy, gray to blue-gray porphyritic rocks with a microcrystalline groundmass. Occurs above red agglomeratic andesitic horizon that delimits top of tuff of Wasson formation (new). Flows extend out of quadrangle for many miles to base of basalts of Pliocene and Pleistocene age; within quadrangle they are typical "andesites of the Western Cascades" of other writers.

Name derived from Heppsie Mountain, Jackson County, where andesites are well exposed.

Herald Beds

Ordovician: Subsurface in northwestern North Dakota, and southern Saskatchewan, Canada.

Saskatchewan Geological Society, 1958, Report of the Lower Palaeozoic names and correlations committee: Saskatchewan Geol. Soc., p. 6, 7, charts A and B [p. 18, 19]. Through the Williston Basin, interior beds comprise several cyclic or rhythmic sequences of fossiliferous dolomitic limestones, argillaceous dolomites, and evaporitic anhydrites reaching maximum known thickness of 130 feet in northwestern North Dakota. Evaporites absent from outlying areas of basin. Conformably overlies Yeoman beds (new).

Type locality: Imperial Herald No. 1–31 (Lsd. 1, sec. 31, T. 1, R. 20, W 2nd Mer., Saskatchewan) between 9,520 and 9,599 feet; Williston Basin.

Herat Shale Member (of Ochre Mountain Limestone)[1]

Upper Mississippian: Western Utah.

Original reference: T. B. Nolan, 1930, Washington Acad. Sci. Jour., v. 20, no. 17, Oct. 19, p. 421–432.

Named for exposures near Herat claims, Gold Hill quadrangle.

Herbert Conglomerate[1] Member (of Bon Air Sandstone)

Herbert Member (of Lee Formation)

Herbert Sandstone

Pennsylvanian (Pottsville Series) : Eastern Tennessee.

Original reference: W. A. Nelson, 1925, Tennessee Div. Geology Bull. 33–A, p. 49–50.

H. R. Wanless, 1939, (abs.) Geol. Soc. America Bull., v. 50, no. 12, pt. 2, p. 1941. Listed as member of Lee formation.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 17). Correlation chart shows Herbert sandstone underlying Eastland formation and overlying Whitwell [shale].

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of Cumberland Plateau. Tennessee Div. Geology [Folio], p. 4. The conglomeratic phase of Newton sandstone in southern Cumberland and northern Bledsoe Counties was the type "Herbert conglomerate" erroneously considered by Nelson (1925) to be older than Newton. Shale thought to be between sandstones and named "Eastland shale" by Nelson is actually Whitwell shale; therefore, names "Herbert" and "Eastland" are discarded.

First described on Glade Creek just north of where road from Herbert, Bledsoe County, to Sparta crosses stream.

†Herculean Shale Member (in Monterey Group)[1]

Miocene: Central western California.

Original reference: C. E. Weaver, 1909, California Univ. Pubs., Bull. Dept. Geol., v. 5, p. 251.

In San Pablo region.

Hercules Shale Member (of Briones Sandstone)[1]

Miocene, upper: Western California.

Original reference: A. C. Lawson, 1914, U.S. Geol. Survey Geol. Atlas, Folio 193.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 17 (table 3), 69 (table 14), 75, 77, pl. 12. In Carquinez and Mare Island quadrangles, the Hercules is well-defined unit averaging 500 feet thick. Lithologically it is siliceous light-brownish-gray shale; in places sandy with abundant flakes of muscovite. Overlies a 1,100-foot sandstone in lower part of Briones and underlies an upper 850-foot sandstone.

Named for Hercules Station on San Pablo Bay, San Francisco region.

Hercules Tower Sandstone (in Lutie Member of Theodosia Formation)

Lower Ordovician: Southern Missouri and northern Arkansas.

J. S. Cullison, 1944, Missouri Univ. School Mines and Metallurgy, Tech. Ser., v. 15, no. 2, p. 29, 31, pl. 2. A massive red to reddish-brown medium-grained friable sandstone about 10 feet thick. Occurs near middle of Lutie and is separated from overlying Pocket Hollow oolite (new) by black and white chert and beds of finely crystalline dolomite and "cotton rock".

Well exposed on Missouri Highway 125 south of Brush Creek about midway between village of Hercules and Hercules fire lookout tower, Taney County, Mo.

Herendeen Limestone[1]

Lower Cretaceous: Southwestern Alaska.

Original reference: W. W. Atwood, 1911, U.S. Geol. Survey Bull. 467, p. 25, 39.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000): U. S. Geol. Survey. Appears on map legend.

Exposed from Herendeen Bay to Port Moller, Alaska Peninsula.

Herington Limestone (in Chase Group)

Herington Limestone Member (of Nolans Limestone)

Herington Limestone (in Sumner Group)[1]

Permian: Eastern Kansas, southeastern Nebraska, and central northern Oklahoma.

Original reference: J. W. Beede, 1909, Kansas Acad. Sci. Trans., v. 21, pt. 2, p. 253.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 41. Member of Nolans limestone. Consists of limestone and dolomite, yellowish-tan, soft and dense, more dolomitic in southern and central Kansas than in northern part of state. Outcrops characterized by siliceous and calcareous geodes and concretions and cauliflowerlike masses of drusy flint weathered from matrix; molluscan fauna abundant. Thickness 7 to 10 feet in northern part and about 30 feet in southern Kansas. Overlies Paddock shale member; underlies Wellington formation of Sumner group. Wolfcamp series.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped as Herington limestone in Chase group.

C. C. Branson, 1960, Oklahoma Geology Notes, v. 20, no. 9, p. 229–235. Term Lyon series (Lyonian epoch) proposed for Sakmarian rocks of Oklahoma. Series would include rocks from top of Brownville limestone to top of Herington limestone.

Named for Herington, Dickinson County, Kans.

Herkimer Limestone[1]

Herkimer Limestone (in Hartmann Group)

Middle Cambrian: Central northern Utah.

Original reference: W. Lindgren and G. F. Loughlin, 1919, U.S. Geol. Survey Prof. Paper 107.

H. T. Morris, 1957, Utah Geol. Soc. Guidebook 12, p. 5 (fig. 2), 7. Described in East Tintic Mountains where it is 350 to 450 feet thick; conformably overlies Dagmar limestone and underlies Bluebird dolomite. Subdivided into three members: lower, about 180 feet thick, composed of medium-bedded blue-gray limestone mottled by thin discontinuous layers and irregular splotches of yellowish-brown argillaceous material; middle, shale, about 20 feet thick; and upper, about 150 to 250 feet thick, composed of thin beds of limestone, limestone flat-pebble conglomerate, and calcareous oolite all separated by shale partings.

J. K. Rigby, 1958, Utah Geol. Soc. Guidebook 13, p. 14 (fig. 3), 17. In Stansbury Mountains, as much as 145 feet thick; underlies Bowman limestone, and overlies Dagmar dolomite (limestone).

J. K. Rigby, 1959, Utah Geol. Soc. Guidebook 14, p. 14 (table 1), 18–21, pl. 1. Assigned to Hartmann group in southern Oquirrh Mountains. Herkimer of this report includes upper half of what Gilluly (1932) mapped as Hartmann limestone. Where best exposed, along Lynch Ridge north of town of Ophir, 466 feet thick. Overlies Teutonic limestone with contract gradational; underlies Bowman limestone with contact conformable and gradational.

Named for occurrence near Herkimer shaft 1½ miles south-southwest of Eureka, Juab County.

Herkimer Sandstone[1] (in Clinton Group)

Middle Silurian: Central New York.

Original reference: G. H. Chadwick, 1918, Geol. Soc. America Bull., v. 29, p. 327–368.

Tracy Gillette, 1940, New York State Mus. Bull. 320, p. 22 (fig. 6), 35; 1947, New York State Mus. Bull. 341, p. 13, 15, 16, 23, 111–113, geol. secs. Top of Clinton group in section east of Cayuga County. Thickness approximately 75 feet. Underlies Lockport dolomite; overlies Willowvale shale; locally overlies Kirkland iron ore; equivalent to Rochester shale of west and west-central New York.

D. W. Fisher and L. V. Rickard, 1953, New York State Mus. Circ. 36, p. 10, fig. 1. In area of Vanhornesville, observed to unconformably underly Brayman shale.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. no. 1. Underlies Ilion shale (new).

Type locality: On Steeles Creek, 5 miles southwest of Herkimer village, Herkimer County.

Herman Creek Lava[1]

Pleistocene: Central northern Oregon and southwestern Washington.

Original reference: R. W. Chaney, 1918, Jour. Geology, v. 26, no. 7, p. 577–592.

Herman Creek is in Hood River County, Oreg.

†Hermansville Limestone[1]

Hermansville Formation

Upper Cambrian and Lower Ordovician: Northwestern Michigan.

Original reference: C. R. Van Hise and W. S. Bayley, 1900, U.S. Geol. Survey Geol. Atlas, Folio 62.

F. T. Thwaites, 1942, Michigan Acad. Sci., Arts and Letters Papers, v. 28, p. 488. Hermansville of Van Hise and Bayley is not clear. In view of this uncertainty of definition, name Hermansville could very well be dropped.

G. V. Cohee, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 9. Hermansville limestone, as originally defined and later used in Northern Peninsula, included dolomite and sandstone of both Lower Ordovician and Cambrian age which can be traced in subsurface studies into northeastern Wisconsin. Jordan sandstone as recognized in this report forms part of Hermansville as currently used in Northern Peninsula.

W. K. Hamblin, 1958, Michigan Dept. Conserv., Geol. Div. Pub. 51, p. 6 (fig. 1), 116–117. Inasmuch as no type locality or type section was presented by Van Hise and Bayley or by any subsequent workers for term Hermansville, and since type of lithology and age of rocks referred to by that term has been vague and confused, name should be abandoned. Au Train formation is proposed for these rocks.

Named for exposures near Hermansville, Menominee County.

Hermit Shale (in Aubrey Group)[1]

Hermit Formation

Permian: Northern Arizona, southeastern Nevada, and southern Utah.

Original reference: L. F. Noble, 1922, U.S. Geol. Survey Prof. Paper 131–B, p. 26, 28, 64.

E. D. Koons, 1945, Geol. Soc. America Bull., v. 56, no. 2, p. 154. Discussion of geology of Uinkaret Plateau. Hermit formation, 1,053 feet thick, overlies Supai formation and underlies Coconino sandstone. Lower 200 feet contains cross-laminated beds of sandstone; upper 800 feet composed of weak shales and sandstones.

A. H. McNair, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 3, p. 515 (fig. 2), 526, 527–528. Referred to as formation. Designation shale is misnomer. Noble in description of type section used term sandstone for compact massive beds and shale for thinly laminated soft beds which are in reality fine-grained sandstones. Thickness: 933 feet at South Hurricane Cliffs; 700 feet at North Grand Wash Cliffs. Underlies Coconino sandstone; overlies Queantoweap sandstone (new) with contact transitional in interval ranging from 5 to 50 feet. If unconformity at base of Hermit at Bass Trail and at Jumpup Canyon on Kanab Creek, described by Noble (1922, and 1928, U.S. Geol. Survey Prof. Paper 150), is present in sections west of Kanab Creek, it would occur between the Queantoweap and Hermit; it may have been overlooked in present work.

Type locality: Hermit Basin, Arizona.

Hermitage Formation[1] or **Limestone** (in Lexington Group)

Hermitage Formation (in Nashville Group)

Middle Ordovician: West-central Tennessee and southern Kentucky.

Original reference: C. W. Hayes and E. O. Ulrich, 1903, U.S. Geol. Survey Geol. Atlas, Folio 95, p. 1.

D. K. Hamilton, 1948, Econ. Geology, v. 43, no. 1, p. 41, 42. Included in Lexington group. Overlies Curdsville limestone; underlies Jessamine limestone. Thickness 35 feet near Lexington, Ky.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 81–107, measured sections. Basal formation in Nashville group (redefined). Includes Curdsville member (at base) and facies or members referred to as laminated argillaceous silty nodular limestone; *Dalmanella* coquina; granular phosphatic; *Ctenodonta*; and blue clay-shale. Maximum thickness 180 feet. Underlies Bigby-Cannon formation; unconformably overlies Carters limestone of Stones River group. Hayes and Ulrich referred to section in vicinity of Hermitage Station but did not locate or reproduce the section. Bassler (1932, Tennessee Div. Geology Bull. 38) stated location of section and gave thickness as 67 feet. In present study, several sections were measured in vicinity of Hermitage Station which together present complete succession of formation in type area. Thickness of 67 feet was measured in section in bed of Stoner Creek and northward up hill located just west of bridge on Central Pike over this creek. This is probably locality where section was measured by Ulrich and Bassler.

Type area: Near Hermitage Station on hill between Stoner Creek and Lebanon-Nashville and Central Pikes. Named for occurrence at Hermitage Station, Davidson County, Tenn.

Hermon Coal Member (of Spoon Formation)

Pennsylvanian: Western Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 33, 45 (table 1), 63, pl. 1. Name applied to thin unit formerly termed Lower DeLong coal. Stratigraphically above Seville limestone member and below Brush coal member which name replaces unit formerly termed Middle Delong coal. Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification retained but is entirely independent of rock-stratigraphic classification.

Type locality: Along Brush Creek, secs. 6 and 8, T. 9 N., R. 2 E., Knox County. Named for village of Hermon about 2½ miles south of type outcrop.

Hermon cyclothem (in Spoon Formation)

Pennsylvanian: Northern and western Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 42, 52 (table 1), pl. 1. Name applied to cyclothem formerly called Lower DeLong. In sequence, occurs above Seville cyclothem and below Seahorne cyclothem. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois. Cyclical classification is independent of rock-stratigraphic classification.

Type locality: Along Brush Creek, secs. 6 and 8, T. 9 N., R. 2 E., Knox County. Named for village of Hermon, about 2½ miles southeast of type locality.

Hermon Granite Gneiss

Hermon type[1] granite

Precambrian: Northeastern New York.

Original reference: A. F. Buddington, 1929, New York State Mus. Bull. 281, p. 52–81.

A. F. Buddington, 1939, Geol. Soc. America Mem. 7, p. 142–145. Typical Hermon type of granite is moderately coarsely porphyritic augen gneiss, with phenocrysts of feldspar in coarse- to medium-grained ground mass. Borders Antwerp type granite. Granite occurs in sheet in Grenville belt.

Occurs in sheet extending from Hermon, St. Lawrence County, to Evans Mills.

Hermosa Formation[1]

Hermosa Group

Middle Pennsylvanian: Southwestern Colorado, northeastern Arizona, northwestern New Mexico, and southeastern Utah.

Original reference: W. Cross and A. C. Spencer, 1899, U.S. Geol. Survey Geol. Atlas, Folio 60, p. 8.

A. A. Baker, 1933, U. S. Geol. Survey Bull. 841, p. 18–23. Overlies Paradox formation (new).

W. S. Burbank and E. N. Goddard, 1937, Geol. Soc. America Bull., v. 48, no. 7, pl. 3. Discussion of thrusting in Huerfano Park region, Colorado. Stratigraphic column for region shows "type of sediments like Hermosa formation" underlying "type of sediments like Rico formation".

N. W. Bass, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 7, accompanied by paper on Paleozoic stratigraphy as revealed by deep wells in parts of southwestern Colorado, northwestern New Mexico, northeastern Arizona, and southeastern Utah. Formation in Animas River valley is about 2,000 feet thick and consists of alternating thick beds of greenish tan-gray arkosic sandstone, grit, and locally conglomerate, thin beds of dark-blue-gray, dense, fossiliferous limestone, and at least one zone that contains beds of gypsum. Includes Paradox member which overlies and underlies unnamed parts of formation. Underlies Rico formation; overlies Molas formation.

S. A. Wengerd, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 5, p. 1038–1051. Formation, exposed in San Juan Canyon where it transects Monument upwarp in southeastern Utah, contains several biostromal layers, one of which changes laterally into small bioherms with typical reef-limestone breccia making up greater part of deposit. At least eight bioherms have been breached by San Juan River, several of which are exposed on only one canyon wall. Reef limestones present through approximately two-thirds of Hermosa thickness below Hermosa-Rico gradational contact. Fossils suggest bioherms are Des Moines in age. Exposed thickness about 1,000 feet.

S. A. Wengerd and J. W. Strickland, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 10, p. 2165–2166, 2167 (fig. 7), 2173–2174, 2188–2190. Described in Paradox salt basin, Four Corners region, Colorado and Utah. Original Hermosa included all beds from top of Rico member of Cutler formation to top of Leadville limestone. Devonian strata referred to by Spencer was actually the presently known Leadville limestone of Mississippian age. Section measured in this report is almost exactly the one designated as type section by Roth (1934, Am. Assoc. Petroleum Geologists Bull., v. 18, no. 7). Hermosa of this report is restricted to clastic facies and carbonate facies that occur above Paradox here treated as a formation. Fusulind control shows carbonate facies as Wolfcamp, Virgil, Missouri, Des Moines (Marmaton, and locally Cherokee) ; clastic facies is Wolfcamp, Virgil, and Missouri. Top of Hermosa has been recognized, in past, in beds ranging from Wolfcamp to Des Moines in age, throughout stratigraphic interval of at least 800 feet. Inconsistent definitions of gross sections and their lithologic character without paleontologic control are responsible for this situation. Research has led to establishment of "R" datum, commonly a sandy limestone found in or near base of marine Wolfcamp series and approximately equivalent to Mendenhall sandstone at Honaker Trail, San Juan Canyon, Utah. This datum believed to be almost true time surface whose position does not vary more than 100 feet from some, as yet unidentifiable, true time-stratigraphic surface. In parts of region, this datum is exactly on top of section commonly considered to be the true Hermosa section and for purposes of regional correlation is considered to mark top of Hermosa section as chosen by Roth in type locality. "R" datum plane is approximately base of Rico transition facies here treated as basal member of Cutler formation.

F. W. Cater, Jr., 1955, U.S. Geol. Survey Geol. Quad. Map GQ–71. Formation described in Davis Mesa quadrangle, Colorado, where it comprises two members: lower or Paradox, consisting largely of intrusive salt and gypsum; and the upper or limestone member. All known surface occurrences of Paradox member are intrusive and beds are complexly folded and contorted; undisturbed thickness of member not known. Wells drilled in Paradox Valley penetrated about 2,300 feet of beds belonging to limestone member and more than 10,800 feet of intrusive beds without reaching pre-Paradox strata. Base of section. Underlies Cutler formation.

F. W. Cater, Jr., 1955, U.S. Geol. Survey Geol. Quad. Map GQ–77. Described in Anderson Mesa quadrangle, Colorado, where it consists of Paradox member below and an upper limestone member. Base of section; unconformably underlies Chinle formation.

J. R. Clair, 1958, Rocky Mountain Assoc. Geologists Symposium on Pennsylvanian rocks of Colorado and adjacent areas, p. 31–46. Group, in subsurface, comprises (ascending) Lime Ridge formation (new), Pinkerton Trail formation, Barker Creek zone, Paradox formation, Ismay zone, and Honaker Trail formation.

S. A. Wengerd and M. L. Matheny, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 9, p. 2056. Rank raised to group. Comprises (ascending) Pinkerton Trail, Paradox, and Honaker Trail (new) formations. Overlies Molas formation; underlies Cutler group.

D. W. Bolyard, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 1911. Discussion of stratigraphy in Sangre de Cristo Mountains between La Veta Pass and Westcliffe, Colo. Name Madera replaces Hermosa and Rico formations of Burbank and Goddard (1937) in south-central Colorado and restricts these terms to southwestern Colorado west of San Luis-Uncompahgre highland.

R. W. Fetzner, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 8, p. 1377–1388. Formation used in this report [Pennsylvanian paleotectonics of Colorado Plateau] comprises lower Hermosa member, Paradox member, and upper Hermosa member. Nomenclature of Wengerd and Matheny (1958) not used in present report because Honaker Trail formation includes early Permian Cutler carbonate facies that occurs in northwestern Paradox Salt basin and present investigation requires Permo-Pennsylvanian division in order to define Pennsylvanian lithofacies.

Type section (Roth): Secs. 26 and 35, T. 37 N., R. 9 W., La Plata County, Colo. Named for Hermosa Creek, which flows into Animas River north of Durango. This is composite section measured across strata which dip gently southward into San Juan basin.

Hermosa Lens (in Newcastle Formation)

Upper Cretaceous: Western South Dakota.

R. M. Grace, 1952, Wyoming Geol. Survey Bull. 44, p. 14, 17. Predominantly sandstone. Thickness 16 feet at north end, about 8 feet in middle, and 54 feet at south end. In this report, seven lenses are named in the Newcastle.

Present in T. 2 S., R. 8 E., near town of Hermosa, Custer County.

Hernshaw Sandstone (in Kanawha Formation)[1]

Pennsylvanian: Southern West Virginia.

Original reference: R. V. Hennen and D. B. Reger, 1914, West Virginia Geol. Survey Rept. Logan and Mingo Counties, p. 155.

Named for Hernshaw, Kanawha County.

Hero Member (of Valcour Formation)

Middle Ordovician (Chazyan): Northwestern Vermont and northeastern New York.

Philip Oxley and Marshall Kay, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 4, p. 825 (fig. 4), 826 (fig. 5), 834–836, 843, 846. In South Hero, lower 101 feet of the Valcour, the Hero member, is dark-gray silt-laminated calcarenite argillicalcisiltite, massive-bedded but weathering to nodular shaly rubble; *Solenoporo* sp. abundant in top 3 feet, and present sparingly with sponge *Zittelella varians* (Billings) and a few *Stromatocerium* masses below. At Chazy, N.Y., member has interbedded dolomite and calcilutite; calcilutites of lower 17 feet here are the dove limestone of authors, earlier mistaken for Beldens limestone. At Sheldon Lane, central Isle La Motte, Rockwell Bay, and Tiger Point, Valcour Island, member has *Glaphurus*-bearing reefs. Underlies Beech member (new); overlies Crown Point formation.

Type section: In South Hero, Vt., near Rutland Railroad station.

Herod Gravel Member (of Manhasset Formation)[1]

Pleistocene: Southeastern New York and islands of southeastern New England.

Original reference: M. L. Fuller, 1905, Geol. Soc. America Bull., v. 16, p. 367–390.

Lawrence Weiss, 1954, U.S. Geol. Survey Prof. Paper 254–G, p. 146. Basal member of Manhasset. Underlies Montauk till member; overlies Jacob sand. Manhasset is generally considered to be of Wisconsin age.

Occurs at nearly all points from Long Island to Boston.

Herrick Formation

Herrick Gravels

Pleistocene: Southeastern South Dakota.

R. E. Stevenson and L. A. Carlson, 1950, Areal geology of the Bonesteel quadrangle (1:62,500): South Dakota Geol. Survey. Fluvial coarse feldspathic sands and gravels on upland surface.

R. E. Stevenson, R. L. Hale, and H. C. Skogstrom, Jr., 1958, Geology of the Gregory quadrangle (1:62,500): South Dakota Geol. Survey. Formation consists of series of lensing crossbedded very coarse to medium-grained arkosic sands with local streaks of small pebbles of granite, quartz, schist, and petrified wood. Thickness as much as 54 feet; at paratype section, 35 to 40 feet. Lies on nearly flat surface developed on Ash Hollow formation.

Paratype section: In Burke Stone and Sand Company pit, 1½ miles west of Burke, Gregory County. Named for exposures near town of Herrick, 7 miles southeast of Burke.

Herrin Coal Member (of Carbondale Formation)

Pennsylvanian: Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 34, 35, 36, 48 (table 1), 65, pl. 1. Assigned member status in Carbondale formation (redefined). In southern area, occurs above Vermilionville sandstone member and below Brereton limestone member; in northern and western area, occurs above Big Creek shale member and below Brereton limestone member; in eastern area, occurs above Harrisburg (No. 5) coal member and below Danville (No. 7) coal member. Thickness about 5 feet. Name Brereton limestone is extended to caprock of No. 6 coal to replace name Herrin, now restricted to the coal. Coal named by Worthen (1870, *in* Geology and Paleontology, v. 4, Illinois Geol. Survey). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: In mines in vicinity of Herrin, Williamson County.

Herrin Limestone (in Carbondale Group)

Herrin Limestone (in McLeansboro Formation)[1]

Pennsylvanian: Southern Illinois.

Original reference: G. H. Cady, 1926, Illinois Acad. Sci. Trans., v. 19, p. 262.

J. R. Ball, 1952, Illinois Geol. Survey Bull. 77, p. 27, 44. Included in Brereton cyclothem, Carbondale group. Overlies Herrin No. 6 coal.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 35. Replaced by Brereton limestone member of Carbondale formation (redefined). Name Herrin now restricted to Herrin (No. 6) coal member.

Named because of its association with Herrin coal. First described in Saline County.

Herringa Flow or Tongue (of Clayton Basalt)

Late Cenozoic: Northeastern New Mexico.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 112, 133, 134, 143 (fig. 20). East of type locality, Clayton basalt consists of many long tongues. For purpose of this report, these tongues have been named, from south to north, Carrizo, Herringa, Clayton Mesa, Apache, Seneca, Gaps, and Van Cleve flows. All basalts rest on sand and gravel of Ogallala-like material in ancient valleys. Vents that gave rise to these basalts are unknown.

Present in eastern Union County.

Herschel Quartzite[1]

Lower Cretaceous(?): Southeastern Arizona.

Original reference: J. A. Church, 1903, Am. Inst. Mining Engrs. Trans., v. 33, p. 3–37.

Tombstone district.

Hersey Red Shale Member (of Pembroke Formation)[1]

Upper Silurian: Southeastern Maine.

Original reference: E. S. Bastin and H. S. Williams, 1914, U.S. Geol. Survey Geol. Atlas, Folio 192, p. 6–7.

Named for exposures on Hersey Neck, Pembroke Township, Washington County.

Hershey Limestone

Middle Ordovician: Southeastern Pennsylvania.

Carlyle Gray, 1952, Pennsylvania Geol. Survey Prog. Rept. 140, p. 4–5; 1952, Pennsylvania Acad. Sci. Proc., v. 26, p. 86, 88. Dark-gray graphitic, shaly or silty limestone. Less pure and darker in color than typical Myerstown limestone below. Weathered exposures typically brownish gray and show well-developed cleavage. Bedding marked by shaly laminations. Beds of conglomerate occur at base in eastern part of mapped area; consist of angular to subrounded fragments of dolomite and magnesian limestone in matrix of dark-gray graphitic shaly limestone and are interbedded with normal Hershey limestone. Total thickness several hundred feet. Conglomerate zone may be more than 100 feet thick in Berks County where it is mapped as an unnamed member. Underlies Martinsburg formation. Unit formerly included in Leesport formation. Name credited to C. E. Prouty.

Carlyle Gray and C. E. Prouty, 1954, Field Conf. Pennsylvania Geologists 20th Ann. Mtg., p. 28–29; C. E. Prouty, 1959, Pennsylvania Geol. Survey, 4th ser., Bull. G–31, p. 20–28. Thickness about 435 feet at type section. Overlies Myerstown; underlies Martinsburg.

Type section: Near covered bridge across Swatara Creek, Dauphin County. Named for Hershey, Dauphin County. Maximum development north of Womelsdorf in Berks County. Poorly exposed in Lebanon County.

Hertha Limestone (in Kansas City Group)[1]

Hertha Limestone (in Bronson Group)

Hertha Limestone Member (of Kansas City Formation)[1]

Pennsylvanian (Missouri Series): Northwestern Missouri, southwestern Iowa, eastern Kansas, and southeastern Nebraska.

Original reference: G. I. Adams, 1899, Kansas Acad. Sci. Trans., v. 16, p. 58, 59.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 193. Hertha limestone, in Bronson group, includes (ascending) Critzer limestone, Mound City shale, and Sniabar limestone members. Thickness. featheredge to about 30 feet. Overlies Bourbon shale; underlies Ladore shale.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2028–2029, 2031 (fig. 4). Underlies Ladore formation; overlies Pleasanton group. Kansas City group redefined in Kansas and Nebraska; lower boundary placed at base of Hertha formation. Bronson reduced to subgroup of Kansas City group (revised). This is classification agreed upon by Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 10, 11. In Missouri, Hertha includes (ascending) Critzer limestone, Mound City shale, and Sniabar limestone members.

T. L. Welp, L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 64, p. 421. Thickness about 3 feet in Madison County, Iowa. Underlies Ladore shale; overlies Pleasanton shale.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 28, fig. 5. Basal formation in Kansas City group. In Madison County, typically composed of three limestones with one thin shale separating the lower two. Middle limestone bed fragmental and fossiliferous; upper and lower limestones argillaceous and lenticular. Thickness about 4 feet in Madison County; about 9 feet in cores from Council Bluffs area. Underlies Ladore shale; overlies Pleasanton group.

Named for occurrence in vicinity of Hertha, Neosho County, Kans.

Hess Limestone Member (of Leonard Formation)

Hess (thin-bedded) Limestone Member (of Leonard Formation).

Permian: Western Texas.

Original reference: J. A. Udden, 1917, Texas Univ. Bull. 1753, p. 43, pl. 3.

P. B. King, 1937, U.S. Geol. Survey Prof. Paper 187, p. 98. Limestones northeast of Hess Ranch were named Hess formation in 1917 because they were thought to be separated by unconformity from Leonard beds above. Later work has shown that this unconformity does not exist, and evidence was presented (King, 1932, Am. Jour. Sci., 5th ser., v. 34) which indicated that limestones of typical Hess formation were largely equivalent to shales and thin limestones typical of Leonard formation. The two facies were interpreted as being separated by limestone reefs. In present report, the two units are brought together in single formation, the Leonard, in accordance with Udden's original definition, and the Hess is designated as Hess thin-bedded limestone member.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 651, pl. 2. Term Hess limestone member used in this report.

C. A. Ross, 1959, Washington Acad. Sci. Jour., v. 49, no. 9, p. 299. Lenoxhills formation (new) is lower 200 to 300 feet of Hess formation of Udden (1917).

Well exposed on Hess Ranch, Glass Mountains, Marathon region.

Hesse Quartzite[1] or **Sandstone** (in Chilhowee Group)

Hesse Quartzite Member (of Erwin Formation)

Lower Cambrian: Eastern Tennessee and western North Carolina.

Original reference: A. Keith, 1895, U.S. Geol. Survey Geol. Atlas, Folio 16.

C. E. Resser, 1939, Geol. Soc. America Spec. Paper 15, p. 4, 5. Hesse sandstone abandoned; evidently synonym for Erwin quartzite.

S. S. Oriel, 1950, North Carolina Div. Mineral Resources Bull. 60, p. 12, 13 (table 3). Two sets of formation names for Lower Cambrian clastic rocks in use in eastern Tennessee and western North Carolina (table 3). Northeast Tennessee names Unicoi, Hampton, and Erwin are used in this report for same rocks which Keith (1904, U.S. Geol. Survey, Geol. Atlas, Folio 116) and Stose and Stose (1947, Am. Jour. Sci., v. 245, no. 10) named Cochran, Nichols, Nebo, Murray, and Hesse, all defined by Keith (1895) in Chilhowee Mountain area, Blount and Sevier Counties, Tenn. Hot Springs area lies midway between type localities for each group of names. Hampton and Erwin formations, as used in this report [Hot Springs Window area], include Hesse quartzite.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, p. 35 (table 3). Table shows Hesse includes Helenmode member at top.

P. B. King and others, 1958, Geol. Soc. America Bull., v. 69, no. 8, p. 964. Chilhowee group as whole is classed as Cambrian and Precambrian(?). Helenmode formation at top of group is Cambrian and remaining unfossiliferous formations [including Hesse quartzite] are termed Precambrian(?).

R. B. Neuman and R. L. Wilson, 1960, U.S. Geol. Survey Geol. Quad. Map GQ–131. Hesse quartzite described in Blockhouse quadrangle. Tennessee, where it is 500 feet thick. Overlies Murray shale; underlies Helenmode formation. Lower Cambrian(?).

P. B. King and H. W. Ferguson, 1960, U.S. Geol. Survey Prof. Paper 311, p. 28 (table), 43. In northeasternmost Tennessee, considered quartzite member of Erwin formation. In places, as many as three ledges, each 25 to 50 feet thick, are separated by beds of siltstone. Only uppermost persists throughout area. Overlies Murray shale member; underlies Helenmode member. Lower Cambrian.

Named for Hesse Creek, Blockhouse quadrangle, Blount County, Tenn.

Heumader Shale Member (of Oread Limestone)[1]

Pennsylvanian (Virgil Series): Northwestern Missouri, southwestern Iowa, eastern Kansas, and southeastern Nebraska.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. Guidebook 6th Ann. Field Conf., p. 94, 96.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2035 (fig. 5). Heumader shale member of Oread limestone; underlies

Kereford limestone member; overlies Plattsmouth limestone member. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 25. Thickness in southeastern Nebraska 2 to 4 feet.

T. L. Welp, L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 64, p. 418 (fig. 1), 419. Thickness 7 feet in section measured near Winterset, Madison County.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 21, fig. 5. Olive green, brown, black; locally black carbonaceous zones and black subfissile beds. Average thickness 3 feet. Overlies Plattsmouth limestone member; underlies Kereford member; where Kereford is missing, underlies Kanwaka shale.

Type locality: Heumader quarry, bluffs of Missouri River just north of St. Joseph, Buchanan County, Mo.

Heuvelton Member (of Tribes Hill Formation)

Heuvelton Sandstone[1]

Lower Ordovician: Northern New York.

Original reference: G. H. Chadwick, 1915, Geol. Soc. America Bull., v. 26, p. 289–291.

R. H. Wheeler, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1938–1939; 1942, Am. Jour. Sci., v. 240, no. 7, p. 518–524. Cambro-Ordovician correlations revised in Champlain, Hudson, Mohawk, and St. Lawrence valleys. Lower "typical" Theresa is physically and faunally separated from "Upper Theresa" (now Heuvelton member of Tribes Hill formation). Two marine cycles represented by Tribes Hill formation (containing Norton equivalent to Heuvelton, Fort Ann equivalent to Bucks Bridge, Benson equivalent to Ogsdenburg members) and Cassin formation, constitute Beekmantown series.

W. H. Twenhofel and others, 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 2 (column 19). Heuvelton sandstone, shown on correlation chart as Lower Ordovician, occurs below Tribes Hill dolomite.

Probably named for Heuvelton, St. Lawrence County.

Hewetts Branch Sandstone (in Allegheny Formation)[1]

Pennsylvanian: Southeastern Ohio.

Original reference: E. Orton, 1884, Ohio Geol. Survey, v. 5, p. 116.

At Carbondale, Athens County.

Hewittville Calcilutites (or Beds)[1]

Lower Ordovician (Beekmantown): Northern New York.

Original reference: G. H. Chadwick, 1920, New York State Mus. Bull. 217, 218, p. 33.

Cap Bucks Bridge formation on west bank of Raquette River just below concrete dam of lower mills at Hewittville, Canton quadrangle.

Hex Formation

Upper Jurassic(?): Southern California.

O. T. Marsh, 1956, Dissert. Abs., v. 16, no. 1, p. 101; 1960, California Div. Mines Spec. Rept. 62, p. 6–8, pls. 1, 2. Brown and gray clay with bentonite at Hex Hill, grading westward into light-blue tuffaceous shale; abundant belemnites and some Foraminifera. Whitish, irregular limestone masses scattered throughout formation. Bedding has been destroyed by squeezing in core of Avenal Ridge piercement anticline. Because of plastic deformation, true thickness of formation cannot be determined. Contacts with other formations are everywhere discordant. Unit rests in fault contact against Badger shale, Risco formation, Serpiente sandstone, Moonlight formation, and probably Red Man sandstone (all newly named units). Fossils have been assigned tentatively to Late Jurassic.

Type locality: Hex Hill, just south of Devils Den, northwestern Kern County. Crops out east of Orchard Peak as single band about one-half mile wide and more than 4 miles long, paralleling base of scarp formed by Avenal Ridge. Occupies core of Avenal Ridge piercement anticline.

Hiawatha Graywacke (in Paint River Group)

Precambrian (Animikie Series): Northern Michigan.

H. L. James, 1958, U.S. Geol. Survey Prof. Paper 314–C, p. 30 (table 1), 38. Predominantly graywacke with considerable amounts of interbedded slate; lower part is commonly a breccia that consists of scattered angular chert fragments in a graywacke matrix. Ranges in thickness from 50 feet or less in eastern part of district to 400 feet more in western part. Underlies Stambaugh formation (new); overlies Riverton iron-formation (new).

Named for Hiawatha mine at Iron River, Iron County. Rocks are exposed in scattered outcrops and formation is crossed by extensive mine workings. Locally well exposed along course of Paint River at north edge of town of Crystal Falls.

Hiawatha Member (of Knight Formation)

Hiawatha Member (of Wasatch Formation)[1]

Paleocene and Eocene, lower: Northwestern Colorado, northeastern Utah, and southwestern Wyoming.

Original reference: W. T. Nightingale, 1930, Am. Assoc. Petroleum Geologists Bull., v. 14, no. 8, p. 1019–1040.

W. J. Morris, 1955, Dissert. Abs, v. 15, no. 3, p. 394. Name Knight formation extended from Bridger basin to include dominantly fluviatile Wasatchian deposits of Washakie basin. Hence, Hiawatha is considered member of Knight formation.

H. R. Ritzma, 1959, Utah Geol. and Mineralog. Survey Bull. 66, p. 40 (fig. 4), 41. Referred to as member of Wasatch. Geographically extended into Daggett County, Utah. Lower half, considered Paleocene, consists of drab claystone, shale, sandstone, coal, coaly shale, and conglomerate; upper half, considered Eocene, consists of varicolored claystone with minor amounts of coal, and coarse sandstone and conglomerate. Thickness as much as 3,500 feet. Underlies Tipton tongue of Green River formation; overlies Fort Union formation.

Names for development on Hiawatha and West Hiawatha domes, Tps. 12 N., Rs. 100 and 101 W., Moffat County, Colo.

Hickey Formation

Pliocene(?): Central Arizona.

C. A. Anderson and S. C. Creasey, 1958, U.S. Geol. Survey Prof. Paper 308, p. 56–58, fig. 2, pl. 1. Interbedded basaltic volcanic rocks and gravels. Volcanic rocks comprise chiefly olivine basalt and lesser amounts of olivine andesite, agglomerate, and basaltic sedimentary rock. Gravel beds consist of boulders and cobbles derived chiefly from local bedrock. Locally gravel is crudely bedded and cemented by lime. In one locality, thin bed of rhyolitic tuff intercalated between flows. Some flows more than 50 feet thick. Thickness about 1,400 feet along northern boundary of Mingus Mountain quadrangle, Jerome area. Erosion has removed top of formation in Jerome area. Unconformably underlies Verde formation; overlies Supai formation.

R. E. Lehner, 1958, U.S. Geol. Survey Bull. 1021–N, p. 549–556, pls. 45, 46, 47. In Clarkdale quadrangle, formation consists of much more volcanic than sedimentary rocks. Well exposed on Woodchute Mountain where there are about 1,400 feet of volcanic flows plus about 50 feet of gravel in minor channels at base of flows. Older than Perkinsville formation (new).

B. E. Sabels, 1960, Dissert. Abs., v. 21, no. 3, p. 596. Late(?) Miocene.

Named from exposures on Hickey Mountain, an upland area contiguous to Mingus Mountain, Jerome area, Yavapai County. Typically exposed on Mingus Mountain, but name Mingus preoccupied.

Hickman Group[1]

Pleistocene: Southwestern Kentucky.

Original reference: R. H. Loughridge, 1888, Kentucky Geol. Survey Rept. Jackson's Purchase Region, p. 37–41.

Named for bluffs of Mississippi River at Hickman, Fulton County, and to the south.

Hickory Sandstone Member (of Oil Creek Formation)

Ordovician: Oklahoma.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 107. Abandoned by Oklahoma Geological Survey. Name used by Edson (1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 8, p. 1127) for member at base of Oil Creek formation. Name preoccupied. No replacement of preoccupied name made, and none seems necessary.

Northeastern flank of Arbuckle Mountains.

Hickory Sandstone Member (of Riley Formation)

Hickory Sandstone[1]

Upper Cambrian: Central Texas.

Original reference: T. B. Comstock and E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept. p. lxi, 285, pl. 3.

P. E. Cloud, Jr., V. E. Barnes, and Josiah Bridge, 1946, Texas Univ. Bur. Econ. Geology Pub. 4301, p. 154 [1945]. Rank reduced to member status in Riley formation (new). Basal member of formation. Sandstone is noncalcareous, and color varies through different shades of brown. Upper boundary is placed at change from calcareous to noncalcareous sandstone. This restricts the member vertically as some quite sandy beds are thus allotted to overlying Cap Mountain limestone member. Thickness in Johnson City area 335 feet.

P. E. Cloud, Jr., and V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Pub. 4621, p. 27, 29, 253 [1946]. In Riley Mountains, member rests nonconformably on varied but mostly dark and schistose metasedimentary rocks of Precambrian Packsaddle schist.

Named for Hickory Creek, Llano County.

Hickory Creek Shale[1] Member (of Plattsburg Formation)

Pennsylvanian (Missouri Series): Eastern Kansas, northwestern Missouri, and southeastern Nebraska.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. 6th Ann. Field Conf., Guidebook, p. 93, 97.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 33. Thickness in Nebraska 1 to 3 feet or more; in Kansas 1 foot in a few places to maximum locally of 15 feet or more. Underlies Spring Hill limestone member; overlies Merriam limestone member. Type locality stated.

Type locality: In railroad cut near center east side sec. 14, T. 15 S., R. 23 E., southern Johnson County, Kans.

Hickory Ridge Member (of Oneota Formation)

Lower Ordovician: Southwestern Wisconsin.

G. O. Raasch, 1952, Illinois Acad. Sci. Trans., v. 45, p. 86–87, 89 (fig. 3), 92–93. Lower 35 to 40 feet of Oneota formation comprise natural unit that can be subdivided into two members and these further subdivided into a number of distinctive strata herein designated by numbers 1 to 9. Below base of stratum 4 (Chiton stratum), dolomites are for the most part arenaceous and are interbedded with sandstones, whereas little sand occurs above. On this basis, the unit is divided into Hickory Ridge member below and Mound Ridge member above. All oolite is confined to Hickory Ridge member, and "chitons" and most of chert are in Mount Ridge member. Overlies Sunset Point formation. Average thickness 24 feet. Fossils rare, but trilobite *Symphisurina* and small planospiral gastropods present locally.

Type section: Quarry and Mississippi bluff in NE¼SE¼ sec. 32, T. 13 N., R. 7 W., Stoddard quadrangle, 1 mile south of Genoa, Vernon County.

Hicks cyclothem (in McLeansboro Group)

Hicks cyclothem (in Modesto Formation)

Pennsylvanian: Northern Illinois.

C. L. Cooper, 1946, Illinois Geol. Survey Bull. 70, p. 12, 16 (fig. 2). Pennsylvanian succession between Gimlet and La Salle cyclothems, exposed in upper Illinois valley, contains several prominent but thin limestones which are basis for recognition of incomplete cyclothems to which names (ascending), Turner, Hicks, and Hall, have been applied by H. B. Willman.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 11, pl. 1. Includes Hicks limestone. Type locality given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 52 (table 2), pl. 1. In Modesto formation (new). Occurs above Trivoli cyclothem and below Hall clothem. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification is independent of rock-stratigraphic classification.

Type locality: NW¼SW¼ sec. 33, T. 16 N., R. 11 E., Bureau County.

Hicks Formation[1]

Upper Cambrian: Western Utah.

Original reference: T. B. Nolan, 1930, Washington Acad. Sci. Jour., 5th, v. 20, no. 17, p. 421–432.

C. B. Bentley, 1958, Brigham Young Univ. Research Studies, Geology Ser., v. 5, no. 6, p. 17–18, 53–54. Thickness in Deep Creek Range 599 feet. Underlies Dunderberg shale; overlies Lamb dolomite. Because of lithic similarities and age relationships, it is recommended that Orr formation and underlying Weeks limestone be extended to other areas of similar lithology in preference to Hicks and Lamb formations.

K. F. Bick, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 5, p. 1067. Evidence indicates that an unconformity is not present at top of Hicks formation; rather the Hicks thins depositionally, and the Cambro-Ordovician boundary lies within the Chokecherry dolostone.

Named for exposures in Hicks Gulch, in North Pass Canyon, Gold Hill district.

Hicks Limestone (in McLeansboro Formation)

Hicks Limestone (in McLeansboro Group)

Pennsylvanian: Northern Illinois.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 29). Shown on correlation chart as limestone in McLeansboro formation. Occurs below Hall limestone (new) and above Turner limestone (new).

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 11, pl. 1. Shown on correlation chart as limestone in McLeansboro group. Included in Hicks cyclothem. Type locality given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 38. Discontinued. Name Hicks preempted. No new name proposed.

Type locality: NW¼ SW¼ sec. 33, T. 16 N., R. 11 E., Bureau County.

Hidalgo Volcanics (in Bisbee Group)

Lower Cretaceous: Southwestern New Mexico.

S. G. Lasky, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 5, p. 532, figs. 2, 4; 1947, U.S. Geol. Survey Prof. Paper 208, p. 20–21, pl. 1. Consists primarily of basaltic lava flows. Breccia common at the base in Little Hatchet Mountains, and a little pyroclastic material present at other horizons. Locally contains 200 feet of thin-bedded light-gray and red limestone, red and green shale, and some conglomeratic layers. Exposed thickness ranges from 900 to 5,000 feet, the wide range being due to disconformities at top and bottom. Underlies Howells Ridge formation (new); overlies Ringbone shale (new) and Broken Jug limestone (new). Trinity age.

Named from Hidalgo County, over which the formation seems to be widely distributed. In Eureka district of Little Hatchet Mountains.

Hidden Falls Member (of Platteville Formation)

Middle Ordovician: East-central Minnesota.

M. P. Weiss and W. C. Bell, 1956, Geol. Soc. America Guidebook for Field Trips Minneapolis Mtg., Field Trip 2, p. 58 (table 1), 60–61. Name applied to the argillaceous dolomitic limestone unit at about the middle of the Platteville in the Twin Cities area, where it is about 6 feet thick; includes bentonite or bentonitic shale at top. Thins to the east, grades into Magnolia lithology, and is not present at Ellsworth, Wis.; extends as far south as Faribault, where it is 17 inches thick, and Cannon Falls, where it is about 8 feet thick and is overlain directly by the Carimona member. In Twin Cities area, underlies Magnolia member and overlies Mifflin member.

R. E. Sloan, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 12, p. 2955–2956. Formal proposal of name. Type section designated.

Type section: In Hidden Falls Park on Mississippi River half a mile south of Ford Motor Co. plant in St. Paul, Ramsey County.

Hidden Treasure Limestone[1]

Lower Mississippian: Central northern Utah.

Original reference: F. M. Wichman, 1920, Eng. Mining Jour., v. 110, no. 12, p. 563.

Probably named for Hidden Treasure mine, Ophir district.

Hidden Valley Dolomite

Silurian and Lower Devonian: Southern California.

J. F. McAllister, 1952, California Div. Mines Spec. Rept. 25, p. 3, 14 (fig. 6), 15, pl. 1, 2, 3. Uniformly consists of dolomite but contains nodular chert near base and a little silt and sand near top. In lowest and highest units dolomite is medium gray and weathers light olive gray and yellowish gray; middle is light gray or creamy; chert is light gray or light brown and weathers to dark brown; contains silicified fossils. Thickness 1,365 feet at type locality and in Andy Hills. Underlies Devonian Lost Burro formation (new); overlies Ely Springs dolomite. Lower fossiliferous part of Hidden Valley is Silurian; near upper boundary of formation is a 50-foot zone containing Lower Devonian fossils. Thus Silurian-Devonian boundary falls within uppermost part of the Hidden Valley; the persistent lithologic change is above the Lower Devonian fossils, and this distinctive formational boundary has been mapped over a broad area.

J. F. McAllister, 1955, California Div. Mines Spec. Rept. 42, p. 9 (fig. 3), 12, pl. 2. In Ubehebe Peak quadrangle, underlies Lippincott member (new) of Lost Burro formation.

Type locality: On eastern flank of mountain about 2½ miles north of Ubehebe Peak, and about three-fourths mile west of the road in Racetrack Valley. Named for good exposure on eastern side of Hidden Valley, about 3 miles east-southeast from bench mark 5980 near Lost Burro Gap, northern Panamint Range, Inyo County.

Higginsville Limestone Member (of Fort Scott Limestone)

Pennsylvanian (Des Moines Series): Western Missouri, southwestern Iowa, southeastern Kansas, and northeastern Oklahoma.

L. M. Cline, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 26–27 (fig. 2), 36, 63. Proposed for upper limestone of Fort Scott formation. Traced into Appanoose County, Iowa.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 38, p. 308, 309. Overlies Little Osage shale member (new). Underlies Labette shale. Average thickness in Kansas about 16 feet.

F. C. Greene, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 6. Overlies Flint Hill sandstone bed (new) in Little Osage member of Fort Scott.

R. D. Alexander, 1954, Oklahoma Geol. Survey Circ. 31, p. 14, 16 (fig. 2). Reaches maximum thickness of 35 feet in Craig County and passes into shale in western Rogers County.

H. G. Hershey, and others, 1960, Iowa Highway Research Board Bull. 15, p. 33, fig. 5. Medium gray, finely crystalline, and massive. Somewhat more fossiliferous to southeast than in Madison County. Thickness 2 feet in Appanoose County; 1 foot in Madison County. Shale section underlies Higginsville; in Appanoose County, carbonaceous shale is found immediately below the limestone; in Madison County, this shale is reddish brown and contains large ostracodes. Shale interval between Higginsville and overlying Houx limestone member is about 15 feet in Appanoose and about 7 feet in Madison County.

Well exposed east of Higginsville, Lafayette County, Mo.

Higham Grit[1]

Triassic(?): Southeastern Idaho, northeastern Utah, and western Wyoming.

Original reference: G. R. Mansfield, 1915, Washington Acad. Sci. Jour., v. 5, p. 492.

J. S. Williams, 1945, Am. Jour. Sci., v. 243, no. 9, p. 473, 475–476, fig. 2. Use extended southward to Park City area and as far east as upper Weber River section, Utah, to replace part of Ankareh shale which is stratigraphically restricted.

G. R. Mansfield, 1952, U.S. Geol. Survey Prof. Paper 238, p. 17, 34, pl. 1. Mapped as Higham grit in Ammon and Paradise Valley quadrangles, Idaho. Underlies Deadman limestone; overlies Timothy sandstone. Type locality designated.

Bernhard Kummel, 1954, U.S. Geol. Survey Prof. Paper 254–H, p. 179–181, fig. 18. Timothy sandstone, Higham grit, Deadman limestone, and Wood shale are each distinct lithologically and are equivalent to Ankareh formation of Wasatch and Uinta Mountains and of western Wyoming. In present report, the Timothy is considered uppermost member of Thaynes formation. The Higham unconformably overlies Timothy sandstone member. Higham grit and Deadman limestone are recognized as independent formations, but Wood shale is considered westward extending tongue of Ankareh. Thickness of 105 feet at Cokeville, Sublette Range, Wyo. Age shown on table as Upper Triassic.

W. F. Scott, 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 104. Discussion of stratigraphy of Triassic sequence in Wasatch and western Uinta Mountains. The thin conglomeratic sandstone unit above Ankareh formation in this area is litho-stratigraphic equivalent of Higham grit of southeastern Idaho and Shinarump(?) conglomerate of eastern Uinta Mountains. Use of names Higham and Gartra to refer to this unit in this region ignores rule of priority. Older name Shinarump conglomerate is recommended.

Type locality: Higham Peak, from which unit takes its name, in sec. 23, T. 3 S., R. 37 E., about 4 miles west of Paradise Valley quadrangle, Idaho.

†High Bluff Blue Sands[1]

Upper Cretaceous (Gulf Series): Southwestern Arkansas.

Original reference: R. T. Hill, 1888, Arkansas Geol. Survey Ann. Rept. 1888, v. 2, p. 72, 75–77, 188.

Named for exposures in High Bluff of Ouachita River, 1½ miles northeast of Arkadelphia, Clark County.

†High Bluff Greensand[1]

Upper Cretaceous (Gulf Series): Southwestern Arkansas.

Original reference: R. T. Hill, 1888, Arkansas Geol. Survey Ann. Rept. 1888, v. 2, p. 72–75, 188.

Named for exposures in High Bluff of Ouachita River, 1½ miles northeast of Arkadelphia, Clark County.

High Bluff Member (of Pendleton Formation)

Eocene, lower: Northwestern Louisiana and northeastern Texas.

Richard Wasem and L. J. Wilbert, Jr., 1943, Jour. Paleontology, v. 17, no. 2, p. 184 (fig. 4), 186, 187. Consists of basal section of fossiliferous glauconitic sand overlain by sand containing calcareous concretions. These sands grade upward into about 65 feet of thin-bedded lignitic silts and sands: uppermost 30-foot part consists of crossbedded sands. Approximately 130 feet thick. Overlies Slaughter Creek member (new); underlies Pierson [Pearson] glauconite bed (new) in Sabinetown formation.

Typically exposed at High Bluff on Sabine River, Sabine Parish, La. Traced from Geneva, Tex., to Hagewood, Natchitoches Parish, La.

High Bridge Gneiss[1]

Precambrian: New York.

Original reference: R. P. Stevens, 1867, New York Lyc. Nat. History Annals, v. 8, p. 116–120.

Along southern shore of Spuyten-Duyvel Creek and Harlem River.

High Bridge Limestone[1] or Group

Middle Ordovician: Central Kentucky.

Original reference: M. R. Campbell, 1898, U.S. Geol. Survey Geol. Atlas, Folio 46, p. 2.

A. C. McFarlan, 1943, Geology of Kentucky: Lexington, Ky., Kentucky Univ., p. 12–13; D. K. Hamilton, 1948, Econ. Geology, v. 43, p. 40–41. High Bridge group comprises (ascending) Camp Nelson, Oregon, and Tyrone limestones.

J. L. Rich, 1951, Geol. Soc. America Bull., v. 62, no. 1, p. 18. Refers to High Bridge limestone, with Camp Nelson, Oregon, and Tyrone members.

Named for exposures at High Bridge (Highbridge), Jessamine County.

High Cascade series

Pliocene, Pleistocene, and Recent: Northern California and Oregon.

Eugene Callaghan, 1933, Am. Geophysical Union Trans., p. 243–249. Discussion of volcanic sequence in Cascade Range in Oregon. Cascade Range south of Mount Hood divided into two parts, Western Cascades and High Cascades, on basis of pronounced unconformity in stratigraphic sequence of lavas. Rocks that form the High Cascades are characterized by large mass of gray olivine basalt, large cones composed mainly of hypersthene andesite, rhyolite and pyroclastics, and small cones, some of them quite recent, of andesite, calcic andesite, and basalt.

Howel Williams, 1949, California Div. Mines Bull. 151, p. 35–49. Most of Macdoel quadrangle occupied by volcanic rocks. These belong to two series: first, the Western Cascade series, Eocene to Miocene, and second, High Cascade series of Pliocene, Pleistocene, and Recent age. Named units in area include Plutos Cave, Butte Creek, Alder Creek, Whaleback, and Copco basalts and Goosenest flows.

High Falls Shale[1] or Formation[1]

Upper Silurian: Eastern New York, northern New Jersey, and northeastern Pennsylvania.

Original reference: C. A. Hartnagel, 1905, New York State Mus. Bull. 80, p. 342–357.

Freeman Ward, 1938, Pennsylvania Geol. Survey, 4th ser., Bull. G–10, p. 4, 5 (fig. 2), 6–7. High Falls formation mapped in Pennsylvania below Delaware Water Gap. Overlies Shawangunk formation; underlies Cayuga group (formation). High Falls (synonymous with Bloomsburg red beds) is shaly but contains some sandstone. Predominantly red with some dull greenish beds. Occurs in wide band on northern and lower slopes of Kittatinny Mountain.

Well exposed on farm of Patrick Winn at High Falls, Ulster County, N.Y.

Highgate Formation

Highgate Slate[1]

Lower Ordovician: Northwestern Vermont.

Original reference: Arthur Keith, 1923, Am. Jour. Sci., 5th ser., v. 5, p. 114–115.

Charles Schuchert, 1937, Geol. Soc. America Bull., v. 48, no. 7, p. 1015, 1021, 1047, 1048, 1070–1074. Referred to as formation. In type area, a tectonic limestone breccia underlies the limestones and slates. Hungerford formation named to distinguish some beds formerly included in this formation. Lower Ordovician. Type locality cited.

A. B. Shaw, 1958, Geol. Soc. America Bull. 69, no. 5, p. 523 (table 1), 532 (fig. 5), 550–553, pl. 1. Keith's first description of Highgate included rocks now assigned to Highgate as well as parts of Gorge formation, Hungerford slate, and Skeels Corners slate. Schuchert included certain Morses Line slates in Highgate. Formation, as herein defined, includes beds named Grandge slate by Schuchert. Beds exposed below Highgate Falls (Schuchert's type area) are now included in Gorge formation; hence, new type locality is designated. Lowest Highgate beds lie above Highgate Falls thrust in north and east walls of Highgate Gorge. These beds were inaccurately called Upper Gorge formation by Shaw (1951, Jour. Paleontology, v. 25; 1953, Jour. Paleontology, v. 27). Several angular unconformities present in formation. Section consists of lower limestone unit 500 to 1,000 feet thick; middle shaly unit about 1,500 feet thick and an upper conglomerate and limestone. These units are gradational vertically through several hundred feet. Overlies Gorge formation; underlies Morses Line formation.

Type locality (Shaw): Series of outcrops above Highgate Falls thrust and on western edge of Highgate Center. Formation lies in strip ½ to 1 mile wide trending about N. 20° E., from type locality. Type area (Schuchert): Upper sequence in gorge of Missiquoi River at Highgate Falls, Franklin County.

Highgate Springs sequence

See Highgate Springs Series.

Highgate Springs Series[1]

Lower and Middle Ordovician: Northwestern Vermont, and southern Quebec, Canada.

Original references: W. E. Logan, 1863, Geology of Canada: Canada Geol. Survey, p. 273–275, 855–859; H. W. McGerrigle, [1931], Vermont State Geologist 17th Rept., p. 179–192.

Charles Schuchert, 1937, Geol. Soc. America Bull., v. 48, no. 7, p. 1016, 1017. Highgate Springs sequence mentioned in report on Cambrian and Ordovician of northwestern Vermont. Sequence is overthrust by Winooski dolomites. Logan (1863) noted Highgate Springs series consisted of Trenton, Black River, and probably Chazy formations.

Marshall Kay, 1958, Am. Jour. Sci., v. 256, no. 2, p. 65–96. Ordovician rocks at Highgate Springs, Franklin County, Vt., are of a distinctive sequence that outcrops in scattered areas from east of St. Hyacinthe, Quebec, to southwest of St. Albans, Vt., for about 80 miles. Succession has been called Highgate Springs series by McGerrigle, the lower part being Division E of Quebec group of Logan (1863). Term Highgate sequence used in this report to avoid connotation that it is a formal stratigraphic series. At Highgate Springs, Vt., sequence includes Beldens limestone, Carman quartzite, Youngman formation, Isle La Motte limestone, Glens Falls limestone, and Canajoharie shale.

Most complete exposure at Highgate Springs, Franklin County, Vt.

Highland Gneiss[1]

Precambrian: Southeastern New York.

Original reference: D. S. Martin, 1888, Geologic map of New York City and vicinity.

T. W. Fluhr, 1950, New York Acad. Sci. Trans., ser. 2, v. 12, no. 6, p. 182, 185. At Somers, Highlands gneisses have been overthrust on the Inwood limestone, the fault plane dipping at 60° to northwest beneath the Highlands massive. Fordham gneiss has been correlated with the gneisses of the Highlands, but evidence which proves that the gneisses of the Highlands are Precambrian is not necessarily applicable to the Fordham. [Author may or may not have intended to use this term in a formal sense.]

Occurs in Highlands of the Hudson.

Highland Shale Member (of Wellington Formation)

Permian: Central Kansas.

W. A. Ver Wiebe, 1937, Wichita Municipal Univ. Bull., v. 12, no. 5, p. 5–6. Consists of soft clay, predominately greenish, and a few thin beds of claystone. Red clays infrequent in north, more frequent to south. Approximately 45 feet thick. Underlies Slate Creek limestone member (new); overlies Carlton limestone member.

Type locality: Highland Township, T. 22 S., R. 1 E.

Highland Boy Limestone Member (of Bingham Quartzite)[1]

Pennsylvanian: Central northern Utah.

Original reference: A. Keith, 1905, U.S. Geol. Survey Prof. Paper 38, p. 41, map.

C. H. Behre, Jr., 1937, Mining Technology, v. 1, no. 1, Tech. Pub. 767, p. 8. Mentioned in discussion of bedding-plane faults and their economic importance.

Occurs in vicinity of Highland Boy mine, Bingham district.

Highland Church Sandstone

Highland Church Sandstone Member (of Forest Grove Formation)[1]

Mississippian: Northeastern Mississippi.

Original reference: W. C. Morse, 1928, Jour. Geology, v. 36, p. 31–43.

Benjamin Gildersleeve, 1946, Tennessee Valley Authority Rept. 2, p. 8, 13. Referred to as Highland Church sandstone. Thickness 10 to 30 feet.

Forms cliffs about Highland Church, east of Tishomingo City, Tishomingo County.

Highlandcroft Granodiorite (in Highlandcroft Plutonic Series)

Upper Ordovician(?): Northwestern New Hampshire.

Original reference: M. P. Billings, 1935, Geology of Littleton and Moosilauke quadrangles, New Hampshire, p. 25, map.

M. P. Billings, 1937, Geol. Soc. America Bull., v. 48, no. 4, p. 499–500, pl. 1. Map bracket shows Highlandcroft granodiorite above Partridge formation and below Clough conglomerate. Late Ordovician?

Large estate called "Highlandcroft" on St. Johnsbury road, 1½ miles west-northwest of Littleton, located on largest body of this rock in Littleton and Moosilauke quadrangles.

Highlandcroft Plutonic Series

Highland Croft Magma Series [1] or Granodiorite

Upper Ordovician: West-central and northwestern New Hampshire and east-central Vermont.

Original reference: M. P. Billings, 1934, Science, v. 79, no. 2038, p. 55–56.

M. P. Billings, 1937, Geol. Soc. America Bull., v. 48, no. 4, p. 499. Magma series includes Highlandcroft granodiorite in Littleton-Moosilauke area, New Hampshire, Lost Nation quartz monzonite of Percy area, New Hampshire, and Fairlee quartz monzonite of Mount Cube quadrangle, New Hampshire-Vermont.

M. P. Billings, 1956, Geology of New Hampshire, pt. 2, Bedrock geology: Concord, New Hampshire State Plan. Devel. Comm., p. 46–48, 106–107, 121–122, 148, 186–187. Summary discussion. Plutonic series includes diorite, quartz diorite, granodiorite, quartz monzonite, and granite. Many are massive but locally show weak to strong secondary foliation. Rocks assigned to series correlated chiefly on basis of lithologic similarity. Type area given.

Type area: Body of plutonic rocks 2 miles northwest of Littleton, Grafton County, N.H. Named from a large farm about 1½ miles west-northwest of Littleton.

Highland Mills Member (of Esopus Formation)

Lower Devonian: Southeastern New York.

A. J. Boucot, 1959, Jour. Paleontology, v. 33, no. 5, p. 728, 731 (fig. 2), 732–733. Name applied to strata that overlie Connelly conglomerate and grade up into middle member (unnamed) of Esopus formation. Consists of interbedded yellow to gray sandstone and dark-gray shale. Sandstone beds thicken and thin rapidly and are not continuous along strike. Basal bed is layer of dark-bluish-gray paper-thin shale which makes abrupt contacts with Connelly conglomerate below and with sandstone above. Fossiliferous. Thickness about 50 feet.

Type section: West side of Thruway cut at Highland Mills, Orange County. Member is known definitely only in this vicinity. Section is located on eastern side of Green Pond-Schunemunk Mountain outlier.

Highland Peak Limestone[1]

Middle and Upper Cambrian: Eastern Nevada.

Original references: L. G. Westgate and A. Knopf, 1927, Am. Inst. Min. and Met. Engrs. Trans. 1647, p. 6; 1932, U.S. Geol. Survey Prof. Paper 171.

H. E. Wheeler and D. W. Lemmon, 1939, Nevada Univ. Bull., Geology and Mining Ser., no. 31, p. 33, 37–42, 45–47, fig. 10. Described in detail in Pioche district. Composite section given; parts derived from north end of Bristol Range in vicinity of Bristol mine; hills northeast of Panaca; west side of Highland Range in vicinity of Comet Peak. Seventeen lithologic units described (designated by letters A to Q). Total thickness 4,080 feet. Overlies Chisholm shale; underlies Mendha limestone. Middle and Upper Cambrian.

H. E. Wheeler, 1940, Nevada Univ. Bull., Geology and Mining Ser., no. 34, p. 12 (fig. 2), 13–14, 17–33. Two unconformities occur in lower part of Highland Peak as originally defined. Hence, Highland Peak is herein restricted to exclude units named (ascending) Peasley and Burrows. Base of restricted formation coincides with base of Highland Peak unit C, as defined by Wheeler and Lemmon (1939). Thickness as restricted about 3,325 feet.

H. E. Wheeler, 1948, Nevada Univ. Bull., Geology and Mining Ser., no. 47, p. 36–37, 42–43, fig. 5. Further restricted; includes only units H to Q of Wheeler and Lemmon (1939). Unit C is herein named Burnt Canyon limestone; units D–E and F–G are same as Dome and Swasey formations, respectively, of House Range, Utah. These names are extended into Nevada.

R. H. Robison, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 50 (fig. 4). In Pioche district, overlies Whirlwind formation (new). Restricted to Wheeler's units C-K.

Named for exposures on western slope of Highland Peak, in Highland Range, Pioche district.

High Park Lake Beds[1]

Miocene, upper, or Pliocene: Eastern Colorado.

Original reference: W. Cross, 1894, U.S. Geol. Survey Geol. Atlas, Folio 7.

Named for High Park, Pikes Peak region.

†High Point Sandstone[1]

Upper Devonian: West-central and southwestern New York.

Original references: H. S. Williams (High-point beds), 1883, Am. Jour. Sci., 3d ser., v. 25, no. 136, p. 100, 101; J. M. Clarke, 1885, New York State Geol. Rept. 1884, p. 22, map; 1885, U.S. Geol. Survey Bull. 16.

W. H. Bradley and J. F. Pepper, 1938, U.S. Geol. Survey Bull. 899–A, p. 15. Nunda sandstone overlies West Hill formation. Luther (1902, New York State Mus. Bull. 52) traced this sandstone from its type locality at Nunda eastward into Naples quadrangle and showed that it is same sandstone as that which caps High Point, a hill 2½ miles northwest of Naples. Name Nunda is used in this report [southwestern New York] in place of High Point sandstone (discarded) which Clarke and Luther (1904, New York State Mus. Bull. 63) later used in Canandaigua and Naples quadrangles.

Named for exposures on summit of High Point, in Naples, highest mountain in Ontario County.

High Rock Sandstone[1]

Pennsylvanian: Southwestern Indiana.

Original reference: G. H. Ashley, 1899, Indiana Dept. Geology and Nat. Resources 23d Ann. Rept. 1898, p. 113.

Daviess and Greene Counties.

High Rock Sandstone[1]

Pennsylvanian: Southeastern Kentucky.

Original reference: I. B. Browning and P. G. Russell, 1919, Kentucky Geol. Survey, 4th ser., v. 5, pt. 2, p. 15.

Named because it is found on several high points exposed in cliffs called High Rocks by natives.

High Tower Granite[1]

Cambrian(?): Northwestern Georgia.

Original reference: W. S. Bayley, 1928, Georgia Geol. Survey Bull. 43, p. 37, map.

G. W. Crickmay, 1952, Georgia Geol. Survey Bull. 58, p. 43. Name Hightower was applied by Bayley (1928) for granite in northwestern Forsyth County, but may be appropriately used for granite gneiss on southwestern side of Ashland belt in Dawson, Lumpkin, and White Counties. Intrusive into Carolina series.

Well developed around Hightower, Forsyth County.

Highway Limestone

Middle Pennsylvanian: North-central Nevada.

H. G. Ferguson, R. J. Roberts, and S. W. Muller, 1952, Geology of the Golconda quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ-15]. Described as massive light-gray limestone. In places cherty near base; thin pebbly and sandy layers throughout. Thickness at type locality 200 feet. Overlies Battle formation at some localities; other places, overlies Preble formation with angular unconformity. Underlies Antler Peak limestone. Lower Pennsylvanian.

R. J. Roberts and others, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2842. Highway limestone, about 200 feet thick, in Osgood and Edna Mountains, is facies of Battle formation composed of limestone and some interbedded conglomerate and calcareous clastics. Middle Pennsylvanian.

Type locality: East flank of Edna Mountain, north of Highway 40.

Highwood Syenite[1]

Eocene(?): Central northern Montana.

Original reference: W. H. Weed, 1899, U.S. Geol. Survey Geol. Atlas, Folio 55.

Southern part of Highwood Peak, Fort Benton quadrangle.

Hignite Formation (in Breathitt Group)

Hignite Formation (in Pottsville Group)[1]

Middle Pennsylvanian: Southeastern Kentucky and northeastern Tennessee.

Original reference: G. H. Ashley and L. C. Glenn, 1906, U.S. Geol. Survey Prof. Paper 49, p. 33, 43, pl. 40-A.

H. R. Wanless, 1946, Geol. Soc. America Mem. 13, p. 7, passim. Underlies Bryson formation; overlies Catron formation. Includes Reynolds sandstone member.

U.S. Geological Survey currently classifies the Hignite as a formation in Breathitt Group on the basis of a study now in progress. Term Pottsville Group not used in Kentucky.

Named for Hignite Creek, near Middlesboro, Bell County, Ky.

Hiirippo (Hirippo) Limestone

Aquitanian: Mariana Islands (Rota).

Risaburo Tayama, 1939, Correlation of the strata of the South Sea Islands: Geol. Soc. Japan Jour., v. 46, no. 549, p. 346 (correlation chart) [English translation in library of U.S. Geol. Survey]. Named on correlation chart. Correlated with Tapotchau limestone on Saipan and Raso limestone on Tinian. Miocene.

Risaburo Tayama, 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 54, table 4 [English translation in library of U.S. Geol. Survey, p. 65]. Oligocene.

S. Hanzawa *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 39. The Hiirippo consists of pinkish hard compact limestone, red sandy limestone, and calcareous sandstone. Overlies Taihanom and Mariiru limestones. Aquitanian. Refers to S. Sugawara (unpub. ms., 1939) and K. Asano (1939, Jubil. Pub. Yabe's 60th Birthday).

Typically exposed in Hiirippo, Rota Island.

Hilina Volcanic Series

Pleistocene(?): Hawaii Island, Hawaii.

H. T. Stearns and G. A. Macdonald, 1946, Hawaii Div. Hydrography Bull. 9, p. 102, pls. 1, 20A. Comprises lava flows and pyroclastics laid down by Kilauea volcano prior to deposition of Pahala ash. At type locality, 1,000 feet of thin-bedded basalts and thin vitric tuff beds are capped by 30 feet of Pahala ash. Lowest tuff bed is 200 feet above base of cliff, and numerous thin tuff beds crop out between it and the top. Base not exposed. Series was formerly mapped as Pahala basalt, but name Pahala herein restricted to persistent ash formation.

D. A. Davis and G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 89. Pleistocene(?).

Type locality: At Hilina Pali on south slope of Kilauea. Also exposed in windows in faces of fault cliffs on southern slope of Kilauea.

Hillabee Chlorite Schist[1]

Post-Carboniferous: Eastern Alabama.

Original reference: W. M. Brewer, 1896, Alabama Geol. Survey Bull. 5, p. 84, 89, 92.

E. W. Heinrich and J. C. Olson, 1953, U.S. Geol. Survey Prof. Paper 248–G, p. 404. Mentioned in discussion of mica deposits of southeastern Piedmont. Considered to be post-Carboniferous.

Named for exposures at Hillabee, on Hillabee Creek, Clay County.

Hill Creek Beds or Member (of Lazy Bend Formation)

Hill Creek Beds or Member (of Millsap Lake Formation)[1]

Pennsylvanian: North-central Texas.

Original reference: E. H. Sellards, 1933, Texas Univ. Bull. 3232, p. 106, 107. From manuscript report by G. Scott and J. M. Armstrong on geology of Parker County.

W. E. Russell, 1956, Soc. Econ. Paleontologists and Mineralogists, Permian Basin sec. [Guidebook] Spring Mtg. and Field Symposium May 11–12, p. 19–27. Referred to as Hill Creek beds in Lazy Bend formation.

Leo Hendricks, 1957, Texas Univ. Bur. Econ. Geology Pub. 5724, p. 13–16, pl. 1. Member of Lazy Bend formation. Consists of 277 feet of beds between base of Dennis Bridge limestone bed and top of Meek Bend limestone bed. Underlies Steussy shale member; overlies undifferentiated Pennsylvanian beds. Type section designated; derivation of name given.

Type section: Section measured across the strike south of Brazos River, Parker County. Outcrop of beds extends to Cretaceous on either side of Brazos River and from bridge at Dennis westward to a scarp west of Hill Creek. Name derived from Hill Creek, a small tributary flowing from southwest into Brazos River at point about midway of outer curve of Lazy Bend of river.

Hillen facies

See **Ludlow Member** (of Fort Union Formation).

Hilliard Formation[1] **or Shale**

Upper Cretaceous: Southwestern Wyoming and northeastern Utah.

Original reference: W. C. Knight, 1902, Eng. Mining Jour., v. 73, p. 721.

R. H. Peterson, D. J. Gauger, and R. R. Lankford, 1953, Utah Geol. and Mineralog. Survey Bull. 47, p. 16 (fig. 4), 17–18. Near Evanston, Wyo., Hilliard formation consists of 5,500 to 6,800 feet of gray to black sandy shales and shaly sandstones. Lenses of white sandstone 3,000 to 3,800 feet occur above base of formation. Overlies Frontier formation; underlies Adaville formation.

W. R. Hansen and M. G. Bonilla, 1954, Colorado Sci. Soc. Proc., v. 17, no. 1, p. 4 (fig. 1), 9, 10. Geographically extended into Daggett County, Utah, where it is 6,300 feet thick in Flaming Gorge area; underlies Blair formation and overlies Frontier formation. In Clay Basin, replaces Blair formation and intertongues with overlying Rock Springs formation.

W. R. Hansen, 1957, U.S. Geol. Survey Geol. Quad. Map GQ–101. In Clay Basin quadrangle, Utah, described as chiefly dark-gray soft silty, somewhat gypsiferous shale about 6,200 feet thick. Only upper part crops out in area. Intertongues with overlying Mesaverde group, contact with Rock Springs formation mapped arbitrarily.

Typical section: Shale beds west of Kemmerer, Lincoln County, and extending as far as east portal of Oregon Short Line tunnel, Wyoming. Town of Hilliard located on formation.

Hillier Member (of Cobourg Formation)

Middle Ordovician (Mohawkian): Ontario, Canada, northern Michigan, and western New York.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 280–281, pl. 4. Upper Cobourg limestone of earlier reports. Light-gray marly limestones in central Ontario and northern Michigan; darker colored limestone with shaly interbeds in New York and southeastern Ontario. Near the base, beds are argillaceous limestones in contrast to massive and resistant crystalline limestones at top of underlying Hallowell member (new); transition zone is 20 feet thick. Thickness 60 to 70 feet; thins rapidly in Lewis County, N.Y. Underlies Collingwood formation in central Ontario with transitional contact; disconformably underlies Deer River shales in northwestern New York.

Exposed for several miles along northern shore of Lake Ontario, west of Wellington, Hillier Township, Prince Edward County, Ontario. Named for the township.

Hillman Gneissoid Tonalite

Precambrian (late Algoman) : Central Minnesota.

M. S. Woyski, 1949, Geol. Soc. America Bull., v. 60, no. 6, p. 1002, 1009, 1011, pl. 1. Gray; foliated medium granitoid, locally seriate; foliation in part primary mostly from lit-par-lit injection of schist; inclusions and schlieren of Thomson formation common, locally making more than half the rock surface; foliation strongest where inclusions are most abundant. One of five major intrusives in late Algoman; these cannot be shown to be members of a single magma series. Age relations of the named intrusive, St. Cloud gray granodiorite, Hillman tonalite, Freedhem tonalite, and Warman quartz monzonite are indeterminate because no contacts are exposed.

Crops out along Hillman Creek, Morrison County, in vicinity of Skunk and Little Skunk Rivers, and on Rum River.

Hillman Limestone[1]

Pennsylvanian: Northeastern Pennsylvania.

Original reference: C. A. Ashburner, 1886, Pennsylvania 2d Geol. Survey Rept. 1885.

Exposed in cut of Lehigh Valley Railroad, southwest of Hillman Colliery breaker, Luzerne County.

Hill Ridge Biotite Schist (in Tacoma Series)

Cambro-Ordovician(?) : Southwestern Maine.

L. W. Fisher, 1936, Am. Mineralogist, v. 21, no. 5, p. 323. Listed in table of formations. Belongs to Tacoma series (new). Older than Minwah limy gneiss (new) ; younger than Stetson Brook limestone (new).

Occurs in Lewiston area, Androscoggin County.

Hillsboro Plutonic Series

Devonian(?) : Southeastern New Hampshire.

M. P. Billings, 1956, Geology of New Hampshire, pt. 2, Bedrock geology: Concord, New Hampshire State Plan. Devel. Comm., p. 45, 65–69, 186–187. Name given to group of plutonic rocks. Consists of four units: Diorite and granodiorite (including Dracut diorite and Exeter diorite) ; granite, quartz monzonite and granodiorite; Ayer granodiorite; and another granite. Foliation is common. Treated as separate series, but may belong to New Hampshire plutonic series. Has many characteristic features of latter, but ages may be different.

Hillsboro Sandstone[1]

Silurian(?) : Southwestern Ohio.

Original reference: E. Orton, 1871, Ohio Geol. Survey Rept. Prog. 1870, p. 271, 301, 306–307.

J. K. Rogers, 1936, Ohio Geol. Survey, 4th ser., Bull. 38, p. 81–83. Occurs in two types of deposits: bedded sandstone resting on either Niagaran or Greenfield dolomites; masses of sandstone which are cavity fillings enclosed in either Niagaran or Greenfield dolomites. White or yellowish sandstone frequently stained to reddish brown.

Occurs near Hillsboro and a few other localities in Highland County.

Hillsdale Member (of Greenbrier Limestone)

Hillsdale Limestone (in Greenbrier Limestone[1] or Series)

Upper Mississippian: Southeastern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 451, 487.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 157–159, pl. 15. Described in Burkes Garden quadrangle where it is about 55 feet thick and overlies Little Valley formation. Name Hillsdale used to replace name St. Louis, used by Butts (1940) for same succession in southwestern Virginia. Some geologists include so-called Warsaw, or Little Valley limestone, in the Hillsdale. Underlies "Ste. Genevieve" limestone.

R. H. Wilpolt and D. W. Marden, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 38, sheet 1. Rank reduced to member status in Greenbrier limestone. Consists of dark-gray grayish-black to black cherty limestone. Lies about 50 to 100 feet below Taggard red member. Equivalent to St. Louis limestone as defined by Butts in southwestern Virginia. Does not extend into northeastern Kentucky. Upper Mississippian (Meramec).

Dana Wells, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 5, p. 887–902. Hillsdale formation conformably underlies Denmar formation (new) from southern Mercer County to northern end of Pocahontas County. Overlies Maccrady, but nature of contact uncertain.

Type locality: In Monroe County, W. Va., in road just east of Hillsdale, on west limb of Hillsdale anticline.

Hillside Mica Schist

Precambrian (Yavapai Series): West-central Arizona.

C. A. Anderson, E. A. Scholz, and J. D. Strobell, Jr., 1955, U.S. Geol. Survey Prof. Paper 278, p. 1, 7, 11–12, pl. 3. Muscovite schist, quartz-muscovite schist, and muscovite quartzite, representing metamorphosed shale and impure sandstone. Minimum thickness 3,000 to 4,000 feet. Overlies Butte Falls tuff (new) with gradational contact. Intruded by Dick rhyolite and Lawler Peak granite, and Cheney Gulch granite (all new).

Most complete section exposed along Boulder Creek in vicinity of Hillside mine, for which this formation has been named; Bagdad area, Yavapai County.

Hills Pond Peridotite

Cretaceous(?): Southeastern Kansas.

H. C. Wagner, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–49. Name proposed for a medium-grained peridotite; olive gray when fresh, grayish yellow when weathered. Occurs in sill-like intrusive bodies.

Type locality: Five hundred feet east and 100 feet south of center of north line of sec. 32, T. 26 S., R. 15 E., south of pond on Hill Farm in southern Belmont Township, Woodson County.

Hilltop Formation

Pennsylvanian (Missouri Series): Central Oklahoma.

W. F. Tanner, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 8, p. 2046–2050; 1956, Oklahoma Geol. Survey Bull. 74, p. 6, 84–88, pls. 1, 2. Proposed for those beds in Seminole County that conformably overlie

Belle City limestone and its sandstone equivalents and unconformably underlie Vamoosa formation. Type section is sequence of dark-blue-gray shales grading upward into massive buff siltstones and fine-grained sandstones and containing thin limestone in lower part of formation. In southern part of county (Seminole), red shales or typical blue-gray shales, as much as 70 feet thick, occur locally as erosional remnants between the Belle City and the Vamoosa. Also in this part of county the Hilltop contains, about 22 feet above base, a single multicolored conglomerate of limestone cobbles, clay plates, and chert and jasper pebbles; this bed is white, yellow, and purple. Thickness ranges from featheredge to 200 feet; variations in thickness due primarily to post-Missouri, pre-Virgil erosion.

Type section: In sec. 11, T. 8 N., R. 7 E., in and near Wewoka Brick and Tile Company pit, north side of Wewoka Creek, in sec. 11, T. 8 N., R. 7 E., Seminole County, traced into Pontotoc County where it is truncated by unconformity at base of Ada formation.

Hilton Shale Member (of Portage Formation)[1]

Upper Devonian: Southwestern Virginia and northeastern Tennessee.

Original reference: J. H. Swartz, 1929, Am. Jour. Sci., 5th, v. 17, p. 436–448.

Named for exposures at or near Hilton, Scott County, Va.

Himes Member (of Cloverly Formation)

Lower Cretaceous: Northwestern Wyoming.

Ralph Moberly, Jr., 1960, Geol. Soc. America Bull., v. 71, no. 8, p. 1139 (fig. 1), 1143 (fig. 2), 1148–1149, 1151 (fig. 5), pl. 1. Comprises three principal lithologies: commonly at base is olive-gray and reddish-brown clay matrixed salt- and pepper sandstone; most of member is variegated reddish- and yellowish-brown and gray kaolinitic claystone and mudstone, containing veinlets and hardpans of iron oxides; clean quartz sandstones which filled fluvial channels are laced through the claystones. Thickness at type section 92 feet. Overlies Little Sheep mudstone member (new) with contact marked by channelling in many places and in others, a disconformable relationship, or at least a hiatus; underlies Sykes Mountain formation (new). In this report [northern Bighorn basin], Cloverly formation is redefined on lithogenetic basis.

Type section: Sec. 15, T. 55 N., R. 95 W., on Little Sheep Mountain. Well exposed between Himes and Lovell, Big Horn County.

Hinchman Sandstone[1]

Hinchman Formation

Upper Jurassic: Northern California.

Original reference: J. S. Diller, 1892, Geol. Soc. America Bull., v. 3, p. 370–394.

P. A. Lydon, T. E. Gay, Jr., and C. W. Jennings, 1960, Geologic map of California Westwood sheet (1:250,000): California Div. Mines. Formation consists of metamorphosed fossiliferous andesite tuff and conglomerate. Mapped with Jurassic and (or) Triassic metavolcanic rocks.

Named for exposures at Curtice Cliff, in lower part of Hinchman Ravine, Plumas County.

Hinckley Sandstone (in Keweenawan Group)

Hinckley Sandstone[1] (in Lake Superior Series)

Precambrian: Southeastern Minnesota.

Original reference: N. H. Winchell, 1886, Minnesota Geol. Nat. History Survey 14th Ann. Rept., p. 336–337.

C. R. Stauffer, G. M. Schwartz, and G. A. Thiel, 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1240–1241. Discussion of St. Croixian series of Minnesota. Hinckley sandstone not considered base of St. Croixian in Minnesota. Mount Simon, basil member of Dresbach, can be distinguished from underlying Hinckley, and over large areas microscopic studies of sedimentary rocks show that both Mount Simon and Hinckley are present between Eau Claire member of Dresbach and Red Clastic series. Atwater and Clement (1935) suggested that term Hinckley be applied only to sandstones that crop out in northeastern Minnesota. There is no structural or petrographic basis for such limitation. Believed in present study that exclusion of Hinckley from the St. Croixian (Stauffer, 1925) and its association with Red Clastic series is correct, but assumption that this implies correlation of Hinckley with Mount Simon (Atwater and Clement, 1935) is not warranted. Recent work indicates Hinckley is equivalent of Devils Island sandstone of Wisconsin.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 10, 15–23. Geologic column shows Hinckley sandstone as upper formation in Lake Superior series. Occurs above Fond du Lac beds. Contact with underlying Fond du Lac not exposed in east-central or southeastern Minnesota. Underlies Mount Simon member of Dresbach. Thickness about 102 feet at Sandstone, Pine County. Now that quarry at Hinckley has been abandoned, section at Sandstone is regarded as typical development of the formation.

F. F. Grout and others, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1021 (table 3), 1061–1062. Included in upper part of Keweenawan group.

Type section: At Hinckley (T. 41 N., R. 21 W.), Pine County.

Hindostan Whetstone[1] or Beds (in Mansfield Sandstone)

Pennsylvanian: Southwestern Indiana.

Original reference: E. T. Cox, 1871, Indiana Geol. Survey 2d Ann. Rept., p. 81, 105; 1876, Indiana Geol. Survey 7th Ann. Rept., p. 6–8.

F. D. Spencer, 1953, U.S. Geol. Survey Circ. 266, p. 13, 14 (fig. 4). Series of thin fine-grained laminated beds in lower part of Mansfield sandstone.

Named for village which was once county seat of Martin County. Village abandoned since 1870.

Hindsville Limestone

Hindsville Limestone Member (of Batesville Sandstone)[1]

Upper Mississippian: Northern Arkansas, southern Missouri, and eastern Oklahoma.

Original reference: A. H. Purdue and H. D. Miser, 1916, U.S. Geol. Survey Geol. Atlas, Folio 202.

E. B. Branson, 1944, Missouri Univ. Studies, v. 19, no. 3, p. 263–265. Geographically extended into southern Missouri, where, in Cassville quadrangle, it is preserved in a down-faulted area. Essentially light- to dark-gray, fine- to medium-grained oolitic limestone with basal chert pebble conglomerate set in limestone matrix; thin mineral-gray to olive-drab calcareous shales, siltstones, and sandstones distributed irregularly through the limestone. Thickness about 47½ feet. Conformable and in places transitional with overlying Batesville; unconformable on Keokuk limestone and chert with limestone filling depressions in weathered Keokuk.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped as Hindsville limestone.

N. B. Degraffenreid, 1953, Tulsa Geol. Soc. Digest, v. 21, p. 163–165. Term "Grand River" (Brant, 1941) is preoccupied. Further, the "Grand River" limestone has been found to be the equivalent of Hindsville limestone member of Batesville formation of Arkansas. Accordingly, "Grand River" should be suppressed as facies term, and name Hindsville should be applied.

Named for exposure near Hindsville, Eureka Springs quadrangle, Madison County, Ark.

Hinkley Valley Complex

Paleozoic or older: Southern California.

W. J. Miller, 1944, California Jour. Mines and Geology, v. 44, no. 1, p. 77–79. Consists largely of metasediments, mostly crystalline limestone, together with some quartzites and schists; igneous material subordinate. Contact with Hodge complex not distinct, differentation made on basis of igneous material present. Considered oldest known rocks in Barstow and Victorville map areas. Paleozoic or older with early Precambrian most probable.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 503–504. Faunal evidence indicates age may be wholly Paleozoic.

Named for outcrops in and around Hinkley Valley, Barstow quadrangle. Not recognized in Victorville area.

Hinsdale Formation[1]

Hinsdale Series

Pliocene(?): Southwestern Colorado and northwestern New Mexico.

Original reference: W. Cross, 1911, U.S. Geol. Survey Bull. 478, p. 22, 29, map.

E. S. Larsen, Jr., and Whitman Cross, 1956, U.S. Geol. Survey Prof. Paper 258, p. 11, 192–207, pl. 1. Subdivided into two members: latite basalt and rhyolite. In general, succession from bottom to top is local rhyolite and quartz latite flows and tuffs followed by flows of basalt that form great plateaus. Thickness commonly 200 feet, although latite basalt may be as much as 1,000 feet and rhyolite as much as 2,000 feet. Generally directly overlies older volcanic rocks, but in extreme southern part of Colorado overlies Los Pinos gravel, and some basalts are interlayered with the gravels. In most places, forms the surface rock, but in San Luis Valley and south into New Mexico gravels overlie the basalt.

Fred Barker, 1958, New Mexico Bur. Mines and Mineral Resources Bull. 45, p. 51–52, pl. 1. Hinsdale series redefined to include Cisneros basalt, Dorado basalt, and Servilleta formation (all new). Cisneros basalt overlies Cordito member (new) of Los Pinos formation with slight angular unconformity. [Proposed by Cross as Hinsdale volcanic series.].

Named for exposures in Hinsdale County, Colo.

Hinsdale Gneiss[1]

Precambrian: Connecticut and western Massachusetts.

Original reference: B. K. Emerson in 1892 used Hinsdale gneiss on U.S. Geol. Survey Hawley sheet, that is, proof sheets of geological maps and text intended for geological folio, but never completed and published in that form, although cited in U.S. Geol. Survey Bull. 191, 1902.

Named for occurrence at Hinsdale, Berkshire County, Mass.

+Hinsdale Limestone[1]

Precambrian: Western Massachusetts.

Original reference: B. K. Emerson, 1898, U.S. Geol. Survey Mon. 29, p. 18, 24–26.

Exposed 50 feet west of Hinsdale Station, Berkshire County.

Hinsdale Member (of Chadakoin Formation)

Hinsdale Sandstone[1]

Hinsdale Sandstone (in Conneaut Group or Chadakoin Group)

Upper Devonian: Southwestern New York and northwestern Pennsylvania.

Original reference: G. H. Chadwick, 1933, Pan-Am. Geologist, v. 60, p. 200, 203.

J. G. Woodruff, 1942, New York State Mus. Bull. 326, p. 17 (fig. 4), 33–37. Included in Conneaut group in Wellsville quadrangle, N.Y., where it is about 15 feet thick; overlies Wellsville formation (new), and underlies Whitesville formation (new).

I. H. Tesmer, 1955, New York State Mus. Sci. Service Circ. 42, p. 10 (fig. 1), 16. Rank reduced to member status in Chadakoin formation. Overlies Wellsville member; underlies Whitesville member.

L. V. Rickard, 1957, New York State Geol. Assoc. [Guidebook] 29th Ann. Mtg., p. 17 (table 2), 19. Hinsdale sandstone included in Chadakoin group. Inasmuch as Upper Devonian strata are still not thoroughly understood, a more or less permanent classification satisfactory to a majority of workers may not be obtained for some time.

Type locality: Ed Hull quarry on hill face east of Scott Corners and about 1 mile north of Hinsdale village, Cattaraugus County, N.Y.

Hinshaw sandstone[1]

Upper Cretaceous: Utah.

Original reference: C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 36, 280.

Derivation of name not stated.

Hinton division[1]

Upper Cambrian or Lower Ordovician: Central Texas.

Original reference: T. B. Comstock, 1890, Texas Geol. Survey 1st Ann. Rept., p. 301–306, pl. 3.

Named for Hinton Creek, San Saba County.

Hinton Formation[1] (in Pennington Group)

Hinton Group

Upper Mississippian: Southern West Virginia, eastern Kentucky, and southwestern Virginia.

Original reference: M. R. Campbell and W. C. Mendenhall, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 2, p. 487.

P. H. Price and E. T. Heck, 1939, Virginia Geol. Survey, Greenbrier County, p. 255–262. Hinton group consists of (ascending) Stony Gap sandstone, unnamed shales, Avis limestone, unnamed shales and sandstones. Thickness 500 to 850 feet. Underlies Princeton group; overlies Bluefield group.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (columns 98, 99). Shown on correlation chart as group. In Randolph County, W. Va., includes (ascending) Stony Gap sandstone, Avis limestone, and Falls Mills sandstone; in southern West Virginia, includes (ascending) Stony Gap sandstone, Payne Branch sandstone, Avis limestone, and Falls Mills sandstone. Chesterian.

R. H. Wilpolt and D. W. Marden, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 38, sheet 1. Upper Mississippian.

L. D. Harris and R. L. Miller, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–111. Assigned to Pennington herein raised to group rank.

R. H. Wilpolt and D. W. Marden, 1959, U.S. Geol. Survey Bull. 1072–K, p. 599–601. Basal formation in Pennington group. The Hinton is identical with Pennington formation as used by Cooper (1944) and with lower half of Pennington of southwestern Virginia as originally defined by Campbell (1896). Traced in surface exposures from Pennington Gap northeastward to Princeton, W. Va., and from Hurricane Gap, in Kentucky, northeastward along Pine Mountain to Blowing Rock Gap. In present report, divided into (ascending) Stony Gap sandstone member, middle red member, limestone member (Avis limestone of Reger), and upper red member. Overlies Bluefield formation; underlies Princeton sandstone.

Named for Hinton, Summers County, W. Va.

†Hinton Limestone (in Hinton Formation)[1]

Mississippian: Southeastern West Virginia.

Original reference: C. E. Krebs, 1916, West Virginia Geol. Survey Rept. Raleigh County, and western portions of Mercer and Summers Counties, p. 75, 76, 88.

Probably named for Hinton, Summers County.

Hinton (Upper) Limestone (in Hinton Formation)[1]

Mississippian: Southeastern West Virginia.

Original reference: C. E. Krebs and D. D. Teets, Jr., 1916, West Virginia Geol. Survey Rept. Raleigh and western parts of Mercer and Summers Counties, p. 167.

Occurs one-half mile southwest of Meadow Creek, Richmond district.

Hinton Sandstone[1]

Mississippian: Southern West Virginia.

Original reference: C. E. Krebs and D. D. Teets, Jr., 1916, West Virginia Geol. Survey Rept. Raleigh and western parts of Mercer and Summers Counties, p. 77.

Occurs at Hinton, Summers County.

Hiram Till

Pleistocene (Wisconsin): Northeastern Ohio and northwestern Pennsylvania

V. C. Shepps and others, 1959, Pennsylvania Geol. Survey, ser. 4, Bull. G-32, p. 10 (fig. 3), 13 (fig. 4), 41–42, pl. 1. Gray to bluish-gray, sparingly pebbly, calcareous, clay to silty clay till deposited during Hiram advance near close of Cary time. Hiram advance preceded by Lavery advance and followed by Ashtabula advance. Name credited to G. W. White (in press).

G. W. White, 1960, U.S. Geol. Survey Bull. 1121–A, p. 2 (table 1), 3 (fig. 1), 8–9. Thickness 10 to 30 feet. Generally underlain unconformably by Kent till. In Portage and Trumbull Counties, Ohio, Windham sand (new) intervenes between tills. Underlies Ashtabula till. Type section designated.

Type section: Northern Hiram Township, in roadcut 100 yards east of Silver Creek and one-half mile east of intersection of east-west road and Hiram-Welshfield Road, 1½ miles north of village of Hiram, Portage County, Ohio.

Hite Bed (in Church Rock Member of Chinle Formation)

Upper Triassic: Southeastern Utah.

J. H. Stewart and others, 1959, U.S. Geol. Survey Bull. 1046–Q, p. 518, 519, 520 (fig. 79). Composed of pale-red and light-greenish-gray very fine grained sandstone and many lenses of pale-reddish-brown siltstone. Thickness 10 to 50 feet. Occurs in upper part of member.

Well developed on exposures about 2 miles south of Hite, San Juan County.

Hitz Limestone Member (of Saluda Limestone)[1]

Hitz Limestone Member (of Whitewater Formation)

Upper Ordovician: Southeastern Indiana and north-central Kentucky.

Original reference: A. F. Foerste, 1903, Am. Geologist, v. 31, p. 347.

James Conkin, 1952, Kansas Acad. Sci. Trans., v. 55, p. 128 (fig. 2), 129, 130. Columnar section (Sleepy Hollow, Oldham County, Ky.) shows Hitz limestone as upper member of Whitewater formation; overlies Saluda limestone member. Thickness 4½ feet; lower 2 feet are silty; upper 2½ feet are dense bird's-eye type, magnesium limestone.

Named for Hitz Hill, near Madison, Jefferson County, Ind. Extends from near Floydsburg, Oldham County, Ky., to southern boundary of Ripley County, Ind.

†Hiwassee Slate[1]

Lower Cambrian: Eastern Tennessee, northern Georgia, and western North Carolina.

Original reference: A. Keith, 1904, U.S. Geol. Survey Geol. Atlas, Folio 116, p. 5.

G. W. Stose and A. J. Stose, 1947, Am. Jour. Sci., v. 245, no. 10, p. 627, 629. In Hot Springs area, North Carolina, name Sandsuck shale is substituted for slate mapped as Hiwassee by Keith.

G. W. Crickmay, 1952, Georgia Geol. Survey Bull. 58, p. 27. Hiawassee [Hiwassee] included in Talladega series believed to be Precambrian.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, p. 27. Sandsuck shale as mapped northeast of Pigeon River corresponds roughly to what Keith mapped as Hiwassee slate in same area. In its type area along Hiwassee River, Hiwassee slate corresponds roughly to whole fine grained part of Ocoee series, and its correlation with units farther northeast is uncertain.

P. B. King and others, 1958, Geol. Soc. America Bull., v. 69, no. 8, p. 961 Walden Creek group (new) corresponds approximately to Wilhite slate, Citico conglomerate, and Pigeon slate, as mapped by Keith in Knoxville quadrangle (1895, U.S. Geol. Survey Geol. Atlas Folio 16), and also to the more inclusive Hiwassee slate of his later terminology. Name Hiwassee has been used so confusingly that it is properly abandoned.

Named for exposures on Hiwassee River, Polk County, Tenn.

Hoadley Formation

Precambrian (Belt Series) : Northwestern Montana.

Charles Deiss, 1943, Geol. Soc. America Bull., v. 54, no. 2, p. 211, 213 (table 1), 216–217. Dark-green-gray and maroon thick-bedded siliceous argillite and some vitreous fine-grained quartzite overlain by red and buff arenaceous calcareous argillite and fine-grained sandstone which grades upward into greenish-buff-weathering calcareous sandstone and much interbedded pink sandstone and argillite; upper part brilliant- and dark-red soft thin- and thick-bedded platy ripple-marked sandstone interbedded with some pale-red argillite. Overlies Cayuse limestone (new) ; underlies Ahorn quartzite (new). Miller Peak argillite, Cayuse limestone, Hoadley formation, and Ahorn quartzite are equivalent in age to lower and middle part of Missoula group of Clapp and Deiss (1931) in Sapphire and Garnet Ranges.

Named from Hoadley Reef, which is less than 1 mile southwest of largest exposure of these rocks in Saypo quadrangle.

Hoback Formation

Paleocene and Eocene, lower : Western Wyoming.

A. J. Eardley and others, 1944, Hoback-Gros Ventre-Teton Field Conf. [geologic map] ; privately printed. Interbedded gray sandstone and shale; several conglomerate lenses and fresh-water impure limestone beds; coal in lower part, Thickness about 15,000 feet. Unconformably overlies Frontier formation; unconformably underlies Pass Peak conglomerate (new).

J. A. Dorr, 1952, Geol. Soc. America Bull., v. 63, no. 1, p. 64–71, pls. 1, 3, 4. Described in detail. Chart shows age ranging from Paleocene (upper Puercan) into lower Eocene (Wasatchian). Type locality designated.

Type locality: Exposures on southeastern side Game Hill, opposite mouth of Cliff Creek, T. 38, N., R. 114 W., Sublette County. Along Hoback River and U.S. Highway 187.

Hobart Hill Andesite[1]

Devonian (?) : Northeastern Maine.

Original reference: H. E. Gregory, 1900, U.S. Geol. Survey Bull. 165, p. 113, 169, 172–173.

Forms Hobart Hill, Aroostook County.

Hobble Formation

Pennsylvanian : North-central Utah.

H. J. Bissell, 1963, Iowa Acad. Sci. Proc., v. 43, p. 240, 241–242. Predominantly limestone and sandstone. Thickness 1,751 feet. Overlies Kelly formation (new). Unit formerly referred to Oquirrh formation. Proposed in this report to elevate Oquirrh to rank of series in this region.

Type section: In Hobble Creek Canyon, east-central part T. 7 S., R. 3 E., east of Springville, Utah County.

Hobo Gulch Formation[1]

Middle Cambrian: Western central Montana.

Original reference: W. H. Weed, 1901, U.S. Geol. Survey 22d Ann. Rept., pt. 2, p. 434, 436, map.

Forms well-marked group of strata seen in railroad cuts near tailing dams and in Queen Gulch, Elkhorn region.

Hoboken Serpentine[1]

Precambrian (?): Northeastern New Jersey and southeastern New York.

Original reference: C. P. Berkey and J. R. Healy, 1912, Columbia Univ. Contr., v. 20, p. 1907–1912.

C. P. Berkey, 1948, Geol. Soc. America Guidebook 61st Ann. Mtg., pl. 1. Shown on map legend of Lower Manhattan. A metamorphosed basic intrusive cutting Manhattan schist.

Forms elevated portion of Staten Island, N.Y., and the Knob at Castle Point in Hoboken, N.J.

Hochelagan Formation[1]

Pleistocene: Canada, and New York and Vermont.

Original reference: J. B. Woodworth, 1905, New York State Mus. Bull. 84, p. 206–222, map.

Probably named for Indian settlement of Hochelaga, Canada.

Hockingport Sandstone

Upper Carboniferous: Southeastern Ohio.

W. D. Martin, 1955, Dissert. Abs., v. 15, no. 8, p. 1371. Relatively local sandstone occurring in parts of Washington, Athens, and Meigs Counties. Ohio, and adjacent parts of West Virginia. Previously considered as part of Waynesburg sandstone. Waynesburg sandstone here restricted in areal extent to southwestern Pennsylvania and northern West Virginia, and term Hockingport is applied to sandstone of southeastern Ohio.

Named for village of Hockingport, Athens County.

Hocking Valley conglomerate facies[1] (of Cuyahoga Formation)

Mississippian (Kinderhook): Central Ohio.

Original reference: J. E. Hyde, 1915, Jour. Geology, v. 23, p. 657, 669, 678.

F. T. Holden, 1941, Illinois Acad. Sci. Trans., v. 34, no. 2, p. 172; 1942, Jour. Geology, v. 50, no. 1, p. 43, 45–46. Here includes Black Hand conglomerate, Fairfield sandstone, and Lithopolis sandstone members. Lies between Granville shale facies to the northeast and the Henley shale facies to the southwest.

Occurs in Hocking Valley, Fairfield and Hocking Counties.

Hockley Mound Sand Member (of Willis Sand)[1]

Pliocene (?): Southeastern Texas and southern Louisiana.

Original reference: J. Doering, 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 5, p. 655, 656, 660–665.

G. R. Pinkley, 1958, South Texas Geol. Soc. Fall Field Trip, p. 35, geol. map. Text refers to Manning (Hockley) shales around Falls City, Hockley shale shown on geologic map.

Named for Hockley Mound, on Willis Plain, 4 miles southwest of Hockley, Harris County, Tex.

Hodge Complex

Paleozoic and (or) Mesozoic: Southern California.

W. J. Miller, 1944, California Jour. Mines and Geology, v. 44, no. 1, p. 79, 97–98. Igneous and metamorphic rocks consisting largely of dioritic and granitic rocks together with remnants of older Hinkley Valley metasediments. Not sharply separable from Hinkley Valley complex except that more igneous material is present in Hodge. Precambrian.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 503–504. Diorite and granite of Hodge complex considered Late Paleozoic or Mesozoic; granite quite certainly is Late Mesozoic.

O. E. Bowen, Jr., 1954, California Div. Mines Bull. 165, p. 36–42. Renamed and redefined as Hodge volcanic series.

Exposed near Hodge, near Barstow, in Barstow quadrangle.

Hodge Volcanic Formation

Hodge Volcanic Series

Mesozoic or older: Southern California.

O. E. Bowen, Jr., 1953, *in* L. A. Wright and others, California Jour. Mines and Geology, v 49, no. 1, pl. 2. Shown on columnar section as sheared tuff and flow lava more than 10,000 feet thick; base not exposed.

O. E. Bowen, Jr., 1954, California Div. Mines Bull. 165, p. 16 (fig. 2), 34–36, pls. 1, 2, 3, 8. Originally included by Miller (1944) in Hodge complex, series is withdrawn, renamed, and redefined. As herein described, Hodge volcanic series is predominantly rocks of the andesite-dacite-rhyolite association. Lower half of the 10,000-foot-thick series consists principally of massive reddish-brown, purplish-brown, and dark-green rocks, chiefly weakly sheared quartz latites and dacites. Upper half consists of alternating variable thicknesses of black, white, and gray-green, strongly sheared metavolcanics and tuffaceous metasediments. Age-determining features of series are few, as series is not in contact with other units except where invaded by igneous intrusions considered Jura-Cretaceous in age. Best estimate is that series is post-Fairview Valley and pre-Sidewinder in age, probably Upper Permian. Figure 2 and plate 1 show age as Upper Paleozoic(?).

U.S. Geological Survey designates the age of the Hodge Volcanic Formation as Mesozoic or older on the basis of a study now in progress.

Named from a homoclinal section exposed north of Mojave River a few miles northwest of Hodge, San Bernardino County. Entire section is exposed on well-eroded hills and on partly dissected, exhumed pediment surfaces.

Hodgeman Shale Member (of Solomon Formation)

Cretaceous: Northwestern Kansas.

R. C. Moore, 1935, Rock formations of Kansas *in* Kansas Geol. Soc., Wichita: [Am. Assoc. Petroleum Geologists 20th Ann. Mtg., Mar. 21–23.] Named on chart. Occurs in lower part of formation below an unnamed sandstone. Unconformable above Rocktown sandstone member of Ellsworth formation (new).

Derivation of name not given. Solomon formation was mapped in 1937 along Solomon River.

Hodges Shale Member (of Bloomington Formation)[1]

Middle Cambrian: Northeastern Utah and southeastern Idaho.

Original reference: G. B. Richardson, 1913, Am. Jour. Sci., 4th, v. 36, p. 406–407.

G. B. Maxey, 1958, Geol. Soc. America Bull., v. 69, no. 6, p. 650, 651–653, 672, 673 (fig. 3). Described near Richmond, Utah, where it is 540 feet thick, and is separated from overlying Calls Fort shale member (new) by unnamed limestone interval about 720 feet thick; overlies Blacksmith formation.

Named for exposures in Hodges Canyon, Rich County, Utah.

Hoffman Flow

Recent: Northern California.

H. A. Powers, 1932, Am. Mineralogist, v. 17, no. 7, p. 276–278, 288, pl. 1; C. A. Anderson, 1941, California Univ. Dept. Geol. Sci. Bull., v. 25, no. 7, p. 373. Composed of dacite lava. About 75 feet thick. Partly buried by later flows. Probably older than Medicine flow.

Occurs in Modoc Lava-Bed quadrangle.

Hoffman Limestone (in Conemaugh Formation)[1]

Pennsylvanian: Western Maryland and northern West Virginia.

Original reference: C. K. Swartz, W. A. Price, and H. Bassler, 1919, Geol. Soc. America Bull., v. 30, p. 573.

Occurs in Georges Creek valley, Allegany and Garrett Counties.

Hoffman Quartz Monzonite

[Cretaceous]; Eastern California.

J. F. Evernden, G. H. Curtis, and J. Lipson, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 9, p. 2122, 2123 (fig. 1). Shown on map in paper dealing with potassium-argon dating of igneous rocks. Age shown on map legend as 83.3 millions of years. Shows intrusive relationships toward older Cathedral Peak granite but does not come into contact with younger Johnson granite porphyry.

Occurs in Yosemite National Park.

Hoffman Sandstone (in Conemaugh Formation)[1]

Pennsylvanian: Western Maryland.

Original reference: W. A. Price and H. Bassler, 1919, Geol. Soc. America Bull., v. 30, p. 573.

Named for occurrence in Hoffman Drainage Tunnel, Allegany and Garrett Counties.

Hoffner Beds (in Ste. Genevieve Limestone)

Hoffner Member (of Ste. Genevieve Limestone)

Mississippian (Meramec Series): Southern Illinois.

J. M. Weller *in* Stuart Weller and F. F. Krey, 1939, Illinois Geol. Survey Rept. Inv. 60, p. 7, 8. Predominantly sandy shale and fine-grained sandstone that is locally massive. Associated with these strata are red shales at several horizons and in middle part of member one or more limestones. Thickness between 50 and 80 feet. Overlies Levias member; unconformably underlies Renault limestone.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 152–153, chart 5 (column 73). Shown on correlation chart as Hoffner beds in Ste. Genevieve limestone, Meramecian series.

Well exposed along Swan Creek northeast of Anna in E½ sec. 17, T. 12 S., R. 1 W., and east of Hoffner School in W½ sec. 8, T. 13 S., R. 1 E., Union County.

Hogan Formation

[Cretaceous] : Montana.

G. W. Viele, 1960, Dissert. Abs., v. 21, no. 4, p. 853. Name applied to 2,477 feet of andesitic to latitic volcanic-rich sedimentary rocks which are stratigraphically equivalent to middle and upper Two Medicine formation. Locally divided into members ascending A through E which consist of A, basal breccias; B, welded tuffs; C, volcanic-rich mudstone, argillites, and shales; D, volcanic-rich graywackes; and E, volcanic-rich graywackes, mudstones, breccias, and tuffs. Disconformably overlies lower Two Medicine; underlies St. Mary River formation.

Report discusses Flat Creek area, Lewis and Clark County.

†Hogback Sandstone[1]

Upper Cretaceous: Southwestern Wyoming.

Original reference: J. W. Powell, 1876, Geology of eastern part of Uinta Mountains, p. 40, 48, 155.

Hogback Schist[1]

Precambrian or Precambrian (?) : South-central Maine.

Original reference: E. H. Perkins and E. S. C. Smith, 1925, Am. Jour. Sci., 5th ser., v. 9, 204–228.

J. M. Trefethen, 1937, Jour. Geology, v. 45, no. 4, p. 358–359. Age designated Precambrian (?).

Forms long ridge known as Hogback Mountain, including Frye Mountain Range, in town of Knox, Waldo County.

Hog Creek Formation (in Caddo Creek Group)

†Hog Creek Shale Member (of Caddo Creek Formation)

Pennsylvanian: Central and central northern Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 387, 397.

C. O. Nickell, 1938, Texas Univ. Bur. Econ. Geology Pub. 3801, p. 115–116. Caddo Creek formation consists of Hog Creek shale member, whose type locality is in northern Brown County, and overlying Home Creek limestone of northern Brown County, which has been correlated with a limestone also called Home Creek occurring at same horizon in Brazos River basin in Palo Pinto County. At section on west side of Mukewater Creek half a mile above its junction with Home Creek, in southeastern Coleman County, the Hog Creek member is 39 feet thick, underlies Home Creek limestone member, and overlies Ranger limestone member of Brad formation.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Shown on correlation chart as Hog Creek shale in Caddo Creek group. Underlies Home Creek limestone; overlies Ranger limestone of Brad group.

M. G. Cheney, 1948, Abilene Geol. Soc. [Guidebook] Spring Field Trip, June 11–12, p. 20. Proposed that name Hog Creek shale, misapplied by Drake and others, be dropped and that name Colony Creek shale be given to beds between Ranger and Home Creek limestones.

Named for Hog Creek, Brown County, Colorado River region.

Hogeye Tuff (in Garren Group)

Tertiary: Western Texas.

Hugh Hay-Roe, 1957, Texas Univ. Bur. Econ. Geology Geol. Quad. Map 21. Proposed for 195-foot sequence of tuff and tuff breccia with basalt member near base. Unconformably overlies Cretaceous rocks in most places; overlies Permian rocks along southern edge of Wylie Mountains and other prevolcanic highs; upper contact with Pantera trachyte (new) disconformable.

P. C. Twiss, 1959, Texas Univ. Bur. Econ. Geology Geol. Quad. Map. 23. Described in Van Horn Mountains. Overlies Buckshot ignimbrite; underlies Pantera trachyte. In northeastern Van Horns, the Hogeye lies on Permian and Cretaceous rocks (Hueco, Yearwood, Cox, Finlay, Benevides, and Loma Plata formations). Thickness 187 to 435 feet.

Type section: South tip of Hogeye Butte, Jeff Davis County.

Hog Mountain Sandstone (in Mineral Wells Formation)[1]

Hog Mountain Sandstone Bed (in East Mountain Formation)

Hog Mountain Sandstone Member (of East Mountain Formation)

Pennsylvanian (Strawn): Central northern Texas.

Original reference: F. B. Plummer, 1929, Texas Bur. Econ. Geology, geol. map of Palo Pinto County.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Shown on correlation chart as member of East Mountain shale.

Leo Hendricks, 1957, Texas Univ. Bur. Econ. Geology Pub. 5724, p. 22, fig. 3. Referred to as sandstone bed in East Mountain formation. In area of this report [Parker County], 22 feet thick, fine to medium grained, poorly to well cemented, and ranges from thick bedded to flaggy.

Typically exposed on top of Hog Mountain, 3 miles southeast of Mineral Wells.

Hogshooter Limestone[1] (in Skiatook Group)

Pennsylvanian (Missouri Series): Northeastern, central northern, and central Oklahoma.

Original reference: C. N. Gould, D. W. Ohern, and L. L. Hutchinson, 1910, Oklahoma State Univ. Research Bull. 3, p. 1, 2.

M. C. Oakes, 1940, Oklahoma Geol. Survey Bull. 62, p. 39–47; 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 4, p. 720 (table 1), 723–725. Included in Skiatook group. As defined here, is substantially equivalent to Dennis formation of Kansas, as redefined by Jewett (1932, Kansas Geol. Soc. Guidebook 6th Ann. Field Conf.). As a formal formation name for this unit, Dennis is perhaps older, but Hogshooter is oldest name in Oklahoma for this formation and is firmly entrenched in literature and usage; therefore, name Dennis is rejected, and Hogshooter retained in Oklahoma. Underlies Nellie Bly formation; overlies Coffeyville formation. Includes (at various places) Winterset limestone, Stark shale, Canville limestone, and Lost City limestone members. Type locality stated.

E. R. Ries, 1954, Oklahoma Geol. Survey Bull. 71, p. 60–64. Described in Okfuskee County.

Type locality: Along Hogshooter Creek, T. 26 N., R. 14 E., Washington County.

Hogskin Member (of Lincolnshire Formation)

Middle Ordovician (Mohawkian) : Northeastern Tennessee.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 66–67, chart 1 facing p. 130). Proposed for yellow-weathering shale and cobbly limestone, both of "Ottosee type" and usually confused with that formation, lying between Eidson member (new) of Lincolnshire and Ward Cove or Rockdell formations. Name credited to B. N. Cooper and G. A. Cooper.

Well exposed along road to Thorn Hill to Washburn especially at Red Hill about 4 miles west-southwest of Thorn Hill, Grainger County.

Hoh Formation[1]

Miocene, middle: Northwestern Washington.

Original reference: C. E. Weaver, 1915, Am. Inst. Min. Engrs. Bull. 103, p. 1424–1427.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 17, 186–187. Type locality designated since none was given in original description. At newly designated type section, formation consists of at least 16,000 feet of coarse gray gritty sandstone; strata are involved in a westerly plunging, highly compressed syncline, which has been eroded and elevated, and upon their beveled surface rest nearly 3,000 feet of basaltic lavas, tuffs, and agglomerates of early and possibly middle Eocene age. Formations in western part of Olympic Mountains which originally were included in general term Hoh formation by Weaver (1915, 1916) are considered as consisting of two separate formations, one of Oligocene and Miocene age, the other, exposed south of Lake Crescent, as pre-Tertiary in age. The latter is included in Solduc formation originally defined by Reagan (1909). Hoh formation restricted to sandstones and shales in vicinity of mouth of Hoh River which contain fossil evidence indicating middle Miocene age.

S. L. Glover, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 2022–2023. Restricted in coastal area of Jefferson County to exclude 5,000-foot unit of buff to gray arkosic sandstone and thin-bedded dark-gray mudstones here termed Browns Point formation.

Type section: Exposures occurring between north fork of Solduc River and Lake Crescent, Clallam County.

Hoing Sandstone[1]

Silurian: Central eastern Iowa.

Original reference: W. H. Norton, 1928, Iowa Geol. Survey, v. 33, p. 30–31, 431.

Hoko Formation[1]

Pliocene(?) : Northwestern Washington.

Original reference: A. B. Reagan, 1909, Kansas Acad. Sci. Trans., v. 22, p. 202.

Occurs from Hoko River in its lower course east to Clallam Bay.

Holbrook Sandstone[1] Member (of Moenkopi Formation)

Triassic: Eastern Arizona.

Original reference: D. Hager, 1922, Mg. and Oil Bull., v. 8, nos. 1, 2, 3, p. 26. 33–34, 73, 81–94.

E. D. McKee, 1951. New Mexico Geol. Soc. Guidebook 2d Field Conf., p. 86, 87 (fig. 1). Characterized by red beds—shaly siltstones and structureless mudstones—alternating with resistant thick-bedded sandstones. Estimated thickness 110 feet. Overlies Winslow member (new); underlies Shinarump conglomerate.

E. D. McKee, 1954, Geol. Soc. America Mem. 61, p. 18 (table 4), 19. Present classification of Moenkopi in Little Colorado River area is (ascending) Wupatki, Moqui (new), and Holbrook members.

Exposed in cliffs just north of railroad between Winslow and Holbrook.

Holcomb Quartz Monzonite

Cretaceous(?): Southern California.

L. F. Noble, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–50. Light-gray to pinkish quartz monzonite, probably varying to granodiorite; cut by aplite and pink pegmatite. Texture normal granitic north of Hidden Springs and Holcomb faults; south of faults, limestone, granodiorite, and rocks of Pleasant View complex are injected by the quartz monzonite.

Type locality: Holcomb Ridge, Valyermo quadrangle. Monzonite is continuous with granitic rocks north of San Andreas Fault in Pearland quadrangle.

†Holden Group[1]

Pennsylvanian: Northwestern Missouri.

Original reference: G. C. Broadhead, 1873, Missouri Geol. Survey Prelim. Rept. on Iron Ores, pt. 2, p. 169, 194.

Named for exposures at Holden, Johnson County.

Holdenvillle Shale[1] (in Marmaton Group)

Pennsylvanian (Des Moines Series): Central Oklahoma, southeastern Kansas, and southwestern Missouri.

Original reference: J. W. Taff, 1901, U.S. Geol. Survey Geol. Atlas, Folio 74.

M. C. Oakes, 1952, Oklahoma Geol. Survey Bull. 69, p. 42–47, pl. 11. Memorial shale, by definition, extends upward from top of Lenapah limestone to base of Seminole formation, and, likewise, Holdenville shale extends upward from top of Wewoka to base of Seminole. As Lenapah has been traced into uppermost Wewoka, the Memorial and Holdenville lie between same stratigraphic limits and are equivalent. Holdenville has priority and is commonly used term. Thickness 40 to 200 feet in Tulsa County. Includes Sasakwa and Homer limestone [members]. In northern Oklahoma and in Kansas, unit occurs in thin ragged patches.

W. B. Howe, 1953, Missouri Geol. Survey and Water Resources Rept. Inv. 9, p. 14–16. Uppermost formation in Marmaton group. Lies between Lenapah formation and base of Hepler sandstone, basal Pleasanton, of Missouri series. Term Memorial, formerly applied to post-Lenapah, pre-Pleasanton beds in Missouri, has been dropped. Use of name Holdenville follows recent work by Oklahoma Geological Survey. Formation in western Missouri is predominantly gray shale. Thickness 0 to at least 15 feet.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Shown on chart at top of Marmaton group. Overlies Lenapah limestone; underlies Hepler sandstone.

Named for Holdenville, Hughes County, Okla.

Holder Formation (in Magdalena Group)

Pennsylvanian (Virgilian) : Southeastern New Mexico.

L. C. Pray, 1954, New Mexico Geol. Soc. Guidebook 5th Field Conf., p. 93. Appears only on columnar section. Consists of limestone, gray and red calcareous shale, sandstone, and conglomerate. Bioherms at base locally. Thickness as much as 850 feet. Underlies Bursum formation; overlies newly named Beeman formation.

Carel Otte, Jr., 1959, New Mexico Bur. Mines Mineral Resources Bull. 50, p. 18–25, pl. 1. Revised to include strata that occur between top of Beeman formation and base of overlying Laborcita (new) or Abo formation. Holder includes Fresnal and Keller groups in classification of Thompson (1942). Thompson's detailed section of Fresnal forms upper 530 feet of Pray's Holder formation and is overlain by Laborcito formation. Thickness 900 feet north of La Luz Canyon. Type section and derivation of name given.

Type section: In NW¼NW¼ sec. 14, T. 17 S., R. 10 E., in central part of Sacramento Mountains. Name derived from Holder Ridge which is capped by basal limestone of formation. Widespread along fringe of Tularosa basin in north and south ends of Sacramento Mountains; in central area, occurs as isolated resistant caps on many high ridges at west front of mountains.

†Holderness Formation (in Mesaverde Group)[1]

Upper Cretaceous: Northwestern Colorado.

Original reference: M. R. Campbell, 1931, Tentative correlation of named geologic units of Colorado, compiled by M. G. Wilmarth, U.S. Geol. Survey, separate chart.

Campbell's report not published. The name Holderness Formation appeared in bold face in the Wilmarth Lexicon on the basis of Wilmarth's correlation chart. Cobban and Reeside (1952, Geol. Soc. Bull. v. 63, no. 10) used the name of Holderness on the Cretaceous correlation chart and cited the Wilmarth Lexicon. U.S. Geological Survey has abandoned the term Holderness Formation.

Well exposed in Holderness Gulch, Yampa coal field, Daton Peak quadrangle.

Holdrege Formation[1]

Holdrege Member (of Blanco Formation)

Holdrege Member (of Chase Channel Formation)

Pleistocene (Nebraska) : Southern Nebraska and western Kansas.

Original reference: A. L. Lugn and G. E. Condra, 1932, Geol. Soc. America Bull., v. 43, no. 1, p. 190.

O. S. Fent, 1950, Kansas Geol. Survey Bull 85, p. 64. Basal member of Chase Channel formation (new), a subsurface unit in western Kansas. Thickness 28 to 56 feet. Medium to fine gravel and sand with fragments of Cretaceous shells and fragments of red shale and siltstone where it overlies Permian rocks. Grades upward into Fullerton member.

G. E. Condra and E. C. Reed, 1950, Nebraska Geol. Survey Bull. 15–A, p. 12 (fig.), 17–18. Formation is coarse, gravelly to pebbly valley fill at high levels in South Platte, Lodgepole, Pumpkin Creek, and North Platte valleys where it originated from Rocky Mountain glaciers and from gravelly Tertiary deposits of High Plains. Occurs in lower course of Niobrara Valley and adjacent areas and on Holt and Springview plains; lies below flood plain of the Platte in vicinity of Grand Island and westward for some distance.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 15; J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 52 (fig. 2), 59, 61. Member of Blanco formation in Kansas.

C. W. Hibbard, 1958, Am. Jour. Sci., v. 256, no. 1, p. 55 (fig. 1). Chart of revised classification of Kansas Pleistocene shows Holdrege as member of unnamed formation in Meade group. Occurs below Fullerton member and above Nebraskan till.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Shown as formation in Kansas.

Named for Trees deep test for oil and gas near Holdrege, Phelps County, Nebr.

Hole-In-The-Wall Member (of Boulder Pass Formation)

Precambrian (Belt Series): Northwestern Montana.

Original reference: C. L. Fenton and M. A. Fenton, 1931, Jour. Geology, v. 39, no. 7, p. 670–679.

C. L. Fenton and M. A. Fenton, 1937, Geol. Soc America Bull., v. 48, no. 12, p. 1877. Name suppressed in favor of Spokane.

Derivation of name not stated but probably Hole-in-the-Wall Falls, Glacier National Park, Flathead County.

Hole-In-The-Wall Member (of Isom Formation)

Eocene(?) or Oligocene, lower(?): Southwestern Utah.

J. H. Mackin, 1960, Am. Jour. Sci., v. 258, no. 2, p. 90 (table 1), 92 (fig. 2), 99. Upper member of formation at type locality; overlies Baldhills member (new). Latite porphyry, lithoidal in texture and purplish gray in color, with light-gray lenticules. Thickness seldom more than 40 feet. Exhibits some features of ignimbrites of highly welded type but also has internal structural features indicative of viscous flow. Discussion of ignimbrites of area.

Named for occurrence at east end of Hole-in-the-Wall Pass, 2 miles north of type locality of Isom formation.

†Holiknuk Series[1]

Upper Cretaceous: Southern Alaska.

Original reference: J. E. Spurr, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 7, p. 159–161, 182.

Probably named for Holiknuk River.

Holitna Group

Ordovician(?), Silurian, and Devonian: Southwestern Alaska.

W. M. Cady and others, 1955, U.S. Geol. Survey Prof. Paper 268, p. 21 (table), 23–27, pl. 1. Includes various types of limestone that have been changed from an originally dense fine-textured rock to more coarsely crystalline types. Recrystallized facies partly dolomitic. Nondolomitic limestone is gray on freshly broken surface and weathers to lighter shades. Dolomitic facies characteristically buff colored. Massive rather than thin-bedded limestone predominates. Small reeflike masses in several places, Intraformational conglomerates and breccias, composed of limestone fragments in limestone matrix, common locally. Neither basal nor upper contacts are exposed in sections studied along Holitna and Chilnuk Rivers. Estimated thickness at least 5,000 feet and probably closer to 10,000 feet. In fault contact with overlying Kuskokwim group (new) along bluffs of Holitna River 9 miles northeast of Nogamut.

Type locality: On Holitna River in area where limestone crosses southwestward plunging major axis of geanticline. Typically exposed between mouths of Itulilik and Portage Creeks.

Holland Limestone (in Staunton Group)

Pennsylvanian: Southern Indiana.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 30, 87. In Ditney folio [84] area, Holland coal below Rock Creek coal is described as having Holland limestone as its roof. Recent field studies showed three locally mined coals cropping out near Holland, each with a limestone roof. It is not known to which of these coals name Holland was originally applied.

D. W. Franklin, 1944, Illinois Acad. Sci. Trans., v. 37, p. 89, 91. Name Holland applied to uppermost of the three limstones as it is most distinctive. Light-gray dense limestone with brown mottling on weathered surface. Thickness 2 feet. Occurs about 7 feet above base of group in exposure near Holland.

Exposed in SE¼NE¼NE¼ sec. 26, T. 3 S., R. 6 W., near Holland, Dubois County.

Holland Sandstone[1]

Lower Devonian: Northwestern Ohio.

Original references: E. Orton, 1888, Ohio Geol. Survey, v. 6, p. 20; 1890, Ohio Geol. Survey 3d Organization, 1st Ann. Rept. p. 24.

Named for Holland, Lucas County

Holland Patent Formation or Shale

Holland Patent Member (of Utica Shale)

Holland Patent[1] zone

Ordovician: Eastern New York.

Original reference: R. Ruedemann and G. H. Chadwick, 1935, Science, new ser., v. 81, no. 2104, p. 400.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 286, pl. 4. Holland Patent formation or Holland Patent member of Utica formation is the "upper Utica, or zone of *Climacograptus pygmeus*" and *Glossograptus quadrimucronatus timidus* of Ruedemann. Consists of about 200 feet of black shales. Grades upward into arenaceous Frankfort shale; disconformably overlies lower Cobourg (Hallowell) limestone.

Holland Patent, Oneida County.

Holland Quarry Shale

Devonian: Northern Ohio.

J. E. Carman, 1960, Fieldiana: Geology, v. 14, no. 1, p. 1–5. Fossiliferous unit that occupies depression in Raisin River dolomite. Underlies Sylvania sandstone.

Occurs in Holland Quarry, 3 miles south-southwest of town of Holland, Monclova Township, Lucas County.

Hollenberg Limestone (in Sumner Group)[1]

Hollenberg Limestone Member (of Wellington Formation)

Permian (Leonard) : Eastern Kansas and southeastern Nebraska.

Original reference: G. E. Condra and J. E. Upp, 1931, Nebraska Geol. Survey Bull. 6, 2d ser., p. 63–66.

W. A. Ver Wiebe, 1937, Wichita Municipal Univ. Bull. 2, p. 5; R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 40–41. Included in Wellington formation.

Named for exposures along Little Blue River 3½ miles southeast of Hollenberg, Washington County, Kans.

Holliday shale[1]

Cambrian : Utah.

Original reference : C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 38.

Derivation of name not stated.

Hollis Member (of Deese Formation)

Pennsylvanian : Central Oklahoma.

C. C. Branson, 1955, The Hopper, v. 15, no. 10–11, p. 129. Shown on manuscript map by Guthrey and Milner in 1933. Name preoccupied by Hollis quartzite (Adams 1926) in Precambrian of Alabama. Renamed Natsy by Tomlinson (1937).

Type locality: On Hollis Farm in SW¼SW¼ sec. 8, T. 5 S., R. 2 E., Carter County.

Hollis Quartzite[1]

Hollis Quartzite (in Pine Mountain Group or Series)

Precambrian : Eastern Alabama and central western Georgia.

Original reference: G. I. Adams, 1926, Alabama Geol. Survey Spec. Rept. 14, p. 33–34, map.

G. W. Crickmay *in* L. M. Pringle, 1935, Georgia Geol. Survey Bull. 46, p. 32 Geographically extended into Georgia where it underlies Manchester formation (new). Included in Pine Mountain series.

D. F. Hewett and G. W. Crickmay, 1937, U.S. Geol. Survey Water-Supply Paper 819, p. 27–28, 30, pl. 1. In Warm Springs quadrangle, Georgia, overlies Sparks schist (new); underlies Manchester schist; in southeast corner of quadrangle, overlies Woodland gneiss (new). Thickness ranges from 275 feet at Dunn's Gap to nearly 800 feet along Flint River at the Cove; along Oak Mountain, seldom more than 300 feet. Chewacla marble, associated with Hollis in Alabama, is not present in Georgia.

J. W. Clarke, 1952. Georgia Geol. Survey Bull. 59, p. 6 (table), 11–14, pls. 3, 10. Described in Thomaston quadrangle where it is 800 to 1,100 feet thick. Underlies Manchester formation; unconformably overlies Woodland gneiss. Included in Pine Mountain group.

Named for exposures at and near Hollis, Lee County, Ala.

Holloway Prairie Formation or terrace

Recent: Southwestern Louisiana.

J. A. Doering, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 8, p. 1822 (table 1), 1826 (fig. 2), 1830, 1831 (table 2), 1833 (fig. 3), 1837 (table 3), 1848 (fig. 8). In description of physiography of southwest Louisiana the following new formation names are introduced (descending): Sicily Island, Holloway Prairie, Eunice, and Oberlin. However, text discusses the Holloway Prairie as a terrace. Name is used for terrace areas given by Fisk (1938) as type localities of his "Prairie terrace;" new name is used to avoid extended correlations of the Prairie.

Well developed at Holloway Prairie, Marksville, Big Cane, Mansura, and Grand Prairie, in Rapides and Avoyelles Parishes.

Holly Creek Formation (in Trinity Group)

†Holly Creek Clay[1]

Lower Cretaceous (Comanche): Southwestern Arkansas and southeastern Oklahoma.

Original reference: H. C. Vanderpool, 1928, Am. Assoc. Petroleum Geologists Bull., v. 12, p. 1079–1080.

R. W. Imlay, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 3. Referred to as Holly Creek formation; includes Ultima Thule gravel member. Underlies De Queen limestone; overlies Dierks limestone (rank raised). Subsurface equivalents discussed.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Geographically extended into southeastern Oklahoma.

L. V. Davis, 1960, Oklahoma Geol. Survey Bull. 86, p. 16–17, 20–22, pl. 1. In McCurtain County [this report], Dierks limestone is absent, and name Holly Creek applies to the Cretaceous stratum below De Queen limestone. Thickness 30 to 100 feet in outcrop area; as much as 1,070 feet in subsurface. In eastern half of area, the Holly Creek is basal unit of Trinity age and rests unconformably upon Paleozoic rocks.

Named for exposures near Little Holly and Holly Creeks, southeast of Dierks, Howard County, Ark.

Hollycrest Formation

Miocene, middle: Southern California.

G. J. Neuerburg, 1953, California Div. Mines Spec. Rept. 33, p. 6 (table 1), 23–24, pl. 1. Consists of thin-bedded light-brown medium- and fine-grained arkose and white to gray silty clay shales. Composed of two unnamed members: a basal conglomerate and a sandstone, contact between the two is conformable and gradational; thin beds of conglomerate are present in lower 50 feet of the sandstone. Thickness about 1,700 feet. Underlies Modelo formation, but nature of contact uncertain, may or may not be a fault; unconformably overlies Topanga formation; locally overlies Cahuenga beds (new).

Occurs in Griffith Park area, city of Los Angeles. Exposed in Griffith, Cahuenga Peak and Cahuenga Pass fault blocks. Name Hollycrest taken from highest point in Cahuenga Pass.

Holly Springs Sand (in Claiborne Group)

Holly Springs Sand Member (of Tallahatta Formation)

Holly Springs Formation (in Wilcox Group)

Holly Springs Sand (in Wilcox Group)[1]

Eocene, middle: Mississippi, Kentucky, and western Tennessee.

Original reference: E. N. Lowe, 1913, Mississippi Geol. Survey Bull. 10, p. 23–25.

Tom McGlothlin, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 1, p. 53. With exception of Bashi and Hatchetigbee in Lauderdale County, Miss., surface Wilcox deposits of the State might well be called undifferentiated Wilcox. It may be true that general zones can be traced locally, but wisdom of giving formational rank to "Ackerman" and "Holly Springs" is questioned. Exposures of typical "Ackerman" are plentiful in area that is supposed to be underlain by "Holly Springs" sand, and many of the exposures of Holly Springs are probably Pleistocene terrace deposits.

F. S. MacNeil, 1946, U.S. Geol. Survey Strategic Minerals Inv. Prelim. Rept. 3–195, p. 17. Type Holly Springs of northern Mississippi, formerly included in Wilcox and correlated with Tuscahoma sand of Alabama, is nonmarine equivalent of Tallahatta formation to south. Name Holly Springs abandoned in favor of Tallahatta for all of Mississippi.

F. S. MacNeil., 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 29. Correlation chart shows Holly Springs sand member of Tallahatta in Mississippi. Note states that nonmarine facies of Tallahatta formation in northern Mississippi was formerly called Holly Springs sand and placed in Wilcox group. For 1945 geologic map of Mississippi, Holly Springs was abandoned in favor of Tallahatta, but it should probably be retained for northern Mississippi, Tennessee, and Kentucky. Claiborne group.

J. S. Attaya, 1951, Mississippi Geol. Survey Bull. 71, p. 14, 20–21. Name Holly Springs should be dropped from literature inasmuch as sands included in formation are actually equivalents of three formations, the Meridian, Tallahatta, and Kosciusko. Discussion of Lafayette County.

Benjamin Gildersleeve, 1953, Kentucky Geol. Survey Spec. Pub. 1, p. 18 (fig. 1). Generalized section—embayment region of Tennessee and Kentucky—shows Holly Springs formation below Grenada formation and above Ackerman formation in Tennessee. Wilcox group. Lower Eocene.

Typically developed at and for several miles east of Holly Springs, Marshall County, Miss.

Holmesville Shale Member (of Doyle Shale)

Holmesville Shale (in Chase Group)[1]

Permian: Southeastern Nebraska and eastern Kansas.

Original reference: G. E. Condra and J. E. Upp, 1931, Nebraska Geol. Survey Bull. 6, 2d ser., p. 43.

K. L. Walters, 1954, Kansas Geol. Survey Bull. 106, p. 42 (table 10), 53–55, pl. 1. Member of Doyle shale. In Marshall County, consists of about 20 feet of green, gray, and maroon calcareous shale; lenticular limestone beds about 1 foot thick present in lower few feet of member. Underlies Towanda member; overlies Fort Riley member of Barneston limestone.

Type locality: One and one-half miles west and one-half mile north of Holmesville, Gage County, Nebr.

Holokuk Basalt

Eocene(?) to Miocene(?): Southwestern Alaska.

W. M. Cady and others, 1955, U.S. Geol. Survey Prof. Paper 268, p. 21 (table), 53–55, pl. 1. Chiefly flows, now disconnected but believed to have formed widespread and rather continuous plateau before stream dissection. Flows and less abundant water-deposited detritus of the flows made up almost exclusively of basalt. Dikes of similar composition well exposed and near valleys of Kolmakof River, upper Oskawalik River, and Vreeland Creek. Volcanic rocks are black on fresh surfaces: weather to browns and buffs. Basalt nearly everywhere porphyritic and little altered. Thickness at least 3,000 feet along southeast slopes of Horn Mountains; 1,500 feet in area east of Holokuk Mountain; and less than 1,000 feet on Kaluvarawluk Mountain. Unconformably overlies Kuskokwim group (new). Probably is older than and overlies Getmuna rhyolite group (new).

Typically exposed in Kaluvarawluk and Kiokluk Mountains east of Holokuk River. Also crops out in flanks of Horn Mountains, north of Kuskokwim River. Named for Holokuk River.

Holston Marble, Limestone, or **Formation**

Holston Marble or Limestone (in Blount Group)[1]

Middle Ordovician: Eastern Tennessee, northwestern Georgia, western North Carolina, and western Virginia.

Original reference: A. Keith, 1895, U.S. Geol. Survey Geol. Atlas, Folio 16, map.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 148–154. With single exception, Holston limestone, wherever present in Virginia, succeeds Lenoir limestone. Northwest of Clinch Mountain, the Holston is directly overlain by Ottosee limestone with hiatus between, resulting from absence of Athens and Whitesburg. Southeast of Clinch Mountain, the Holston is overlain by Whitesburg limestone or Athens shale. Blount group. Chazyan series.

B. N. Cooper and C. E. Prouty, 1943, Geol. Soc. America Bull., v. 54, no. 6, p. 816–886. Lower Middle Ordovician succession of Tazewell County, southwestern Virginia, is subdivided into 29 distinctive zones grouped into eight formations. Study has led to recognition of inconsistencies in use of names Stones River, Murfreesboro, Mosheim, Lenoir, Blount, Holston, Ottosee, Lowville, and Moccasin. In proposed revised stratigraphic nomenclature, Cliffield formation includes beds which Butts (1940) has called Murfreesboro, Mosheim, Lenoir, Holston, and Ottosee. Some coarse-grained limestones which have been called Holston underlie beds carrying fauna of Murfreesboro limestone. Other so-called Holston beds overlie limestones containing fossils which are supposed to be valid guides to Ottosee and Lowville.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 59–60. In Burkes Garden quadrangle, term Holston replaced by Effna limestone (new). Previous workers have identified the limestone as Holston though without adequate basis. Direct correlation on basis of fossils is impossible. Beds identified by Butts (1940) as Holston along northwest base of Clinch Mountain are facies of limestone which interfingers with the Blackford, Five Oaks, Lincolnshire, Ward Cove, and Peery members of Cliffield in Russell and Scott Counties, Va. This belt of so-called Holston continues southwest into Tennessee where it was mapped as lentils of marble in Chickamauga limestone by Keith. Because Keith's Holston marbles interfinger with beds of different ages, name should not be used to imply time equivalency of any similar appearing beds far away from Knoxville region in Tennessee.

C. E. Prouty, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 7, p. 1156, 1182. Discussion of lower Middle Ordovician of southwest Virginia and northeast Tennessee. Measured sections compared with revised classification of Tazewell County, Va. Holston should be discontinued as definite formational name. "Holston" marble of Knoxville area is renamed Farragut limestone.

Charles Butts and Benjamin Gildersleeve, 1948, Georgia Geol. Survey Bull. 54, p. 28, geol. map. Holston marble occurs only in one narrow belt extending into Georgia from Tennessee just east of State Highway 71 to within 6 miles north of Dalton. Thickness 50 to 100 feet. Overlies Lenoir limestone. North of Dalton, underlies Ottosee (Sevier) shale. Blount group.

John Rodgers, 1952, Geology of the Athens quadrangle, Tennessee (1:24,000): U.S. Geol. Survey Geol. Quad. Map. Holston limestone, 400 feet thick, underlies Ottosee shale and overlies Athens shale. Athens has been mistakenly placed above Holston limestone instead of below. Name Tellico sandstone has been applied to Holston in this area.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, p. 68–75, pls. Name Holston marble was first used by Keith on maps in Knoxville (1895), Loudon (1896), and Morristown (1896) folios, but he did not mention it in text until Maynardville folio (1901). He apparently considered it a member or lentil in Chickamauga limestone and did not specify type locality, though clearly he named it for Holston River. Type locality herein proposed. In belt next southeast of Saltville fault, rocks above Knox group are continuous from about 3 miles west of New Market to 2 miles north of Athens. To northeast, a few small outliers extend past Jefferson City; to southwest, beyond a 30-mile break, the rocks reappear with virtually no change 4 miles south of Cleveland and continue to Georgia line and some miles beyond. Rocks are divided into (ascending) Lenoir limestone, Holston formation, Ottosee shale, and Bays formation. This sequence is here considered as standard of reference for rocks of this age, and belt is referred to as standard belt. Thickness of Holston 200 to 400 feet in standard belt. Holston formation of standard belt consists of several different kinds of rock that together form mappable unit. All are composed largely of calcite, and most contain large amount of finely divided hematite, which colors the rocks and derived soils pink to dark red. Dominant lithology is pink to red, coarsely crystalline limestone ("marble") showing crossbedding; this lime-sandstone (calcarenite) has furnished bulk of "Tennessee marble" of commerce, but it is neither the whole of the Holston nor confined to it. A second rock type is dark-red fine-grained limestone that contains algal heads, unbroken bryozoans, and crinoid bases; this lithology occurs as irregular masses and heads surrounded by limestones and clearly formed reef masses. A third rock type resembles the lime-sandstone but contains more quartzite; in many places, it overlies the other rock types. Keith and others have mapped this third rock type as Tellico sandstone. For present map, the rocks that Keith and others have mapped Tellico are included in the Holston. Holston in other belts differs slightly from that in standard belt. Overlies Athens shale in Blount County.

R. B. Neuman, 1955, U.S. Geol. Survey Prof. Paper 274–F, p. 157. In Tellico-Sevier belt, Chota formation (new) is same unit as sandstone lentil of Sevier formation of Keith and Holston formation of Rodgers (1953).

J. M. Cattermole, 1955, U.S. Geol. Survey Geol. Quad. Map GQ–76; 1960, Map GQ–126. In Shooks Gap and Bearden quadrangles, Tennessee, Holston formation overlies Lenoir limestone and underlies Chapman Ridge sandstone (new).

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 67–68. Because of uncertainty and inaccuracy of present application of Holston, name should be dropped as a stratigraphic term.

Josiah Bridge, 1956, U.S. Geol. Survey Prof. Paper 277, p. 57. Term Blount group discarded.

Type locality (Rodgers): Along and near Holston River, 7 miles east-northeast of center of Knoxville where Holston River leaves standard reference belt just south of the John Sevier yards; includes quarry of Volunteer Portland Cement Co., just went of Holston River.

Holt Shale Member (of Topeka Limestone)[1]

Pennsylvanian (Virgil Series): Northwestern Missouri, southwestern Iowa, eastern Kansas, and southeastern Nebraska.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 42, 52, 53.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2035 (fig. 5); 1949, Kansas Geol. Survey Bull. 83, p. 128 (fig. 22), 164; F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 18. Holt shale member of Topeka formation; underlies Coal Creek limestone member; overlies Du Bois limestone member. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May, 1947.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 15, fig. 5. Fossiliferous dark- to light-gray shale with an underlying black fissile shale. Thickness 2 to 3 feet. Underlies Coal Creek member; overlies Du Bois limestone member; where Du Bois is absent, overlies Turner Creek shale member.

Type locality: In Missouri River bluff southeast of Forest City, Holt County, Mo.

Holtsclaw Sandstone[1]

Lower Mississippian: Western and northern Kentucky and southern Indiana.

Original reference: Charles Butts, 1915, Kentucky Geol. Survey, 4th ser., v. 3, pt. 2, p. 151.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 143–144. Name abandoned. Holtsclaw Hill facies (new) off Brodhead formation (new) comprises the two units "Rosewood shale" and "Holtsclaw sandstone" proposed by Butts (1915).

Named for Holtsclaw Hill, Jefferson County, Ky.

Holtsclaw Hill facies (of Brodhead Formation)

Lower Mississippian: North-central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 76, 139–145. Consists of silty shale that grades upward into massive siltstone. Thickness 200 to 220 feet. Lacks consistent horizons to justify its subdivision into smaller units of stratigraphic rank. Facies combines the Rosewood shale and Holtsclaw sandstone of Butts (1915) and is the equivalent of Locust Point formation, Spickert Knob facies, and Carwood formation, Knob Creek facies, in Indiana. At type area, underlies Floyds Knob formation and overlies Silver Hills facies of New Providence formation. Passes laterally eastward into Pilot Knob facies (new).

Typical exposure: At Holtsclaw Hill, 12½ miles south of Ohio River at Louisville, along winding road following ravine immediately west of hill, Jefferson County. Named for Holtsclaw Hill, just north of southern boundary line of Jefferson County.

Holts Summit Formation

Upper Devonian: Central Missouri.

M. G. Mehl, 1960, Denison Univ. Jour. Sci. Lab., v. 45, art. 5, p. 78–80. Alternating beds of sandstone and arenaceous shale. Average thickness about 4 feet with maximum not more than 8 or 10 feet. Unconformably overlies Snyder Creek or Callaway; unconformably underlies Massie Creek formation (new).

Type locality: NE¼SE¼SE¼ sec. 11, T. 45 N., R. 11 W., on major branch of Clifton Creek about 2½ miles northwest of Holts Summit, Callaway County.

Holy Cross Sandstone

Silurian: Central Kentucky.

W. R. Jillson, 1952, The Holy Cross sandstone: Frankfort, Ky., Roberts Printing Co., p. 5–14. Tawney fine-grained shaley fossiliferous sandstone 6 to 8 feet thick. Occurs above Crab Orchard shale and is separated from Middle or Upper Devonian strata by major unconformity.

Occurs about 0.8 miles south of village of Holy Cross, Marion County.

Holy Cross Schist[1]

Precambrian: Central Colorado.

Original reference: J. T. Stark and F. F. Barnes, 1935, Colorado Sci. Soc. Proc., v. 13, no. 8, p. 466–479, map.

The Mountain of the Holy Cross occurs in midst of mass mapped as Holy Cross schist and migmatite. The other schist seems to have been named for Sawatch Range.

Holyoke Basalt (in Newark Group)

Holyoke Diabase (in Newark Group)[1]

Holyoke Lava

Holyoke Lava Member (of Meriden Formation)

Upper Triassic: Central Massachusetts and central Connecticut.

Original reference: B. K. Emerson, 1891, Geol. Soc. America Bull., v. 2, p. 451–456.

G. W. Bain, 1941, Am. Jour. Sci., v. 239, no. 4, p. 266, 267–268, fig. 1. Referred to as lava. Overlies Sugarloaf arkose.

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Rank reduced to member occurring between upper and lower sedimentary members of Meriden formation.

Robert Balk, 1957, Geol. Soc. America Bull., v. 68, no. 4, p. 486–494, pl. 1. Current description and summary discussion of diabase in Mount Holyoke quadrangle, Massachusetts.

E. P. Lehmann, 1959, Connecticut Geol. and Nat. History Survey Quad. Rept. 8, p. 8 (table 1), 12–14, pl. 1. Term Meriden not used in this report [Middletown quadrangle]; units given formational status in Newark group. Holyoke basalt crops out extensively along west edge of quadrangle in belt 3,000 to 5,000 feet wide, trending slightly east of north. Estimated stratigraphic thickness 450 to 500 feet. Represents two successive lava flows, the second being thinner. Overlies Shuttle Meadow formation (new); underlies East Berlin formation (new).

R. W. Schnabel, 1960, U.S. Geol. Survey Geol. Quad. Map GQ–134. Described in Avon quadrangle, Connecticut, where it is 250 to 350 feet thick. Lower contact not exposed in quadrangle. Conformably underlies East Berlin formation.

Named for occurrence in Mount Holyoke Range, Mass.

Holyoke Conglomerate[1]

Precambrian (middle Huronian): Northwestern Michigan.

Original reference: M. E. Wadsworth, 1893, Michigan Geol. Survey Rept. 1891 and 1892, p. 63–66.

Named for occurrence at Holyoke, in Cascade Range, Marquette district.

Holyoke Formation[1]

Precambrian (upper Huronian): Northwestern Michigan.

Original reference: M. E. Wadsworth, 1890 and 1891, Lake Superior along the south shore, by Julian Ralph, p. 77–99; 1st ed., 1890; 2d ed., 1891.

Named for occurrence at Holyoke, in Cascade Range, Marquette district.

Holz Shale Member (of Ladd Formation)

Upper Cretaceous: Southern California.

W. P. Popenoe, 1937, Jour. Paleontology, v. 11, no. 5, p. 380. Upper member of Ladd formation (new). Dark-bluish- to brownish-gray micaceous sandy shale or siltstone, with interbedded arkosic sandstones and nonpersistent coarse conglomerate lenses; fossiliferous in upper half. Thickness about 1,500 feet. Unconformably underlies Schulz member of Williams formation (both new); overlies Baker member of Ladd formation (both new).

W. P. Popenoe, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 2, p. 166, 168 (fig. 2), 171–173. Type locality designated.

W. P. Woodring and W. P. Popenoe, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 12. Shown on stratigraphic section as underlying Silverado formation (new).

Type locality: Holz Ranch on north side of Silverado Canyon just west of mouth of Ladd Canyon. Holz is most persistent and thickest member of Cretaceous sequence in Santa Ana Mountains; extends in virtually unbroken exposure from Santa Ana Canyon south to near Trabuco Canyon —about 15 miles.

Homberg Group

Mississippian (Chester Series): Southern Illinois and western Kentucky.

J. M. Weller, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 131, 135. In southern Illinois and western Kentucky, consists of four formations (ascending): Cypress sandstone, Golconda limestone, Hardinsburg sandstone, and Glen Dean limestone. In this area, the sandstones are prominent and persistent formations; in Mississippi River counties, they thin, become shaly, and locally, the Hardinsburg sandstone is entirely absent. In Mississippi River counties, succession is Ruma formation at base and Okaw limestone. Underlies New Design group (new); overlies Elvira group (new).

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 829–830. Derivation of name given.

Name derived from village of Homberg, Pope County, Ill., near which group is well and typically developed.

Home Glacial Substage

Pleistocene (Wisconsin): Southern Rocky Mountains.

L. L. Ray, 1938. (abs.) Geol. Soc. America Proc. 1937, p. 314. Two stages of glaciation, believed to be of Wisconsin age, are recognized along northern Front Range. Older is designated Home stage and the younger Corral Creek stage.

L. L. Ray, 1939, (abs.) Geol. Soc. America Bull., v. 50, no. 12, pt. 2, p. 2007; Kirk Bryan and L. L. Ray, 1940, Smithsonian Misc. Colln., v. 99, no. 2, p. 30–33; L. L. Ray, 1940, Geol. Soc. America Bull., v. 51, no. 12, pt. 1, p. 1857–1860. Represents second of five substages in southern Rocky Mountains. Preceded by Twin Lakes (new) and followed by Corral Creek substage.

Named for Home post office where terminal moraine stretches almost completely across Cache la Poudre Canyon.

Home Creek Limestone Member (of Caddo Creek Formation)[1]

Home Creek Limestone (in Caddo Creek Group)

Upper Pennsylvanian: Central and central northern Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 387, 398.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 88. Rank raised to formation in Caddo Creek group. Redefined to include shales found locally above highest limestone member of Home Creek formation and below disconformity at base of the Cisco. Overlies Hog Creek shale; underlies Gonzales formation.

M. G. Cheney, 1948, Abilene Geol. Soc. [Guidebook] Spring Field Trip, June 11–12, p. 20. Overlies Colony Creek shale (new) which replaces Hog Creek shale.

D. H. Eargle, 1958, San Angelo Geol. Soc. Guidebook, Apr. 17–19, p. 51. Member consists of limestone, light-gray to nearly white, nodular to slabby to thick-bedded, fine-grained, locally cherty; middle part generally marly, contains "seaweed" structures and a few fusulinids. Contains reefs in vicinity of Colorado River. Thickness about 30 feet. Overlies Colony Creek shale member; underlies Bluff Creek shale member of Graham formation.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 67–68, pl. 27. Unusual thickening of limestone units in uppermost part of Canyon group near junction of Home Creek and Colorado River has resulted in confusion in correlation with limestone units in Caddo Creek and Brad formations as mapped elsewhere. Drake originally applied term "Home Creek bed" to upper noncherty limestone in walls of creek and name

"Cherty bed" to lower massive limestone, which contains abundant nodules of rounded nodules of chert. The chert bearing limestone is now included in Brad formation. Plummer and Moore (1921, Texas Univ. Bull. 2132) applied name "Home Creek" to prominent limestone at top of Canyon group in Brazos and Colorado River valleys. By tracing this member across northern McCulloch County to the type locality, and by studying stratigraphy of northern Brown County, Nickell (1938, Texas Univ. Bur. Econ. Geology Pub. 3801) found that limestone called Home Creek limestone by most geologists correlated with one higher on the slope than the one to which Drake had originally applied term "Home Creek" at type locality. Drake's Home Creek limestone, he found, was the one that Plummer and Moore had subsequently named Ranger. Other miscorrelations to north have been made in the past. Beds mapped as Home Creek across southern Brown County to outlier of Cretaceous rocks on which town of Bangs is located were mapped as Ranger limestone member of Brad formation (Plummer and Moore, 1921) north of outlier. Thus, Hog Creek shale of Drake (1893), named for creek north of outlier—in which Bluff Creek shale as used by Cheney (1948, Abilene Geol. Soc. Guidebook, Spring Field Trip, June 11–12) is exposed—was believed to lie below Plummer and Moore's Home Creek limestone. Actually, Hog Creek shale of Drake lies above the Home Creek. Because of this confusion, Cheney proposed name Colony Creek to replace term Hog Creek.

Named for Home Creek, Coleman County.

Homer Limestone Member (of Wayan Formation)[1]

Lower(?) Cretaceous: Southeastern Idaho.

Original reference: G. R. Mansfield, 1921, Geol. Soc. America Bull., v. 32, p. 249–266.

Named for exposures in valley of Homer Creek, Cranes Flat quadrangle.

Homer Limestone Member (of Holdenville Shale)[1]

Pennsylvanian: Central southern Oklahoma.

Original reference: G. D. Morgan, 1924, [Oklahoma] Bur. Geology Bull. 2, p. 104–105.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 107. Abandoned by Oklahoma Geological Survey. Name preoccupied; no replacement of name made.

Named for exposures near Homer School, in sec. 25, T. 4N., R. 6E., Pontotoc County.

Homer Quartzite (in Kaweah Series)

Triassic(?): Southern California.

Cordell Durrell, 1940, California Univ. Dept. Geol. Sci. Bull., v. 25, no. 1, p. 15, 116, fig. 29, geol. map. Third in sequence (ascending) of four units. Younger than Lemon Cove schist and older than Three Rivers schist (both new). Consists predominantly of graphitic schists or phyllites and bedded siliceous rocks, which are interpreted in origin, as cherts. Thickest section, which occurs in central part of Dry Creek area, measures about 7,000 feet.

Named for Homer Ranch in Dry Creek Valley, in the southern Sierra Nevada, north-central Tulare County.

Homestake Formation[1]

Precambrian: Southwestern South Dakota.

Original reference: J. O. Hosted and L. B. Wright, 1923, Eng. and Min. Journal-Press, v. 115, p. 793–799, 836–843, maps.

T. A. Dodge, 1942, Geol. Soc. America Bull., v. 53, no. 4, p. 563–565. In Lead district, underlies Ellison formation and overlies Poorman formation. Consists chiefly of quartz carbonate schist, locally much altered. Thickness 200 to 300 feet. Unit tightly folded.

E. P. Rothrock, 1944, South Dakota Geol. Survey Bull. 15, p. 24. In vicinity of Homestake mine, underlies Ellison formation and overlies De Smet formation. Thickness 70 feet.

J. A. Noble and J. O. Harder, 1948, Geol. Soc. America Bull., v. 59, no. 9, p. 944, 945, 946–947. Term De Smet dropped; unit included in Poorman formation; hence, Homestake underlies Ellison formation and overlies Poorman formation. In Rochford district, where Northwestern formation is missing, Flag Rock formation cuts across Ellison and in some places rests on Homestake.

Derivation of name not stated but probably Homestake mine, Lead district, Lawrence County.

Homestake Limestone Member (of Carmel Formation)

Homestake Limestone[1]

Jurassic: Southwestern Utah.

Original reference: C. R. Leith and E. C. Harder, 1908, U.S. Geol. Survey Bull. 338, p. 24.

J. H. Mackin, 1954, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–14. Limestone portion of Leith and Harder's Homestake limestone is redefined as Homestake limestone member of Carmel formation, Carmel being herein geographically extended into Iron Springs area. Member consists chiefly of gray, "blue," and black limestone, massive to thick-bedded, which ranges in thickness from 220 to 250 feet in Granite Mountain area. Grades upward through a few feet of mud-cracked and ripple-marked limy mudstone into Entrada sandstone. Jurassic.

First mapped and described in vicinity of Homestake mine, Iron Springs quadrangle.

Homewood Formation (in Pottsville Group)

Homewood Sandstone Member (of Pottsville Formation)[1]

Homewood Sandstone and Shale (in Mercer Formation)

Homewood sandstone member

Homewood shale and (or) sandstone member

Pennsylvanian: Western Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

Original reference: I. C. White, 1878, Pennsylvania 2d Geol. Survey Rept. Q, p. 67.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 40–41. Homewood shale and (or) sandstone member of Brookville cyclothem in report on Perry County. Base of Homewood considered boundary between Pottsville and Allegheny series.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 49 (table 7), 50–51. Homewood sandstone member of Brookville cyclothem in report on Athens County. At type exposure, the Homewood is reported to include coalesced sandstones of several cycles of deposition, but in Ohio, Homewood member is recognized as the sandstone immediately below the Brookville member and above Tionesta coal. Either Brookville underclay or marine Putnam Hill shale overlies the Homewood, contact, where observed, is thin gradational one. Thickness 30 feet.

E. G. Williams, 1960, Jour. Paleontology, v. 34, no. 5, p. 909, 910 (fig. 2). Homewood sandstone and shale is at top of Mercer formation.

Named for occurrence at Homewood Station, Beaver County, Pa.

Homewood (Lower) Sandstone (in Kanawha Formation)[1]

Pennsylvanian: Southern West Virginia.

Original reference: C. E. Krebs and D. D. Teets, Jr., 1916, West Virginia Geol. Survey Rept. Raleigh and western parts of Mercer and Summers Counties, p. 56.

†Hominy Formation[1]

Pennsylvanian and Permian: Central northern Oklahoma.

Original reference: C. N. Gould, 1905, U.S. Geol. Survey Water-supply Paper 148, map.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 101. Abandoned by Oklahoma Geological Survey.

Named for Hominy, Osage County.

Homochitto Member (of Pascagoula Formation)

Miocene: Southwestern Mississippi.

G. F. Brown and W. F. Guyton, 1943, Mississippi Geol. Survey Bull. 56, p. 22, 23 (chart), 32–37. Proposed to replace preoccupied name Knoxville member. Consists of sand, blue-green clay, and silt; very coarse sand or fine gravel at base. Thickness 181 to 252 feet. Underlies Fort Adams member; overlies a shale, sandy shale, siltstone unit 362 to 466 feet thick in lower portion of formation.

Crops out in narrow belt across southwestern Franklin County.

Honaker Limestone[1] or **Dolomite**[1] (in Conasauga Group)

Middle Cambrian: Southwestern Virginia, western North Carolina, and northeastern Tennessee.

Original reference: M. R. Campbell, 1897, U.S. Geol. Survey Geol. Atlas, Folio 44, p. 2.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 1 (plates); pt. 2, p. 46 (fig. 3), 51–53. In eastern Tennessee, Conasauga [group] varies in lithology, and three phases are recognized; in southeastern phase sequence includes (ascending) Honaker dolomite, Nolichucky shale, and Maynardville limestone. Dolomite in Honaker includes all types—light and dark, fine- and coarse-grained, shaly and massive. Limestone is also present. Thickness about 1,300 feet. Overlies Rome formation.

Named for exposures at Honaker, Russell County, Va.

Honaker Trail Formation (in Hermosa Group)

Pennsylvanian and Permian: Southeastern Utah.

S. A. Wengerd and M. L. Matheny, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 9, p. 2056, 2075, 2080, figs. 3, 17. Introduced to replace previously used phrase "Upper Hermosa" in Four Corners region. Comprises gray to reddish-gray fine-crystalline to coarsely granular limestone with gray and red chert, and reddish-gray to buff-gray calcareous sandy siltstones. This lithologic association, however, is typical of only one of the several high stable-shelf associations found in formation. Westward and northwestward high on the shelf, formation grades into dolomite, basinward into sandier arkosic facies, and near Uncompahgre uplift it contains massive lentils of greenish-gray mica-siltstones and arkosic granulite. Thickness ranges from 0 to 1,750 feet in a northeasterly direction toward Uncompahgre uplift. Underlies Rico formation; overlies Paradox formation. Late Cherokee, Marmaton, Missourian, and Virgilian age.

S. A. Wengerd, 1958, Intermountain Assoc. Petroleum Geologists Guidebook 9th Ann. Field Conf., p. 115, figs. 4, 5, table 1. Upper Des Moines, Missouri, Virgil, and Wolfcamp.

Type locality: At Honaker Trail in sec. 29, T. 41 S., R. 18 E., along San Juan Canyon in San Juan County, Utah. Isopachous map shows formation in northeastern Arizona, southwestern Colorado, northwestern New Mexico, and southeastern Utah.

Honda Formation

Upper Jurassic: Southern California.

T. W. Dibblee, Jr., 1950, California Div. Mines Bull. 150, p. 22, pls. 1, 2. Consists of several thousand feet of dark greenish-brown clay shale commonly containing buff-weathering calcareous concretions; poorly bedded and intensely sheared; locally contains thin layers of fine-grained sandstone. Unconformably underlies Espada formation (new); either overlies or is intruded by serpentinized pyroxenite to the north. Hondo shale may be equivalent to type Knoxville, but its highly sheared condition and unconformable relationship to Espada formation suggests that it may be shale member of Franciscan.

Type locality: North side of Canada Honda 3 miles east of Point Pedernales, Santa Barbara County.

Hondo Sandstone Member (of San Andres Limestone)

Hondo Sandstone Member (of Chupadera Formation)[1]

Permian: Southeastern New Mexico.

Original reference: W. B. Lang, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 7.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 542 (fig. 2), 687, pl. 2. Hondo sandstone reallocated to member status in San Andres herein rank raised to formation. Term Chupadera abandoned.

Crops out near bottom of valley of Hondo River and its tributaries.

Hondo Shale or Formation

See **Arroyo Hondo Shale Member** (of Lodo Formation).

Hondo Slate

Precambrian (Proterozoic): Central northern New Mexico.

Evan Just, 1937, New Mexico School Mines Bull. 13, p. 11, 13 (table 1), 23, pl. 2. Characteristically black carbonaceous slate, has well-developed schistosity. Weathers rusty color. In many places, particularly along Arroyo Hondo, the black slate grades into quartz-muscovite schist. Ranges up to a mile in thickness. Overlies Ortega quartzite (new).

Arthur Montgomery, 1953, New Mexico Bur. Mines Mineral Resources Bull. 30, p. 6, 19. Renamed Pilar phyllite member of Ortega formation because name Hondo preempted.

Most conspicuous occurrence is belt extending from near Dixon northeast to central part of drainage system of Arroyo Hondo. Smaller belt between Harding mine and Copper Hill. Also exposed along Dixon-Penasco Road a few miles east of Dixon.

Honesdale Sandstone Member (of Catskill Formation)

Honesdale Sandstone Group (in Catskill Formation)[1]

Upper Devonian: Northeastern Pennsylvania.

Original reference: I. C. White, 1881, Pennsylvania 2d Geol. Survey Rept. G_5, p. 66–68, 132, 140.

Bradford Willard, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 279 (table 30), 288–291, fig. 72. Honesdale sandstone included in Catskill facies.

Harry Klemic and R. C. Baker, 1954, U.S. Geol. Survey Circ. 350, p. 2. Willard's (1939) classification interpreted as Honesdale sandstone member of Catskill formation. Occurs above Damascus red shale member and below Cherry Ridge red beds member.

First described at Honesdale, Wayne County.

Honey Creek Formation (in Timbered Hills Group)

Honey Creek Limestone[1]

Upper Cambrian: Central southern Oklahoma.

Original reference: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, p. 624, 642, 661, 666, pl. 27.

C. E. Decker, 1939, Oklahoma Geol. Survey Circ. 22, p. 16 (table 1), 19–20, measured sections. Uppermost formation in Timbered Hills group. In most places, rests directly on Reagan formation; contact gradational in many areas. Along west edge of Blue Creek Canyon, overlaps the Reagan and rests directly upon Precambrian igneous rock. Underlies Fort Sill formation. Thickness 51 to 90 feet in Arbuckle Mountains; 44 to 226 feet in Wichita Mountains.

E. A. Frederickson, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 7, p. 1349–1355. Redefined to include units termed Cap Mountain and "basal limestone" in Timbered Hills group by Decker (1939). Both units are equivalents of all or portions of Honey Creek formation.

W. E. Ham, 1949, Oklahoma Geol. Survey Circ. 26, p. 23 (fig. 2), 31–39. Formation in Mill Creek-Ravia area consists of sandy and nonsandy dolomite 63 to 234 feet thick, overlying Reagan sandstone and underlying, with slight disconformity Fort Sill limestone.

Named for Honey Creek, a tributary of Washita River which rises in Arbuckle Mountains and flows northeastward around west end of East Timbered Hills.

Honeycut Formation (in Ellenburger Group)

Lower Ordovician: Central Texas.

V. E. Barnes and P. E. Cloud, Jr., 1945, Texas Univ. Bur. Econ. Geology Mineral Resources Circ. 34, p. 1, 3–7, 31–41. Uppermost formation in group. Overlies Gorman formation (new). Limestone and dolomite.

Thickness at type section (Blanco County) 679 feet; Cherokee Creek section, San Saba County, 142 feet.

P. E. Cloud, Jr., V. E. Barnes, and Josiah Bridge, 1946, Texas Univ. Bur. Econ. Geology Pub. 4301, p. 146–147, pls. 4, 6 [1945]. All known Ellenburger strata above Gorman formation here termed Honeycut formation. Upper and lower parts consist of interbedded limestones and dolomites separated by prominent median sequence of microgranular to very fine grained dolomite; this tripartite division is fairly persistent laterally. Cannonballs of chert and siliceous limestone common. Due to post-Ellenburger truncation, Honeycut ranges in thickness from maximum of 678 feet at type section in southeast corner of Llano uplift to a feather edge, disappearing entirely in western part of uplift.

P. E. Cloud, Jr., and V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Pub. 4621, p. 40–42, 197, 257, 314, 321–333, pls. 3, 13 [1946]. Type section and local stratigraphy described in detail.

V. E. Barnes, P. E. Cloud, Jr., and Helen Duncan, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 5, p. 1033. Stratigraphic relations at base of Burnam limestone (new) uncertain. Whether these Upper Ordovician rocks rest directly on Honeycut formation, or whether other rocks intervene between Honeycut and Burnam cannot be determined without drilling, if then. In north-central and northwestern parts of area, Stribling rocks rest directly on flat Honeycut rocks. In northeastern part of same area, horizontal beds of Stribling formation directly overlap steeply dipping beds of Honeycut.

Type section: In reach of Pedernales River known as Honeycut Bend, about 5 miles east of Johnson City, Blanco County. Also present in Burnet and Llano Counties.

Honolua Volcanic Series

Pliocene, upper(?), or Pleistocene, lower: Maui Island, Hawaii.

H. T. Stearns *in* H. T. Stearns and G. A. Macdonald, 1942, Hawaii Div. Hydrography Bull. 7, p. 65 (table), 159 (table), 173–179, pl. 1. Andesites and soda trachytes characterized by platy cleavage. Individual flows range from 25 to 300 feet in thickness; some are 500 feet near vents. Lavas attain maximum thickness of 750 feet near Eke. Separated from underlying Wailuku volcanic series (new) by thin red soil.

G. A. Macdonald *in* H. T. Stearns and G. A. Macdonald, 1942, Hawaii Div. Hydrography Bull. 7, p. 320–325. Petrography discussed.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 89. Late Pliocene(?) or early Pleistocene.

Named from village of Honolua West Maui Mountains on northwest coast Maui Island. Village is on bay bounded on both sides by cliffs of andesitic lavas 100 to 150 feet high.

Honolulu Volcanic Series[1]

Honolulu Series

Pleistocene and Recent: Oahu Island, Hawaii.

Original reference: H. T. Stearns, 1935, Hawaii Div. Hydrog. Bull. 1.

Horace Winchell, 1947, Geol. Soc. America Bull., v. 58, no. 1, p. 1–48. Termed Honolulu series. Units correlated with Pleistocene and Recent stands of sea.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 90–91. Series of olivine basalt, nepheline basalt, melilite-nepheline basalt lava flows, and associated cinder cones and ash beds, and tuff cones. Overlies Koolau volcanic series, erosional unconformity. Correlated with successive stands of sea higher or lower than present stand during Pleistocene time.

Includes following named units (not in sequence) : Ainoni Volcanics, Aliamanu Basalt. Aliamanu Tuff, Black Point Basalt, Castle Volcanics, Diamond Head Tuff, Haiku Volcanics, Hawaiiloa Volcanics, Kaau Volcanics, Kaimuki Basalt, Kalama Volcanics, Kalihi Volcanics, Kamanaiki Basalt, Kaneohe Volcanics, Kaohikaipu Volcanics, Kaupo Basalt, Koko Volcanics, Makalapa Tuff, Makawao Breccia, Manana Tuff, Maunawili Volcanics, Mauumae Volcanics, Mokapu Basalt, Mokolea Basalt, Moku Manu Volcanics, Nuuanu Volcanics, Pali Volcanics, Punchbowl Volcanics, Pyramid Rock Basalt, Rocky Hill Volcanics, Salt Lake Tuff, Sugar Loaf Basalt, Tantalus Basalt, Training School Volcanics, and Ulupau Tuff.

Named for city and county of Honolulu, in which it occurs. Present as many small masses and valley-filling lava flows covering total of about 27 square miles on both southwest and northeast flanks of southeast end of Koolau Range.

Honomanu Volcanic Series

Tertiary, upper (?) : Maui Island, Hawaii.

H. T. Stearns *in* H. T. Stearns and G. A. Macdonald, 1942, Hawaii Div. Hydrography Bull. 7, p. 61, 63, 65 (table), 66 (table), 68–74, pl. 1. Oldest rocks in East Maui. Exposed over less than 1 percent of Haleakala but believed to form basement of entire mountain to an unknown depth below sea level. Underlies Kula volcanic series (new).

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat. v. 6, Océanie, fasc. 2, p. 90–91. Late Tertiary (?).

Type locality: Northeast slope Haleakala (East Maui) volcano in Honomanu Valley, a gorge 1,300 feet deep. Basalts form lower 950 feet of cliff and are exposed northwestward in sea cliffs and in mouths of deeper gulches as far as Waipo Bay. Exposed eastward from type locality nearly to Nahiku and for 5½ miles up Keanae Valley.

Hood Glacial Epoch

Pleistocene : Central northern Oregon.

E. T. Hodge, 1938, Geol. Soc. America Bull., v. 49, no. 6, p. 836, 841 (table 1). Youngest of series of five glacial epochs in area. Preceded by Jeffersonian epoch.

Hoodoo Quartzite[1]

Precambrian (Belt Series) : Southern central Idaho.

Original references: C. P. Ross, 1932, Idaho correlation chart compiled by M. G. Wilmarth ; 1934, U.S. Geol. Survey Bull. 854.

C. P. Ross and J. D. Forrester, 1958, Idaho Bur. Mines and Geology Bull. 15, p. 7. Belt series in vicinity of middle Fork of Salmon River, includes Yellowjacket formation, at least 9,000 feet thick, overlain by Hoodoo quartzite over 3,560 feet thick.

Type locality: Hoodoo Creek, northwestern part of Casto quadrangle.

Hood River Conglomerate[1] or Formation

Miocene, upper, or Pliocene, lower: Northwestern Oregon and southwestern Washington.

Original reference: J. P. Buwalda and B. N. Moore, 1927, Science, new ser., v. 66, p. 236.

R. W. Chaney, 1938, Carnegie Inst. Washington Pub. 476, p. 208–212. Plant fossils from formation indicate Pliocene rather than Pleistocene age.

C. R. Warren, 1941, Am. Jour. Sci., v. 239, no. 2, p. 106–127. Conglomerate deeply weathered, moderately well indurated, fluvial conglomerate resting conformably or nearly so on Yakima basalt and deformed with it. Traced from type locality northeast past Golden, Wash., to Sunnyside. Contemporaneous with Dalles and Ellensburg formations, both of late Miocene and early Pliocene.

Type section: In cut immediately east of Columbia River Highway bridge across Hood River, east of town of Hood River, Oreg.

Hook Limestone Member (of Macy Formation)

Middle Ordovician: Southeastern Missouri.

E. R. Larson, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 9, p. 2060–2061. Name applied to lower member of formation. Composed of yellowish-brown fucoidal, fine calcitite with irregular buff-weathering dolomitic partings, and layers of intraformational conglomerate. Thickness at type locality 55 feet; here contains a 6-inch bed of orange metabentonite at 27 feet and a 1-inch bed of metabentonite at 46 feet; generally thins northward; thickens southward to 69 feet in Perry County. Underlies Zell member (new); overlies Hagar formation (new).

Type exposure: Along Missouri Highway 25, east of Macy, Ste. Genevieve County.

Hooker Slate[1]

Lower Cambrian: West-central Vermont.

Original reference: Arthur Keith, 1932, Washington Acad. Sci. Jour., v. 22, p. 360, 402.

E-an Zen, 1956, (abs.) Geol. Soc. America Bull., v. 67, no. 12, pt. 2, p. 1829–1830. Revised stratigraphic sequence proposed for north end of slate belt, Taconic Range. Consists of basal Biddie Knob formation (new); intermediate Bull formation; and the Hooker, a black slate formation with subsidiary dolomite, limestone, and quartzite beds. Fossils in Bull and Hooker formations indicate bulk of section is early Cambrian although some Ordovician slate may be present at top.

Named for Hooker Hill 2 miles north of Castleton, Rutland quadrangle.

Hook Mountain Flow

See **Watchung Basalt or Lava Flows.**

Hookton Formation

Pleistocene, middle to upper: Northwestern California.

B. A. Ogle, 1953, California Div. Mines Bull. 164, p. 13 (fig. 3), 57–63, pls. 1, 2. Sediments include gravel, sand, silt, and clay; characteristically yellow-orange in color. Thickness as much as 400 feet. Stratigraphically below, though not in contact with, Rohnerville formation (new); unconformably overlies Carlotta formation (new). No positive age can be established for formation; inferences suggest that it is probably middle to upper Pleistocene. [Columnar section shows Pleistocene; map bracket shows upper Pleistocene.]

Name derived from Hookton-Table Bluff area where there are numerous, more or less typical, random exposures. Area of study, Eel River valley, Humboldt County. Exposed on north and south sides of Eel River syncline; passes over Tompkins Hill anticline where folding has been more intense.

Hooper Clay Member (of Rockdale Formation)

Hooper Formation

Eocene, lower (Wilcox) : East-central Texas.

W. W. Sharp, Jr., 1953, *in* Am. Assoc. Petroleum Geologists, Soc. Econ: Paleontologists and Mineralogists, Soc. Explor. Geolphysicists Guidebook Field Trip Routes Joint Ann. Mtg. March, p. 53 (geol. map) Black to gray carbonaceous clay and shale containing lignite, concentric concretionary clayironstone, and sand layers. Disconformably underlies Simsboro formation.

R. L. Folk (leader), 1960, Texas Univ. Geol. Soc. Tertiary Field Trip, Dec. 10, p. 5, strat. section. Shown on stratigraphic section as clay member of Rockdale formation. Underlies Simsboro member; overlies Caldwell Knob member of Seguin formation.

Mapped in northern Bastrop County.

Hoosac Schist[1]

Hoosac Formation

Lower Cambrian(?): Western Massachusetts, western Connecticut, and southern Vermont.

Original reference: J. E. Wolff, 1894, U.S. Geol. Survey Mon. 23, p. 23–107.

J. B. Thompson, Jr., 1952, *in* M. P. Billings, John Rodgers, and J. B. Thompson, Jr., Geol. Soc. America Guidebook for Field Trips in New England, p. 40–41. Formation subdivided in southeastern Vermont. Contains Bull Hill member near base and Turkey Mountain and Plymouth members in upper part. Underlies Pinney Hollow formation; overlies Tyson formation. Cambrian or Lower Ordovician.

Occurs on top of Hoosac Mountain, northwestern Massachusetts.

Hooser Shale Member (of Bader Limestone)

Hooser Shale (in Council Grove Group)[1]

Permian: Eastern Kansas and southeastern Nebraska.

Original reference: G. E. Condra and J. E. Upp, 1931, Nebraska Geol. Survey Bull. 6, 2d ser., p. 20, 25.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 166; R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 46. Member of Bader limestone. Consists of shale and impure limestones. Thickness across line of outcrop in Kansas about 10 feet. Underlies Middleburg limestone member; overlies Eiss limestone member.

M. R. Mudge and H. R. Burton, 1959, U.S. Geol. Survey Bull. 1068, p. 13 (table 2), 79–80, pls. Member described in Wabaunsee County, Kans., where it is 5½ to 15½ feet thick, overlies Eiss limestone member and underlies Middleburg limestone member.

Type locality: Highway cut and ravine just east of Hooser, Cowley County, Kans.

Hoover conglomerate unit (in Sycamore Canyon Member of Puente Formation)

Miocene, upper : Southern California.

C. J. Kundert, 1952, California Div. Mines Spec. Rept. 18, p. 6 (fig. 2), 7, pl. 2. Cobble-pebble conglomerate bed containing some boulders and a few intercalated sandstone lenses in a red sandy or earthy matrix. Thickness about 750 feet. Overlies Cental Fee sandstone unit (new).

Occurs in Whittier-La Habra area, south of Whittier fault, Los Angeles County.

Hoover division[1]

Upper Cambrian or Lower Ordovician : Central Texas.

Original reference: T. B. Comstock and E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., p. lxii, 295–306, pl. 3.

Named for Hoover Valley, Burnet County.

†Hop Brook Limestone[1]

Precambrian : Massachusetts.

Original reference : B. K. Emerson, 1899, U.S. Geol. Survey Bull. 159, p. 52.

Exposed in bottom and steep banks of Hop Brook at Sodom, eastern part of Berkshire County.

Hope Gypsum (in Sumner group)[1]

Permian : Central Kansas.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 10, 11.

Named for Hope, Dickinson County.

Hope Limestone[1]

Silurian (?) : Central southern Maine.

Original reference : C. T. Jackson, 1837, 1st Rept. Maine, p. 57–58.

Extensively quarried in Hope Township, Knox County.

Hope Valley Alaskite Gneiss

Mississippian (?) or older : Southern Rhode Island.

G. E. Moore, Jr., 1958, U.S. Geol. Survey Geol. Quad. Map GQ–105. Pinkish gray to flesh colored, generally coarse to medium grained but locally medium to fine grained. Characterized by low content of biotite and by flattened rod-shaped aggregates of quartz, commonly 15 to 20 mm long, that produce strong lineation. Foliation moderately strong in southern part of area; generally weak or absent elsewhere. Locally porphyritic, with somewhat granulated phenocrysts of pink feldspar as much as 20 mm long. Intrusive into and contains inclusions of the Blackstone series, Intruded by sills and dikes of fine-grained granite, aplite, and pegmatite.

U.S. Geological Survey currently designates the age of the Hope Valley Alaskite Gneiss as Mississippian (?) or older on basis of a study now in progress.

Named for exposures on low knobs 1 mile north of village of Hope Valley, Hope Valley quadrangle. Particularly well exposed on one of these knobs known as Goat Rock. Widespread in southern part of state.

Hopewell Series

Precambrian (Proterozoic) : Central northern New Mexico.

Evan Just, 1937, New Mexico School Mines Bull. 13, p. 10–11, 13 (table 1), 21–22, 42–43, pls. 2, 3. Succession of metamorphosed igneous flows, with which are interspersed metamorphosed sediments in Picuris and Petaca areas. Flows were principally andesite and basalt (Picuris basalts), most of which are now dark hornblende-chlorite schists. There are some flows of rhyolite and trachyte (Vallecitos rhyolites), most of which are but little changed. Contains some slates and arkosites. In Picuris area, the most conspicuous quartzite is mapped separately as Badito quartzite. In Petaca area, between Tusas and Kiawa Mountains a particularly prominent member is called Cleveland Gulch quartzite. As exposed up to 1½ miles in thickness, may be considerably thicker. Underlies Ortega quartzite.

Fred Barker, 1958, New Mexico Bur. Mines Mineral Resources Bull. 45, p. 14. Name has been applied previously to another formation and is therefore replaced by name Moppin metavolcanic series for greenschist amphibolite, schist, and other, much less abundant rock types exposed in northwest-trending belt extending from Hopewell to Cow Creek, American Creek, and in part, the southeast part of Kiawa Mountain.

Mapped in Picuris and Petaca areas between towns of Hopewell on northwest and Picuris on southeast, Rio Arriba and Taos Counties.

Hopkinton Dolomite[1]

Middle Silurian : Eastern Iowa.

Original reference : S. Calvin, 1906, Jour. Geology, v. 14, p. 572, 574.

E. H. Scobey, 1938, Jour. Geology, v. 46, no. 2, p. 207, 215, 216. About 70 feet of beds formerly referred to lower part of Hopkinton formation of Niagaran series are placed in Alexandrian series. Illinois formation names Edgewood and Kankakee are extended into Iowa sections. Hop kinton overlies Kankakee and in most areas grades conformably into it.

E. H. Scobey, 1940, Jour. Sed. Petrology, v. 10, no. 1, p. 34 (table 2), 35, table 3), 37, 38 (fig. 1). Consists of maximum of 180 feet of medium-bedded to massive, buff dolomite with zones containing beds and nodules of white chert. Text refers to underlying Gower, but tables and figures show Gower overlying Hopkinton.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Correlation chart shows Hopkinton (restricted) below Gower dolomite and above Waucoma limestone.

C. E. Brown and J. W. Whitlow, 1960, U.S. Geol. Survey Bull. 1123–A, p. 43–44, pls. 1, 3. Described in Dubuque South quadrangle, Iowa-Illinois, where it is about 195 feet thick. The Hopkinton, as used in this report, includes all beds overlying Kankakee formation, as Gower dolomite of Norton (1899, Iowa Geol. Survey, v. 9) which overlies Hopkinton in eastern Iowa, has not been recognized in Dubuque South Quadrangle.

Named for Hopkinton, Delaware County.

Hopkintonian series

Silurian (Early Yorkic) : Missouri.

C. R. Keyes, 1941, Pan-Am. Geologist, v. 75, no. 2, p. 157 (chart). Name appears on chart of formations in Missouri. Includes (ascending) Noix limestones, unnamed interval, Bowling Green dolomites. In sequence, younger than Maquoketan series and older than Goweran series.

Hoppin Slate[1]

Hoppin Formation

Lower Cambrian: Eastern Massachusetts.

Original reference: B. K. Emerson, 1917, U.S. Geol. Survey Bull. 597, p. 36.

B. F. Howell and others, 1944, Geol. Soc. America Bull., v. 55, no. 8, chart 1. Referred to as formation.

Exposed at Hoppin Hill, North Attleboro and in Wrentham.

Hopwood Conglomerate

Lower Mississippian: Southwestern Pennsylvania.

W. M. Laird, 1941, Pennsylvania Topog. and Geol. Survey Prog. Rept. 126, p. 14. Name will probably be used, following more definitive study of area, for unit here termed Conglomerate F and described as sandstone and conglomerate member. Consists of two parts, a lower massive cliff-making brown-gray sandstone and an upper conglomerate composed of white vein-quartz pebbles in a matrix of coarse greenish-gray sandstone. Conglomerate is contorted into large boulderlike masses in zone near its base. Total thickness about 28 feet. Conformably underlies Sandstone G (Pine Knob sandstone); lower contact not exposed.

Type section: Cliff at highway scenic lookout about one-fourth mile below Summit Hotel on Route 40, east of Hopwood, Fayette County.

Hordes Creek Limestone Lentil (in Admiral Formation)[1]

See **Hords Creek Limestone Member** (of Admiral Formation)

Hords Creek Limestone Member (of Admiral Formation)

Hordes Creek Limestone Lentil (in Admiral Formation)[1]

Hords Creek Formation (in Admiral Group)

Permian (Wolfcamp Series): Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 421, 422.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Rank raised to formation in Admiral herein restricted and given group status. Underlies Fisk formation (new); overlies Coleman Junction formation in Putnam group.

R. C. Moore *in* A. K. Miller and Walter Youngquist, 1947, Kansas Univ. Paleont. Contr. 2, Mollusca, art. 1, p. 1 (footnote). Hords Creek limestone underlies Wildcat Creek shale member (new) of Admiral formation.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheet 2. Columnar section shows Hords Creek limestone member underlying Wildcat Creek shale member and overlying Lost Creek shale member of Admiral formation.

Named for Hords (Hordes) Creek, Coleman County.

Hornbrook Formation

Upper Cretaceous: Northern California and southwestern Oregon.

F. G. Wells, 1955, U.S. Geol. Survey Mineral Inf. Field Studies Map MF-38. Named on map legend. Indurated uniform fine-grained greenish-gray arkosic sandstone with local lenses of coarse conglomerate and sandy shale; fossiliferous and calcareous in places.

D. L. Peck, R. W. Imlay, and W. P. Popenoe, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 8, p. 1968–1984. Defined to include Upper Cretaceous sedimentary rocks in southwestern Oregon and northernmost

California. These rocks have generally been referred to as Chico group although they are more than 80 miles north of nearest exposures of Upper Cretaceous rocks in Sacramento Valley, near Redding, Calif., and more than 140 miles north of type locality of Chico. These upper Cretaceous rocks nonconformably overlie deformed and in part metamorphosed volcanic and sedimentary rocks, ranging in age from Paleozoic to Late Jurassic, and granitic intrusive rocks, of Late Jurassic or Early Cretaceous age, and are overlain disconformably by clastic sedimentary rocks and volcanic rocks of Eocene age; in Hornbrook area, unconformably overlie Triassic Applegate group. Comprises at least 2,500 feet of arkosic wacke sandstone, siltstone, mudstone, and conglomerate and contains fossils of Cenomanian, Turonian, and Campanian age. In Hornbrook area, formation consists of six unnamed members (numbered I to VI from oldest to youngest) ; which have been traced northward from south side of Klamath River to vicinity of Hilts, Calif. An unconformity of unknown magnitude occurs between members II and III. The 700 feet of nonfossiliferous rock above the unconformity and the 100 feet of nonfossiliferous rock below it could represent either much or very little of the Coniacian to early Campanian stages. If future mapping demonstrates that more than one formation name is necessary, it is suggested that term Hornbrook be restricted to members I and II. Comparisons of time span of the Hornbrook with the Chico at its type locality shows that most of the Hornbrook is either younger or older than the Chico and that the unconformity within the Hornbrook represents most and perhaps all of the time represented by the Chico. Also the Cretaceous sequence in Redding area, which lies between the Chico and Hornbrook areas, is mostly older than type Chico. Therefore, distinct formational names are needed for each area in order to avoid ambiguity of geologic discussions. Type locality designated.

Type section: Exposures near town of Hornbrook, Siskiyou County, Calif. Discontinuous exposures form a northwest-trending band that extends from near Yreka, Calif., along valleys of Cottonwood and Bear Creeks to Grave Creek, Oreg.

Horned Toad Formation

Pliocene, lower and middle: Southern California.

T. W. Dibblee, Jr., 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 1, p. 137 (fig. 1), 138 (fig. 2), 143. Name applied to sequence of stream-laid and lacustrine sediments. Composed of upper member of gray gypsiferous clay, middle member of indurated green muddy sandstone with several layers of white caliche, and lower member of gray-white arkosic sands and interbedded light-reddish sandy siltstone with a basal granitic conglomerate. Formation moderately deformed. Thickness 1,055 feet. Mammalian fossils indicate early or middle Pliocene age. Overlies quartz monzonite of pre-Tertiary age and intrusive quartz latite of Tertiary age; unconformably underlies light-reddish sand, siltstone, and fanglomerate of probable Plestocene age.

Type locality: Horned Toad Hills, 4 miles northwest of Mojave, Mojave quadrangle, Kern County. Crops out from Warren Station, southwestward about 3 miles.

Hornerstown Sand (in Rancocas Group)

Hornerstown Formation

Hornerstown Marl (in Rancocas Group)[1]

Paleocene: New Jersey and Delaware.

Original reference: W. B. Clark, 1907, Johns Hopkins Univ. Circ., new ser., 1907, no. 7, Whole No. 199, p. 3.

S. K. Fox, Jr., and R. K. Olsson, 1955, [abs.] Jour. Paleontology, v. 29, no. 4, p. 736. Stratigraphic evidence indicates an unconformity between Cretaceous and Tertiary formation in New Jersey. Hornerstown rests successively from northeast to southwest on Tinton, Red Bank and Navesink formations. In each case, the Hornerstown lies upon a weathered surface, and basal few feet contain fragments of the underlying formation.

H. W. Miller, Jr., 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 4, p. 722–736. Formation correlated with Midway stage (Paleocene) of Gulf Coast. Presence of "middle greensand" unit between Navesink (Cretaceous) and Hornerstown formation recognized, and it is suggested that this is southwestward extension of Red Bank formation (Cretaceous).

A. R. Loeblich, Jr., and Helen Tappan, 1957, Jour. Paleontology, v. 31, no. 6, p. 1113 (fig. 2), 1128 (fig. 5), 1129–1132. Paleocene (Danian-Landenian). Determination made on basis of foraminiferal studies. Overlies Monmouth group; underlies Vincentown formation. Report summarizes opinions of several workers and cites bibliography.

H.G. Richards, J. J. Groot, and R. M. Germeroth, 1957, Geol. Soc. America Guidebook Field Trips Atlantic City Mtg., p. 184 (table 1), 186 (table 3), 198–199, 201 (table 4). Marl (formation) lies disconformably on Navesink marl in southern New Jersey. In Monmouth County where Red Bank and Tinton formations are present, relationship may be conformable. Consists of glauconite with clay and sand; resembles parts of Navesink, but distinguished from it by its more sandy natures. Thickness at outcrop 30 feet; average dip 30 feet per mile. Exact age uncertain; recent work on microfossils has shown formation should be regarded as Paleocene. Geographically extended into Delaware.

R. K. Olsson, 1959, Dissert. Abs., v. 19, no. 8, p. 2063–2064. Units studied: Navesink, Redbank, Tinton, New Egypt (new), and Hornerstown formations. The New Egypt in outcrop is lateral equivalent of Tinton formation and in subsurface represents both Tinton and Hornerstown formations. Paleocene-Eocene boundary lies within a lithic unit [in subsurface] (Hornerstown and New Egypt formations).

J. P. Minard and J. P. Owens, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B184. Rancocas group includes (ascending) Hornerstown sand, Vincentown formation, and Manasquan formation.

Named for occurrence at Hornerstown, Monmouth County, N. J. Extends in belt across New Jersey from vicinity of Atlantic Highlands through Freehold, Hornerstown, Birmingham, Mullica Hill, Sewell, and Woodstown to Delaware River and then into Delaware.

Hornsboro Sandstone[1] or zone[1]

Upper Triassic: Northeastern South Carolina.

Original references: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, advance copies; published in 1908, in South Carolina Geol. Survey, ser. 4, Bull. 2; 1907, Summary of mineral resources of South Carolina, p. 11, 12.

Named for exposures around Hornsboro, Chesterfield County.

Hornsilver Dolomite Member (of Minturn Formation)

Pennsylvanian: Northwestern Colorado.

Ogden Tweto, 1949, Colorado Sci. Soc. Proc., v. 15, no. 4, p. 152 (table 1), 199, 216–217. Massive gray dolomite 12 to 16 feet thick overlain by 8 to 14 feet of thin-bedded gray dolomite. About 2,900 feet above base of formation. Lies about 800 feet below base of Resolution dolomite member (new); about 300 feet above Wearyman dolomite member (new).

Named for outcrops on south slope of Hornsilver Mountain, Pando area, Eagle County.

Horquilla Limestone (in Naco Group)

Middle and Upper Pennsylvanian: Southeastern Arizona and southwestern New Mexico.

James Gilluly, J. R. Cooper, and J. S. Williams, 1954, U.S. Geol. Survey Prof. Paper 266, p. 16–18, 31–35. Series of thin-bedded blue-gray limestones with a few thicker beds, as much as 6 or even 8 feet thick. A few beds of reddish-weathering shaly limestone intercalated in upper half of formation. Most limestone is dense and pinkish gray on fresh fracture. Some beds, especially the thicker ones, are coarsely crystalline limestone consisting largely of crinoidal fragments. Base of limestone is obscure surface of disconformity which, north of Dragoon Mountains, appears to fall in weak zone of shale immediately above Black Prince limestone. No complete section exposed in Tombstone Hills or Dragoon Mountains, Pearce or Benson quadrangles. Total thickness estimated at 1,200 feet; type section 999 feet thick. Southward in Gunnison Hills, unfaulted section has thickness of 1,600 feet. Underlies Earp formation. Pennsylvanian.

James Gilluly, 1956, U.S. Geol. Survey Prof. Paper 281, p. 8, 36–39, pl. 5. Lower and lower Upper Pennsylvanian.

Elliot Gillerman, 1958, New Mexico Bur. Mines Mineral Resources Bull. 57, p. 31–35, tables 1, 2, pl. 1. Most widespread Paleozoic formation in Peloncillo Mountains, N. Mex., where it consists almost entirely of limestones. A 14-foot argillaceous sandstone layer about 250 feet above base. Incomplete section 819 feet thick at Silver Hill mine, total much thicker. Overlies Paradise formation. Rocks of all middle and lower Pennsylvanian series and of Wolfcamp series of Permian are present.

U. S. Geological Survey currently designates the age of the Horquilla Limestone as Middle and Upper Pennsylvanian on basis of a study now in progress.

Type section: On spur of east Horquilla Peak from which it takes its name, Tombstone Hills, central Cochise County, Ariz., about 1 mile southeast of Ajax Hill. Widespread in Tombstone Hills, also in Mule Mountains, Dragoon Mountains, and in Courtland and Gleeson districts. In Peloncillo Mountains, N. Mex.

Horry Clay

Pleistocene: Eastern South Carolina.

C. W. Cooke, 1937, Washington Acad. Sci. Jour., v. 27, no. 1, p. 1–5. Dark-brown clay containing plant fragments, woody tissues, and diatoms. Thickness 3 feet; covered by water at high tide. Cypress stumps and knees rotted at top. Some of the stumps extend a few inches above clay into overlying shell bed. Top of clay perforated by tubular holes, presumably made by boring creatures. Presence of rooted stumps beneath thick marine deposit that evidently accumulated in quiet water gives evidence that sea stood lower on land when they grew than in immediately succeeding epoch. Underlies Pamlico formation. Apparently represents early part of Peorian stage.

D. G. Frey, 1952, Am. Jour. Sci., v. 250, no. 3, p. 212–225. Thickness about 9 feet. Horry clay below section described by Cooke is fresh-water deposit. Nearby Myrtle Beach peat (new) is presumably younger than the Horry though stratigraphic relationship uncertain. No known unconformable relationship exists between Horry clay and Pamlico formation.

Named for Horry County. Section described is west of railway bridge across Intracoastal Waterway 2½ miles northwest of Myrtle Beach.

Horse Bench Sandstone Bed (in Evacuation Creek Member of Green River Formation)

Horse Bench Sandstone Lentil (in Green River Formation)[1]

Eocene: Northeastern Utah.

Original reference: W. H. Bradley, 1931, U.S. Geol. Survey Prof. Paper 168, p. 16.

C. H. Dane, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 3, p. 409 (fig. 2). Shown on chart as Horse Bench sandstone bed in Evacuation Creek member of Green River formation.

Named for fact that it forms broad tableland between Minnie Maud Creek and Jack Creek known as Horse Bench in northeastern Carbon County.

Horse Creek Clay and Shale (in Strawn Formation)[1]

Pennsylvanian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 374, 479.

D. A. Zimmerman and G. D. Glover, 1956, Soc. Econ. Paleontologists and Mineralogists, Permian Basin Sec. [Guidebook] Spring Field Trip, May 11–12, p. 70. Overlies Fox Ford bed; underlies Bull Creek sandstone. Strawn series.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 58, pl. 27. Drake (1893) separated rocks of Strawn group [division] into 20 units of alternating sandstone and shale beds. He gave local names to these units, or "beds," as he termed them, and numbered them from top to bottom, 4 to 23. Only Drake's name for upper unit, the Ricker, in common use today, and that name has been restricted to base of Drake's Ricker bed.

Named for Horse Creek, San Saba County.

Horse Creek Formation (in Moran Group)

†Horse Creek Limestone Member (of Moran Formation)[1]

Permian (Wolfcamp Series): Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 387, 419.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Rank raised to formation in Moran group. Overlies "Dothan" formation; underlies Sedwick formation Wolfcamp series.

R. C. Moore, 1949, U. S. Geol. Survey Oil and Gas Inv. Prelim. Map 80. Name Gouldbusk is here applied to limestone beds and included thin shale that were called Horse Creek limestone by Drake. Sellards (1933, Texas Univ. Bull. 3232) pointed out duplication by Drake in use of this name, as applied to beds in his Strawn division farther east in Colorado River valley and to limestone, now considered Permian(?) in age, exposed in Coleman County. Sellards restricted application of Horse Creek to beds in Strawn sequence but did not rename the upper beds, which confusingly have continued to be called Horse Creek (Cheney, 1940; King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4).

Named for Horse Creek, Coleman County.

Horsehead Tongue (of Mancos Shale)

Upper Cretaceous (mid-Carlile) : Northwestern New Mexico.

W. S. Pike, Jr., 1947, Geol. Soc. America Mem. 24, p. 9, 11, 13, 35, pl. 12. Dark-gray marine shale. Thickness 40 feet in area of typical exposures and thins southward, and assumed to pinch out in that direction. Underlies lower part of Gallup member of Mesaverde and overlies Atarque member (new) of Mesaverde formation.

Named from typical exposures on east side of valley of Horsehead Creek, in Ts. 9 and 10 N., R. 17 W., McKinley County.

Horseshoe Bar Quartz Diorite

[Jurassic] : Northern California.

G. H. Curtis, J. F. Evernden, and J. Lipson, 1958, California Div. Mines Spec. Rept. 54, p. 6. Discussed in report dealing with potassium-argon age determinations. Age 142.9 million years. Rock dated was called gabbro by Lindgren and considered to be local variation of Rocklin granodiorite which surrounds it.

Dated samples collected from quarry in NE¼ sec. 18, T. 11 N., R. 8 E., MD., approximately 3 miles southeast of Loomis.

Horse Spring Formation[1]

Eocene(?) : Southeastern Nevada and northwestern Arizona.

Original references: C. R. Longwell, 1921, Am. Jour. Sci., 5th v. 1, p. 53; 1928, U.S. Geol. Survey Bull. 798.

C. R. Longwell, 1936, Geol. Soc. America Bull., v. 47, no. 9, p. 1423. Highly tilted strata near mouth of Bitter Spring Wash that include breccia, gray sandstone, and peculiar green volcanic tuff, in addition to clay and gypsum previously assigned to Horse Spring formation found to be conformable with overlying Muddy Creek deposits and now believed to belong in later unit.

T. B. Nolan, 1943, U.S. Geol. Survey Prof. Paper 197–D, p. 163. Probable that formation is of Upper Cretaceous age.

C. R. Longwell, 1952, Utah Geol. Soc. Guidebook 7, p. 34 (fig. 4), 35. Age probably either very Late Cretaceous or Early Cenozoic. Thickness probably exceeds 3,000 feet in Muddy Mountains where it unconformably overlies Overton fanglomerate and unconformably underlies Muddy Creek formation. In Frenchman Mountain area, unconformably overlies Thumb formation (new).

C. M. Tschanz, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B293. Assigned to Miocene on basis of potassium-argon (K–Ar) date of biotite from interbedded tuff. Horse Spring previously assigned to Cretaceous or early Tertiary on basis of plants, ostracodes, and snails.

U.S. Geological Survey currently designates the age of the Horse Spring as Eocene(?).

Well exposed on east side of Horse Spring Valley, near St. Thomas Gap, Clark County, Nev.

†Horsetail Creek Beds[1]

Horsetail Creek facies (of Chadron Formation)

Horsetail Creek Member (of White River Formation)

Oligocene, lower : Northeastern Colorado.

Original reference: W. D. Matthew, 1901, Am. Mus. Nat. History Mem., v. 1, pt. 7, p. 355–374, 444.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 22, pl. 1. Referred to as Horsetail Creek facies of Chadron formation, Chadronian age.

E. C. Galbreath, 1953, Kansas Univ. Paleont. Contr. 13, Vertebrata, art. 4, p. 12–14, 15 (fig 5), 24, 25, 27 (fig. 8). Referred to as member of White River formation. As herein described, based on exposures in Logan County where gray massive silts rest upon Cretaceous surface (Fox Hills sandstone and Pierre shale). Top grades upward into tan to pink silt of Cedar Creek member or is separated from it by erosional unconformity. Locally, member contains beds of olive-colored silt and freshwater limestone with interfingering beds of whitish-gray silt at top. Thickness at type locality 110 feet. Location of type section for Horsetail Creek beds, as described Matthew, is matter of debate; therefore, type locality is herein designated.

Type locality: Secs. 29, 31, and 32, T. 11 N., R. 53 W., Logan County. Named for Horsetail Creek, Logan and Weld Counties.

Horsethief Formation

Pliocene : California.

O. P. Jenkins, 1938, Geologic map of California (1 :500,000) : California Div. Mines, sheet 4. Shown on map legend.

Horsethief Sandstone (in Montana Group)[1]

Upper Cretaceous: Northwestern Montana, and southern British Columbia, Canada.

Original reference: E. Stebinger, 1913, Am. Inst. Mining Engrs. Bull. 81, p. 2337.

J. G. Bartram, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 7, p. 910. Suggests abandonment of term and inclusion of unit in Fox Hills sandstone.

W. A. Cobban, 1955, Billings Geol. Soc. Guidebook 6th Ann. Field Conf., p. 108 (fig. 1), 118. Restricted to massive cliff-forming sandstone above slope-forming unit here termed Bearpaw-Horsethief transition beds. This unit had been included in Horsethief by Stebinger (1914, U.S. Geol. Survey Bull. 540). Near Blacktail Creek, where Horsethief sandstone is 90 feet thick, threefold division is apparent: lower 45 feet is cliff-forming massive fine-grained sandstone; 20 feet of soft fine-grained highly cross-bedded sandstone that contains large calcareous sandstone concretions weathering dark brown; and 25 feet massive cliff-forming crossbedded medium- to coarse-grained sandstone. On Blackfeet Indian Reservation, top few feet is titaniferous magnetite sandstone. West of South arch, upper 30 to 40 feet weathers dark brown and locally contains pebbles of igneous rocks. Underlies St. Mary River formation.

Type locality: Horsethief Ridge, Blackfoot quadrangle, Montana.

Horsetown Formation[1]

Horsetown Group

Horsetown Stage

Lower Cretaceous (Shasta Series): Northern California and southern Oregon.

Original reference: C. A. White, 1885, U.S. Geol. Survey Bull. 15, p. 19–32.

F. M. Anderson, 1938, Geol. Soc. America Spec. Paper 16, p. 38 (table 1), 61–68, table 2. Upper group of Shasta series. Overlies Paskenta group. Comprises Cottonwood beds (new) below and Hulen beds (new) above. Top of Horsetown indicated generally by basal beds of Chico series resting unconformably upon it. Group typically developed in Cottonwood district. Becomes progressively thicker southward from North Fork of Cottonwood Creek toward delta axis, increasing from thickness of 6,430 feet near Ono to more than 12,500 feet in its maximum section. No clearly marked stratigraphical break between Paskenta and Horsetown groups has been found here, although conglomerate beds extending south from Ono may be taken as such. Otherwise, only an arbitrary line has been drawn for it. Fauna of Ono zone at bottom of Horsetown group seems to represent a low Hauterivian horizon on scale of Europe and, for this reason, forms convenient reference plane, serviceable for correlation. Term Horsetown, as formational name for succession of strata to which it has been applied, is not a good choice. The area about the old mining camp of this name is detached from district in which group is most typically and completely represented and at best exposes not more than 500 feet of uppermost Shasta series, which beds are scarcely representative of great body of older strata included under the name by White, Stanton, and Diller, and later writers. Name retained in this report only because it is well established in literature. Term Cottonwood group would be more appropriate.

F. M. Anderson, 1943, California Div. Mines Bull. 118, pt. 2, p. 184 (fig. 68) [preprint 1941]. Underlies Pioneer group of Chico series.

J. M. Kirby, 1943, California Div. Mines Bull. 118, pt. 3, p. 606–608. Oldest strata exposed along axis of Sites anticline [north-central Colusa and central Glenn Counties] belong to Lower Cretaceous Shasta group. About 5,000 feet of beds belonging to Horsetown formation and consisting chiefly of well-bedded dark-gray to greenish drab siltstones and shales with interbedded hard thin sandstones and dense limestone layers form pronounced anticlinal valley and lowland west of lower Chico group rimrock. Formation underlies Golden Gate formation of Chico group. [Preoccupied name Golden Gate later replaced by Venado formation.]

N. L. Taliaferro, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 4, p. 458–459. Anderson (1938) divided Lower Cretaceous in northern California into Paskenta and Horsetown groups. There is no justification for use of group as designation for these beds. It is believed that names Paskenta and Horsetown should be used as approximate faunal stages rather than group terms. Name Marmolejo formation proposed for Lower Cretaceous of Santa Lucia Range.

A. S. Huey, 1948, California Div. Mines Bull. 140, p. 16 (fig. 2), 23–24. Rocks of Horsetown formation occur in two fault-wedge blocks along Tesla fault zone in Tesla quadrangle. Thickness 0 to 500 feet. Eastern mass of Horsetown rocks is wedge between Franciscan and Panoche formations. In Corral Hollow, the shales have vertical attitude and are separated from Franciscan by Tesla fault zone. Contact with Panoche not exposed.

F. G. Wells, P. E. Hotz, and F. W. Cater, Jr., 1949, Oregon Dept. Geology and Mineral Industries Bull. 40, p. 14–15. Formation, in Kerby quadrangle, Oregon, crops out in southern part of Illinois Valley. To the south, unconformably overlies steeply dipping Galice formation. Covered by Recent alluvium to the west and north. Exposed thickness about 5,000 feet.

L. I. Briggs, Jr., 1953, California Div. Mines Bull. 167, p. 22. Name Wisenor formation proposed for strata of Horsetown age in Ortigalita Peak quadrangle.

F. G. Wells, 1955, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–38. Formation mapped in southern Oregon.

M. A. Murphy, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2100–2103, 2112–2119. Discussion of Lower Cretaceous stratigraphic units of northern California. District is type area for stratal unit previously called Horsetown "group" or "formation", here redefined as Horsetown stage. Eight biostratigraphic zones, ranging in age from Hauterivian to late Albian in European time scale, defined within this stage. Upper and lower boundaries of stage are defined by the bases of zones *Pervinquieria hulenana* and *Neocraspedites aguila*, respectively. As defined by Anderson (1938), "Horsetown group" is separated from units above and below by faunal criteria. At type section, "Horsetown group" lies within single formational unit here termed Ono formation. Since a group must contain two or more formations, Horsetown strata as restricted by Anderson cannot be designated properly by term "group". If Horsetown group were to be redefined to include Ono and Rector formations of this report, then obstacle to retention of term would be removed. However, such a redefinition would require that about 200 feet of strata above Anderson's "Horsetown group" be included in redefined group and that base of redefined group be lowered to coincide with unconformity at base of Cretaceous section. First requirement would include in the Horsetown younger strata than have been included in it before, and second requirement would lead to restriction or perhaps suppression of the Paskenta as stratal unit. Until more extensive mapping has been done, it does not seem wise to recommend further modification of use of stratigraphic unit named "Horsetown." As defined by Anderson, it is a stage which encompasses most of Neocomian, Aptian, and lower Albian of European authors. It seems best to continue to use it as defined by Anderson and to recognize that he misused term "group" as that term presently is defined.

W. P. Irwin, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 10, p. 2284–2297. Franciscan group is widely held to be restricted to Late Jurassic age, the Knoxville formation to be an upper shaly phase of the group, and the two to be overlain by detrital strata of Cretaceous age. Paleontologic evidence indicates this view to be incorrect. Rather, Franciscan group seems mainly to have been deposited contemporaneously with Knoxville, Paskenta, Horsetown, and lower Upper Cretaceous strata.

R. W. Imlay and others, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2783. Name Days Creek formation (new) replaces Horsetown formation and Cretaceous part of Knoxville formation, as used by Diller and Kay (1924, U.S. Geol. Survey Geol. Atlas, Folio 218).

Type district (Anderson, 1938): Cottonwood district, north of delta axis, Tehama County, Calif. Named for exposures at Horsetown, Shasta County, Calif.

Hortontown basic eruptives[1]

Age(?): Southeastern New York.

Original reference: C. E. Gordon, 1911, New York State Mus. Bull. 148, p. 11, 37–39.

Probably named for occurrences at Hortontown, Poughkeepsie quadrangle.

Hortonville Slate[1]

Middle Ordovician: West-central Vermont.

Original reference: Arthur Keith, 1932, Washington Acad. Sci. Jour., v. 22, p. 360, 369.

W. M. Cady, 1945, Geol. Soc. America Bull., v. 56, no. 5, p. 522 (fig. 3)-524 (strat. column), 558–561. In west-central Vermont, overlies Glens Falls limestone. An interbedded zone, in most places less than 5 feet thick, forms gradation between the Glens Falls and Hortonville east of Champlain thrust. Thickness about 400 feet.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, p. 13, 34–37, pl. 1. Includes all autochthonous black slate and phyllite previously included in Keith's Ira slate which had same stratigraphic position and is now abandoned. Maximum thickness in Castleton area at least 1,000 feet. Overlies Whipple marble (new).

E-an Zen, 1959, New England Intercollegiate Geol. Conf. Guidebook 51st Ann. Mtg., p. 2. Discussion of stratigraphy and structure at north end of Taconic Range and adjacent areas. "Hortonville formation" overlies the Glens Falls perhaps unconformably. This is a black slate or phyllite which resembles West Castleton formation (new) and also some of black slate of Poultney River group (new). Age of type Hortonville subject to question. Writer [Zen] suggests reviving Keith's (1932) name Ira formation for belt that runs from Florence south toward Dorset Mountain, a belt that cannot be traced into type Hortonville with certainty.

E-an Zen, 1959, (abs.) Geol. Soc. America Bull., v. 70, no. 12, pt. 2, p. 1705. Hortonville of west-central Vermont is largely black slate unit. Its Late Trenton age assignment was based on correlation with Snake Hill formation, separated from Hortonville by major faults, and underlying fossiliferous Glens Falls limestone near Hortonville village. Dale's graptolites in the black slate have not been authenticated, and localities yielded no new specimens. Recent mapping in Lower Cambrian allochthonous Taconic sequence immediately south of Hortonville shows that contact between type Hortonville and the Glens Falls may be a fault. Type Hortonville slate was traced into an outcrop from which Schuchert reported *Olenellus*(?) fragments. Stratigraphically and geometrically, type Hortonville corresponds to Lower Cambrian black slate of Taconic sequence, and in field no contact is discernible between them. Hortonville also reported as traceable into fossiliferous Upper Trenton black slate in Middlebury synclinorium. It is urged that name Hortonville not be used with time connotations.

Well exposed around Hortonville, Castleton quadrangle.

Hoskinnini Member or **Tongue** (of Moenkopi Formation)

Hoskinnini Member (of DeChelly Sandstone)

Hoskinnini Tongue or Member (of Cutler Formation)[1]

Triassic(?): Southeastern Utah and northeastern Arizona.

Original reference: A. A. Baker and J. B. Reeside, Jr., 1929, Am. Assoc. Petroleum Geologists Bull., v. 13, no. 11, p. 1422, 1423, 1441, 1443, 1446.

J. A. Momper, 1957, Four Corners Geol. Soc. Guidebook 2d Field Conf., p. 90. Reallocated to member status in DeChelly sandstone herein raised to formational rank.

J. H. Stewart, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 8, p. 1852–1868. Recent work indicates unit originally defined as Hoskinnini tongue of Cutler formation extends into parts of southeastern Utah, where it has not been previously reported. Hoskinnini is correlated with part or all of unit defined as Tenderfoot member of Moenkopi formation in salt anticline region of east-central Utah and west-central Colorado. Hoskinnini redefined as member of Moenkopi. The Hoskinnini and laterally continuous strata in Tenderfoot member are exposed within a north-northeast oriented area about 180 miles long and 50 miles wide extending from Monument Valley area, in northeastern Arizona and southeastern Utah, to west-central Colorado. Thickness of Hoskinnini 0 to 126 feet; in most areas 50 to 120 feet. Overlies Organ Rock tongue of Cutler in most of southeastern Utah; overlies DeChelly sandstone member of Cutler near junction of Green and Colorado Rivers and southward into White River Canyon area. Problems of nomenclature discussed.

Named for exposures on north face of Hoskinini [Hoskinnini] Mesa, San Juan County, Utah. Exposed in elongate area extending from Monument Valley in Arizona to about 6 miles southwest of Moab, Utah. Gregory (1916, U.S. Geol. Survey Water-Supply Paper 380) shows Hoskinnini Mesa in southern part of San Juan County, Utah.

Hosmer Conglomerate[1]

Hosmer Run Conglomerate[1]

Devonian or Carboniferous: Northwestern Pennsylvania.

Original reference: J. F. Carll, 1883, Pennsylvania 2d Geol. Survey Rept. I_4, p. 250, 254, 259, 268.

On Hosmer Run, near east line of Spring Creek Township, Warren County.

Hospital Porphyry

Pliocene(?): Southwestern Arizona.

James Gilluly, 1946, U.S. Geol. Survey Prof. Paper 209, p. 44. Dark-gray fine-grained rock with phenocrysts of glassy plagioclase as much as 2 centimeters in length. Microscopic studies suggest that it is an augite andesite porphyry approaching a latite. Forms group of dikes which range in thickness from a few feet to 125 feet, and individual segments are from a few hundred feet to 2,500 feet long. Much younger than Cornelia quartz monzonite because it cuts Locomotive fanglomerate, which rests on eroded surface of the monzonite, and petrographically strongly resembles porphyritic latite of Childs latite flows; thus is probably related to this much younger regional volcanic activity rather than to Cornelia quartz monzonite.

Rocks named for good exposures on hill just west of Phelps Dodge Hospital at Ajo, where they form a group of dikes trending north-northwestward in region between Ajo and Black Mountain, western Pima County.

Hosselkus Limestone[1]

Upper Triassic: Northern California.

Original reference: J. S. Diller, 1892, Geol. Soc. America Bull., v. 3, p. 370–394.

A. F. Sanborn, 1960, California Div. Mines Spec. Rept. 63, p. 6, 7, pl. 1. Described in Big Bend quadrangle, Shasta County, where it is about 150 feet thick in Devils Canyon and 20 feet thick near Hawkins Creek. Overlies Pit formation; underlies Brock shale.

Named for fact it forms prominent ledges on divide between Genesee Valley and Hosselkus Creek, 1 mile northeast of Hosselkus Ranch, Plumas County.

Hosselkus Series[1]

Upper Triassic: Northern California.

Original reference: G. H. Ashley, 1923, Eng. Mining Jour.-Press, v. 115, p. 1106–1108.

Hosston Formation

Lower Cretaceous: Subsurface in Louisiana, Arkansas, and eastern and southern Texas.

R. W. Imlay, 1940, Arkansas Geol. Survey Inf. Circ. 12, p. 28–30. Name chosen by Shreveport Geological Society to designate Lower Cretaceous red and gray shales, dolomites, and sandstones above Cotton Valley formation and below Sligo formation. Replaces Travis Peak, as applied to beds older than real Travis Peak of Texas. Base of Hosston is placed above highest black shale unit of Cotton Valley formation; it is marked by a basal conglomerate in Arkansas and in northern Louisiana. Formation grades offshore, south of Shreveport area, into fossiliferous dark shales and limestones which contain minor amounts of interbedded red shale and sandstone. Thickness ranges from about 800 feet in Arkansas to over 2,000 feet in northern Louisiana and eastern Texas.

Type well: Dixie Oil Co. Robertshaw No. 92 (Dillion No. 92), in sec. 13, T. 21 N., R. 15 W., Caddo Parish, La. Named after town of Hosston located about 7 miles north of top of Pine Island anticline.

Hosta Tongue (of Point Lookout Sandstone)

Hosta Sandstone Member (of Mesaverde Formation)[1]

Upper Cretaceous: Northwestern New Mexico.

Original reference: J. D. Sears, 1934, U.S. Geol. Survey Bull. 860–A.

E. C. Beaumont, C. H. Dane, and J. D. Sears, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2156. In revised nomenclature of lower part of Mesaverde, Point Lookout sandstone as a formation in Mesaverde group replaces Hosta sandstone member where that member is undivided, and also replaces upper part of Hosta sandstone member where its lower part is absent or is separated from its upper part by tongue of Mancos shale. Hosta tongue of Point Lookout sandstone replaces lower part of Hosta sandstone member where that is present.

Named for exposures on Hosta Butte, Gallup region.

Hostetter Limestone and Clay

Permian (Greene Series): Eastern Ohio.

A. T. Cross, W. H. Smith, and Thomas Arkle, Jr., 1950, Field guide for the special conference on the stratigraphy, sedimentation, and nomenclature of the Upper Pennsylvanian and Lower Permian strata (Monongahela, Washington, and Greene series) in the northern portion of the Dunkard basin of Ohio, West Virginia, and Pennsylvania: West Virginia Geol. and Econ. Survey, [pl. 1]. Hostetter limestone and clay shown on columnar section of names of strata applied in Ohio. Occurs above Fish Creek sandstone and below (Burton sandstone).

Hostler Formation (in Hatter Group)

Hostler Member (of Hatter Formation)

Middle Ordovician (Bolarian): Central and south-central Pennsylvania.

G. M. Kay, 1943, Econ. Geology, v. 38, no. 3, p. 193, 195. Uppermost member of formation. Lower part dark, tan-weathering, siliceous and argillaceous limestone, massive in fracture, richly fossiliferous, and less impure near base; upper part dark impure well-bedded, somewhat laminated limestone, sparsely fossiliferous. Thickness 63 feet in type section. Overlies Grazier member (new); underlies Snyder member of Benner limestone. Chazyan series.

G. M. Kay, 1944, Jour. Geology, v. 52, no. 1, p. 10–11. Lower limit of unit normally not sharply defined because lower beds become similar to Grazier member. Middle zone with brachiopod- and bryozoan-rich very siliceous, and argillaceous limestone or calcareous siltstone readily recognizable. Upper zone, well-bedded and containing fucoidal siliceous partings, is in places difficult to separate from less siliceous coarser, commonly cross-laminated ledges of lowest Snyder limestone. In type section, top of unit is at re-entrant beneath white-weathering sub-lithographic limestone ledges of the Snyder. Thickness 40 to 60 feet in most localities. Derivation of name.

Marshall Kay, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1402 (fig. 2), 1407. Rank raised to formation in Hatter group or Hatterian subseries (of Bolarian series).

Marshall Kay, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 82, 102. Discussed as a member.

Type section: On two sides of Pennsylvania Railroad cut north of Union Furnace, Huntingdon County. Named for village of Hostler in Centre County, 9 miles northeast of Union Furnace.

Hotauta Conglomerate (in Unkar Group)[1]

Hotauta Formation

Precambrian (Grand Canyon Series): Northern Arizona.

Original reference: L. F. Noble, 1914, U.S. Geol. Survey Bull. 549.

Charles Keyes, 1938, Pan-Am. Geologist, v. 70, no. 2, p. 107 (table), 109–110. Basal formation in Grand Canyon series. Somewhat irregular formation; sometimes attains thickness of 50 feet. Underlies Newberry formation (new).

R. P. Sharp, 1940, Geol. Soc. America Bull., v. 51, no. 8, p. 1242–1243. Conglomerate is dark-reddish-brown, poorly bedded and poorly sorted sandstone or conglomerate, locally arkosic. Maximum thickness 30 feet, although average is between 2 and 6 feet. In Hotauta Canyon, underlies Bass limestone.

Named for Hotauta Canyon, Shinumo quadrangle, Grand Canyon region.

Hothouse Formation (in Great Smoky Group)

Precambrian: Central northern Georgia and southwestern North Carolina.

V. J. Hurst, 1955, Georgia Geol. Survey Bull. 63, p. 35–40, pl. 1, map. Interbedded metagraywacke, quartzite, and metaconglomerate at top; downward these beds become less and less prominent; base principally mica schist. Estimated thickness 8,000 to 11,000 feet; dip of bedding steep; no important repetition of beds recognized. Underlies Dean formation (new); hybrid character of rocks between the two makes position of boundary largely interpretative; overlies Hughes Gap formation (new).

Crops out in two parallel belts in Mineral Bluff quadrangle; each belt is limb of Murphy syncline; larger belt trends northeast-southwest across central part of quadrangle; second belt crosses southeastern corner of quadrangle. Named from Hothouse Creek which flows along central part of larger belt, Fannin County, Ga.

Hot Springs Formation[1]

Quaternary: Yellowstone National Park.

Original reference: W. H. Weed, 1896, U.S. Geol. Survey Geol. Atlas, Folio 30.

Named for Hot Springs, which formed deposit.

Hot Springs Formation (in Mud Springs Group)

Pennsylvanian (Derry Series): Central New Mexico.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 27 (table 2), 37–39. Name applied to basal formation of Mud Springs group (new). At type locality, composed of dark- to light-gray massive to nodular highly cherty limestone and thick shale beds; at least six distinct limestone sequences present. Thickness at type locality about 85 feet; about 24 feet thick at Derry where it is composed almost entirely of limestone. Underlies Apodaca formation (new); overlies Cuchillo Negro formation (new); in northern part of area, overlaps on the Precambrian and there contains coarse clastics in its lower part.

M. L. Thompson, 1948, Kansas Univ. Paleont. Contr. 4, Protozoa, art. 1, p. 73. Replaced by Fra Cristobal formation (new). Term Hot Springs preoccupied.

Type locality: West end of Whiskey Canyon and just west of westernmost box canyon, near north end of Mud Springs Mountains, Sierra County. Name derived from town of Hot Springs on Rio Grande about 3 miles southeast of south end of Mud Springs Mountains.

Hot Springs Sandstone[1]

Mississippian: Southwestern Arkansas.

Original reference: A. H. Purdue, 1910, Jour. Geology, v. 18, p. 282–283.

W. H. Hass, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 7, p. 1578, 1582. On basis of conodont studies, Stanley shale is regarded as ranging in age from the Meramec part of Mississippian into basal Pennsylvanian. Hot Springs sandstone which underlies Stanley shale in vicinity of Hot Springs is considered to be Mississippian (Meramec).

August Goldstein, Jr., 1959, *in* Geology of the Ouachita Mountains—a symposium: Dallas, Tex., Dallas Geol. Soc. and Ardmore Geol. Soc., p. 103. Exposed only in and near city of Hot Springs where it ranges in thickness up to about 200 feet. Unconformably overlies Arkansas novaculite; underlies Stanley shale, contact gradational.

First described in vicinity of Hot Springs, Garland County.

Houchen Creek Limestone Bed (in Hamlin Shale Member of Janesville Shale)

Houchen Creek Limestone[1] Member (of Hamlin Shale)

Permian: Southeastern Nebraska and northeastern Kansas.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 84, 89.

R. C. Moore, 1936, Kansas Geol. Survey Bull. 22, p. 50 (fig. 12). Permian.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2273, 2274 (fig. 1). Rank reduced to bed in Hamlin shale herein reduced to member status in Janesville shale (new). Wolfcamp series.

M. R. Mudge and R. H. Burton, 1959, U.S. Geol. Survey Bull. 1068, p. 51. Suggested herein that Houchen Creek limestone bed be used as formal name. Recent work has shown that this bed of Hamlin shale cannot be correlated south of Pottawatomie County. Algal limestone identified as Houchen Creek in Chase County (Moore, Jewett, and O'Connor, 1951, Kansas Geol. Survey Rept., v. 11, pt. 1) does not correlate with type section of Houchen. Pottawatomie County, the Houchen Creek limestone bed does correlate northward with type section in stratigraphic position and lithologic and paleontologic characteristics.

Named for exposures on Houchens Creek, sec. 29, T. 6 N., R. 13 E., Nemaha County, Nebr.

Houden Formation

Precambrian: East-central Arizona.

Gordon Gastil, 1958, Geol. Soc. America Bull., v. 69, no. 12, pt. 1, p. 1498 (table 1), 1501–1502, pl. 1. Can generally be subdivided into three or four members: basal gravel conglomerate 40 to 100 feet thick; lower quartzite 380 to 1,200 feet thick, lower part of which is cross-laminated in beds 3 to 8 inches thick, upper part vitreous, faintly bluish or greenish; middle member distinguished by gray, purple, or brick-red, predominantly fine-grained quartzite in lower part and slate and graded wacke in upper part, thickest section 380 feet on Houden Mountain; and upper quartzite 390 to 420 feet thick divisible into three submembers in Board Cabin Draw. Unconformably overlies Flying W formation (new); conformably underlies Board Cabin formation (new).

Type section: On southwestern corner of Colcord Mesa and begins on boundary of section 18, one-quarter mile west of elevation marker 5687, from which it extended N. 25° W. for approximately one-half mile, or to elevation marker 5651. Other good sections on Board Cabin, Houden Mountain, and Spring Creek opposite Buzzard Roost Mesa. Name derived from Houden Mountain in south-central part of Diamond Butte quadrangle.

Houghton Conglomerate[1] (in Portage Lake Lava Series)

Precambrian (middle Keweenawan): Northern Michigan.

Original reference: A. R. Marvine, 1873, Michigan Geol. Survey, v. 1, pt. 2, p. 80–81, chart.

W. S. White, 1952, Jour. Sed. Petrology, v. 22, no. 4, p. 190–198. One of about 20 sedimentary beds included within Portage Lake lava series (new). At Allouez No. 3 shaft of Calumet & Hecla Consolidated Copper Co., the conglomerate lies about 3,750 feet stratigraphically below top of series. Separated by about 500 feet of lava flows from the next higher conglomerate bed, the Allouez, and by 850 feet of lava flows from the next lower, the Calumet and Hecla. At the shaft, the conglomerate is a lenticular body, 1,000 to 1,800 feet wide measured parallel to the strike, at least 4,000 feet long in direction of dip, and ranging in thickness from less than 1 foot as its lateral margins to as much as 25 feet along its principal axis.

Named for occurrences in Houghton County.

Hounsfield Bentonite[1]

Hounsfield Metabentonite

Middle Ordovician (Mohawkian): New York, Iowa, Kentucky, Minnesota, Missouri, Tennessee, and Wisconsin.

Original reference: G. M. Kay, 1930, Science, new ser., v. 72, p. 365.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 252–253. Restudy of sequence at type section indicates that metabentonite occurs 3 feet above base of Selby member (new) of Rockland formation (Mohawkian). Previously was mistakenly believed to separate Leray and Watertown members of Chaumont formation. [Kay (1930, 1931) shows unit occurring in several named formations; assignment to formation depends on geographic area.]

Type section: In small quarry just north of Dexter-Brownville Road at foot of west slope of hill 2 miles east of Dexter, Jefferson County, N.Y.

House Limestone (in Pogonip Group)

Lower Ordovician (Canadian): West-central Utah.

L. F. Hintze, 1951, Utah Geol. and Mineralog. Survey Bull. 39, p. 9 (fig. 2), 12–13, 29 (fig. 4), 30–37. Lowermost formation of Pogonip group (restricted). Underlies Fillmore limestone (new); overlies Notch Peak limestone. At type locality, consists of 475 feet of typically medium-gray medium- to thin-bedded cherty silty calcilutite; limestone contains much fine quartz detritus. Chert nodules and stringers common in middle third of formation, becoming less prominent upwards. Southward from type section, the House limestone disappears below overlying strata in Yersin Ridge syncline, and upper beds reappear on south limb in Ibex section B.

R. E. Cohenour, 1959, Utah Geol. and Mineralog. Survey Bull. 63, p. 71–72. In Sheeprock Mountains area, conformably overlies Ajax limestone. House and Fillmore formations not differentiated. Thickness of House-Fillmore sequence 1,088 to 1,111 feet. House limestone probably represents lower 160 feet of 1,088-foot sequence measured in West Lookout Hills.

Type section: North side of small butte near mouth of westward-flowing wash, about one-half mile east of Tule Valley Grazing Service road, and approximately in sec. 23, T. 20 S., R. 14 W., Millard County, at south end of House Range where Ordovician beds, dipping from Notch Peak, approach valley level.

House Mountain Shales[1]

Upper Ordovician: Central western Virginia.

Original reference: J. L. Campbell, 1879, Am. Jour. Sci., 3d, v. 18, p. 29.

Houston Andesite[1]

Tertiary: Southwestern New Mexico.

Original reference: H. G. Ferguson, 1927, U.S. Geol. Survey Bull. 787.

Named for exposures in valley of Houston Canyon, in southeastern part of Mogollon district.

Houston Group[1]

Pleistocene: Coastal Plain of eastern Texas.

Original reference: F. B. Plummer, 1933, Texas Univ. Bull. 3232, p. 530, 780.

Crops out along coastal border of Gulf of Mexico. Named for city of Houston, Harris County.

Houston Marl[1]

Upper Cretaceous: Northeastern Mississippi.

Original reference: E. W. Hilgard, 1860, Mississippi Geology and Agriculture Rept., p. 96–97.

Houston, Chickasaw County.

Housum Member (of Mercersburg Formation)

Middle Ordovician (Trentonian): South-central Pennsylvania.

L. C. Craig, 1949, Geol. Soc. America Bull., v. 60, no. 4, p. 715 (fig. 1), 732–733. Name proposed for lower member of formation. Described at type section as tan to medium-gray fine-grained argillaceous slabby cream- to buff-weathering limestone with 10-foot interval of dark-gray thin crinkly gray-weathering limestone near top. Contains lowest metabentonite of formation. Buff-weathering beds not present in western belts of outcrop of formation. Maximum thickness 67 feet at type locality; thins northeastward. Conformably underlies Kauffman member (new); disconformably overlies Fannettsburg member (new) of Shippensburg formation. Beds originally included in Shippensburg formation.

Type section: Along Cumberland Valley Railroad 2 miles southwest of Marion, Franklin County. Named for small community 1.7 miles north of type section.

Houten sandstone[1]

Eocene: New Mexico.

Original references: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 257; 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 2, 8.

Derivation of name not stated.

Houx Limestone Bed (in Little Osage Limestone Member of Fort Scott Formation)

Houx Limestone Member (of Fort Scott Formation)

Pennsylvanian (Des Moines Series): Western Missouri, southern Iowa, and eastern Kansas.

L. M. Cline, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 36, 37. Northward from type locality, Fort Scott limestone has three limestone members termed by Missouri Survey: lower Fort Scott (Mulky cap rock), "Rhomboidal," and upper Fort Scott (Lexington bottom-rock). Term Houx limestone proposed for the "Rhomboidal." These limestones are herein named Blackjack Creek, Houx, and Higginsville. The limestones persist into Iowa.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 38, pt. 11, p. 306. In Kansas, occurs in Little Osage member (new) of Fort Scott. Thickness a few inches to little more than 1 foot.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. v (fig. 1), 6. In Missouri, considered limestone bed in Little Osage member of Fort Scott. Underlies Blackwater Creek shale.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 33, fig. 5. Houx limestone member is persistent and maintains its position from Madison County southward into Missouri. Consists of light- to dark-gray shale, characteristically earthy and very fossiliferous. Thickness varies from 8 inches in south to 4 inches in Madison County. Underlying Houx is shale that varies in thickness with greater development in the south. Shale interval between Houx and Higginsville is about 15 feet in Appanoose County and about 7 feet in Madison County.

Type locality: Well exposed at Houx Ranch, in sec. 15, T. 46 N., R. 27 W., Johnson County, Mo.

Houy Formation

Middle(?) Devonian to Lower Mississippian: Central Texas.

P. E. Cloud, Jr., V. E. Barnes, and W. H. Hass, 1957, Geol. Soc. America Bull., v. 68, no. 7, p. 807–816. Devonian-Mississippian transition outcrops of central Texas described summarily and assigned to new stratigraphic unit, the Houy formation. Beds included are mainly Upper Devonian but partly Lower Mississippian; locally a basal fraction may be Middle Devonian. Deposits are diverse, and their associations are complex. Maximum surface thickness about 17 feet. In more complete sections, formation characteristically includes (ascending) 1 to 3 feet of chert breccia, the Ives breccia member; 2 to 15 feet of black, fissile shale, the Doublehorn shale member (new); 2 feet or less of phosphoritic material of early Mississippian and, at places, of late Devonian age. King Creek marl member of Plummer's (1950) Chappel formation is an argillaceous limestone that has been surely identified only at its type site where it constitutes a few inches of the Houy. Underlies Chappel limestone and in places Barnett formation; overlies beds ranging in age from Middle or Lower Devonian to Lower Ordovician. The Houy is central Texas representative of the widespread Upper Devonian and Lower Mississippian black shale succession that includes such eastern and midcontinent deposits as Chattanooga, Ohio, New Albany, and Woodford shales.

W. H. Hass, 1959, U.S. Geol. Survey Prof. Paper 294–J, p. 366. Houy formation is early Late (and probably late Middle) Devonian to early Mississippian (early Kinderhook).

Type section: At juncture of Burnam Branch with Doublehorn Creek in an eastward extension of the R. M. Burnam Ranch, southeastern Burnet County. Name taken from reference section on Houy Ranch.

Howard Arkose[1]

Miocene(?): Central Washington.

Original reference: C. E. Weaver, 1912, Washington Geol. Survey Bull. 7, p. 34–50.

Named for Howard Creek, just below Howard Lake, Snohomish County.

Howard Limestone (in Wabaunsee Group)

Howard Limestone or Limestone Member (of Shawnee Group or Formation)[1]

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: Erasmus Haworth, 1898, Kansas Univ. Geol. Survey, v. 3, p. 67, 105.

R. C. Moore, 1932, Kansas Geol. Soc. Guidebook 6th Ann. Field Conf., p. 20, 21, 94, 96. Comprises (ascending) Bachelor Creek limestone, Aarde shale, Church limestone, Winzeler shale, and Utopia limestone members. Included in Wabaunsee group. Type locality given.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 20–21. Bachelor Creek limestone missing in northeastern Kansas, southeastern Nebraska, northwestern Missouri, and southwestern Iowa where base of Church limestone member marks boundary between the Howard and Severy. Aarde shale missing in northeastern Kansas and southeastern Nebraska. Wabaunsee group.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 20–21. Church, Winzeler, and Utopia members distinguishable in Missouri. Bachelor Creek is possibly a sandy limestone previously included in Severy shale; Aarde shale member not identified in Missouri. Wabaunsee group.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 57 (fig. 22), 60. Consists of three limestone members and two shale members. Middle limestone [Church] is the most persistent. Thickness of formation ranges from about 8 to 40 feet. Underlies White Cloud shale; overlies Severy shale.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull., v. 15, p. 14, fig. 5. Forms caprock for persistent Nodaway coal and can be identified on that basis. In eastern part of area, the Howard is dark-gray to black coarsely crystalline limestone. To the west, fine-grained gray limestone occurs above this bed, and in some places a dark shale is present separating the limestone beds. Thickness seldom more than 1½ feet. In areas where development of Howard is complete, it is composed of three limestones and two shale units. Lowermost limestone missing in Iowa section, and lower shale unit and included Nodaway coal are considered part of underlying Severy shale. Wabaunsee group.

Type locality: Near Howard, Elk County, Kans., T. 30 S., R. 10 E.

†Howard Sandstone Member (in Tuscarora Sandstone)[1]

Silurian: Central Pennsylvania.

Original reference: F. M. Swartz, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 101.

Near Mount Union, Huntingdon County, and Lewistown, Mifflin County.

Howard Quarry Sandstone

Upper Devonian (Conewango): Northwestern Pennsylvania.

K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 81. Incidental mention. Name is synonymous with Panama conglomerate member of Venango stage.

K. E. Caster, 1939, Jour. Paleontology, v. 13, no. 5, p. 532. Represents basal part of Conewango series. Geographic location stated.

Occurs in old Howard quarry, Howard Falls, Erie County.

Howe Limestone[1] Member (of Red Eagle Limestone)

Permian: Southeastern Nebraska and northeastern Kansas.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 84, 86, 88.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 48. Member of Red Eagle limestone variable in lithology and thickness; contains foraminifera in central Kansas. Thickness ranges from less than 1 foot to maximum of about 15 feet. Overlies Bennett shale member; underlies Roca shale. Wolfcamp series.

M. R. Mudge and R. H. Burton, 1959, U.S. Geol. Survey Bull. 1068, p. 14 (table 2), 61–62. Thickness 2 to about 5 feet in Wabaunsee County, Kans. Overlies Bennett shale member; underlies Roca shale.

Named for exposures south of Howe in T. 4 N., R. 14 E., Nemaha County, Nebr.

Howell Formation[1]

Howell Limestone

Middle Cambrian: Western Utah.

Original reference: C. D. Walcott, 1908, Smithsonian Misc. Colln., v. 53, no. 1804, p. 9, 11.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1135–1138, 1141 (fig. 5), 1144–1145. Howell limestone (emended) overlies Tatow limestone (new) and underlies Dome limestone. Thickness 835 feet. Lower 275 feet consists of black and dark-gray fine-grained extremely thick- to thin-bedded limestone which contains buff clay flakes and nodules and numerous algae. Next 340 feet composed of pale-gray, pinkish, and light tan-gray massive fine-grained more or less argillaceous thick- and thin-bedded limestone which contains blebs of white calcite and tan clay flakes interbedded with pinkish zones near middle. Upper 225 feet composed of alternating thicker zones of dull- and black-gray fine-grained limestone which contains buff and reddish-tan clay flakes with thinner zones of gray and tan fissile shale. Walcott gave thickness 435 feet. Emended section approximately 5 miles south of Walcott's type locality.

H. E. Wheeler, 1948, Nevada Univ. Bull., Geology and Mining Ser. no. 48, p. 38. In House Range, Burnt Canyon limestone (new) consists of uppermost 225 feet of Howell limestone as emended by Deiss (1938).

R. A. Robison, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 50–51. Proposed that definition of Howell be further restricted to include only carbonate sequence of western Utah that underlies Chisholm formation and overlies Busby and Tatow formations or their equivalents. Further proposed that Millard limestone be rank reduced to member status to include *Girvanella* limestone facies of Howell when other carbonate lithofacies are also represented in the formation. Upper member of Howell in House Range left unnamed at present.

Type locality: Slopes of Howell Peak on west side of House Range, about 5 miles west of Antelope Springs.

Howells Ridge Formation (in Bisbee Group)

Lower Cretaceous: Southwestern New Mexico.

S. G. Lasky, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 5, p. 533, figs. 2, 4; 1947, U.S. Geol. Survey Prof. Paper 208, p. 21–23, pl. 1. Lower part consists commonly of red beds of mudstone, shale, limestone, sandstone, and conglomerate; locally beds are gray to black. There is transition along the strike from one kind of rock to another within very short distances. Topmost part of formation in Eureka section consists of massive and thin-bedded black limestone and massive crystalline creamy white limestone. In Sylvanite part, the limestone at the top is much thinner than in the Eureka part. Locally the formation contains a layer of andesite flows and breccia whose thinner parts grade into purple shaly mudstone and arkosic volcanic grit. Thickness approximately 4,900 feet in Sylvanite section; may range from 1,100 feet to 5,200 feet in Eureka section. Conformably underlies Corbett sandstone (new); overlies Hidalgo volcanics (new).

Named from high cliff-capped ridge in Eureka section that is composed entirely of rocks of this formation, Little Hatchet Mountains.

†Howenstein Limestone (in Allegheny Formation)[1]

Pennsylvanian: Northeastern Ohio.

Original reference: G. F. Lamb, 1910, Ohio Nat., v. 10, p. 130.

M. T. Sturgeon, 1943, Ohio Jour. Sci., v. 43, no. 6, p. 236. Lamb, apparently the first to observe and mention Vanport limestone in this area [Columbiana and Mahoning Counties], described it in 1910 under name of Howenstein limestone on Ira Unger Farm along tributary to Meander Creek in NW¼ sec. 4, Green Township, Mahoning County.

Named for Howenstein (Howenstine), Stark County.

Howson Andesite[1]

Pliocene(?): Central Washington.

Original reference: G. O. Smith and F. C. Calkins, 1906, U.S. Geol. Survey Geol. Atlas, Folio 139.

R. J. Foster, 1960, Geol. Soc. America Bull., v. 71, no. 2, p. 110–111, pl. 1. Apparently youngest formation in area of this report [northern parts of Mount Stuart and Snoqualmie folios] and surrounding area. Overlies Swauk formation that has been intruded by Teanaway dikes. Howson, unlike other andesites in area, is unaltered and is very similar to hornblende andesite boulders in Ellensburg formation. Smith and Calkins suggested that it may be source of Ellensburg detritus. This may put upper limit on age of Howson, as age of Ellensburg, according to Waters (1955, Geol. Soc. America Bull., v. 66. no. 6) lies near Miocene-Pliocene border.

Named for exposures on Sasse Mountain north and northeast of Howson Creek, Snoqualmie quadrangle.

Hoxbar Formation[1]

Hoxbar Group

Pennsylvanian (Missouri Series): Central Oklahoma.

Original reference: W. L. Goldston, Jr., 1922, Am. Assoc. Petroleum Geologists Bull., v. 6, no. 1.

R. H. Dott, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 9, p. 1667–1668. Restricted to exclude Confederate member which is assigned to underlying Deese formation. Disconformity at top of Confederate member taken as top of the Des Moines. Missouri beds of Ardmore basin are wholly represented by the Hoxbar as thus restricted. Where best developed south of Ardmore is about 4,000 feet thick. Named members include (ascending) Crinerville sandstone and limestone, 400 to 500 feet above base; Anadarche conglomerate and limestone, about the middle; Daube limestone; and Zuckerman sandstone about 500 to 1,000 feet below top.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, p. 697, chart 6 (column 37). Shown on correlation chart as Hoxbar group. Lower Hoxbar beds are Missourian in age; upper Hoxbar deposits, including

Zuckerman sandstone, are tentatively correlated with the Vamoosa and Ada formations and may be Virgilian in age.

C. W. Tomlinson and William McBee, Jr., 1959, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 2: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 6 (fig. 2), 40–44. Group, in Ardmore basin, includes (ascending) Confederate limestone, Crinerville beds, Anadarche beds, Daube member, and Zuckerman beds. Overlies Deese group; underlies Vanoss formation (Pennsylvanian).

B. H. Harlton, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 2, p. 213 (fig. 3), 216–220. Group (in subsurface) in Cement Pool area, Caddo and Grady Counties, includes (ascending) Crinerville, Dolman, and No-Ho-Co (new) formations. Overlies Deese group; underlies Cisco group.

Named for exposures west of Hoxbar, Carter County.

Hoyt Dolomite[1]

Hoyt Limestone Member (of Theresa Dolomite)[1]

Hoyt Limestone Member (of Whitehall Formation)

Upper Cambrian: Eastern New York.

Original reference: J. M. Clarke, 1903, New York State Mus. Handb. 19, p. 16, chart.

R. H. Wheeler, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1938–1939. Cambro-Ordovician correlations revised in Champlain, Hudson, Mohawk, and St. Lawrence Valleys. Revisions involve definitions and succession of previously accepted Cambro-Ordovician formations: Potsdam, Theresa, Hoyt, and Little Falls of Upper Cambrian and Whitehall, Tribes Hill, and Beekmantown of Lower Ordovician. Hoyt fauna occurs in lower half of emended Whitehall formation above Little Falls dolomite. Each revised unit tied in with Divisions A through E of original "Calciferous" formation.

R. H. Wheeler, 1942, Am. Jour. Sci., v. 240, no. 7, p. 518–524. Base of Whitehall formation raised to coincide with contact of Little Falls dolomite and Hoyt limestone, and latter redefined as lower member of Whitehall formation. In corrected Skene Mountain section, Hoyt limestone member, about 40 feet thick, underlies Skene dolomite member (new).

D. W. Fisher and G. F. Hanson, 1951, Am. Jour. Sci. v. 249, no. 11, p. 795–813. Evidence is presented to substantiate radical change in interpretation of Paleozoic stratigraphy of Saratoga Springs region. Previously accepted sequence of beds (Potsdam sandstone, Theresa formation, Hoyt limestone, Little Falls dolomite, Amsterdam limestone, Trenton limestone, Canajoharie shale) is revised to read Potsdam sandstone, Galway formation, Hoyt limestone, Ritchie limestone (new), Mosherville sandstone (new), Gailor dolomite (new), Lowville limestone, Amsterdam limestone, Trenton limestone (Rockland?, Hull Sherman Fall representatives) and Canajoharie shale. Term "Theresa" not applicable in area; name Galway formation reintroduced for strata younger than Potsdam and older than Hoyt. Strata formerly classed as lower Hoyt are here included in redefined Galway. Wheeler (1942) classified the Hoyt as basal member of Whitehall formation and the Skene as upper member, the latter being a very late Upper Cambrian offlapping unit. It is evident that he mistook Ordovician Gailor dolomite for older Little Falls dolomite, for the Hoyt and his supposed "Little Falls" are in fault contact in his "unfaulted" area 4 miles west of Saratoga Springs. In some areas Hoyt underlies Mosherville sandstone, and in some areas Ritchie limestone.

Named for exposures at Hoyt's quarry, 3 miles west of Saratoga Springs, Saratoga County.

Hozomeen Series[1]

Carboniferous: Southern British Columbia, Canada, and central northern Washington.

Original reference: R. A. Daly, 1912, Canada Geol. Survey Dept. Mines Mem. 38, maps 14, 15.

C. E. Weaver, 1937, Washington [State] Univ. Pub. in Geology, v. 4, p. 16. Cherty quartzite together with greenstone and phyllite beds. Believed to be oldest rocks exposed on western side of summit of Cascades immediately south of international line.

Occurs in Hozomeen Range, British Columbia, and on Mount Hozomeen, Wash.

Hualalai Volcanic Series

Hualalai pyroclastic materials

Pleistocene and Recent: Hawaii Island, Hawaii.

C. K. Wentworth, 1938, Hawaiian Volcano Observatory 3d Spec. Rept., p. 88, 147. Ash and cinder formations of Hualalai Rift referred to as Hualalai pyroclastic materials.

H. T. Stearns and G. A. Macdonald, 1946, Hawaii Div. Hydrography Bull. 9, p. 139–148; D. A. Davis and G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6., Océanie, fasc. 2, p. 92. Series includes all volcanic rocks of Hualalai volcano. All are basalts except Waawaa volcanics member (new) which consists of trachyte cone and flow. As defined, includes most series of ash beds named Kona tuff formation (Wentworth, 1938). Maximum thickness 500 feet; base not exposed. Interfinger with Kau volcanic series (new).

Type locality: Western slope of Hualalai volcano near Kailau. Eruption continued into historic time; series includes flows of 1800–1801.

Hualpai Limestone

Pliocene(?): Northwestern Arizona and southeastern Nevada.

C. R. Longwell, 1936, Geol. Soc. America Bull., v. 47, p. 1429–1431. Consists chiefly of white though gray to pink or light-brown limestone, in thin and rather regular beds, many of which have porous structure characteristic of travertine. Rock compact and nearly aphanitic between scattered openings. Contains scattered pebbles and sand near base, and locally includes thin beds of shale and siltstone. Also contains gray to pink or light-brown chert nodules and lenses. Degree of porosity varies considerably from bed to bed as well as laterally in any one layer. In some parts, openings occupy full fifty percent of the volume, and rock would be described as tufa. Opening diameters range from one-half inch down to limit of visibility. In most western outcrops, thickness varies up to 150 to 200 feet. Delmar Butte and Temple, north of Colorado River are capped by 80 to 100 feet of limestone. Original maximum thickness certainly exceeded 1,000 feet.

C. B. Hunt, 1956, U.S. Geol. Survey Prof. Paper 279, p. 16 (fig. 12), 33, 34, 35. Overlaps edges of underlying fanglomerate and extends onto Precambrian rocks along east and west sides of Grand Wash trough. Overlies Muddy Creek formation.

Displayed prominently along Hualpai Wash, Arizona, from which unit is named. Distributed over irregular area, measuring 25 miles east-west and comparable distance north-south, Mohave County, Ariz., and Clark County, Nev.

Hubbard Hill Member (of Littleton Formation)

Lower Devonian : Western New Hampshire.

M. T. Heald, 1950, Geol. Soc. America Bull., v. 61, no. 1, p. 45–50, 55, pl. 1. Lowermost part of Littleton formation in Lovewell Mountain quadrangle. Thickness about 6,000 feet. Composed chiefly of mica-quartz schist, sillimanite schist, pseudo-sillimanite schist, quartz conglomerate, and quartzite, interbedded lime-silicate granulite and schist, and amphibolite. Underlies May Pond member (new. In northern part of quadrangle, the two members are separated by a sill of Kinsman quartz monzonite.

C. A. Chapman, 1952, Geol. Soc. America Bull., v. 63, no. 4, p. 387–390, pl. 1. In Sunapee quadrangle, the Hubbard Hill underlies Dakin Hill member and overlies undifferentiated Littleton.

Hubbard Hill is in Cheshire County.

Hubbardston Granite[1]

Late Carboniferous or post-Carboniferous : Central Massachusetts.

Original reference: B. K. Emerson, 1917, U.S. Geol. Survey Bull. 597, p. 231–236, map.

Named for occurrence at Hubbardston, Worcester County.

Hubbardton Slate[1]

Lower Cambrian : Southwestern Vermont.

Original reference: A. Keith, 1932, Washington Acad. Sci. Jour., v. 22, p. 360, 401.

Named for occurrence in village of Hubbardton, Rutland County.

Huckleberry Andesites[1]

Cenozoic : Northern California.

Original reference: H. Williams, 1932, California Univ. Pub., Dept. Geol. Sci. Bull., v. 21, no. 8, p. 251, 252, 254.

O. P. Jenkins, 1943, California Div. Mines Bull. 118, pt. 4, p. 678. Cenozoic.

Named for occurrence near Huckleberry Lake, Lassen National Park.

Huckleberry Clay (in Pottsville Formation)[1]

Pennsylvanian (Pottsville series) : Northern Kentucky and southeastern Ohio.

Original reference: W. Stout and others, 1923, Ohio Geol. Survey, 4th ser., Bull. 26, p. 150–151.

N. K. Flint, 1951, Ohio, Geol. Survey, 4th ser., Bull. 48, p. 23 Included in Huckleberry cyclothem.

Type locality and derivation of name not given.

Huckleberry Conglomerate

Lower Cambrian : Northeastern Washington.

W. A. G. Bennett, 1941, Washington Div. Geology Rept. Inv. 5, p. 8. Pebble conglomerate of quartzite, argillite, and carbonate rocks. Coarseness of fragments increases northeastward concurrently with diminution in thickness, which ranges from a few hundred feet at north to approximately 3,000 feet at south. Generally schistose but in southwest becomes hard flinty hornfels. Apparently deposited on eroded surface of Deer Trial rocks [group]; overlain by what appears to be Lower Cambrian greenstone in overlapping relations.

Ian Campbell and J. S. Loofbourow, Jr., 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1250. Included in Huckleberry group.

Crops out along east side of Huckleberry Mountain and north of Spokane Indian Reservation, Stevens County.

Huckleberry cyclothem

Pennsylvanian (Pottsville Series) : Southeastern Ohio.

N. K. Flint, 1949, Ohio Acad. Sci. [Guidebook] 24th Ann. Field Conf., p. 18. Incidental mention in road log.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 22–23, geol. map, table 1. Includes Huckleberry shale and (or) sandstone, Huckleberry clay, and coal members. Occurs above Anthony cyclothem and below Quakertown cyclothem. In area of this report, Pottsville series is described on cyclothemic basis; 10 cyclothems are named. [For sequence see Anthony cyclothem.]

Most exposures are in Monday Creek Township and in vicinity of Junction City, Jackson Township, Perry County.

Huckleberry Greenstone

Lower Cambrian : Northeastern Washington.

H. E. Culver, 1939, Washington State Coll. Monthly Bull., v. 22, no. 7, pt. 1, p. 19. In sequence of formations named, Huckleberry greenstone underlies Addy quartzite and overlies a conglomerate.

W. A. G. Bennett, 1941, Washington Div. Geology Rept. Inv. 5, p. 8–9. Described as predominantly metamorphosed basaltic flows in which ferro-magnesiam minerals have been chloritized. Thickness ranges from about 3,000 feet on Stensgar Mountain to a few hundred feet at north and south ends of formation. Overlaps on underlying [Huckleberry] conglomerate and on upper part of Deer Trail group; appears to wedge out laterally beneath Addy quartzite.

Ian Campbell and J. S. Loofbourow, Jr., 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1250. Included in Huckleberry group.

Crops out north of Colville Valley; main mass follows east slope of Huckleberry Mountain, crosses the divide west of Red Marble quarry, and wedges out to the south, Stevens County

Huckleberry Group

Precambrian (Belt Series) : Northeastern Washington.

Ian Campbell and J. S. Loofbourow, Jr., 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1250. Named as group including Huckleberry conglomerate and Huckleberry greenstone. Unconformably overlies Deer Trail group; unconformably underlies Addy quartzite.

Report discusses magnesite belt, Stevens County.

Huckleberry Lavas

See Union Peak Lavas.

Hudson Formation,[1] Shales,[1] or Group[1]

See Hudson River Formation.

Hudson Grits or White Beds

See Poultney River Group.

Hudson Member (of Franconia Sandstone)[1]

Upper Cambrian: Western Wisconsin and southeastern Minnesota.

Original reference: A. C. Trowbridge and others, 1935, Kansas Geol. Soc. Guidebook 9th Ann. Field Conf., p. 81, 92, 134, 140, 159, 160, 431, 446, 449, 454.

C. R. Stauffer, G. M. Schwartz, and G. A. Thiel, 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1238 (table 2); C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 30, 40. In Minnesota overlies Taylors Falls member (new). Replaces name Minneiska member.

R. R. Berg, 1953, Jour. Paleontology, v. 27, no. 4, p. 553, 554, 555; 1954, Geol. Soc. America Bull., v. 65, no. 9, p. 858 (fig. 1), 869. Name abandoned. Franconia member names used by Twenhofel, Raasch, and Thwaites (1935) are geographic names applied to faunal zones. New member names proposed to designate rock types, as distribution of faunal zones in formation is largely independent of natural rock units. Hudson member is *Ptychaspis-Prosaukia* zone. This zone is represented in Reno and Mazomanie members.

First described at Hudson, St. Croix County, Wis.

†Hudson Schist[1]

Precambrian, Cambrian, and Ordovician: Eastern New York.

Original reference: F. J. H. Merrill, 1902, U.S. Geol. Survey Geol. Atlas, Folio 83.

Occurs along Hudson River.

†Hudson System[1]

Cambrian: Eastern New York.

Original reference: T. A. Conrad, 1839, New York Geol. Survey 3d Rept., p. 57–63.

Hudson River region.

Hudson trilobite beds[1]

Upper Cambrian: Western Wisconsin.

Original reference: L. C. Wooster, 1878, Wisconsin Geol. Survey Rept. 1877, p. 36–41.

Probably named for Hudson, St. Croix County.

Hudson Bridge Limestone (in Palo Pinto Formation)[1]

Pennsylvanian: North-central Texas.

Original reference: G. Scott and J. M. Armstrong, 1932, Texas Univ. Bull. 3224, p. 21.

Crops out about 3 miles southeast of Bridgeport, on south side of West Fork of Trinity River, in east end of Rebecca Coleman survey, along margin of Trinity River flood plain, and crosses road 200 yards south of Hudson Bridge, Wise County.

Hudson Highlands Complex

Precambrian: Southeastern New York.

K. E. Lowe, 1950, Geol. Soc. America Bull., v. 61, no. 3, p. 142–144, 150–157, pls. 2, 3. Term Hudson Highlands complex or Highlands complex includes entire sequence of crystalline rocks older than Storm King granite. Colony (1921, New York State Mus. Bulls. 249–250) considered Highlands complex synonymous with Highlands crystallines, that is, including Storm King granite. Complex is cut by a variety of pegmatities, and it is not always easy to relate individual ones to specific magmatic interval. Complex includes Grenville metasediments (oldest units of complex), Pochuck diorite phase, and Canada Hill granite phase.

Report discusses area around Bear Mountain, a prominent summit of Hudson Highlands, about 40 miles north of New York City. Complex, in this area, is a relatively broad syncline or synclinorium plunging about 40° NE. Storm King granite fills core of syncline.

†Hudsonian Substage (of Wisconsin Stage)[1]

Pleistocene, upper: Great Lakes region.

Original reference: M. M. Leighton, 1931, Jour. Geology, v. 39, p. 51–53.

Name derived from Hudson Bay about which the ice fields were developed.

†Hudson River Formation,[1] Beds,[1] Group,[1] Shales, or Phyllite

Cambro-Ordovician: Southeastern New York.

Original reference (Hudson River slate group): W. W. Mather, 1840, New York Geological Survey 4th Rept., p. 212, 256–258.

Sidney Paige, 1956, Geol. Soc. America Bull., v. 67, no. 3, p. 391, 392 (fig. 1), 393. Hudson River shales and phyllite mentioned in discussion of Cambro-Ordovician age of "Inwood" limestone and "Manhattan" schist near Peekskill. Hudson River shales and phyllite stratigraphically above Wappinger dolomite and limestone.

Southeastern counties of New York.

Hueco Limestone[1]

Permian (Wolfcamp Series): Western Texas and southern New Mexico.

Original reference: G. B. Richardson, 1904, Texas Univ. Min. Survey Bull. 9, p. 32–38.

C. O. Dunbar, 1953, Am. Jour. Sci., v. 251, no 11, p. 798–804. In Sierra Diablo, Trans-Pecos, Texas, includes Kriz lens in upper part.

M. L. Thompson, 1954, Kansas Univ. Paleont. Contr. 14, Protozoa, art. 5, p. 19, 20 (fig. 5). Fusulinid faunas indicate that upper part of Hueco, commonly referred to the Leonardian with question, is younger than type section of Wolfcampian. Proposed here that Wolfcampian series be defined to include upper Hueco limestone.

F. E. Kottlowski and others, 1956, New Mexico Bur. Mines Mineral Resources Mem. 1, p. 6 (table 2), 49–52. Summary description in San Andres Mountains area. Thickness 417 to 1,355 feet. Overlies Bursum formation; underlies Abo redbeds; in some areas, overlies Panther Seep formation (new). Wolfcampian.

Hugh Hay-Roe, 1957, Texas Univ. Bur. Econ. Geology Geol. Quad. Map. 21. As described in Wylie Mountains and vicinity, overlies Powwow conglomerate and underlies Victorio Peak formation. Well in area penetrated 1,240 feet of Hueco limestone.

G. O. Bachman and P. T. Hayes, 1958, Geol. Soc. America Bull,. v. 69, no, 6, p. 690 (fig. 1), 693 (fig. 2), 694 (fig. 3), 695. Described in Sand Canyon area, New Mexico. In most of mapped area, Hueco comformably overlies Danley Ranch tongue (new) of Abo sandstone into which it grades laterally northward; locally rests with angular unconformity on lower part of

Magdalena group; upper part grades laterally into, and is conformably overlain by sequence of red beds herein referred to as Lee Ranch tongue of Abo sandstone. Thickens from about 350 feet 1 mile north of map area to nearly 600 feet near Culp Canyon, a distance of about 5 miles; most of this gain is attributed to intertonguing with Abo. All but uppermost part is probably Wolfcamp; at south end of Sand Canyon area, uppermost beds are known to be lateral equivalents of part of Lee Ranch tongue of Abo, which is apparently early Leonard.

Named for exposures in Hueco Mountains, El Paso County, Tex.

†Huehue Flow

Recent: Hawaii Island, Hawaii.

H. T. Stearns and G. A. Macdonald, 1946, Hawaii Div. Hydrog. Bull. 9, p. 148. Olivine basalt flow. Contains partly charred wood.

Believed to have been erupted from last activity of Hualalai in 1801.

Huelster Formation (in McCutcheon Volcanic Series)

Tertiary: Southwestern Texas.

G. K. Eifler, Jr., 1951, Geol. Soc. America Bull., v. 62, no. 4, p. 342–345, pl. 1. Composed almost entirely of tuff, with thin layers of sandstone and conglomerate, lenses of fresh-water limestone, and trachydoleritic lava. At type locality approximately 400 feet thick; thins eastward,. Includes Jeff conglomerate member (new) at base. Forms lower part of series. Overlies marine Upper Cretaceous; underlies Star Mountain rhyolite (new).

Type locality: Near head of deep ravine about 1½ miles south of ruins of Huelster ranchhouse in northwestern part of Barrilla Mountains, Reeves County.

Huerfano Formation[1]

Eocene, lower and middle: Southeastern Colorado.

Original reference: R. C. Hills. 1888, Colorado Sci. Soc. Proc., v. 3, pt. 1, p. 148–164.

R. B. Johnson and J. G. Stephens, 1954, U.S. Geol. Survey Oil and Gas Inv. Map OM–146. Formation, deposited during Wasatch and early Bridger time, unconformably overlies Cuchara formation at southern end of Huerfano Park. Consists of lower member of red and tan semiconsolidated sandstone and red, green, and gray shale and upper member of rust-colored granule and pebble conglomerate and tan shale.

R. B. Johnson and G. H. Wood, Jr., 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 4, p. 709 (fig. 2), 717–718. In Raton basin, formation unconformably overlaps Cuchara formation, Poison Canyon formation, and Pierre shale. Thickness as much as 2,000 feet. Consists mainly of variegated maroon shale beds with gray and green zones, and red, white, and tan sandstone beds. Underlies Farisita conglomerate (new), which unit has been mapped as Huerfano by Burbank and Goddard (1937, Geol. Soc. America Bull., v. 48, no. 7).

Typical exposure occurs on drainage of Muddy Branch of Huerfano River, Huerfano County.

†Huerfano Series[1] or Beds

Eocene: Southeastern Colorado.

Original references: R. C. Hills, 1888, Colorado Sci. Soc. Proc., v. 3, pt. 1, p. 148–165; 1893?, Colorado Sci. Soc. Proc., v. 4, p. 7–9.

Well exposed in Muddy Branch of Huerfano River.

Huerto Quartz Latite or Formation (in Potosi Volcanic Group)

Huerto Andesite (in Potosi Volcanic Series)[1]

Tertiary, middle or upper: Southwestern Colorado.

Original reference: E. S. Larsen, 1917, Colorado Geol. Survey Bull. 13, p. 20, 36.

E. S. Larsen, Jr., and Whitman Cross, 1956, U.S. Geol. Survey Prof. Paper 258, p. 13, 93 (table 18), 143–144. Huerto quartz latite proposed to replace Huerto formation [andesite]. Defined as that body of quartz latites that lies between Alboroto rhyolite below and Piedra rhyolites above. Lower contact regular; upper contact irregular. Thickness in central part about 2,500 feet.

U.S. Geological Survey currently designates the age of the Huerto Quartz Latite or Formation as middle or late Tertiary. This designation made on the basis of age change of Potosi Volcanic Group.

Named for occurrences on Huerto Peak in southern part of San Cristobal quadrangle, west of Huerto Creek.

Huethawali limestones[1] (in Aubreyan series)

Carbonic: Northern Arizona.

Original reference: C. [R.] Keyes, 1922, Pan-Am. Geologist, v. 38, p. 251, 336.

Charles Keyes, 1936, Pan-Am. Geologist, v. 66, no. 3, p. 215 (chart), 223. Underlies Havasupai sandstones; overlies Chiquito sandstones. Carbonic.

In Grand Canyon region. Derivation of name not stated, but probably Huethawali Peak, which is just west of head of Bass Canyon.

Huevo member (of Serpiente Sandstone)

See Serpiente Sandstone.

Hughes Creek Shale Member (of Foraker Limestone)

Hughes Creek Shale[1]

Permian: Southeastern Nebraska, northeastern Kansas, and Oklahoma.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 84, 85, 89.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 168. Reallocated to member status in Foraker limestone. In northern Kansas comprises light-gray to nearly black shale and thin limestone beds containing fusulines, and in lower part, a brachiopod fauna; in southern Kansas is a nearly continous limestone section, massive in lower part and containing much light-blue flint. Thickness about 40 feet. Underlies Long Creek limestone member; overlies Americus limestone member. Wolfcamp series.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 82–83, pl. 1. Described in Pawnee County, Okla., where it is classified as member of Foraker limestone. Thickness 30 to 43 feet. Overlies Americus limestone member; underlies Long Creek limestone member. Wolfcamp.

Named for Hughes Creek, Nemaha County, Nebr.

Hughes Gap Formation (in Great Smoky Group)

Precambrian: Central northern Georgia and southwestern North Carolina.

V. J. Hurst, 1955, Georgia Geol. Survey Bull. 63, p. 9, 21–35, pl. 1, map. Characterized by garnet-mica schist, staurolite schist, metaquartzconglomerate, quartzite, and pseudodiorite with beds of metagraywacke and mica shist near base. Strata range in thickness from fraction of inch to more than 50 feet; commonly less than 10 feet thick; changes in thickness and lithology common along strike. Thickness difficult to determine as present outcrop pattern is due partly to facies changes in original sediments and partly to local structures, but repetition of beds is not common; estimated thickness 4,000 to 6,000 feet.Underlies Hothouse formation (new); overlies Copperhill formation (new) with transistion zone a few hundred feet thick.

Named from Hughes Gap, Mineral Bluff quadrangle, Fannin County, Ga., where an almost complete section is exposed. Formation crops out in a belt that enters Mineral Bluff quadrangle near Franklin Mountain, N.C., and leaves the quadrangle in vicinity of Gravelly Gap, Ga.

Hughes River Flint (in Conemaugh Formation)[1]

Pennsylvanian: Northwestern West Virginia.

Original reference: R. V. Hennen, 1911, West Virginia Geol. Survey Rept. Wirt, Roane, and Calhoun Counties, p. 258.

Probably named for occurrence on South Fork of Hughes River.

Huginnin Porphyrite[1]

Precambrian: Northern Michigan.

Original reference: A. C. Lane, 1898, Michigan Geol. Survey, v. 6, pt. 1, p. 98, 141, 205–206, 207, 209, 212, pls. 1, 13.

Named for exposures in bed of Huginnin Creek, about 50 feet from shore of Huginnin Cove and about 200 feet from mouth of the creek, in Isle Royale.

Huichica Formation

Pleistocene: Northwestern California.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 16 (table 3), 98, pl. 11. Terrace deposits composed of poorly stratified gravels, conglomerates, sands, and clays; nonmarine. Basal deposits consist of reworked tuffs, pebbly conglomerates, and poorly consolidated clayey sandstone; upper beds largely pebbly sandstone and conglomerate. Thickness 250 to 500 feet. Unconformably overlies tilted andesites and rhyolites. May be contemporaneous with Glen Ellen formation (new).

Named from Huichica Creek at head of San Pablo Bay in northern part of Mare Island quadrangle, Napa County. Exposed around margins of Napa and Sonoma Valleys.

Hulah Sandstone Member (of Tallant Formation)

†Hulah Sandstone Member (of Nelagoney Formation)[1]

Pennsylvanian (Missouri Series): Northeastern Oklahoma.

Original reference: M. I. Goldman and H. M. Robinson, 1920, U.S. Geol. Survey Bull. 686–Y, p. 362, 365.

W. F. Tanner, 1956, Oklahoma Geol. Survey Circ. 40, p. 37–38. Reallocated to Tallant formation. Well exposed north of Caney River, Osage County, where it is a fossiliferous yellow or orange sandstone about 4 feet thick. South of Caney River, the Hulah appears in upper part of Revard sandstone member and would therefore seem to be an equivalent of the latter. The Hulah mapped at type locality by Goldman and Robinson (1920) is believed to be the Bigheart, and elsewhere in same township the bed named Hulah appears as a lens between the Bigheart and Revard members; unit was given a name in this report because of its distinctive appearance north of Caney River.

Type locality: Top of small ridge at east edge of Hulah, near center SE¼ sec. 5, T. 28 N., R. 12 E., Osage County.

Hulen Beds (in Horsetown Group)

Lower Cretaceous (Shasta Series) : Northern California.

F. M. Anderson, 1938, Geol. Soc. America Spec. Paper 16, p. 32 (fig. 1), 38 (table 1), 67–68, table 2. Name applied to upper part of Horsetown group. Beds contain succession of distinctive faunal zones. Underlies lowest beds of Chico series or Tehama formation; overlie Cottonwood beds (new) of Horsetown group; boundary is more one of paleontological distinction. In type area, lower part of beds consists of dark argillaceous shales with only occasional layers of sandstone and sandy shales and zones of fossiliferous calcareous concretions. Thickness (fig. 1), 2,645 feet.

Type area; North fork of Cottonwood Creek [Shasta County]. Area is traversed by eastern branches of Hulen Creek, hence the name.

Hulett Sandstone Member (of Sundance Formation)

Hulett Sandstone Member (of Rierdon Formation)

Upper Jurassic: Northwestern Wyoming and southwestern South Dakota.

R. W. Imlay, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 2, p. 255–257, geol. sections. Includes 25 to 120 feet of marine sandy beds consisting mainly of grayish, moderately hard thin- to thick-bedded, fine-grained, calcareous, glauconitic, ripple-marked sandstone. Thickness at type section 82 feet. Grades into underlying Stockade Beaver member and overlying Lak member (both new).

J. A. Peterson, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 4, p. 466 (table 2), 475, 482. Reallocated to member status in Rierdon formation herein assigned to Sundance group.

Type section: On north side of Bush Canyon about 2½ miles north of Hulett, Crook County, Wyo., in secs. 25 and 36, T. 55 N., R. 65 W.

Huling Tongue (of Ono Formation)

Lower Cretaceous: Northern California.

M. A. Murphy, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2101 (fig. 2), 2104 (fig. 3) 2106–2107 (fig. 4), 2111–2112. Mostly graywacke; mudstone and thick extremely lenticular conglomerate units interbedded in lower part. Lowest unit, about 500 feet thick, is lenticular cobble conglomerate with well-rounded clasts, predominantly granitic, volcanic, and argillaceous rocks, which are uniform in size and roundness. About 200 feet of sandy mudstone and thinly bedded graywacke overlies the conglomerate. Next in sequence is interbedded graywacke and conglomerate unit. Next 200 feet of section starting at upper end of gorge along Huling Creek is a well-indurated massive non-bedded sandstone that grades into flaky weathering, very thickly bedded unit that comprises upper 500 feet of Huling tongue. Latter is fossiliferous in its upper half and zone of sandstone concretions. Lower contact usually very distinct and lower beds form north-facing cuesta-like escarpment overlooking less resistant mudstone of lower Ono. Upper contact gradational with overlying mudstones.

Named for exposures along Huling Creek, Shasta County.

Hull Agglomerate[1]

Middle Jurassic: Northern California.

Original references: C. H. Crickmay, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 81; no. 5, p. 895–903.

Occurs in lower end of Hinchman Ravine and many other places on slopes of Mount Jura.

Hull Limestone[1] or Formation

Middle Ordovician: Ontario and Quebec, Canada, and northern New York.

Original reference: P. E. Raymond, 1914, Canada Geol. Survey Summ. Rept. 1912, p. 348.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 261–262. In southeastern Ontario and New York, formation extends from top of *Triplecia cuspidata*-bearing Napanee member (new) of Rockland formation to base of Sherman Fall limestone, in which *Prasopora orientalis* Ulrich is abundant. *Parastrophina hemiplicata* (Hall), normally abundant in basal Hull in New York, is rare in top of Rockland and recurs at higher horizons; thus, its presence aids in distinguishing Hull from Rockland. Thickness 85 to 110 feet. Formation enters New York at Sackets Harbor, forms narrowed belt south and west of Black River as far as Boonville, and then thins rapidly toward Mohawk Valley where it constitutes Larrabee member (new) of Glens Falls formation. In its original usage, term Kirkfield limestone was synonymous with Hull formation, but term Kirkfield later was applied as provincial name for Trenton group of central Ontario.

G. M. Kay, 1943, Am. Jour. Sci., v. 241, no. 10, p. 598, 599. Discussion of West Canada Creek area, New York. Term Kirkfield used in preference to term Hull for unit overlying Rockland limestone and underlying Shoreham limestone. Term Kirkfield has priority over term Hull.

Named for exposures at Hull, Quebec, Canada.

Hull Meta-Andesite[1]

Hull Formation

Upper Jurassic: Northern California.

Original reference: J. S. Diller, 1908, U.S. Geol. Survey Bull. 353.

P. A. Lydon, T. E. Gay, Jr., and C. W. Jennings, 1960, Geologic map of California Westwood sheet (1:250,000): California Div. Mines. Formation consists of metaandesite tuff and breccia. Mapped with Jurassic and (or) Triassic metavolcanic rocks.

Named for exposures east of Hull diggings (called Taylor diggings on Taylorsville map).

Hull porphyry[1]

Precambrian: Northwestern Iowa.

Original references: C. R. Keyes, 1914, Iowa Acad. Sci. Proc., v. 21, p. 187; 1914, Science, new ser., v. 40, p. 144.

Probably named for Hull, Sioux County.

Hull Stage

Middle Ordovician (Trentonian): Eastern North America.

G. M. Kay, 1937, Geol. Soc. America Proc. 1936, p. 82. Rockland and Hull are early Trenton stages.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 260–262, 293, 298. Discussion of stratigraphy of Trenton group. Hull limestone and Larrabee member (new) of Glens Falls formation are of Hull age. In late Rockland time, seas overlapped Adirondack arch in a narrow strait somewhat north of Mohawk Valley. Hull stage is essentially a continuation of this overlap.

Name derived from Hull, Quebec, Canada, for which Hull limestone was named.

Humboldt Formation[1]

Humboldt Limestone Member (of Syrena Formation)

Pennsylvanian: Southwestern New Mexico.

Original reference: H. Schmitt, 1933, Am. Inst. Mining Metall. Engineers Contr. 39, p. 2, 13.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 23. Schmitt's term Humboldt is three times preoccupied. It is not used in this report as stratigraphic name for Pennsylvanian rocks in New Mexico.

P. F. Kerr and others, 1950, Geol. Soc. America Bull., v. 61, no. 4, p. 283 (fig. 5), 284–285. Syrena formation has been divided into two mapping units by Schmitt: lower is Mountain Home member and upper is Humboldt limestone (also called Don limestone). Consists of some 250 feet of alternating limestone and shale with several discontinuous quartz diorite sills. Underlies Beartooth quartzite.

Derivation of name not indicated.

Humboldt Formation[1]

Miocene and Pliocene(?): Northern Nevada.

Original reference: C. King, 1878, U.S. Geol. Expl. 40th Par., v. 1, p. 434–443.

R. P. Sharp, 1939, Jour. Geology, v. 47, no. 2, p. 133–160. Consists of 5,800 feet of continental deposits which range in grain size from coarse fanglomerate to fine shale and in composition from lake deposits of limestone and oil shale to stream-laid conglomerate sandstone, and mudstone interbedded with fine pyroclastics of water-laid and air-borne types. Beds divided into three members: lower, mostly lake beds; middle, characterized by ash and tuff beds; upper, mostly stream-laid deposits. As here defined consists of beds deposited chiefly in late Miocene and possibly early Pliocene. Lake Lahontan beds should not be included in Humboldt. Type section suggested.

R. H. Dott, Jr., 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 11, p. 2245. Overlaps Tomera formation (new) at Tomera Ridge.

T. G. Fails, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 10, p. 1695 (fig. 1), 1699. Unconformably overlies Carlin Canyon formation (new).

Type section: Exposures along Huntington Creek, tributary of South Fork of Humboldt River, Elko County. Formation occupies basins separated by northward-trending fault-block mountains.

Humboldt Limestone[1]

Pennsylvanian: Southeastern Kansas.

Original reference: R. Hay, 1887, Kansas Acad. Sci. Trans., v. 10, p. 7.

Probably named for Humboldt, Allen County.

Humboldt Oolite (in Kinderhook Group)[1]

Mississippian: Central northern Iowa.

Original reference: F. M. Van Tuyl, 1925, Iowa Geol. Survey, v. 30, p. 109–114.

Occurs in east bank of West Fork of Des Moines River in southwestern part of town of Humboldt, Humboldt County.

Humbug Formation[1]

Upper Mississippian: Central northern Utah.

Original reference: G. W. Tower, Jr., and G. O. Smith, 1899, U.S. Geol. Survey 19th Ann. Rept., pt. 3, p. 625–626.

H. T. Morris, 1957, Utah Geol. Soc. Guidebook 12, p. 15 (fig. 4), 19–20, pl. 1. In East Tintic Mountains, overlies Deseret limestone (replaces Pine Canyon) and underlies Great Blue limestone. Thickness 600 to 675 feet.

A. E. Disbrow, 1957, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–131. Mapped in Fivemile Pass quadrangle where it consists of alternating beds of brown crossbedded sandstone and light-gray weathering limestone interbedded with thin beds of dolomite and shale; about 600 feet thick. Underlies Great Blue limestone; overlies Deseret limestone.

J. K. Rigby, 1958, Utah Geol. Soc. Guidebook 13, p. 38 (fig. 5), 45–46. In Stansbury Mountains, overlies Pine Canyon formation and underlies Great Blue limestone. Thickness 710 to 900 feet. Pine Canyon used here in preference to Deseret.

H. J. Bissell, 1959, Utah Geol. Soc. Guidebook 14, p. 52–55. In southern Oquirrh Mountains, 635 feet thick; underlies Great Blue limestone and overlies Deseret limestone (restricted).

H. J. Bissell, 1959, Utah Geol. Soc. Guidebook 14, p. 158, 161–163, pl. 1. In Fivemile Pass and North Boulter Mountains quadrangles, conformably overlies Pine Canyon formation and underlies Great Blue limestone. Thickness 450 to 475 feet.

Named for exposures near Humbug tunnels, 1¼ miles southeast of Eureka.

†Humbug Limestone[1]

Mississippian: Utah.

Original reference: G. W. Crane, 1915, Am. Inst. Mining Engrs. Bull. 106, p. 2159–2151.

In Tintic district.

Humbug Sandstone[1]

Upper Mississippian: Utah.

Original reference: G. W. Crane, 1915, Am. Inst. Mining Engrs. Bull. 106, p. 2149–2151.

In Tintic district.

Hume Shale Member (of Perrysburg Formation)

Hume Shale (in Canadaway Group)

Hume Shale Member (of Canadaway Formation)

Upper Devonian: Western and west-central New York.

J. F. Pepper and Wallace de Witt, Jr., 1951, U.S. Geol. Survey Oil and Gas Inv. Chart OC–45. Name applied to about 70 feet of predominantly black, brown, and dark-gray shale exposed above Canaseraga sandstone member in stream and along banks of Wiscoy Creek at Mills Mills. Member rests on siltstone of upper part of Canaseraga along Wiscoy Creek and grades laterally eastward into siltstone of Canaseraga in area between Mills Mills and Dalton. In Genesee River Valley, overlain by Caneadea member.

I. H. Tesmer, 1955, New York State Mus. Sci. Service Circ. 42, p. 10, fig. 1, 16. Reallocated to member status in Canadaway formation.

L. V. Rickard, 1957, New York Geol. Soc. Guidebook 29th Ann. Mtg., p. 15, 17, 18. In Wellsville area, term Perrysburg formation not applied. Hume shale considered formation in Canadaway group.

Type locality: At Mills Mills, on Wiscoy Creek, Hume Township, Allegheny County.

Hummel facies (of Muldraugh Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 76, 214–217. Characterized by unit of gritty siltstone in lower part. Bounded by greenish-black bands of glauconitic silt and argillaceous limestone with bluish to greenish shaly partings in upper part. Thickness 35 to 50 feet or more. Contains Wildie siltstone member (new) at base. Merges with Maretburg facies (new) on the west and with Olive Hill facies (new) on the east. Underlies unclassified Upper Mississippian rocks; overlies Floyds Knob formation.

Well exposed at northwest end of tunnel of Louisville and Nashville Railroad 1½ miles south-southeast of Wildie, Rockcastle County. Section is in center of facies area. Name derived from Hummel, station on Louisville and Nashville Railroad, 4 miles northeast of Mt. Vernon, north-central Rockcastle County.

Humpback Gneiss

Precambrian (Archean?): Western North Carolina.

C. E. Hunter and P. W. Mattocks, 1936, TVA Div. Geology Bull. 4, p. 11–12. A light-gray rock of sedimentary origin composed mostly of fragments of feldspar and quartz in matrix of secondary micas, chlorites, and other metamorphic minerals. A thin yellowish clay schist commonly interbedded with the more coarse and thick-bedded materials.

Appears along Humpback Mountain in Linville Falls quadrangle.

Humphrey Shale (in Wabaunsee Group)[1]

Pennsylvanian: Northeastern Kansas, southwestern Iowa, and southeastern Nebraska.

Original reference: A. J. Smith, 1905, Kansas Acad Sci. Trans., v. 19, p. 151.

Named for exposures on Humphrey's Ford, 6 miles southeast of Emporia, Kans.

Humphrey Creek Shale (in Wabaunsee Group)[1]

Pennsylvanian: Kansas.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. Guidebook 6th Ann. Field Conf.

Hundred Sandstone (in Washington Formation)[1]

Permian: Northern West Virginia and southeastern Ohio.

Original reference: R. V. Hennen, 1909, West Virginia Geol. Survey Rept. Marshall, Wetzel, and Tyler Counties, p. 214.

Wilber Stout, Karl Ver Steeg, and G. F. Lamb, 1943, Ohio Geol. Survey, 4th ser., Bull. 44, p. 153, table facing p. 108. Geographically extended into Ohio where it is 17 feet thick and occurs below Upper Washington limestone and above Upper Marietta sandstone.

Thomas Arkle, Jr., 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 118 (table 1). Sandstone in Washington series. Above Hundred coal and below Upper Washington limestone.

Named for village of Hundred, Wetzel County, W. Va.

Hungerford Formation

Hungerford Slate (in Woods Corners Group)

Middle Cambrian: Northwestern Vermont.

Charles Schuchert, 1937, Geol. Soc. America Bull., v. 48, no. 7, p. 1045, 1047–1049, 1055. Chiefly blue-black to gray well-banded slates with local lentils of sandy dolomites also many white limestone bioherms. Hungerford beds formerly considered same as Highgate formation. Near Highgate Center, the name, Russell slate, is abandoned and beds are named Hungerford. Maximum thickness about 700 feet. Disconformably underlies Rockledge breccia (new) or Georgia formation; overlies Mill River breccia, St. Albans slate, or Parker slate.

B. F. Howell, 1939, (abs.) Geol. Soc. America Bull., v. 50, no. 12, pt. 2, p. 1964. Stratigraphically restricted. Lowermost fossiliferous beds named Skeels Corners formation; the sandstone disconformably overlying them named Saxe Brooke formation.

A. B. Shaw, 1958, Geol. Soc. America Bull., v. 69, no. 5, p. 523 (table 1), 532 (fig. 5), 547–548, pl. 1. Schuchert (1937) misinterpreted structures at type locality and believed that Hungerford slate lay below Rockledge conglomerate. Detailed mapping has proved that Rockledge plunges northward under slate at Hungerford Brook and that Hungerford slate is younger than Rockledge conglomerate. Because of this misinterpretation of stratigraphic position of Hungerford, Schuchert and subsequent workers have referred to Hungerford slate all beds now designated as Skeels Corners slate. Ruedemann (1947) referred to this formation as Russell slate. Consists almost entirely of black slate, commonly in beds 2 to 10 mm thick, alternating with beds of fine-grained white sandstone, commonly less than 3 mm. thick. Thickness about 400 feet at type locality; about 200 feet at international boundary. Overlies Rockledge conglomerate, contact gradational; overlies Skeels Corners slate where Rockledge is absent; underlies Gorge formation. Uppermost formation in Woods Corners group (new). Middle Cambrian.

Type area: Where Hungerford Brook crosses Highgate Road, about 1¼ miles south of Highgate, Franklin County. Thick sections also found west of Georgia Center and in Milton Township.

Hungry Run Sandstone Member (of Orangeville Shale)

Mississippian: Northwestern Pennsylvania.

Wallace de Witt, Jr., 1951, Geol. Soc. America Bull., v. 62, no. 11, p. 1347, 1351, 1364–1366; J. F. Pepper, Wallace de Witt, Jr., and D. F. Demarest, 1954, U.S. Geol. Survey Prof. Paper 259, p. 18 (fig. 9), 43–45. Name proposed for massive iron-stained coarse-grained sandstone and underlying massive siltstone. Sandstone is crossbedded, conglomeratic in upper part, and includes zone of clay galls and lens of petroliferous sandstone. Lenses of flattened discoidal pebbles occur in conglomerate. Thickness 12 feet. Overlying beds not exposed at type locality; in some Crawford County localities, underlies dark silty part of Orangeville shale. Overlies either siltstones of Corry sandstone or Cussewago sandstone. Lower Mississippian.

Type locality: Small quarry on a headwater of Hungry Run, 1 mile west of southeastern corner of Union Township, Erie County. Also exposed in Crawford County.

Hungry Valley Formation (in Ridge Basin Group)

Pliocene, upper: Southern California.

J. C. Crowell, 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 8, p. 1626 (fig. 4), 1629 (fig. 5), 1633–1637. Name applied to about 4,000 feet of nonmarine sandstone and conglomerate conformably overlying Peace Valley beds (new). Consists of five unnamed lithologic members (ascending): conglomerate-breccia, brown conglomerate, white sandstone, gray silty sandstone, and buff sandstone. Basal contact of formation in type area is gradational. Youngest exposed beds of formation crop out along San Andreas fault zone and Frazier Mountain thrust near northern boundary of area.

J. C. Crowell, 1954, California Div. Mines Bull. 170, map sheet 7. Shown on columnar section as the top 4,500 feet of Ridge Basin group.

Type section: Just east of Hungry Valley and along Freeman Canyon. Hungry Valley is in Transverse Ranges about 55 miles northwest of Los Angeles.

Hunt Beds (in Bluestone Group or Formation)

Hunt Member (of Bluestone Formation)

Mississippian (Chester Series): Southwestern Virginia and southeastern West Virginia.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 185–186, pl. 15. Reger (1926) subdivided the 50 feet of the Bluestone into 3 units (ascending): Hunt shale, Hunt sandstone, and Hunt coal. These three units here considered the Hunt member of the Bluestone. In Burkes Garden quadrangle, member is 50 to 74 feet thick and consists of maroon-drab, apple-green, and reddish-buff shales; the redbeds are overlain by 12-foot zone of black carbonaceous shale, gray underclay, and coal. Underlies Bent Mountain member (new); overlies Bratton sandstone member. Relations indicate Hunt member is in trough of overturned syncline.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5 (columns 97, 98). Correlation chart shows Hunt beds in Bluestone group or formation.

Type locality: Near Hunt School, Mercer County, W. Va.

Hunt Sandstone (in Bluestone Formation)[1]

Hunt Shale (in Bluestone Formation)[1]

Mississippian (Chester Series): Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 293, 317.

B. N. Cooper, 1944, Virginia Geol. Survey Bull. 60, p. 185. Hunt shale, Hunt sandstone, and Hunt coal, named by Reger (1926), here considered the Hunt member of Bluestone formation.

All units exposed in Stony Gap section, Mercer County, on north side of Big Ridge, about three-fourths mile south of Belcher School.

Hunt Creek Sandstone (in Mancos Shale)

Upper Cretaceous: Northwestern Colorado.

R. E. Kucera, 1959, Rocky Mountain Assoc. Geologists 11th Field Conf., Symposium, p. 42, fig. 3. Prominent sandstone sequence at base of upper Mancos shale consisting of three prominent yellowish-gray to light-gray fine-grained crossbedded sandstone units with intervening slope-forming sandy shale and thin sandstone zones, 240 to 260 feet thick.

Exposed in escarpment along Hunt Creek, 2 miles southwest of Phippsburg.

Hunter Group

Hunterian Subseries

Middle Ordovician (Bolarian): Pennsylvania, Maryland, New York, Virginia, and West Virginia, and Ontario, Canada.

Marshall Kay, 1947, (abs.) Geol. Soc. America Bull., v. 58, no. 12, p. 1198–1199. Upper Bolarian (Hunterian) comprises Snyder, Stover, and Curtin limestone, about 300 feet at Bellefonte, Pa., thinning by truncation to about 60 feet, predominantly Snyder, near Maryland, and to about 30 feet of Snyder at James River. The thickening Gratton, Bowen, Wardell, and basal Witten take the place of the Snyder west of New River, and Witten type section in Tazewell County seems to contain the Stover-Nealmont disconformity within the "*Camarocladia* zone." Lower Bolarian is the Hatterian (new).

Marshall Kay, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1409–1410. Hunter group includes Snyder, Stover, and Curtin limestones of central Pennsylvania. First two described as members of Benner formation. Hunterian subseries is of rocks younger than base of Snyder and older than unconformity separating the Curtin and lower Trentonian Nealmont limestone. Inasmuch as the Curtin is thickening northwestward beneath an unconformity as it passes beneath the Appalachian Plateau, there are Hunterian sediments younger than those exposed.

Marshall Kay, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 97. Hunter group (Kay, 1948) is not significant, and Benner group should be applied to upper Bolarian.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 7. Bolarian includes two divisions—Hatterian and Hunterian. These names unsatisfactory to show relationships as understood in this report. Hatter formation, whose time designation is Hatterian, appears to be same as Hunterian if, as shown in this report, the Hatter is equivalent to Ridley formation.

Name derived from Hunter Park, on Bellefonte Central Railroad in Centre County, Pa.

Hunter Sandstone and Conglomerate (in Puente Formation)

Miocene, upper: Southern California.

M. L. Krueger, 1943, California Div. Mines Bull. 118, p. 363. Shown on structure section as underlying Peculiar shale (new) and overlying Cubierto shale (new).

A. O. Woodford, T. G. Moran, and J. S. Shelton, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 4, p. 521. Sandstone, conglomerate, and clay shale 216 feet thick. Upper part of Puente. Measured section noted.

Exposed in Slaughter Canyon in southeastern Puente Hills, between Chino and Santa Ana River, San Bernardino County.

Hunter Canyon Formation (in Mesaverde Group)[1]

Upper Cretaceous : Western Colorado.

Original reference: C. E. Erdmann, 1934, U.S. Geol. Survey Bull. 851, p. 22, 33.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 22, pl. 1. Late Montanan to early Lance.

R. G. Young, 1955, Geol. Soc. America Bull., v. 66, no. 2, p. 187. Proposed to drop terms Mount Garfield and Hunter Canyon formations and to adopt term Neslen facies for all coal-bearing rocks of Price River formation and term Farrer facies for non-coal-bearing rocks above Neslen facies.

D. J. Fisher, C. E. Erdmann, and J. B. Reeside, Jr., 1960, U.S. Geol. Survey Prof. Paper 332, p. 11 (table), 20. Consists of massive brown-buff and gray sandstone and soft gray shale beds. Thickness 375 to 1,400 feet. Overlies Mount Garfield formation. Essentially equivalent to Tuscher formation.

Named for Hunter Canyon, Book Cliffs coal field.

Hunter Mountain Quartz Monzonite

Cretaceous (?) : Eastern California.

J. F. McAllister, 1956, U.S. Geol. Survey Geol. Quad. Map GQ-95. Name applied to map unit of plutonic rocks. Described as principally light-gray medium- to coarse-grained hornblende quartz monzonite but includes wide range of border facies (commonly syenodiorite, monzonite, syenite), pegmatite, aplite, and lamprophyre. Greatest topographic relief of an exposed part is about 4,000 feet in Nelson Range. Plutonic rocks intruded and metamorphosed Bird Spring (?) formation of Pennsylvanian and Permian age and lie nonconformably under continental deposits of late Pliocene or Pleistocene age.

Named for Hunter Mountain in Panamint Range. Exposed continuously from contact at least 8 miles east of quadrangle, across Hunter Mountain and for 17 miles along Nelson Range. Exposure is at least 10 miles broad across Hunter Mountain and southward to Darwin quadrangle.

Hunters Island Iron-Bearing Series[1]

Precambrian : Northeastern Minnesota.

Original reference: C. R. Van Hise and C. K. Leith, 1911, U.S. Geol. Survey Mon. 52, p. 118.

Occurs on east extension of north arm of Vermilion Range, Vermilion district.

Huntersville Chert (in Onodaga Group)

Huntersville Chert (in Oriskany Group)[1]

Lower or Middle Devonian : Southeastern West Virginia.

Original reference: P. H. Price, 1929, West Virginia Geol. Survey Rept. Pocahontas County, p. 106, 108, 233, 236–237, 397.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Age shown on correlation chart as Lower or Middle Devonian.

H. P. Woodward, 1943, West Virginia Geol. Survey, v. 15, p. 256–278. Huntersville is rock unit for which it is difficult to find precisely descriptive lithologic term and to which name chert is only partly appropriate. Mostly it is highly silicified black shale which contains many beds that have been brecciated and recemented with amorphous silica; at least one prominent glauconitic-bearing sandstone and numerous other sandy phosphatic, or glauconitic, layers are commonly present; many layers of brittle clay-shale, but little or no limestone and less true chert than commonly supposed. Thickness 15 to nearly 100 feet. Unconformably overlies Ridgeley sandstone; where it underlies Needmore shale, the two formations grade into each other; where Needmore is absent, underlies Marcellus black shale. Present in southwestern Virginia. Included in Onondaga group, Middle Devonian.

J. M. Dennison, 1960, Dissert. Abs., v. 21, no. 3, p. 593. Includes Bobs Ridge quartz sandstone member (new). Needmore shale, Huntersville chert, and Onondaga limestone are contemporaneous facies of Onesquethaw stage.

Type locality: Vicinity of Huntersville, southeastern Pocahontas County.

Hunter Valley[1] Cherts (in Amador Group)

Middle or Upper Jurassic: East-central California.

Original reference: N. L. Taliaferro, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 149.

N. L. Taliaferro, 1943, California Div. Mines Bull. 125, p. 283, 303–323. Assigned to Amador group. Consist of red, chocolate, gray, green, and black radiolarian chert, both massive and thin-bedded with partings of red, lilac, purple, chocolate, gray-green, and black slates and tuffaceous slates; schistose green tuffs and thin flows; impure cherts and siliceous mudstones near top of section. In Merced River section, Hunter Valley cherts overlie pillow basalts and underlie Penon Blanco volcanics. Thickness 950 feet. Age of Amador group believed to be upper Middle to lower Upper Jurassic.

Occurs along Merced River in southern type section of Amador group. [Name probably derived from Hunter Valley, Mariposa County.]

Huntingdon Formation[1]

Eocene: Southern British Columbia, Canada, and central northern Washington.

Original reference: R. A. Daly, 1912, Canada Geol. Survey Dept. Mines Mem. 38, map 17.

H. A. Coombs, 1939, Geol. Soc. America Bull., v. 50, no. 10, p. 1498. Sedimentary sequence several thousand feet thick borders western margin of Mt. Baker. Various sandstones, shales, arkoses, and thin coal seams are known collectively as Chuckanut formation. Daly (1912) gave name Huntingdon formation to similar strata to the north, but this is only a provisional name to be used until definite correlation can be made with the Chuckanut.

Occurs at and north of Huntingdon, British Columbia, and in northern Washington.

Hunting Hill Greenstone (in Blackstone Series)

Precambrian (?) : Northeastern Rhode Island.

Alonzo Quinn, R. G. Ray, and W. L. Seymour, 1948 *in* Alonzo Quinn and others, Rhode Island Port and Indus. Devel. Comm. Geol. Bull. 3, p. 12–13, geol. map; A. W. Quinn, R. G. Ray, and W. L. Seymour, 1949, Bedrock geology of the Pawtucket quadrangle, Rhode Island-Massachusetts: U.S. Geol. Survey Geol. Quad. Map [GQ–1]. Dark-green to nearly black fine- to medium-grained greenstone, partly massive and partly schistose; includes several types of metamorphosed basaltic rocks. Fine-grained porphyritic andesite facies occurs one-half mile south of Olney

Pond. Contains several small serpentine and talc bodies, also inclusions and intercalated beds of schist, quartzite, and marble. In some areas, interbedded with Mussey Brook schist (new); locally intrudes Westboro quartzite; dikes and sills of Hunting Hill greenstone occur in Sneech Pond schist (new). Included in Blackstone series.

Named for Hunting Hill, Pawtucket quadrangle, Providence County. Numerous ledges of greenstone exposed on top and west side of this hill.

Huntington Dolomite[1]

Middle Silurian: Northeastern Indiana and west-central Ohio.

Original reference: E. M. Kindle, 1904, Indiana Dept. Geology and Nat. Resources 28th Ann. Rept., p. 408.

D. A. Busch, 1939, (abs.) Geol. Soc. America Bull., v. 50, no. 12, pt. 2, p. 1976. Huntington (restricted) represents that part of Huntington formation of northern Indiana which contains Guelph fauna. Lower 43 feet of 70-foot section of Huntington, as exposed at Ridgeville, Randolph County, Ind., relegated to underlying Cedarville formation. Huntington (restricted) and overlying New Corydon limestone are geographically extended into west-central Ohio.

J. B. Patton, 1949, Indiana Div. Geology Rept. Prog. 3, p. 12. Existence of Huntington as a formation has been questioned. Although dolomite identified as Huntington is exposed at numerous places throughout an area of more than 1,600 square miles, contact of base of Huntington on an older formation has not been observed. Many exposures termed Huntington are reefs or beds associated with reefs. Some reefs formerly called "Huntington" are now considered to be Liston Creek or even Mississinewa in age.

J. B. Sangree, Jr., 1960, Dissert. Abs., v. 21, no. 6, p. 1528. Revision of Silurian stratigraphy of northern Indiana proposed, including abandonment of Huntington dolomite of Cumings and Shrock [1928, Indiana Dept. Conserv., Div. Geology Pub. 75].

Type section (redefined): Along dredged rock channel of Little River from NE cor. SW cor. NE¼ sec. 13, T. 28 N., R. 10 E., eastward to west line of sec. 8, T. 28 N., R. 10 E., Huntington County, Ind.

Huntington Series[1]

Triassic(?): Northeastern Oregon.

Original reference: W. Lindgren, 1901, U.S. Geol. Survey 22d Ann. Rept., pt. 2, p. 579.

Occurs in vicinity of Huntington, Baker County.

Hunton Limestone[1] **or Group**

Silurian and Devonian: Southeastern Oklahoma.

Original reference: J. A. Taff, 1902, U.S. Geol. Survey Geol. Atlas, Folio 79.

R. A. Maxwell, 1936, Northwestern Univ. Summ. Doctoral Dissert., v. 4, p. 131–136. Taff gave name Hunton formation to series of limestones and shale that occur between Sylvan shale of Ordovician and Woodford chert of Mississippian(?) age. Reeds (1911, Am. Jour. Sci., 4th, v. 32) divided Taff's Hunton into four units of formational rank (ascending): Chimneyhill limestone (Silurian), Henryhouse shale (Silurian), Haragan shale (Devonian), and Bois d'Arc limestone (Devonian). Reeds (1926) added Frisco limestone (Devonian) above the Bois d'Arc. In this report, Hunton formation as defined by Taff and redefined and subdivided by Reeds is again redefined as follows: Silurian, Chimneyhill limestone with Hawkins, Keel, Cochrane, and Dillard members; Henryhouse formation; Devonian, Kite group with Haragan and Cravatt formations; Bois d'Arc limestone; and Frisco limestone.

T. W. Amsden, 1957, Oklahoma Geol. Survey Circ. 44, p. 1–57; 1959, Oklahoma Geol. Survey Bull. 84, pt. 6, p. 7–311 [1960]. Group consists of sequence of limestones and marlstones unconformably underlain by Sylvan formation and unconformably overlain by Woodford formation. Thickness ranges up to slightly more than 400 feet, but at most places it is much less, due in part to unconformities and facies changes. In areas where group is relatively thick and complete, typical sequence consists of basal series of calcilutites and calcarenites (Chimneyhill formation), overlain by marlstones (Henryhouse and Haragan formations), followed by cherty marlstones (lower Bois d'Arc formation) and calcarenites (upper Bois d'Arc formation) and, locally, Frisco formation. Interpretation of stratigraphic and faunal relationships within group differs from that given by previous workers. However, names introduced by earlier authors, even those proposed in abstract form, have been retained if they are not preoccupied.

Named for exposures near former townsite of Hunton (T. 1 S., R. 8 E.), Coal County. Well exposed within Arbuckle complex and known to have wide distribution in subsurface.

Huntsville Fanglomerate

Pliocene, upper: North-central Utah.

A. J. Eardley, 1955, Utah Geol. Soc. Guidebook 10, p. 39, fig. 9. Incidental mention in discussion of Tertiary history of north-central Utah. Deposited contemporaneously with Harkers fanglomerate in Jordan-Oquirrh area and Mink Creek conglomerate in Cache Valley. Name credited to B. Lofgren.

Recognized in Morgan area.

†Huntsville[1] (Formation)

Mississippian: Northeastern Alabama.

Original reference: E. A. Smith, 1892, Sketch of geology of Alabama: Birmingham, Roberts & Son, pamph.

Named for exposures at Huntsville, Madison County.

Huron Gritstone[1]

Mississippian: Michigan.

Original reference: A. Winchell, 1871, Am. Philos. Soc. Proc., v. 11, p. 73–82.

Probably named for outcrops along Lake Huron in Michigan.

†Huron Group[1]

Upper Devonian and Mississippian: Michigan.

Original reference: A. Winchell, 1861, Michigan Geol. Survey 1st Bienn. Rept. Prog., p. 71, 139.

Probably named for outcrops along Lake Huron in Michigan.

†Huron Group[1]

Mississippian: Indiana.

Original reference: T. C. Hopkins, 1902, Geol. Soc. America Bull., v. 13, p. 519–520.

Named for Huron, Lawrence County.

Huron Member (of Ohio Shale)

Huron Shale[1]

Upper Devonian: Northern Ohio.

Original reference: J. S. Newberry, 1870, Ohio Geol. Survey Rept. Prog. 1869, p. 18.

J. F. Pepper, Wallace de Witt, Jr., and D. F. Demarest, 1954, U.S. Geol. Survey Prof. Paper 259, p. 15–16. Member of Ohio shale. Consists of grayish-black shale which contains large septarian concretions in lower part and thin beds of cone-in-cone limestone in upper part. Cleveland and Huron members essentially identical in lithologic character, and in Erie and Lorain Counties contact between these black shales is drawn arbitrarily below lowest cone-in-cone layer and uppermost zone containing large concretions.

K. V. Hoover, 1960, Ohio Geol. Survey Inf. Circ. 27, p. 16–18. In northern Ohio, the Ohio shale regarded as consisting of three members (ascending): Huron, Chagrin, and Cleveland. Stratigraphic position of Ohio and Chagrin has been disputed. Some researchers regard the Huron as basal member and others the Chagrin. Huron and Cleveland members are for most part lithologically identical. Base of Huron taken as the black shale bed resting upon highest most gray shale (or limestone) bed of underlying formation or unit, which in different places is Plum Brook shale, Prout limestone, Ten Mile Creek dolomite, Olentangy shale, or locally, Silurian or Devonian limestone. Upper limit defined as uppermost black shale in area where gray carbonaceous Chagrin is present, or as top of uppermost layer of carbonate concretions, or base of cone-in-cone structure, if these are observable. Such an arbitrarily placed boundary leaves much to be desired. No divisions have been established in Huron shale. Generally supposed that shale termed "Huron shale" by Newberry comprises all of black shale which Andrews, later in same report, named "Ohio black shale." Newberry's Huron shale represented only the lower mass of black shale which occurs in northern part of State. Presently top of Ohio shale in southern Ohio is considered as corresponding to top of Cleveland shale. Andrew's Ohio shale is regarded equivalent to Newberry's Huron, Chagrin, and Cleveland shales of northern Ohio. Hass (1947, Jour. Paleontology, v. 21) found from study of conodonts that certain genera and species are common only to Huron shale (zone). These same conodonts are mutually present in south-central Ohio as well as in northern part of State. Hass referred to "Huron shale" of central and northern Ohio as the lower Ohio shale zone. Total thickness of Huron not seen in outcrop. Reported average thickness 410 feet.

Named for exposures on Huron River, Huron and Erie Counties. From Berea west to Norwalk, the Huron forms cliffs 5 to 70 feet high along many streams and along shore of Lake Erie.

Huron Bay Slates[1]

Age(?): Northeastern Michigan.

Original reference: T. B. Brooks, 1873, Michigan Geol. Survey, v. 1, pt. 1, p. 155.

Huron City Sandstones and Shales (in Lower Marshall Sandstone)

Mississippian (Kinderhook): Southern Michigan.

H. M. Martin, 1936, The centennial geological map of the southern peninsula of Michigan (1:500,000): Michigan Dept. Conserv., Geol Survey Div. Pub. 39, Geol. Ser. 33. Shown on map legend.

Huronian Series[1]

Precambrian: Great Lakes region.

Original references: W. E. Logan and T. S. Hunt, 1855, Esquisse géologique du Canada p. 29–31; F. D. Adams and others, 1905, Jour. Geology, v. 13, p. 103–104.

F. F. Grout and others, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1070, 1072. In Minnesota classification, the Precambrian is divided into Earlier Medial, and Later. Later Precambrian includes Animikie and Keweenawan groups. Term Huronian not used, principally because only tentative correlations can be made with type Huronian. A further reason to avoid use of term Huronion for Animikie formations is based on original naming of Huronian. When Logan named formations north of Lake Huron, he thought (J. F. Alcock and Committee, 1934, Royal Soc. Canada Trans., v. 28, no. 4) the Animikie and Keweenawan were Paleozoic and excluded them from the Huronian.

Named for exposures on shores of Lake Huron.

Hurrah Slate[1]

Post-Ordovician(?): Northwestern Alaska.

Original reference: P. S. Smith, 1910, U.S. Geo. Survey Bull. 433, p. 50, 59.

Well exposed in Big Hurrah mine located at junction of Big and Little Hurrah Creeks, and on lower 2 or 3 miles of Big Hurrah Creek, Seward Peninsula.

Hurricane Graywacke

Precambrian (Ocoee Series): Western North Carolina, northern Georgia, and eastern Tennessee.

G. W. Stose and A. J. Stose, 1946, (abs.) Geol. Soc. America Bull., v. 57, no. 12, pt. 2, p. 1233. In list of formations, oldest unit in Ocoee series; underlies Great Smoky quartzite.

G. W. Stose and A. J. Stose, 1949, Geol. Soc. America Bull., v. 60, no. 2, p. 274–277, pl. 1. Name Hurricane graywacke is applied to oldest formation of Ocoee series because of its fine exposures on Little Hurricane Creek and at Hurricane settlement, North Carolina, 6 miles northeast of Hot Springs, N.C. Initial sediments of graywacke in this vicinity and northeastward rest on granite gneiss of injection complex. In Asheville and several folios, Keith (1904, folio. 116; 1905, folio 124; 1907, folio 151; Mount Guyot, unpub.) used name Snowbird formation for these beds which he assigned to Lower Cambrian. He included part of Great Smoky conglomerate in Snowbird formation at type locality and elsewhere. In 1904 and 1907, he applied name Snowbird also to well-established Lower Cambrian rocks. For these reasons, it is believed that name Snowbird is misleading, and new name Hurricane is applied to graywacke which underlies Great Smoky quartzite and is basal formation of Ocoee series. Hurricane is fine- to medium-grained grayish-black or grayish-green graywacke consisting principally of angular grains of glassy quartz and feldspar in matrix of mica and black, iron-oxide dust. On southeast side of belt of series, the Hurricane rests unconformably on Precambrian injection complex. On northwestern side of belt it is exposed in places along Great Smoky overthrust. Occurs in anticlines within the belt, and in Georgia surrounds early Precambrian rocks exposed in Fort Mountain, Corbin, and Salem Church anticlines. North of Blairsville, Ga., the Hurricane is basal part of Ocoee series that was mapped as Carolina gneiss by La Forge and Phalin (1913, U.S. Geol. Survey Geol. Atlas, Folio 187). Southwest of Cartersville, Ga., and in Alabama, the formation is green phyllite. In Georgia, Hayes (unpub. folio) called part of this phyllite Gilmer schist, and Crickmay (1936) included it in Talladega series. In Alabama, it was mapped as Talladega slate by Butts (1926, Paleozoic rocks of Alabama: Alabama Geol. Survey). In Corbin anticline, the Hurricane is thrust over Corbin granite. In Fort and Cohutta Mountains, overlies Fort Mountain gneiss.

S. S. Oriel, 1950, North Carolina Div. Mineral Resources Bull. 60, p. 26–27. Discussion of Hot Springs Window, Madison County. Term Snowbird considered preferable to Hurricane graywacke in this area.

Type locality: Exposures on Little Hurricane Creek and at settlement of Hurricane, N.C., at junction of the creek with Big Laurel Creek (Asheville quadrangle), 6 miles northeast of Hot Springs, N.C. Southeastern belt extends from 3 miles southwest of Erwin, Tenn., through type locality, and southwestward to northern Georgia and ends at Mount Oglethorpe.

Hurricane Marine Lentil (in Landrum Member of Cook Mountain Formation)

Eocene, middle: Eastern Texas.

H. B. Stenzel, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 9, p. 1665–1670. Fossilliferous, bentonite-bearing marine lentil about 25 feet thick in lower part of Landrum member [of middle Eocene age].

Probably named for occurrence near Hurricane Bayou, Houston County.

Hurricane Bridge Limestone

Middle Ordovician: Southwestern Virginia.

R. L. Miller and W. P. Brosgé, 1950, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 104 (2 sheets). Cryptocrystalline tan and gray thin-bedded limestone with prominent zones of massive-bedded cryptocrystalline birdseye limestone and zones of buff- and red-weathering argillaceous shaly limestone. Thickness 288 to 368 feet. Overlies Martin Creek limestone (new); underlies Woodway limestone (new). Same as redbed member of Lowville limestone on U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 76.

R. L. Miller and W. P. Brosgé, 1954, U.S. Geol. Survey Bull. 990, p. 32 (table 1), 33–34, 47–51, pl. 1. Further described, and type locality and type section given. Discussion of problems of correlation and summary of nomenclature of Middle Ordovician formations in Lee and Tazewell Counties.

Type locality: Vicinity of Hurricane Bridge and Hurricane Chapel on Powell River 2½ miles southwest of Jonesville, Lee County, Lee County, Va. Type section is along State Route 70 north of Sewell Bridge.

Hurricane Mesa Volcanics

Tertiary: Northwestern Wyoming.

R. D. Krushensky, 1960, Dissert. Abs., v. 21, no. 4, p. 849. Flows, tuffs, and tuff-breccias. Overlie unit referred to as post-Closed volcanics.

Hurricane Mesa area, Park County.

Hurwal Formation

Upper Triassic: Northeastern Oregon.

W. D. Smith and J. E. Allen, 1941, Oregon Dept. Geology and Mineral Industries Bull. 12, p. 6 (fig. 2), 13–14. Name applied to conformable series of argillaceous sediments that lies both stratigraphically and topographically above Martin Bridge formation. Grades within a few tens of feet from underlying Martin Bridge limestone through argillaceous limestone and calcareous shale, to shale and hornfels. Thickness 1,500 feet on Hurricane Divide and Sentinel Peak. Top not exposed although upper limestone interbedded in formation on Hurricane Divide may represent highest Mesozoic horizon in area.

Named from Hurwal Divide in center of Wallowa quadrangle, Wallowa County.

Hushpuckney Shale[1] Member (of Swope Limestone)

Pennsylvanian (Missouri Series) : Eastern Kansas, southwestern Iowa, and northwestern Missouri.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. 6th Ann. Field Conf. Guide Book, p. 85, 90, 97.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4) ; 1949, Kansas Geol. Survey Bull. 83, p. 68 (fig. 14), 88; F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 11. Hushpuckney shale member of Swope formation; underlies Bethany Falls limestone member; overlies Middle Creek limestone member. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

T. L. Welp, L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 64, p. 418 (fig. 1), 421. Thickness about 4 feet in section measured near Winterset, Madison County.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 28, fig. 5. Gray and fossiliferous above and black and fissile at base. Underlies Bethany Falls limestone member; overlies Middle Creek limestone member.

Typically exposed at railway cut, center north side sec. 13, T. 19, S., R. 23 E., Miami County, Kans. Named for creek south of Fontana.

Hutchinson Salt Member (of Wellington Formation)

Hutchison Salt Bed (in Sumner Group)[1]

Permian: South-central Kansas (subsurface).

Original reference: I. Perrine, 1918, Am. Assoc. Petroleum Geologists Bull., v. 2, p. 73–90.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 40–41. Occurs in middle part of Wellington; does not crop out.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Shown on correlation chart as Hutchinson Saltstone Member of Wellington.

Probably named for Hutchinson, Reno County.

Hutchison limestones[1]

Devonian: Iowa.

Original reference: C. R. Keyes, 1931, Pan-Am. Geologist, v. 56, p. 318, 348.

Hyampom Lake Beds[1]

Miocene: Northwestern California.

Original reference: J. S. Diller, 1902, U.S. Geol. Survey Bull. 196, p. 41–43.

O. P. Jenkins, 1943, California Div. Mines Bull. 118, pt. 4, p. 41–43. Oligocene or Eocene.

Occurs in Hyampom Valley, Trinity County.

Hyco Quartz Porphyry[1]

Precambrian: South-central Virginia and central northern North Carolina.

Original reference: F. B. Laney, 1917, Virginia Geol. Survey Bull. 14, p. 15, 19, 20–23, map.

H. E. LeGrand, 1960, Virginia Div. Mineral Resources Bull. 75, p. 16–17. Underlies Aaron slate in Halifax County.

Named for exposures along Hyco River, Halifax County, Va.

Hyde Formation (in Izee Group)

Middle Jurassic: East-central Oregon.

R. L. Lupher, 1941, Geol. Soc. America Bull., v. 52, no. 2, p. 227 (table 1), 229, 255–259. More than 1,000 feet of massive blue-gray sandstones in lower part of Izee group. Underlies Snowshoe formation (new); overlies Warm Springs formation of Colpitts group (both new).

Type area: At South Fork Bridge, sec. 30, T. 17 S., R. 28 E., in bottom of South Fork Valley. Named for John Hyde Ranch at mouth of Poison Creek, Crook County.

Hyde Granite[1]

Precambrian: Northwestern New York.

Original reference: A. F. Buddington, 1934, New York State Mus. Bull. 296, p. 85, 86–88.

Occurs southwest of Hickory Lake in bend between Hickory Creek, Hammond quadrangle. Probably named for Hyde School.

Hyde Manor Limestone[1]

Middle Ordovician: West-central Vermont.

Original reference: Arthur Keith, 1932, Washington Acad. Sci. Jour., v. 22, p. 360, 368–369.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, p. 34. Keith (1932) named Hortonville slate from town off Hortonville, where it overlies Trenton "Hyde Manor limestone" (Orwell and Glens Falls).

Named for exposures at summer resort, called Hyde Manor, south of Sudbury, Brandon quadrangle.

Hyder Quartz Monzonite[1]

Jurassic or Cretaceous: Southeastern Alaska.

Original reference: A. F. Buddington, 1929, U.S. Geol. Survey Bull. 807, p. 29–39, 58–59, maps.

F. M. Byers, Jr., and C. L. Sainsbury, 1956, U.S. Geol. Survey Bull. 1024–F, p. 126, pl. 13. Mentioned in report on tungsten deposits of Hyder region. Hyder quartz monzonite and Boundary granodiorite are included in younger Coast Range intrusives.

Named for exposures at Hyder.

Hye Granite

Precambrian: Central Texas.

V. E. Barnes, R. F. Dawson, and G. A. Parkinson, 1947, Texas Univ. Bur. Econ. Geology Pub. 4246, p. 49, 50 (fig. 3). Mapped as Hye granite. Crops out as mass of weathered boulders and is part of old monadnock of

Precambrian peneplain which is surrounded by Cambrian sediments up to base of Wilberns formation.

Outcrops in area along Pedernales River at Blanco-Gillespie County line, about 22 miles from Fredericksburg.

Hygiene Sandstone Member (of Pierre Shale)[1]

Upper Cretaceous: Central northern Colorado.

Original reference: N. M. Fenneman, 1905, U.S. Geol. Survey Bull. 265.

G. R. Scott and W. A. Cobban, 1959, Rocky Mountain Assoc. Geologists 11th Ann. Field Conf. Symposium, p. 124–126, 129 (fig. 3). About 6 miles north of Boulder, consists of basal 240-foot thick light-olive- to yellowish-gray thin-bedded friable sandstone with large light-gray silty limestone concretions in upper part; a medial 38-foot dark-gray clayey shale with orange-brown iron-stained limestone concretions; and an upper 126-foot-thick ridge-forming dusky-yellow thick-bedded friable medium-grained sandstone. Three miles north of Kassler, member is 1,420 feet above base of Pierre, is 600 feet thick and consists of dusky-yellow soft shaly sandstone that contains, in lower part and at top, masses as much as 12 feet in diameter of gray rough hard crystalline limestone; beds of orange-brown ironstone present in upper half. Separated from younger Terry member by as much as 387 feet of olive-gray sandy shale. Marine invertebrate megafossils.

Typically developed in ridge which passes within 1½ miles of village of Hygiene, Boulder County.

Hyndman Formation[1]

Precambrian(?): Central Idaho.

Original reference: L. G. Westgate and C. P. Ross, 1930, U.S. Geol. Survey Bull. 814, p. 10–17.

C. P. Ross and J. D. Forrester, 1947, Geologic map of the State of Idaho (1:500,000): U.S. Geol. Survey. Precambrian(?)

C. P. Ross and J. D. Forrester, 1958, Idaho Bur. Mines and Geology Bull. 15, p. 3. Precambrian(?) rocks in Pioneer Mountains include Hyndman formation, about 6,600 feet thick, and East Fork formation, about 1,560 feet thick. Hyndman consists mainly of quartzite but includes green hornfels in upper part and schist member in lower part.

Well exposed in Hyndman Peak and in cirques at its southern base, Hailey quadrangle.

Hyrum Dolomite Member (of Jefferson Formation)

Devonian: Northern Utah.

J. S. Williams, 1948, Geol. Soc. America Bull., v. 59, no. 11, p. 1139, 1140. Predominantly black dolomite and limestone; minor amounts of calcareous sandstone. Thickness 840 to 1,200 feet. Underlies Beirdneau sandstone member (new), contact gradational; disconformably overlies Water Canyon formation (new).

Named for exposures in mouth of Blacksmith Fork Canyon, sec. 7, T. 10 N., R. 2 E., east of town of Hyrum, Logan quadrangle.

Iaeger Sandstones (in New River Formation[1] or Group)

Pennsylvanian: Southern West Virginia.

Original reference: R. V. Hennen and R. M. Gawthrop, 1915, West Virginia Geol. Survey Rept. Wyoming and McDowell Counties, p. 186–191.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey [Repts.] Greenbrier County, p. 215, 216, 224–226. Occurrence of Iaeger sandstones and shales discussed in Greenbrier County. Included in New River group, Pottsville series.

Named for occurrence at Iaeger, McDowell County.

Iatan Limestone (in Pedee Group)

Iatan Limestone (in Lansing Group)

Iatan Limestone or Limestone Member (in Douglas Group or Formation)[1]

Pennsylvanian (Missouri Series): Northwestern Missouri, southwestern Iowa, and eastern Kansas.

Original reference: C. R. Keyes, 1899, Am. Geologist, v. 23, p. 306.

H. S. McQueen and F. C. Greene, 1938, Missouri Geol. Survey and Water Resources, 2d ser., v. 25, p. 28. Included in Pedee group in Missouri.

L. W. Wood, 1941, Iowa Geol. Survey, v. 37, p. 294 (table), 295. Iatan and Weston formations included in Lansing group. Term Pedee dropped from Iowa nomenclature.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. vi (fig. 2), 15. Overlies Weston shale. Youngest known formation of Missouri series in Missouri.

R. C. Moore, 1949, Kansas Geol. Survey Bull. 83, p. 121–122. Conformably overlies Weston shale and disconformably overlain by Stranger formation of Virgil series. Limestone is light bluish gray or nearly white, but parts are mottled brown after prolonged weathering. Thickness less than 5 feet to about 22 feet, maximum is short distance south of Iatan. In Kansas, occurs southward to vicinity of Baldwin, Douglas County. Limestone that has been called Iatan in country farther south is mostly a lower Virgilian unit, the Haskell, but some limestone outcrops may represent true Iatan. Pedee group.

Named for exposures at Iatan, Platte County, Mo.

Iberville Formation[1]

Middle Ordovician: Southern Quebec, Canada, and northwestern Vermont.

Original reference: T. H. Clark, 1934, Geol. Soc. America Bull., v. 45, no. 1, p. 5.

David Hawley, 1957, Geol. Soc. America Bull., v. 68, no. 1, p. 58, 63–68. Noncalcareous shale, rhythmically interbedded with thin quartz-silty dolomite beds; uniform, fine-grained dolomite beds; and in lower part, with calcareous shale. Thickness 1,000 to 2,000 feet. Underlies Hathaway formation (new); overlies Stony Point formation. Derivation of name given.

Named for wide outcrop belt in Iberville County, southern Quebec.

Ibex Limestone

Lower Permian: North-central Texas.

M. G. Cheney, 1948, Abilene Geol. Soc. [Guidebook] Spring Field Trip, June 11–12, p. 5. Proposed to replace preoccupied "Dothan" limestone. Normally 2 to 3 feet thick, between clays of Watts Creek shale. Resistant bed; outcrops characterized by large slabs at various angles.

Typical outcrops occur 500 feet east of northwest corner of Blind Asylum Survey No. 51, one-half mile southeast of Ibex townsite, and also just north and west of Ibex field along Hubbard Creek. Name derived from Ibex oil field in east-central Shackelford County.

Ice Box Shale

Middle Ordovician: Western South Dakota.

M. R. McCoy, 1952, Billings Geol. Soc. Guidebook 3d Ann. Field Conf., p. 45–46. Olive-green shale 30 to 45 feet thick. Conformably underlies Roughlock siltstone (new); conformably overlies Aladdin sandstone (new).

Type section: In secs. 14 and 23, T. 5N., R. 3 E., about one-half mile west of junction of U.S. Highways 14 and 85 [Lawrence County]. Named from Ice Box Gulch.

Ice Springs Craters Flow

Recent: Central Utah.

G. B. Maxey, 1946, Am. Jour. Sci., v. 244, no. 5, p. 328, pl. 1. Basalt flow. Occurred subsequent to disappearance of Lake Bonneville and probably at a time well into Recent. Covers small area on eastern edge of Pavant flow (new), earliest flow in area.

P. E. Dennis, G. B. Maxey, and H. E. Thomas, 1946, Utah State Engineer Tech. Pub. 3, p. 26, pl. 1. Basalt scoria, lapilli, and lava in flows having thickness of 30 feet or more. Maximum thickness 400 feet.

Occurs in Pavant Range, about 8 miles west of Fillmore, Millard County.

Iconium Member (of Wellington Formation)[1]

Permian: Central northern Oklahoma.

Original reference: J. M. Patterson, 1933, Am. Assoc. Petroleum Geologists Bull., v. 17, no. 3, p. 243, 249.

D. A. Green, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 12, p. 1522 (fig. 2). Permian of Oklahoma divided into three major time divisions (ascending) Wanette, Minco, and Upper Red-Beds. Iconium shale is in Minco division.

Named for town of Iconium, near [S¼ cor. sec. 10,] T. 16 N., R. 1 E., Logan County.

Idaho Group

Idaho Formation[1]

Pliocene and Pleistocene: Western and southern Idaho and southeastern Oregon.

Original reference: E. D. Cope, 1884, Philadelphia Acad. Nat. Sci. Proc. 1883, v. 35, p. 135.

H. E. Wheeler and E. F. Cook, 1954, Jour. Geology, v. 62, p. 528. Discussion of structural and stratigraphic significance of Snake River capture, Idaho-Oregon. On basis of this study it is believed that Idaho formation as restricted by Lindgren (1898, U.S. Geol. Survey Ann. Rept., pt. 3) is essentially valid and that Idaho formation as redefined by Kirkham (1931 Jour. Geology, v. 39, no. 3) is composite and invalid.

C. P. Ross and J. D. Forrester, 1958, Idaho Bur. Mines and Geology Bull. 15, p. 16–17. Rocks shown on Idaho State map (Ross and Forrester, 1947) as Payette and related strata include beds that, although having many resemblances, have considerable range in age. Rocks so grouped have affinities to Payette formation (commonly regarded as Miocene), Latah formation (middle or upper Miocene), and Idaho formation (Pliocene). Early concept that Payette and Idaho formations represent two successive stages of large lake, with division between them at some horizon not definitely fixed, within sedimentary succession above Columbia River basalt (Lindgren, 1898) is so much at variance with facts now known that it must be abandoned. Kirkham (1931) restricted Payette to sedimentary rock that generally occurs interbedded with Columbia River basalt, commonly 600 feet below top of basalt unit—a suggestion that has much to commend it in areas in which he worked. In a general way, term Idaho formation is applied to Cenozoic sedimentary rocks in and near western part of Snake River Plain that have broad lithologic and genetic resemblance to Payette but are younger. Strata of Idaho formation as thus limited are, on the average, somewhat finer grained and less firmly consolidated than Payette, but this distinction not sufficient to be readily used in mapping. The unit [Idaho], probably several thousand feet thick, is most extensive of those grouped as Payette and related strata on State map. It is interbedded with Snake River basalt and overlies silicic and older rocks, in many places with appreciable unconformity. Name Idaho formation has not been applied in eastern Idaho although similar rocks exist there. In those places, the tendency has been to assign local names to strata of Idaho affinities, as for example, name Hagerman lake beds.

E. M. Baldwin, 1959, Geology of Oregon: Ann Arbor, Mich., Edwards Brothers, Inc., p. 108. Thick series of continental sediments that crop out along eastern margin of [Owyhee] reservoir have been referred to as Idaho formation in accordance with usage proposed by Kirkham (1931) in which he restricted Payette formation to pre-Owyhee basalt sediments and included remaining post-basalt Tertiary sediments in Idaho formation. Idaho formation as originally used by Cope referred to beds that are probably younger in age and somewhat different in lithology. Evidence indicates that several stratigraphic units are present in post-Owyhee continental sediments and term Idaho formation is not applicable. It is used here in broader sense as Idaho group.

Name was applied to sediments deposited in Lake Idaho.

Idaho Springs Formation[1]

Precambrian (Gunnison River Series) : Central northern Colorado.

Original reference: S. H. Ball, 1906, Am. Jour. Sci., 4th, v. 21, p. 374.

T. S. Lovering and E. N. Goddard, 1950, U.S. Geol. Survey Prof. Paper 223, p. 19–20, pls. Oldest known rocks in Front Range. Consists chiefly of quartz-biotite schists and quartz-biotite-sillimanite schists; quartzite, quartz schists, or quartz gneisses are common in some localities. Full thickness unknown; estimated thickness about 20,000 feet. Underlies Swandyke hornblende gneiss.

Richard Van Horn, 1957, U.S. Geol. Survey Geol. Quad. Map GQ–103. Described in Golden quadrangle where it is principally gneiss and schist; some quartzite; hornblende gneiss; and garnet gneiss. Intruded by pegmatite and biotite syenite dikes. Underlies Fountain formation, angular unconformity.

Typically exposed in hills surrounding Idaho Springs, Georgetown quadrangle.

†Idak Basalt

Tertiary and Quaternary: Southwestern Alaska.

F. M. Byers, Jr., and others, 1947, U.S. Geol. Survey Alaskan Volcano Inv. Rept. 2, pt. 3, p. 28, pl. 3. Thickness of about 2,000 feet of basalt flows and subordinate interbedded tuff-breccia. Individual flows from 10 to 100 feet thick. Flow rocks are gray basalt and range in texture from aphanitic to coarsely porphyritic. Lava flows composing peak of Mount Idak are intruded by closely spaced network of dikes comprising 20 to 30 percent of total rock.

F. M. Byers, Jr., 1959, U.S. Geol. Survey Bull. 1028–L, p. 309. Name abandoned. Unit included in Ashishik basalt (redefined).

Exposed on Mount Idak and ridges to the northeast, which are remnants of an ancient volcano, herein named Idak Volcano, on Umnak Island in eastern part of Aleutian Islands.

Idalia Clay[1]

Tertiary: Southeastern Missouri.

Original reference: C. F. Marbut, 1902, Missouri Univ. Studies, v. 1, no. 3, p. 18, 21, 32.

Named for exposures at Idalia, Stoddard County.

Ideal Quarry Member (of Chimneyhill Limestone)

Lower Silurian: South-central Oklahoma.

T. W. Amsden, 1957, Oklahoma Geol. Survey Circ. 44, p. 6 (fig. 2), 7, 9-11, fig. 4. Name introduced to replace Maxwell's (1936) Hawkins limestone which is preoccupied. Maximum thickness 5 feet; commonly 3 feet or less. Member actually represents basal part of the Keel and grades upward into it through transitional beds; upper contact arbitrary, but below this transitional zone the strata have a distinctive lithology and color which warrants their separation from the overlying Keel. Overlies Sylvan formation.

Type section: Ideal quarry of the Ideal Cement Company at Lawrence, sec. 36, T. 3 N., R. 5 E., Pontotoc County.

Idenbro Limestone Member (of Lenapah Limestone)

Pennsylvanian (Des Moines Series): Southeastern Kansas, south-central Iowa, western Missouri, and northeastern Oklahoma.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 38, pt. 11, p. 339, 340. Light-gray nodular crystalline algal limestone. Thickness about 3 feet. Overlies Perry Farm shale member (new); underlies Memorial shale.

J. M. Jewett, 1945, Kansas Geol. Survey Bull. 58, p. 69–70. Discussed as cyclothem in Lenapah megacyclothem.

L. M. Cline and F. C. Greene, 1950, Missouri Geol. Survey and Water Resources Rept. Inv. 12, p. 25; C. M. Cade 3d, 1953, Tulsa Geol. Soc. Digest, v. 21, p. 134. Idenbro limestone can be traced into Sni Mills limestone member in Jackson County, Mo.; therefore, name Idenbro is suppressed as a synonym of Sni Mills.

Type locality: SW¼ sec. 2, T. 32 S., R. 18 E., Labette County, Kans.

Iditarod Basalt

Lower(?) and Upper Cretaceous: Southwestern Alaska.

W. M. Cady and others, 1955, U.S. Geol. Survey Prof. Paper 268, p. 21 (table), 42, 47–50, pl. 1. Chiefly massive basalt lava flows underlain by comparatively thin but widely distributed basal zone of sedimentary breccia. Similar breccia zones, irregularly distributed, are interbedded with flows. Dense, uniformly fine-grained and massive, dark-colored basalt predominates. Fresh specimens commonly greenish black, though some are blue black and purplish black. Rock weathers brown. Breccia commonly mottled with dark shades against light background; weathers shades of brown and mottling does not show on weathered surface. Breccia composed of rock eroded chiefly from lava flows. Thickness estimated between 2,000 and 3,000 feet. Disconformably overlies Kuskokwim group (new) and possibly intertongues with group. Believed to be of middle or late Late Cretaceous age.

Typically and best exposed in wide tract northeast of Montana Creek in vicinity of DeCourcy Mountain. Forms range of hills southeast of Iditarod River, and named after the river. Range extends northeastward from Russian Mountains for nearly 50 miles.

Idlefornso Formation

See Ildefonso, correct spelling.

Ignacio Quartzite[1]

Upper Cambrian: Southwestern Colorado.

Original reference: W. Cross and A. C. Spencer, 1899, U.S. Geol. Survey Geol. Atlas, Folio 60, p. 8.

Harley Barnes, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 8, p. 1780–1791. Heretofore Ignacio quartzite in southwestern Colorado has been thought to be Late Cambrian in age, disconformably overlain by Elbert formation of Late Devonian age, and everywhere underlain by eroded older rocks. Recent fieldwork suggests that the quartzite is Devonian in age, that it forms essentially continuous depositional sequence with overlying Elbert formation and Ouray limestone, and that, in Animas River valley, Ignacio has been intruded by granite porphyry of Devonian or younger age.

F. H. T. Rhodes and J. H. Fisher, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 11, p. 2508–2518. Referred to Late Cambrian or Early Ordovician on basis of occurrence of oboloid brachiopods. This is contrary to recent conclusion of Barnes (1954) but in support of age provisionally assigned by earlier workers. Major unconformity occurs between Ignacio and overlying Elbert of Late Devonian age. Ignacio was deposited on essentially Precambrian terrane. Suggested that rocks underlying Ignacio in Animas Valley are not intrusive into the Ignacio. Thickness about 112 feet. Locally overlies Twilight granite.

Named for development on bench where Ignacio Lake is situated, Silverton quadrangle.

Ignek Formation[1]

Lower and Upper Cretaceous: Northern Alaska.

Original reference: E. D. Leffingwell, 1919, U.S. Geol. Survey Prof. Paper 109, p. 103, 120, map.

R. W. Imlay and J. B. Reeside, Jr., 1954, Geol. Soc. America Bull., v. 65, no. 3, pl. 1 (facing p. 246). Lower and Upper Cretaceous.

Type locality: On south side of Red Hill, in Ignek Valley at west end of Sadlerochit Mountains.

Iisa Beds or Formation

Pliocene: Caroline Islands (Kusaie).

Risaburo Tayama, 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 70 (table 5) [English translation in library of U.S. Geol. Survey, p. 85]; S. Hanzawa *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 40. Conglomerate and gravelly agglomerate; resembles conglomerate of East Caroline beds. In contact with lower basalt and East Caroline beds. Some silicified wood and marine mammalian bones.

Kasaie Island.

Ijamsville Phyllite

Lower Paleozoic(?) (Glenarm Series): Western Maryland.

A. I. Jonas and G. W. Stose, 1938, Washington Acad. Sci. Jour., v. 28, no. 8, p. 346. Blue, green, or purple phyllitic slate probably of tuffaceous origin. Part of a volcanic series including green metabasalt, blue meta-andesite, and purplish-red aporphyolite flows. In part, contains flattened amygdaloidal blebs, but in many places close folding and metamorphism have obscured its volcanic character. In places, is infolded with Silver Run limestone (new). Lies to west of Marburg schist (new) and may be in part equivalent to it. Precambrian(?).

A. J. Stose and G. W. Stose, 1946, Maryland Dept. Geology, Mines and Water Resources [Rept. 12] Carroll and Frederick Counties, p. 66, 67, 121–126. In vicinity of Shriver's Mill, phyllite is bordered on southeast by Wissahickon albite-chlorite schist and west and southwest of Taylorsville by Marburg schist. From point near New Windsor westward to Bark Hill, band of phyllite follows north border of Sams Creek metabasalt (new) and Wakefield marble. In region southwest of Union Bridge, phyllite is folded with the metabasalt and [Libertyville] metarhyolite (new). Near Ijamsville and Moravia, the Ijamsville is surrounded by Urbana phyllite. Along western edge of Martic overthrust block, east of Frederick Valley, phyllite forms narrow belt that extends from vicinity of Ladiesburg, at border of Triassic rocks, southwestward to Monocacy River. Sugarloaf Mountain syncline encloses Urbana phyllite and associated quartzites, and Sugarloaf Mountain quartzite. Syncline is overturned to northwest and beds dip southeast.

D. M. Scotford, 1951, Geol. Soc. America Bull., v. 62, no. 1, p. 49. Phyllites of Sugarloaf area, which have been considered volcanic members of Glenarm series (Stose and Stose, 1946), are Harpers phyllite. This conclusion based on structural evidence that local stratigraphic section is reverse of that previously reported and therefore section shows same sequence of beds as known Cambrian section 8 miles to west. Stose and Stose, who considered area to be a syncline, divided phyllite [Harpers] into Ijamsville and Urbana phyllites. Although this division may be valid, it is difficult to map the contacts accurately and both units are considered to be part of the Harpers.

U.S. Geological Survey currently designates the age of the Glenarm Series as Lower Paleozoic(?)

Named from Ijamsville, Frederick County, Md., where it has been quarried.

Ilchester Granite[1]

Precambrian(?): Eastern Maryland.

Original reference: W. H. Hobbs, 1889, Am. Jour. Sci., 3d, v. 38, p. 225–228.

Occurs at Ilchester, Howard County.

Ildefonso Formation

Upper Cretaceous: Puerto Rico.

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm. and Princeton Univ. Dept. Geology, p. 24–44, geol. map. Consists of volcanic conglomerate, conglomeratic sandstone, tuffaceous siltstone, thin-bedded argillaceous limestone, and massive argillaceous limestone. The massive limestone occurs as lenses throughout formation; the two largest lenses are herein named Santa Ana and Jueyes. Total thickness difficult to calculate because of irregular structural trends imposed by Palmarejo stock and because top of formation is nowhere exposed. Lower part of formation (Santa Ana lens to base) is about 3,000 feet. Intruded by Pasto andesite (new). Formation includes part of Río Jueyes, Guayama, and Sierra de Cayey "series" of Hodge (1920) which could not be recognized in present study. Part of Hodge's Río Descalabrado[s] "series" also assigned to Ildefonso. Disconformably overlies Robles formation; unconformably underlies Jacaguas group; interfingers with Toa Vaca formation (new).

Type area: Barrio San Ildefonso to southeast of Coamo. Crops out largely in Coamo quadrangle but extends into Barranquitas, Orocovis, and Río Descalabrado quadrangles.

Iles Formation (in Mesaverde Group)[1]

Upper Cretaceous: Northwestern Colorado.

Original reference: Named by E. T. Hancock, but publication of report delayed so that name first appeared in U.S. Geol. Survey Press Memo. 16037, Oct. 1, 1923 on map of Hamilton and Seeping Spring Gulch domes and vicinity, Moffat County.

N. W. Bass, J. B. Eby, and M. R. Campbell, 1955, U.S. Geol. Survey Bull. 1027–D, p. 154–157, pl. 19. In lower part of Mesaverde group. Conformable with Mancos shale below and Williams Fork formation above. Lower two-thirds of formation, 1,000 to 1,100 feet, consists of massive ledge-forming beds of light-brown, light-gray, and white sandstone interbedded with gray sandy shale, shale, and, in its upper part, coal beds; upper one-third is shale sequence capped by cliff-forming sandstone, which together are about 600 feet thick. Contains four persistent sandstones: Tow Creek member at base, double ledge-forming sandstone sequence 400 feet or more above base; light-gray sandstone sequence of variable composition associated with upper (no. 3) coal of lower group and situated about 900 to 1,000 feet above base; and Trout Creek limestone member at top.

R. E. Kucera, 1959, Rocky Mountain Assoc. Geologists [Guidebook] 11th Ann. Field Conf., p. 43–44, figs. 3, 4. Described in Yampa district. Thickness 1,350 to 1,580 feet. Includes Tow Creek sandstone member at base, Oak Creek sandstone member (new) 920 feet above base, and Trout Creek sandstone member at top. Overlies Mancos shale; underlies Williams Fork formation.

Forms nearly all of Iles Mountain.

Ilion Shale

Middle Silurian (Lockportian): Central New York.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser., no. 1. Consists of about 60 feet of sparsely fossiliferous calcareous gray-black shale with interbedded dolomite layers containing stromatoporoids. Overlies Herkimer sandstone; underlies Vernon shale.

Type section: Starch Factory Creek, 5 miles west-southwest of Ilion, Herkimer County.

Illahe Formation[1]

Oligocene, middle: Northwestern Oregon.

Original reference: T. P. Thayer, 1933, Pan-Am. Geologist, v. 59, no. 4, p. 317.

T. P. Thayer, 1936, Jour. Geology, v. 44, no. 6, p. 703, 704; 1937, Geol. Soc. America Bull., v. 48, no. 11, p. 1614. May be 2,000 to 3,000 feet thick. Middle Oligocene

T. P. Thayer, 1939, Oregon Dept. Geology and Mineral Industries Bull. 15, p. 6–7. Underlies Stayton lavas. Type locality designated. As geological mapping of Willamette Valley progresses, it may be advisable to drop name Illahe as synonym for either Eugene or Pittsburg Bluff formations.

Type locality: Illahe Hill, which crosses range line east of sec. 1, T. 8 S., R. 4 W., about one-half mile east of Willamette River, Marion County.

Illinoian Glaciation

Illinoian Drift,[1] Till

Illinoian Stage, Age

Illinoian stage of glaciation[1]

Pleistocene: Mississippi Valley.

Original reference: T. C. Chamberlain, 1896, Jour. Geology, v. 4, p. 872–876.

M. M. Leighton and H. B. Willman, 1950, Jour. Geology, v. 58, no. 6, p. 602 (fig. 2). Illinoian stage includes (ascending) Payson, Jacksonville, and Buffalo Hart substages.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 35, 52 (fig. 2), 110. Illinoian age (stage) is glacial interval next following Yarmouthian. Followed by Sangamonian. Illinoian stage represented in Kansas by Crete and Loveland members of Sanborn formation. Crete and Loveland are classed as formations in Nebraska. In Iowa and Illinois, term Centralian used to include Illinoian and Sangamonian.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 133–139. Illinoian stage subdivided into Loveland, Payson, Jacksonville, and Buffalo Hart substages. Illinoian drift forms principally till plains or ground moraines —the Buffalo Hart, which crosses Beardstown and Vermont quadrangles, and the Jacksonville, which crosses Beardstown quadrangle and is overridden by Buffalo Hart moraines in northeast part of quadrangle.

Name amended to Illinoian Glaciation to comply with Stratigraphic Code adopted 1961.

Named for development in Illinois.

Illipah Formation

Upper Mississippian: Nevada and Utah.

F. W. Christiansen, 1951, Utah Geol. Soc. Guidebook 6, p. 76. Mentioned in summary of structural history of Great Basin province in Utah and eastern Nevada. Referred to as tongues of sandstone and conglomerate that lense eastward into dark-gray marine shales.

H. J. Bissell, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 8, p. 1427 (fig. 3), 1433 (fig. 9), 1434–1435 (fig. 10). As shown on correlation chart and diagrams, the Illipah underlies Ely, Callville, and Bird Spring formations and overlies Chainman, Rogers Spring, and Monte Cristo formations.

Walter Sadlick, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 81–82, 83 (fig. 1), 84. Discussion of aspects of Chainman formation. The Chainman is recognized as a valid stratigraphic unit. Rather than formally recognize Diamond Peak and Scotty Wash as distinct units, the writer [Sadlick] prefers to refer to these as facies within the Chainman. Term Illipah (Christiansen, 1951) is suppressed as synonomous with Diamond Peak, and term should not be used for limestone sequence in upper part of Chainman.

Grant Steele, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 99. Scotty Wash quartzite of Pioche district and Illipah sandstone of Hamilton district are same lithogenetic units. Scotty Wash quartzite has priority; recommended that name Illipah be abandoned.

Type locality and derivation of name not stated.

Illipah Formation

Eocene: Northeastern Nevada.

T. E. Eakin, 1960, Nevada Dept. Conserv. Nat. Resources Rept. 1, p. 26. Fresh-water limestone, conglomerate, and interbedded tuff. Thickness 1,500 feet or more. Unconformably underlies Lake Newark formation (new); unconformably overlies Newark Canyon formation. Name credited to F. L. Humphrey (in press).

F. L. Humphrey, 1960, Nevada Bur. Mines Bull. 57, p. 41–42, pl. 1. Formal proposal of name. Includes two members; lower consists of limestone and chert conglomerate, calcareous sandstone, and vuggy limestone which resembles tufa; and upper member contains well-bedded marl and fresh-water limestone with interbedded altered tuffs near middle. Total thickness, measured from partial sections, more than 1,500 feet. Unconformably underlies Lake Newark formation; overlies unnamed conglomerate and sandstone.

Named for exposures on Illipah Creek in northern part of White Pine mining district, White Pine County.

Ilmon Basalt

Miocene, lower(?); Southern California.

T. W. Dibblee, Jr., and C. W. Chesterman, 1953, California Div. Mines Bull. 168, p. 12 (fig. 2), 37–38, pls. 1, 2, 3. Dark-brown basic andesite lava. Thickness ranges from less than 1 inch to 100 feet. Conformably overlies Walker formation in Caliente Canyon. Underlies Bena gravels and sandstone (new). About 3 miles northwest of Bena, where lava is about 15 feet thick, it separates Walker formation below from Freeman-Jewett shale above.

Lava is traceable through series of isolated outcrops from point 2 miles west of Ilmon Station northwestward for about 3 miles to west border of map [Breckenridge Mountain quadrangle, Kern County].

†Ilo Formation[1]

Upper Cretaceous: Northwestern Wyoming.

Original reference: D. F. Hewett, 1914, U.S. Geol. Survey Bull. 541, p. 91, 103.

H. E. Summerford and others, 1947, *in* Wyoming Geol. Assoc. Guidebook 2d Ann. Field Conf., p. 19. Road log of Bighorn basin mentions Ilo Ridge member of Lance formation on east flank of Grass Creek anticline. Basal unit of formation; overlies Meeteetse formation.

Well exposed in open valley, in Park County, northwest of Ilo, settlement 50 miles southeast of Cody, hence the name.

Ilo Ridge Member (of Lance Formation)

See Ilo Formation.

Imperial Formation[1]

Miocene, lower : Southern California.

Original reference: G. D. Hanna, 1926, California Acad. Sci. Proc., 4th ser., v. 14, no. 18, p. 434–435.

L. A. Tarbet and W. H. Holman, 1944, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 28, no. 12, p. 1782. Marine mudstone, siltstones, and sandstones unconformably overlying all older rocks. Thickness 0 to 3,600 feet. Overlies Alverson Canyon formation (new) ; underlies Palm Spring formation. Upper Miocene.

A. M. Keen and Herdis Bentson, 1944, Geol. Soc. America Spec. Paper 56, p. 21 (fig. 4), 22. Age in doubt. Latest evidence, unpublished, seems to suggest that Pliocene assignment of early workers is preferable to Miocene allocation adopted by some authors. Includes Latrania sand member.

J. W. Durham, 1950, Geol. Soc. America Mem. 43, pt. 2, p. 30–33. Believed that San Marcos and Imperial formations are best assigned to lower Pliocene.

T. W. Dibblee, Jr., 1954, California Div. Mines Bull. 170, chap. 2, p. 22, 23. Formation is series of marine clays and sandstones that lie with essential concordance on Alverson andesite or lava (new), Split Mountain formation, and Fish Creek gypsum (new), or in some areas, unconformably on basement rocks. Grades upward into Palm Spring formation. Canebrake conglomerate (new) is coarse marginal conglomerate facies of Imperial and Palm Spring formations. Fauna indicates upper Miocene or possibly lower Pliocene.

C. R. Allen, 1954, California Div. Mines Bull. 170, map sheet 20; 1957, Geol. Soc. America Bull., v. 68, no. 3, p. 327–328. In San Gorgonio Pass area, formation is about 300 feet thick; conformably overlies Hathaway formation (restricted and redefined) and conformably underlies Painted Hill formation (new). Considered to be early Pliocene(?).

Type locality: Coral reef exposed in Alverson Canyon on south side of Coyote Mountain [also called Carrizo Mountain], Imperial County.

Incarnacion Fire Clay[1]

Pennsylvanian : Central northern New Mexico.

Original reference : C. L. Herrick, 1904, Jour. Geology, v. 12, p. 242.

Occurs near Socorro, Socorro County. Named for mining district in which it occurs.

Incarnacion Granite[1]

Age(?) : Central New Mexico.

Original reference : C. L. Herrick, 1904, Jour. Geology, v. 12, p. 237–251.

Named for mining district in which it occurs.

Indart Sandstone

Eocene : West-central California.

N. L. Taliaferro, 1945, Geologic map of the Hollister quadrangle, California (1:62,500) : California Div. Mines Bull. 143, pls. 1, 2 [preprint?]. Shown on map legend as underlying Los Muertos Creek shales and unconformably overlying Cretaceous sandstones, shales, and conglomerates.

Present west of Tres Pinos fault, in southeastern part of quadrangle. Locality is west of Indart Ranch.

†Independence Limestone[1]

Pennsylvanian : Southeastern Kansas.

Original reference: E. Haworth and W. H. H. Piatt, 1894, Kansas Univ. Quart., v. 2, p. 115–117.

Named for Independence, Montgomery County.

Independence Shale

Independence Shale Member (of Wapsipinicon Limestone)[1]

Middle Devonian : Central eastern Iowa.

Original reference: S. Calvin, 1878, Am. Jour. Sci., 3d, v. 15, p. 460–462.

G. A. Cooper and A. S. Warthin *in* G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1737 (fig. 1), 1766–1767, chart 4. Position and age of Independence shale have been subjects of debate for many years. One group holds that the Independence normally underlies the Cedar Valley and the other that the shale is not in its true stratigraphic position. Stainbrook (1935) maintains that the shale underlies the Cedar Valley conformably but overlies Davenport limestone of the Wapsipinicon unconformably and cites as supporting evidence the sinking of an artesian well at Shellsburg which showed Independence shale carrying typical fossils below 65 feet of Cedar Valley limestone. Writers hold that the Independence is not in normal position because (1) it fills sinks and caverns; (2) its occurrence is spotty, there being no definite outcrop belt; and (3) its fauna is that of the Nunda or High Point (Chemung) sandstone and the Frasnian (F) of Belgium.

M. A. Stainbrook, 1945, Am. Jour. Sci., v. 243, no. 1, p. 66–83; no. 2, p. 138–158. Discussion of age and stratigraphic position of Independence shale and summary of all available evidences noted in natural and artificial exposures and secured from deep and shallow well records. All evidence indicates that, normally, Independence lies immediately below Cedar Valley limestone and above Wapsipinicon formation. Fauna is definitely lower Upper Devonian.

Named for occurrence at Independence, Buchanan County.

Index Granodiorite[1]

Jurassic(?) : Central Washington.

Original reference: C. E. Weaver, 1912, Washington Geol. Survey Bull. 7, p. 34–50.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 19. Intrudes Gunns Peak formation.

Typically exposed near Index, Snohomish County.

Indian Conglomerate[1]

Eocene(?) : Southern California.

Original reference: R. N. Nelson, 1925, California Univ. Pub., Dept. Geol. Sci. Bull., v. 15, no. 10, p. 344, 350–352, pl. 46, map.

Well developed in and named for Indian Canyon, Santa Barbara County.

Indiana glaciation

Indiana till[1]

Pleistocene (pre-Nebraskan) : Illinois and Indiana.

Original reference: C. R. Keyes, 1932, Pan-Am. Geologist, v. 58, p. 203,217.

C. R. Keyes, 1938, Pan-Am. Geologist, v. 68, no. 2, p. 129. Referred to as glaciation.

Indianan till[1]

Pleistocene: Indiana

Original reference: C. R. Keyes, 1926, Pan-Am. Geologist, v. 45, p. 151.

Indian Bluff Group

Pennsylvanian (Pottsville Series): Eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 1, 6, pls. 2, 3, 4. Includes strata between top of Slatestone group (new) and base of Graves Gap group (new). Thickness at type section 455 feet; in southwestern part of Cumberland Mountains 300 to 470 feet; thins northwestward; on Cumberland Block, 150 to 200 feet. Includes (ascending) shale interval, Seeber Flats sandstone (new), shale interval, Stockstill sandstone (new), shale interval, Indian Fork sandstone (new), shale interval, and Pioneer sandstone. Indian Fork sandstone not present at type locality.

Type section: Cross Mountain, Lake City quadrangle. Named from Indian Bluff on eastern edge of Braden Flats, a short distance northeast of Graves Gap, Anderson County. Section begins at top of Jellico coal on Militia Hill and ends on top of Pioneer sandstone upon which Mountain View Church is located.

Indian Cave Channel Sandstone Bed (in Towle Shale Member of Onaga Shale)

Indian Cave Sandstone[1]

Indian Cave Sandstone Member (of Towle Shale)

Permian: Southeastern Nebraska and eastern Kansas.

Original reference: R. C. Moore, 1936, Kansas Geol. Survey Bull. 22, p. 50 (fig. 12), 201.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 37. Gives areal distribution and derivation of name.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 52. Member of Towle shale. Consists of sandstone, siltstone, and locally conglomerate in part; occurs as local channel fillings that grade upward into basal part of the unnamed upper member of the Towle. Reported maximum thickness about 200 feet. Type locality in Nebraska. Wolfcamp series.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2273, 2274 (fig. 1). Rank reduced to bed in Towle shale member of Onaga shale.

Occurs at Peru, in southeastern Nemaha County (at Indian Cave), and near Falls City, Richardson County, Nebr., and at places in Kansas.

Indian Creek Bed (in Strawn Formation)[1]

Pennsylvanian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 374, 386.

D. A. Zimmerman and G. D. Glover, 1956, Soc. Econ. Paleontologists and Mineralogists Permian Basin Sec. [Guidebook] Spring Mtg., p. 74. Shaly sandy clay. Overlies Antelope Creek bed or, where that is absent, Comanche Creek bed; underlies Ricker bed. Strawn series.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 58, pl. 27. Drake (1893) separated rocks of Strawn group [division] into 20 units of alternating sandstone and shale beds. He gave local names to these units, or "beds" as he termed them, and numbered them from bottom to top, 4 to 23. Only Drake's name for upper unit, the Ricker, is in conmmon use today, and that name has been restricted to base of Drake's Ricker bed.

Named for Indian Creek, Brown County.

Indian Creek Granite

Precambrian : Central Colorado.

M. F. Boos and E. J. Aberdeen, 1936, (abs.) Geol. Soc. America Proc. 1935, p. 67; 1940, Geol. Soc. America Bull., v. 51, no. 5, p. 699, 728, pl. 1. Name applied to granite in Indian Creek pluton. In field relationships, physical appearance, and crystalline character, closely related to granite of Silver Plume batholith.

Named for Indian Creek Park. Crops out as a group of plutons which make four belts of subparallel, slightly en echelon, granite bodies concentrically aligned along north and east margins of Rosalie lobe of Pikes Peak batholith.

Indian Creek Shale Member (of Admiral Formation)[1]

Permian : Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 421, 423.

R. C. Moore *in* A. K. Miller and Walter Youngquist, 1947, Kansas Univ. Paleont. Contr. 2, Mollusca, art. 1, p. 1, 2; R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheet 2. Renamed Wildcat Creek shale. Name Indian Creek preoccupied by Indian Creek of Pennsylvanian age.

Named for Indian Creek, Coleman County.

Indian Fields Formation[1]

Silurian : East-central Kentucky.

Original references: A. F. Foerste, 1905, Kentucky Geol. Survey Bull. 6, p. 145; 1906, Kentucky Geol. Survey Bull. 7, p. 10, 60.

Named for Indian Fields, Clark County.

Indian Fork Member (of Wells Formation)

Permian (Wolfcampian) : Idaho.

H. J. Bissell, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 8, p. 1427 (chart). Name appears on correlation chart accompanying preliminary statement on eastern Great Basin Permo-Pennsylvanian strata. Overlies Sublett member (new) ; underlies unnamed cherty orthoquartzite member.

Present in Sublett Mountain area.

Indian Fork Sandstone (in Indian Bluff Group)

Pennsylvanian (Pottsville Series) : Eastern Tennessee.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [folio], p. 6, 19, pls. 2, 3, 4. Thickness 15 to 60 feet. Separated from overlying Pioneer sandstone by shale interval that is as much as 80 feet thick in places; separated from underlying Stockstill sandstone (new) by a shale interval that averages 40 to 60 feet in thickness.

Named from exposures along incline on north side of Indian Fork, Fork Mountain quadrangle, Anderson County.

Indian Fort Shale Member (of Brodhead Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 76, 170, 174, 188, pl. 15. Uppermost member of Brodhead formation (new) in area of Irvine facies (new). Typically silty to argillaceous shale, olive-gray with distinct maroon to purple patches. Thickness 30 to 45 feet. In type area, underlies Floyds Knob formation and overlies Combs Mountain siltstone member (new) of Brodhead formation. Extends beyond area of Irvine facies across the southwestern third of the area of the Morehead facies (new), as far as Rowan County. In area of Morehead facies, Indian Fort overlies Haldeman siltstone member (new). In this area the Indian Fort member together with Rothwell shale member (new) of Muldraugh formation (new) and intervening Floyds Knob horizon constitute "Morris Mountain shaly member" (Butts, 1922) which name should be discarded as a single stratigraphic unit.

Type section: Along secondary road up steep hill to old Indian Fort; base of section at juncture with State Highway 21, 1¼ miles east of road intersection at Big Hill, 3½ miles east-southeast of Berea, Madison County. Named for old Indian Fort located on cliff 3½ miles southeast of Berea.

Indian Gap Limestone (in Kanawha Formation)[1]

Pennsylvanian: Southern West Virginia.

Original reference: C. E. Krebs and D. D. Teets, Jr., 1916, West Virginia Geol. Survey Rept. Raleigh and western parts of Mercer and Summers Counties, p. 52, 108, 326, 340.

Occurs at Indian Gap, Raleigh County.

Indian Gulch[1] (Formation)

Mesozoic: East-central California.

Original reference: N. L. Taliaferro, 1933, Geol. Soc. America Bull., v. 44, no. 1, p. 149.

Occurs on Merced River and southward into Indian Gulch quadrangle.

Indian Hill Series[1]

Upper Cretaceous: Southeastern Massachusetts.

Original reference: N. S. Shaler, 1888, U.S. Geol. Survey 7th Ann. Rept., p. 340, pl. 20, map.

Probably named for Indian Hill on Marthas Vineyard.

Indian Hills Volcanics (in Alder Group)

Precambrian (Yavapai Series): Central Arizona.

C. A. Anderson and S. C. Creasey, 1958, U.S. Geol. Survey Prof. Paper 308, p. 20–21, pl. 1. Divided into two interbedded (lithologic and not stratigraphic) units: one andesitic and basaltic, the other rhyolitic. Andesitic and basaltic flows greenish black. Rocks porphyritic with holocrystalline, but commonly aphanitic, groundmass. Amygdules, composed of members of epidote group, and vesicles abundant. Rhyolitic flows inconspicuously porphyritic. Groundmass aphanitic; in places appears siliceous. Thickness not known because base of formation does not crop out. Outcrops in hills west of Coyote Spring ranch reveal maximum width of 6,500 feet. Conformably underlies Spud Mountain volcanics (new). Younger than Texas Gulch formation (new).

Named from exposures in low hills of this name along western front of Black Hills, Jerome area, Yavapai County. Only other major outcrops are 2 miles to north in low hills west of Coyote Spring Ranch.

Indian Hollow Sands[1]

Pleistocene: Northwestern Pennsylvania.

Original reference: E. H. Williams, Jr., 1920, Am. Philos. Proc., v. 59, p. 62, 73.

Named for Indian Hollow, Warren County.

Indian Ladder Formation

Indian Ladder Beds[1]

Upper Ordovician: Eastern New York.

Original reference: J. M. Clarke, April 15, 1911, New York State Mus. Bull. 149, p. 10–12.

Theodore Arnow, 1949, New York State Water Power and Control Comm. Bull. GW-20, p. 9 (table 1), 11 (fig. 3), 13, pl. 2. Formation described in Albany County where it consists of dark-gray to black argillaceous shales, which alternate with thin, yellow, rusty-looking calcareous sandstone beds; occasional heavy sandstone bed present. Thickness about 400 feet. Underlies Brayman shale; overlies Schenectady formation.

Named for exposures at Indian Ladder, near Meadowvale, Albany County.

Indian Meadows Formation

Eocene, lower: Northwestern Wyoming.

J. D. Love, 1939, Geol. Soc. America Spec. Paper 20, p. 10, 11 (fig. 2), 58–63, pl. 17. Proposed for lower Lower Eocene strata unconformably overlying rocks ranging from Precambrian to Upper Cretaceous, and unconformably underlying Wind River and other younger rocks. Chiefly variegated clays, sandstones, and coarse and fine conglomerates; a few algal ball limestones and small amounts of volcanic material. Thickness about 1,000 feet.

Type section: Eastern side North Fork River valley, in secs. 14, 15, and 16, T. 6 N., R. 6 W., in Wind River basin, 6 miles from front of Washakie Range. Name derived from Indian Meadows, a bottom-land area along North Fork River, about 1½ miles north of Circle Ranch, southwestern corner Kirwin quadrangle.

Indian Mills Sandstone (in Bluefield Formation)[1]

Mississippian: Southeastern West Virginia and southwestern Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Mercer, Monroe, and Summers Counties, p. 300, 400.

Type locality: On north side of Indian Creek just west of Indian Mills, Summers County, W. Va.

Indian Mills Shale (in Bluefield Formation)[1]

Mississippian: Southeastern West Virginia.

Original reference: D. B. Reger, 1926, West Virginia Geol. Survey Rept. Mercer, Monroe, and Summers Counties, p. 300, 401.

Type locality: On north side of Indian Creek just west of Indian Mills, Summers County.

Indian Mountain Leucogranodiorite

Cretaceous: Southern California.

E. S. Larsen, Jr., 1948, Geol. Soc. America Mem. 29, p. 85–87, pl. 1. Nearly white in color, rather fine grained, and contains very little biotite. Upper part of mass shows faint streaking due to orientation of dark minerals, and this becomes more prominent as lower contact is approached. For some feet above base, the rock is well-banded micaceous gneiss with much more mica than usual. In contact with and intrudes Bonsall tonalite.

Named from exposures on Indian Mountain, northern part of San Luis Rey quadrangle.

Indianola Group

Upper Cretaceous: Central Utah.

S. L. Schoff, 1938, Ohio State Univ. Abs. Doctors Dissert. 25, p. 378. Series of conglomerates, sandstones, shales, and minor limestones. Thickness 9,350 to 14,680 feet. In Gunnison Plateau, overlies Arapien shale (new); underlies Price River formation. Name credited to E. M. Spieker.

E. M. Spieker, 1946, U.S. Geol. Survey Prof. Paper 205–D, p. 122, 126–130. In Thistle, Sixmile, and Salina Canyon areas, the unit, truncated by Price River and younger formations, is subdivided into four formations (ascending): Sanpete, Allen Valley shale, Funk Valley, and Sixmile Canyon (all new); in other areas undifferentiated. Overlies the Morrison(?) formation. Type area designated.

S. L. Schoff, 1951, Geol. Soc. America Bull., v. 62, no. 6, p. 622, 624–627. In Cedar Hills, undifferentiated Indianola is about 14,680 feet thick. Unconformably overlain by fluviatile and lacustrine deposits ranging from Montana to Eocene in age (Price River, North Horn, Flagstaff, Colton, and Green River formations).

Type area: Indianola district [Sanpete and Utah Counties], Wasatch Plateau.

Indian River Hornblende Syenite

Precambrian: Northeastern New York.

A. F. Buddington, 1939, Geol. Soc. America Mem. 7, p. 85, 285, 286. Mentioned in discussion of Adirondack igneous rocks. Hornblende syenite near village of Indian River is described under heading of Diana quartz syenite complex.

Village of Indian River is in Lowville quadrangle, Lewis County.

Indian River Slate[1]

Indian River Formation

Middle Ordovician: Eastern New York and southwestern Vermont.

Original reference: A. Keith, 1932, Washington Acad. Sci. Jour., v. 22, p. 360, 403.

George Theokritoff, 1959, New England Intercollegiate Geol. Conf. Guidebook 51st Ann. Mtg., p. 53, 56. Referred to as Indian River formation. Overlies Poultney formation; underlies unnamed Normanskill greywackes and black slates.

Named for Indian River, a few miles south of Granville, Washington County, N.Y.

Indian Spring Redbeds
Indian Spring Sandstone } (in Tonoloway Limestone)[1]

Upper Silurian: Northern Maryland.

Original reference: C. K. Swartz, 1923, Maryland Geol. Survey Silurian vol., p. 46–49.

H. P. Woodward, 1941, West Virginia Geol. Survey [Repts.], v. 14, p. 213. Indian Springs sandstone and associated Indian Springs red beds apparently represent extensions of the red Bloomsburg facies into the Tonoloway.

Named for occurrence at Indian Spring, Washington County.

Indian Springs Member (of Bird Spring Formation)[1]

Upper Mississippian: Southeastern Nevada.

Original reference: C. R. Longwell and C. O. Dunbar, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 9, p. 1200–1207.

J. C. Hazzard, 1951, (abs.) Geol. Soc. America Bull., v. 62, no. 12, pt. 2, p. 1503. Incidental mention in discussion of revision of Devonian and Carboniferous sections, Nopah Range, Inyo County, Calif.

Described in vicinity of Indian Springs, 50 miles northwest of Las Vegas.

Indian Springs Shale[1]

Mississippian (Chesterian): Southwestern Indiana.

Original reference: C. A. Malott and J. D. Thompson, Jr., 1920, Science, new ser., v. 51, p. 521–522.

D. J. McGregor, T. G. Perry, and W. J. Wayne, 1957, Indiana Geol. Survey Field Conf. Guidebook 9, pl. 3. On chart showing evolution of nomenclature in Chester series of Indiana, unit termed Indian Springs shale is apparently included in Golconda formation.

Probably named for Indian Springs, Martin County.

†Indian Territory division[1]

Lower Cretaceous: Oklahoma.

Original reference: R. T. Hill, 1891, Geol. Soc. America Bull., v. 2, p. 504.

†Indio Formation[1]

Miocene, middle or upper: Southern California.

Original reference: J. P. Buwalda and W. L. Stanton, 1930, Science, new ser., v. 71, p. 101–106.

C. R. Allen, 1954, California Div. Mines Bull. 170, map sheet 20; 1957, Geol. Soc. America Bull., v. 68, no. 3, p. 328. Preoccupied name Indio replaced by Painted Hill formation (new). Bramkamp (1934, unpub. thesis) termed this unit [Painted Hill] Indio formation because its stratigraphic position is similar to that of Indio formation in Indio Hills (Buwalda and Stanton, 1930). Dibblee (1954) included in Palm Spring formation those beds of Indio Hills that are immediately post-Imperial in age. No assurance that post-Imperial rocks at Painted Hill and those in Indio Hills are actually parts of same formational unit.

Type section: Along northeast-southwest line through Indio Hills, about 2 miles northwest of Thousand Palm Canyon, Riverside County.

Indio Formation (in Wilcox Group)[1]

Eocene, lower: Southern Texas.

Original reference: A. C. Trowbridge, 1923, U.S. Geol. Survey Prof. Paper 131–D.

C. C. Mason, 1960, Texas Board Water Engineers Bull. 6003, p. 15–25. Composed predominantly of thin-bedded to laminated clayey sand and sandy shale, but includes some thick layers of sandstone, discontinous beds of lignite, and numerous calcareous, arenaceous, and ferruginous concretions. Thickness 0 to about 1,520 feet in Dimmit County. Lies unconformably on and overlaps Kincaid formation. Underlies Carrizo sand. Wilcox group. Type locality stated.

Type locality: On old Indio Ranch in Maverick and Dimmit Counties. Crops out in belt extending northward from Rio Grande through western Dimmit and western Maverick Counties.

Ingalls Formation

Oligocene(?) : Northeastern California.

Cordell Durrell, 1959, California Univ. Pubs. in Geol. Sci., v. 34, no. 3, p. 165 (fig. 1), 167–170. Pyroxene and hornblende andesite mudflow breccia; local thin volcanic conglomerate at base; black-weathering craggy outcrops. Thickness along Red Clover Creek about 550 feet; in west-central part of quadrangle, maximum thickness appears to be about 800 feet, but section may be partly duplicated by faulting. Separated from underlying Eocene Lovejoy formation and overlying middle Miocene(?) Delleker formation by unconformities, both intervals marked by extensive faulting and erosion. In Red Clover Creek area, the Ingalls is on Lovejoy at all points where base is exposed; in east-central part of quadrangle, rests in many places on granitic and metamorphic rocks; in west-central part, lies on basement of metamorphic rocks but also overlaps edge of channels of unit here referred to as auriferous gravel, and in several instances it rests on metamorphic rocks on one side of a fault and on auriferous gravels on the other. No area can be designated as type because of variability of composition and thickness from one part of quadrangle to another.

Named for Mount Ingalls in northern part of Blairsden quadrangle. Well exposed along Red Clover Creek.

Ingalls Peridotite

Pre-Tertiary: Northwestern Washington.

R. C. Ellis, 1959, Dissert. Abs., v. 20, no. 3, p. 990. Rocks of Mount Stuart block exposed along east margin of mapped area consist of Hawkins greenstone, Ingalls peridotite (largely sepentinized), and Mount Stuart granodiorite.

Report discusses geology of Dutch Miller Gap area.

Inglefield Sandstone[1]

Upper Pennsylvanian: Southwestern Indiana.

Original reference: M. L. Fuller and G. H. Ashley, 1902, U.S. Geol. Survey Geol. Atlas, Folio 84.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 87. Massive sandstone between Wabash above and Ditney formations; later erroneously correlated with Merom sandstone.

C. A. Malott, 1947, Indiana Acad. Sci. Proc., v. 57, p. 131. Part of Fuller's Inglefield formation (as mapped in Ditney and Patoka folios) is included in Dicksburg Hills sandstone.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 25). Shown on correlation chart as overlying Ditney formation and separated from overlying Parker limestone by Parker coal.

Named for Inglefield, Vanderburgh County.

†Ingles Conglomerate Member[1] (of Price Formation)

Silurian: Southwestern Virginia.

Original reference: M. R. Campbell, 1925, Virginia Geol. Survey Bull. 25.

Exposed on Ingles Mountain, back of Radford, Montgomery County.

Ingleside Chert Member (of Franciscan Formation)

Ingleside Chert (in Franciscan Group)[1]

Jurassic and Cretaceous: Northern California.

Original reference: A. C. Lawson, 1914, U.S. Geol. Survey Geol. Atlas, Folio 193.

U.S. Geological Survey currently classifies the Ingleside Chert as a member of the Franciscan Formation on the basis of a study now in progress.

Named for exposures in San Miguel Hills, east of Ingleside, San Francisco County.

Ingleside Formation[1]

Lower Permian: Central northern Colorado.

Original reference: R. M. Butters, 1913, Colorado Geol. Survey Bull. 5, p. 68, 75.

C. S. Lavington and W. O. Thompson, 1948, Colorado School Mines Quart., v. 43, no. 2, p. 38–40. Overlies and interstratifies with Fountain formation; underlies Lyons sandstone. Considered southward tongue of Casper formation of Wyoming.

T. S. Lovering and E. N. Goddard, 1950, U.S. Geol. Survey Prof. Paper 223, p. 34. Increases in thickness from featheredge near Boulder to about 250 feet near Wyoming-Colorado line. At type locality, near Fort Collins, formation consists of three beds of limestone separated by layers of crossbedded red sandstone. Rests with slight unconformity on Fountain formation; conformably underlies Satanka shale north of Ingleside, but to south unconformably underlies Permian Lyons sandstone.

E. K. Maughan and R. F. Wilson, 1960, *in* Guide to the geology of Colorado: Denver, Rocky Mountain Assoc. Geologists, p. 35–37, 41. Ingleside formation, part of Casper formation equivalent to Ingleside, and part of Fountain formation equivalent to Ingleside are of early Permian age.

Typically developed at Ingleside quarries and at Owl Canyon, 3 miles north of Ingleside, Larimer County.

Ingleside Formation

Recent: Southern Texas.

W. A. Price, 1939, (abs.) Am. Assoc. Petroleum Geolgists Bull., v. 23, no. 12, p. 1875. Lake Charles formation (new) and Ingleside formation replace Beaumont formation.

Present in Rio Grande delta. Type locality and derivation of name not given.

Inglis Formation (in Ocala Group)

†Inglis Limestone

Inglis Member (of Moodys Branch Formation)

Eocene, upper: Florida.

R. O. Vernon, 1951, Florida Geol. Survey Bull. 33, p. 115–140. Member is base of Jackson group in Florida and is a miliolid- and echinoid-rich cream-colored marine limestone. Complete thickness not exposed in any one place; as much as 54 feet in core holes; outcrops 2½ to as much as 30 feet. Conformably underlies Williston member (new); unconformably overlies Avon Park limestone.

H. S. Puri, 1953, (abs.) Jour. Sed. Petrology, v. 23, no. 2, p. 130; 1957, Florida Geol. Survey Bull. 38, p. 24–28. Rank raised to formation in Ocala group. Type locality stated.

C. W. Cooke, 1959, U.S. Geol. Survey Prof. Paper 321, p. 2 (table 1), 3. Referred to as limestone. Rocks now assigned to Inglis, though equivalent to the Moodys Branch were formerly included in Ocala limestone. Contains late Eocene echinoids.

Type locality: Around town of Inglis, Levy County, where limestone is exposed in several pits and quarries, and also along Withlacoochee River.

Ingramian Stage

Late Cretaceous: California.

P. P. Goudkoff, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 7, p. 960 (table 1), 985–987, 1005. One of six stages, based on foraminiferal assemblages, in Upper Cretaceous column between top of Moreno and base of Panoche, as defined by Anderson and Pack (1915). Roughly correlative with upper part of type Panoche formation. Includes interval between Ciervian stage (new) above and Tracian stage (new) below.

Occurs in Great Valley in both surface and subsurface. Named from Ingram Creek [Fresno County].

Inman Formation (in Eden Group)

Upper Ordovician: Central Tennessee.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 2 (fig. 1), 175–179. Greenish-gray calcareous shale with zones of red shale interbedded with beds of uniformly bedded greenish-gray to gray dove-colored fine-grained, dense limestone; at some localities limestone is clayey and laminated and in other places is uniformly medium grained. Beds of limestone range between 1 and 6 inches in thickness. Thickness 45 feet in Giles County, 48 feet in Franklin County, and 40 to 70 feet in Sequatchie Valley. Overlaps upon Catheys and overlapped by Leipers.

Named for exposures at Inman, Marion County. Restricted to synclinal belt in southwestern Lincoln County and east-central Giles County and in similar belt in Franklin and Moore Counties that is connected with the formation as exposed in Sequatchie Valley.

Inola Limestone Member (of Boggy Shale)[1]

Pennsylvanian (Des Moines Series): Northeastern Oklahoma.

Original reference: S. W. Lowman, 1932. Summaries and abstracts of technical papers presented before Tulsa Geol. Soc. 1932, unpaged.

R. D. Alexander, 1954, Oklahoma Geol. Survey Circ. 31, p. 12, 16 (fig. 2). Immediately above Bluejacket sandstone member is sequence of four cyclical units, each containing zone of marine fossils. Cap rock limestone of lowest of these cycles contains abundant fusulinids. Name Inola here restricted to lowest limestone, the only one that yields fusulinids. Fusulinids reported from Inola at type locality.

C. C. Branson, 1954, Oklahoma Geol. Survey Guide Book 2, p. 6. Referred to as Inola coal cycle.

Named for outlier on hill east of Inola, Rogers County.

Inskip Formation

Mississippian(?) : North-central Nevada.

S. W. Muller, H. G. Ferguson, and R. J. Roberts, 1951, Geology of the Mount Tobin quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–7]; 1951, Geology of the Winnemucca quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–11]. Lower half, mostly quartzite and slate with thin beds of limestone, some chert, a few greenstone flows, some graywacke, conglomerate, and quartzitic grit. Upper half, thin-bedded limestone interbedded with siliceous and calcareous slate and quartzite. Thickness more than 9,000 feet at type locality. Underlies Tallman fanglomerate (new) and Koipato formation with angular unconformities.

R. J. Roberts and others, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2848. Throughout most of outcrop area Inskip and Leach formations are in fault contact, and their stratigraphic relations are not definitely known. The Leach appears to underlie the Inskip. Probably Late Mississippian.

Type locality: Inskip Canyon, west flank of East Range, Winneumcca quadrangle.

Institute Limestone[1]

Pennsylvanian: Eastern Kansas.

Original reference: E. Haworth, 1894, Kansas Univ. Quart., v. 2, p. 122, 124.

Exposed at Haskell Institute, Lawrence, Douglas County.

Interior Formation[1]

Interior Member (of Pierre Shale)

Upper Cretaceous: Southwestern South Dakota and northwestern Nebraska.

Original reference: F. Ward, 1922, South Dakota Geol. Nat. History Survey Bull. 11, p. 18–20, map.

A. L. Moxon, O. E. Olson, and W. V. Searight, 1939, South Dakota State Coll. Agriculture and Mech. Arts Tech. Bull. 2, p. 20, 23–25. Rank reduced to member status in Pierre shale. Name has precedence over Mowbridge member. Underlies Elk Butte member; overlies Virginia Creek member.

A. L. Moxon, O. E. Olson, and W. V. Searight, 1950, South Dakota State Coll. Agriculture and Mech. Arts Tech. Bull. 2 (revised), p. 20, 23. Replaced by Mowbridge now the accepted term.

Named for development in vicinity of town of Interior, Jackson County, S. Dak.

Intermediate Dolomite Member (of Boardman Formation)

Intermediate Limestone

Lower Ordovician: West-central Vermont.

G. W. Bain, 1931, Am. Jour. Sci., 5th ser., v. 22, no. 132, p. 508, 509. Intermediate limestone is slightly silicified dolomitic rock. Maximum thickness 190 feet.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, p. 25, 26. Rank reduced to Intermediate dolomite member, the middle member of Boardman formation in Castleton area, Rutland County. Formally described as thick-bedded rather porous light-gray dolomite generally containing some sandy beds and typical large quartz knots. Some patches of white marble enclosed in dolomite. Underlies Columbian marble member of Boardman formation; overlies Sutherland Falls marble member of Boardman formation.

Occurrence: Addison and Rutland Counties.

Intervale Clay Slate[1]

Silurian (?): East-central New Hampshire.

Original reference: M. Billings, 1928, Am. Acad. Arts and Sci. Proc., v. 63, p. 80, map.

Occurs two miles northeast of Intervale [village], Carroll County.

Intracanyon basalt formation

Recent: Central Oregon.

E. T. Hodge, 1940, Oregon State Coll. Studies in Geology, Mon. 1, [map with text]. Named and mapped as Intracanyon basalt formation. Described as basalt flows occupying and partly filling Deschutes, Crooked, and Metolius River canyons. Lies against old talus slopes, or Madras sediments.

Occurs in Madras quadrangle, Jefferson County.

Inwood Limestone[1]

Inwood Marble (in New York City Group)

Precambrian: Southeastern New York and western Connecticut.

Original reference: F. J. H. Merrill, 1890, Am. Jour. Sci., 3d, v. 39, p. 389–390.

J. J. Prucha, 1956, Am. Jour. Sci., v. 254, no. 11, p. 673. Inwood marble included in New York City group (new). Overlies Fordham gneiss; underlies Manhattan formation. White to gray, moderately silicated, medium-grained rock ranging in composition from calcite to nearly pure dolomite. Indistinguishable lithologically from marble layers occurring within Fordham and Manhattan formations. Correlations indicate lower Paleozoic age for New York City group.

J. W. Clarke, 1958, Connecticut Geol. Nat. History Survey Quad. Rept. 7, p. 18–21, geol. map. Geographically extended into Danbury quadrangle, Connecticut. On State Geological Map of 1906, it is called Stockbridge limestone. In subsequent work dealing with the quadrangle, Moore (1935, Connecticut Geol. Nat. History Survey Bull. 56) used term Stockbridge series; Balk (1936, Geol. Soc. America Bull., v. 47, no. 5) used term Wappinger marble. Inwood lies stratigraphically above Fordham gneiss and below Manhattan formation. It is excellent stratigraphic marker and helps to distinguish Manhattan and Hartland formations. New York City group.

Named for exposures in vicinity of Inwood on Manhattan Island.

Inwood Sandstone[1]

Silurian (?): Southeastern Pennsylvania.

Original reference: C. K. Swartz and F. M. Swartz, 1931, Geol. Soc. America Bull., v. 42, p. 635.

Bradford Willard, 1952, Pennsylvania Acad. Sci. Proc., v. 26, p. 75. Mentioned in report on lower Oriskany contact in eastern Pennsylvania. Thickness 49 feet. Occurs between Bloomsburg red beds and Onondaga limestone. Age unknown. Probably Silurian.

Occurs in section east of Swatara Creek at Swatara Gap near Inwood Station on Philadelphia and Reading Railway.

Inyan Kara Group[1]

Lower Cretaceous: Northeastern Wyoming and western South Dakota.

Original reference: W. W. Rubey, 1930, U.S. Geol. Survey Prof. Paper 165–A.

K. M. Waagé, 1959, U. S. Geol. Survey Bull. 1081–B, p. 13–90. Darton's subdivision of beds, originally called Dakota in Black Hills, has been difficult to apply outside of limited area in southeastern Black Hills in which names were first applied. In 1930, principal subdivisions, Lakota, Fuson, and Fall River (Dakota of Darton) formations, were placed in Inyan Kara group because they could not be distinguished consistently as separate units. Early miscorrelation of the Fall River (Dakota) with Dakota sandstone of southeastern Colorado has led to confusion in application of Darton's terminology outside of Black Hills. Stratigraphic studies of group reveal basic twofold lithogenetic subdivision which has been recognized in equivalent beds elsewhere in western interior region. Deposits of lower part of this division are dominantly sandy sediments of varied continental facies and are allied lithogenetically with underlying Morrison formation. Deposits of upper part are dominantly sandy sediments of marginal marine facies allied lithogenetically and gradational with overlying marine Skull Creek shale. Contact of the two parts is transgressive disconformity [see Dakota group for explanation] of regional extent marking initial incursion of Cretaceous sea. Subdivision and nomenclature of group is adjusted to conform to this lithogenetic division by redefinition of Fall River formation so that it corresponds with upper part and extending term Lakota, which here comprises Minnewaste and Fuson members, to include entire lower part. The transgressive disconformity becomes contact of Lakota and Fall River formations. Because of strictly local nature of much of the group, neither its name nor names Fall River and Lakota should be used outside of Black Hills region.

Named for exposures along Inyan Kara Creek, northeastern part of Moorcroft quadrangle, Crook County, Wyo.

Inyo Granite[1]

Upper Jurassic: Eastern California.

Original reference: J. H. Maxson, 1934, Pan-Am. Geologist, v. 61, no. 4, p. 311.

On east side of Inyo Range.

Inyo Marble[1]

Lower Cambrian: Eastern California.

Original reference: H. G. Hanks, 1886, California State Mining Bur. 6th Ann. Rept. State Min., pt. 1, p. 25.

Caps White Mountain, Inyo Range.

Inyo Series[1]

Lower and Middle Triassic: Eastern California.

Original reference: J. P. Smith, 1910, Jour. Geology, v. 18, table opposite p. 217.

Inyo Range.

Inyoan series[1]

Lower Triassic: Southeastern California and southwestern Nevada.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 52, 59, 79.

Named for Inyo County, Calif.

†Iola Beds[1]

Pennsylvanian: Eastern Kansas.

Original reference: L. C. Wooster, 1905, The Carboniferous rock system of eastern Kansas.

Iola Limestone (in Kansas City Group)[1]

Iola Limestone (in Ochelata Group)

Iola Limestone Member (of Kansas City Formation)[1]

Pennsylvanian (Missouri Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, southeastern Nebraska, and northeastern Oklahoma.

Original reference: E. Haworth and M. Z. Kirk, 1894, Kansas Univ. Quart. v. 2, p. 109.

R. C. Moore and others, 1937, Kansas Geol. Soc. Guidebook 11th Ann. Field Conf., p. 40 (table 1), 43. Included in Ochelata group in Oklahoma. Overlies Chanute shale; underlies Lane-Vilas shale. Comprises (ascending) Paola limestone, Muncie Creek shale, and Avant limestone members. Avant has priority over Raytown.

M. G. Oakes, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 4, p. 718 (fig. 2), 720 (table 1), 726. In Oklahoma, overlies Chanute formation; underlies Wann formation (revived, restricted, redefined).

J. R. Clair, 1943, Missouri Geol. Survey and Water Resources, 2d ser., v. 27, pl. 1. In Missouri, Iola limestone comprises (ascending) Frisbie limestone. Quindaro shale, and Argentine limestone members. Overlies Liberty Memorial shale member (new) of Chanute shale; underlies Island Creek shale member of Lane shale, Kansas City group.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 13. Iola formation redefined for Missouri. Iola of Kansas was incorrectly correlated with higher limestone, the Argentine, in Missouri by Haworth and Bennett (1908, Kansas Univ. Geol. Survey, v. 9), and the correlation was accepted by Hinds and Greene (1915, Missouri Bur. Geology and Mines, v. 13). Error was discovered by Newell in 1932, but change was not made in Missouri until 1947, when Kansas and Missouri geologists traced the Paola, Muncie Creek, and Raytown succession into type section of Iola. Hence, Iola formation in Missouri, like that of Kansas, consists of Paola limestone, Muncie Creek shale, and Raytown limestone members. Overlies Chanute shale (redefined for Missouri); underlies Lane shale (redefined for Missouri). Kansas City group.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 35–36. Thickness of formation 9 feet, Cass County, Nebr.; about 7 feet, Winterset, Iowa; 10

to 12 feet, Kansas City, Mo.; 7 to 8 feet, northeastern Kansas; 10 to 30 feet, Iola, Kans. Includes Paola limestone, Muncie Creek shale, and Raytown limestone members.

T. L. Welp, L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 64, p. 418 (fig. 1), 420. Thickness of formation about 10 feet in Madison and Adair Counties, Iowa. Includes only Raytown limestone member. Underlies Lane formation; overlies Chanute shale. Kansas City group.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 26, fig. 5. Includes Raytown limestone member, 9 feet; Muncie Creek shale member about 2½ feet; Paola limestone, about 1 foot. Overlies Chanute shale; underlies Lane shale. Kansas City group.

Typically developed at Iola, Allen County, Kans.

†Iola Shale[1]

Pennsylvanian: Eastern Kansas.

Original reference: E. Haworth, 1894, Kansas Univ. Quart., v. 2, p. 124.

Probably named for Iola, Allen County.

Ion Dolomite Member[1] (of Decorah Formation)

Ion Submember (of Decorah Shale Member of Galena Formation)

Middle Ordovician: Northeastern Iowa, northwestern Illinois, southeastern Minnesota, and southwestern Wisconsin.

Original reference: G. M. Kay, 1928, Science, new ser., v. 67, p. 16.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 9 (geol. column), 81, 83–85. Considered submember of Decorah shale member of Galena formation in Minnesota. Occurs at top of Decorah; overlies Guttenberg submember. Consists of calcareous shale with layers or lenses of argillaceous limestone. Thickness 15 to 20 feet in St. Paul area.

M. P. Weiss, 1955, Jour. Paleontology, v. 29, no. 5, p. 763. Members of Decorah formation (Spechts Ferry, Guttenberg, and Ion) not recognizable rock units in Minnesota.

A. F. Agnew and others, 1956, U.S. Geol. Survey Prof. Paper 274–K, p. 285, 293–295. Member of Decorah formation. Type section, herein redescribed, consists of limestone, gray, or greenish gray, gray mottled, thin bedded, fossiliferous—1.3 feet; limestone, thin bedded, argillaceous, interbedded greenish shaly partings, ledge containing *Glyptorthis*—3.2 feet; shale, greenish, calcareous, and thin grayish-green shaly limestone beds, ledges contain *Glyptorthis* and *Dinorthis*—15.5 feet; shale, green, *Prasopora*—0.5 foot; limestone, grayish, coarsely crystalline, fossiliferous, numerous, *Prasopora*—1 foot; shale, olive-brown—0.3 foot. Total thickness 22 feet. Overlies Guttenberg limestone member; underlies cherty zone of Galena dolomite. In eastern part of zinc-lead mining district, Ion is predominantly dolomitic. Hence, consists of two facies: a western, typified by type section, and an eastern, of light- to medium-grayish-blue crystalline to granular vuggy medium- to massive-bedded less fossiliferous dolomites, with subordinate amounts of olive-gray argillaceous patches and dolomitic shale beds.

Type locality: In ravine along road in NW¼ sec. 35, T. 96 N., R. 4 W., about 1 mile southwest of hamlet of Ion, Allamakee County, Iowa.

Ione Formation[1]

Eocene: Northern California.

Original reference: W. Lindgren, 1894, U.S. Geol. Survey Geol. Atlas, Folio 5.

Ralph Stewart, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 34. Includes "Dry Creek" sandstone member. A similar silty sand in a similar stratigraphic position has been described in Sierra foothills, 25 miles north of Marysville, by Allen (1929) who named it Dry Creek formation. However, name Dry Creek was preoccupied by Dry Creek shale in Montana. Although a valid name should be assigned to the unit, "Dry Creek" is used here in a quotational sense.

Named for exposures at Ione, Amador County.

Ionia Sandstone Member (of Saginaw Formation)

Ionia Sandstone[1]

Ionia Sandstone (in Grand River Group or Formation)

Pennsylvanian: Southern Michigan.

Original reference: A. Winchell, 1871, Michigan Geol. Survey Rept. Prog., p. 26–33.

W. A. Kelly, 1936, Michigan Dept. Conserv., Geol. Div. Pub. 40, Geol. Ser. 34, p. 207. Name applied to crossbedded, coarse-grained, varicolored sandstones outcropping in Grand River valley near Ionia. Overlies shales and micaceous sandstones of Saginaw group. Included in newly proposed Grand River group. Stratigraphic relations to Eaton sandstone (new) not determined.

G. V. Cohee, Carol Macha and Margery Holk, 1951, U.S. Geol. Survey Oil and Gas Inv. Chart OC–41, sheet 5. Recommended that Ionia sandstone be considered a member in Saginaw formation.

Michigan Geol. Soc., 1954, *in* Geologic cross section of Paleozoic rocks central Mississippi to northern Michigan: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 28, 29. Herein considered member of Grand River formation. It is probable that future study will show that the Eaton is a brown-weathering facies of the Ionia as exact stratigraphic position of Eaton and Ionia members in the Grand River is not known. No paleontological evidence available to establish age of Ionia.

Probably named for exposures in abandoned quarries near Grand River between Lyons and Ionia, Ionia County.

Iowa Marble[1]

Mississippian: Central northern Iowa.

Original reference: C. A. White, 1870, Iowa Geol. Survey, v. 2, p. 312–313.

In Le Grand quarries, Marshall County.

Iowa Series[1]

Mississippian: Mississippi Valley region.

Original reference: S. Weller, 1920, Jour. Geology, v. 28, no. 4, p. 282; no. 5, p. 408–416.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 766 (fig. 1), 771, 777–822. Series comprises (ascending) Kinderhook, Osage, and Meramec groups. Underlies Chester series. Report follows classification of Illinois Geological Survey. However, authors believe that Mississippian should have three-fold division, that

Kinderhook should be raised to rank of series, and that Valmeyer series should be recognized.

L. E. Workman and Tracey [Tracy] Gillette, 1956, Illinois Geol. Survey Rept. Inv. 189, p. 12. In previous Illinois Geological Survey reports, Kinderhook strata have been considered a group in Iowa series. In this report, Kinderhook is raised to series rank. Name Iowa is dropped, following usage in Mississippian correlation chart of Weller and others (1948). Valmeyer series is accepted to include Osage and Meramec groups.

Probably named for Iowa.

Iowa Falls Dolomite[1]

Iowa Falls Dolomite Member (of Hampton Formation)

Mississippian: Central northern Iowa.

Original reference: F. M. Van Tuyl, 1925, Iowa Geol. Survey, v. 30, p. 52, 92, 97.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, chart 5. Shown on correlation chart as uppermost member of formation. Overlies Eagle City beds; underlies Gilmore City limestone.

L. A. Thomas, 1960, Tri-State Geol. Soc. Guidebook 24th Ann. Field Conf., p. [3, 17–19]. Stratigraphic reconstruction of Lower Mississippian rocks across Iowa Falls area, when adjusted to orthodox system of classification, presents anomalous situation that is irreconcilable with stratigraphic relationships observed elsewhere in State. Believed that this stems from miscorrelations resulting in exaggerated thickness of Eagle City limestone and misunderstanding of relationships of Gilmore City limestone to Iowa Falls dolomite. Van Tuyl (1925) considered Eagle City limestone to be about 80 feet thick, to consist of two limestones separated by thick dolomite, and to be unconformable beneath Iowa Falls dolomite. Present evidence suggests that formation is essentially limestone, about 20 feet thick, and conformable with Iowa Falls and Maynes Creek dolomites. Van Tuyl considered Gilmore City limestone to be younger than Iowa Falls dolomite. Present study suggests that Iowa Falls is in part a dolomitized lateral equivalent of Gilmore City limestone.

Named for exposures in gorge of Iowa River at Iowa Falls, Hardin County.

Iowa Gulch Porphyry (in Gray Porphyry Group)

Upper Cretaceous(?) or Tertiary, lower: Central Colorado.

C. H. Behre, Jr., E. N. Goddard, and A. E. Sandberg, 1939, Preliminary geologic map of west slope of Mosquito Range in vicinity of Leadville, Colorado (1:12,000): U.S. Geol. Survey. Named on map legend. In older part of Gray porphyry group.

C. H. Behre, Jr., 1939, Colorado Sci. Soc. Proc., v. 14, no. 2, p. 64–65. Includes two facies—a typical porphyry and a breccia. The porphyry, which is more common, is light gray to brownish gray, nonclastic, distinguished by conspicuous well-crystalized phenocrysts of white feldspar and brown biotite in a dark-gray stony groundmass, frequently characterized by flow structure. The breccia, highly localized, shows matrix of finely fragmental material containing sharp-edged rock fragments of same composition as porphyry and very rarely small blocks of the sedimentary rocks cut by the breccia. Cut by Johnson Gulch porphyry. Type occurrence and derivation of name given.

C. H. Behre, Jr., 1953, U.S. Geol. Survey Prof. Paper 235, p. 46, 54–56, pl. 1. Megascopically most varied of rocks in Gray porphyry group. Differs from Johnson and Lincoln types in lack of conspicuous quartz phenocrysts and from Sacramento in its larger proportion of ground mass; resembles Evans Gulch and Mount Zion in its relatively fine texture and small average size of its phenocrysts, but is somewhat darker, more stony, and as a whole its texture more distinctly porphyritic; blue-gray facies in contrast to lighter gray or flesh colors of Evans Gulch. In igneous sequence, intrusion of Evans Gulch, Sacramento, and Lincoln porphyries was followed by intrusion of Iowa Gulch porphyry; relative ages of Evans Gulch, Sacramento, and Lincoln not determinable. Igneous rocks that are younger than Precambrian in area of this report [west slope of Mosquito Range] are either wholly or mainly Tertiary and only possibly in part late Cretaceous or early Pleistocene in age.

Well exposed in Iowa Gulch, west slope of Mosquito Range, where type occurrence is thick sill that lies under Manitou limestone, about 1 mile west of Hellena mine, Lake County.

Iowan Stade

Iowa(n) Drift,[1] Loess, Till

Iowan Glacial Substage

Iowan stage of glaciation[1]

Pleistocene (Wisconsin): Mississippi Valley.

Original reference: T. C. Chamberlain, 1895, Jour. Geology, v. 3, p. 270–277.

M. M. Leighton and H. B. Willman, 1950, Jour. Geology, v. 58, no. 6, p. 602 (fig. 2). 603–604. Chart shows Iowan substage between Farmdale (pro-Wisconsin) substage and Tazewell substage. Materials of Iowan are loess and till. In Illinois, west and south of Shelbyville, terminal moraine (outermost Tazewell), the Iowan loess constitutes lower part of Peorian loess. No clear separation of Iowan and Tazewell loesses, except at border of Wisconsin drift, where Iowan drift lies under and Tazewell loess lies upon Shelbyville drift.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 24, 36, 37, 44, 52, 123, 128. Five substages of Wisconsinan recognized in Kansas: Iowan, Tazewellian, Bradyan (new), Caryan, and Mankatoan; also mentions Iowa and Iowan loess, Iowa till, Iowan stage and subage.

R. V. Ruhe, Meyer Rubin, and W. H. Scholtes, 1957, Am. Jour. Sci., v. 255, no. 10, p. 671–689. New radiocarbon dates in Iowa permit a grouping of age values and raise new problems in stratigraphic correlation of late Pleistocene deposits in Iowa and adjacent regions. An older group of ages greater then 29,000 years dates Iowan substage and pre-Iowan deposits. An old group of ages of 22,900 to 25,100 years dates the Farmdale substage. An intermediate group of ages ranges 14,000 to 17,000 years. A possible interpretation of the dates places Iowan substage in older position than the Farmdale rather than younger as heretofore believed. Iowan till yields wood with dates beyond present range of radiocarbon dating.

J. C. Frye and H. B. Willman, 1960, Illinois Geol. Survey Circ. 285, p. 1, 3, 7. Presentation of revised time-stratigraphic classification of Wisconsinan stage of Lake Michigan lobe. Stage consists of (ascending) Altonian, Farmdalian, Woodfordian, Twocreekan, and Valderan substages. Radiocarbon dates indicate that till of type Iowan of Iowa is older than type Farmdale of Illinois rather than younger. This reverses relative position of these two units. Dates from Iowan till are greater than 35,000 years and do not define age of the till or indicate its placement with the Illinois glacial succession. The Woodfordian includes Iowan substage of Illinois usage (but not of the type), type Tazewell and Cory substages.

M. M. Leighton, 1960. Jour. Geology, v. 68, no. 5, p. 529–552. Presentation of classification of Wisconsin glacial stage of north-central United States. Iowan glacial substage is separated from older Farmdale glacial substage by Farm Creek intraglacial substage and from younger Tazewell glacial substage by Gardena intraglacial substage. Author [Leighton] does not agree with classification presented by Frye and Willman (1960) and cites reasons.

Name amended to Iowan Stade to comply with Stratigraphic Code adopted 1961.

Named for exposures in eastern Iowa.

Iowa Point Shale Member (of Topeka Limestone)

Iowa Point Shale (in Calhoun Shale)[1]

Pennsylvanian (Virgil Series): Northeastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 40, 43, 51, 102.

G. E. Condra and E. C. Reed, 1937, Nebraska Geol. Survey Bull. 11, 2d ser., p. 7, 12, 15, 20, 46, 51. Reallocated to member status in Topeka limestone. Underlies Cruzen [Curzon] limestone member; overlies Wolf River limestone member (new). Occurrences in Iowa noted.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2035 (fig. 5); 1949, Kansas Geol. Survey Bull. 83, p. 126 (fig. 22), 162–163; F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 18. Iowa Point shale member of Topeka formation: underlies Curzon limestone member; overlies Hartford limestone member. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 21. Condra and Reed (1937) were uncertain regarding relation of the Hartford of southern Kansas to lower member of Topeka in northeastern Kansas, southeastern Nebraska, northwestern Missouri, and southwestern Iowa, so they proposed name Wolf River for basal member of Topeka in this area. Nebraska Survey will drop name Wolf River if it proves to be correlative with the Hartford, which was loosely defined by Kirk (1896) and may have priority, if it does not include beds of Du Bois, Iowa Point, and Wolf River age.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 16, fig. 5. Commonly olive to dark brown in upper part grading to greenish gray below. Varies locally from calcareous shale to a complex of thin limestone beds. Thickness ranges from about ½ foot to 3½ feet. Member of Topeka limestone; underlies Curzon limestone member; overlies Hartford limestone member.

Type locality: In Missouri River bluff just east of Iowa Point, Doniphan County, Kans.

Ipava Shale and Sandstone (in Carbondale Formation)[1]

Pennsylvanian: Central western Illinois.

Original reference: T. E. Savage, 1927, Am. Jour. Sci., 5th, v. 14, p. 307–316.

Probably named for Ipava, in Fulton County.

Ira Slate[1]

Lower Ordovician: Southwestern Vermont.

Original reference: Arthur Keith, 1932, Washington Acad. Sci. Jour., v. 22, p. 360, 398.

Phillip Fowler, 1950, Vermont Geol. Survey Bull. 2, p. 34. Name abandoned. Has similar lithology to and is in same stratigraphic position as Hortonville slate in which beds are now included.

E-an Zen, 1959, New England Intercollegiate Geol. Conf., 51st Ann. Mtg., p. 3, Age of type Hortonville subject to question. Herein suggested that Keith's name Ira formation be revived for belt that runs from Florence south towards Dorset Mountain, a belt that cannot be traced into type Hortonville. Name Ira is appropriate as the writer [Zen] has found Middle Ordovician fossils in limestone lenses in the phyllite near Ira village.

Exposed in town of Ira which is south of West Rutland in Castleton quadrangle.

Irasburg Conglomerate[1]

Ordovician(?): Northeastern Vermont, and Quebec, Canada.

Original reference: C. H. Richardson, 1906, Vermont State Geologist 5th Rept., p. 82.

L. W. Currier and R. H. Jahns, 1941, Geol. Soc. America Bull., v. 52, no. 9, p. 1488, 1508, 1509. Considered an intraformational bed in the Waits River formation which is designated Middle Ordovician or later(?).

C. G. Doll, 1951, Vermont Geol. Survey Bull. 3, p. 15, 32–33. Basal conglomerate of Barton River formation of Silurian age. Type locality stated more specifically.

Named for Irasburg, Orleans County, Vt., where it is best represented in bed of Lords Creek and on adjacent slope to south.

Irasburg Granite[1]

Devonian: Northeastern Vermont.

Original reference: E. J. Foyles and C. H. Richardson, 1929, Vermont State Geologist 16th Rept., table opposite p. 288.

Probably named for Irasburg Township or Irasburg village, in Orleans County.

Ireland Sandstone[1] **Member** (of Lawrence Shale)

Pennsylvanian (Virgil Series): Central Kansas.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. 6th Ann. Field Conf. Guidebook, p. 93, 96, 113.

H. C. Wagner and L. D. Harris, 1953, U.S. Geol. Survey Oil and Gas Inv. Chart OC–48. In Fredonia quadrangle, generally a 5- to 20-foot grayish-orange to moderate-brown channel-filling sandstone, locally crossbedded and ripple-marked; sparsely fossiliferous. Shales in lower part of Lawrence thin and thicken laterally, and in places where the shales are missing the lower sandstones of Lawrence merge into single unit, making the Ireland as much as 60 feet thick. Filling of channels cut into underlying rocks abnormally increases thickness of Ireland also: locally, channels are cut as much as 15 feet into underlying Robbins shale member of Stranger formation. Basal member of formation; separated from overlying Amazonia member by an unnamed interval of shale and sandstone lenses.

Type locality: On Ireland Creek and farm of W. E. Ireland, 5 miles southwest of Yates Center, Woodson County.

Irene Conglomerate[1]

Precambrian (Belt Series): Southeastern British Columbia, Canada, and northwestern Idaho.

Original reference: R. A. Daly, 1912, Canada Geol. Survey Dept. Mines Mem. 38, maps 6, 7.

Named for outcrops on summit and slopes of Irene Mountains, British Columbia.

Irene Volcanic Formation[1]

Precambrian (?): Southeastern British Columbia, Canada and northwestern Idaho.

Original reference: R. A. Daly, 1912, Canada Geol. Survey Dept. Mines Mem. 38, maps 6, 7.

Named for outcrops along west slope of Irene Mountains, British Columbia.

Ireson Felsite

Upper Silurian or Lower Devonian: Southeastern Maine.

G. H. Chadwick, 1939, Am. Jour. Sci., v. 237, no. 5, p. 361. Incidental mention.

G. H. Chadwick, 1942, (abs.) Geol. Soc. America Bull., v. 53, no. 12, pt. 2, p. 1796, 1797. Occurs in form of laccolith and intrusive dikes. Older than Prettymarsh diorite (new); younger than Frenchmans Bay series. Upper Silurian or Lower Devonian.

G. H. Chadwick, 1944, New York Acad. Sci. Trans., ser. 2, v. 6, no. 6, p. 173, 177. Dikes described as pink weathering. Areal distribution given.

Occurs at Ireson's Hill and its cliffs at The Ovens on north shore of Mount Desert Island, Hancock County. Other exposures also on this island.

Iron Canyon Agglomerate Member (of Tuscan Formation)

[Pliocene]: Northern California.

R. C. Treasher, 1947, (abs.) Geol. Soc. America Bull., v. 58, no. 12, pt. 2, p. 1257. Tuscan formation subdivided into five members. Iron Canyon agglomerate fourth in sequence (ascending). Underlies Sacramento tuff and sand member; overlies Seven-Mile tuff and sand member.

Occurs at Iron Canyon dam site near Red Bluff, Tehama County.

Iron Creek Glaciation

Pleistocene: West-central Alaska.

D. M. Hopkins, 1953, *in* T. L. Péwé and others, U.S. Geol. Survey Circ. 289. p. 10, 13 (table 1). Four Quaternary glaciations recognized on Seward Peninsula. Iron Creek, the earliest, preceded Nome River glaciation (new). Represented by till and outwash encountered at Iron Creek. Faceted spurs adjoining bedrock benches several hundred feet above stream grade in Nome River valley and in nearby valleys assigned to Iron Creek glaciation.

D. M. Hopkins, F. S. MacNeil, and E. B. Leopold, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 4, p. 46–57. Discussion of coastal plain at Nome. Three marine stratigraphic units (Submarine Beach, Third Beach-Intermediate Beach, and Second Beach) record at least three distinct intervals during which sea level stood as high or higher than at present and during which sea temperatures were warmer than at present. A fourth interval of high sea level may be represented by "Fourth Beach" at inner edge of coastal plain. Glacial drift of Iron Creek (Nebraskan or Kansan) glaciation and of Nome River (Illinoian) glaciation separates the three units. Outwash, alluvium, colluvium, windblown silt, and peat that accumulated during Wisconsin and Recent time cover the glacial drift and youngest of marine sediments.

In southwestern part of Seward Peninsula.

Irondale Limestone (in Conemaugh Formation)[1]

Pennsylvanian: Northern West Virginia, western Maryland, and southern Pennsylvania.

Original reference: I. C. White, 1891, U.S. Geol. Survey Bull. 65, p. 95.

Occurs at Irondale, Preston County, W. Va., and adjoining regions.

Irondequoit Limestone (in Clinton Group)

Irondequoit Limestone Member (of Clinton Formation)[1]

Middle Silurian: Central and western New York, and Ontario, Canada.

Original reference: J. M. Clarke, 1906, New York State Mus. 2d Rept. Dir. Sci. Div., 1905, p. 12.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Correlation chart shows Irondequoit limestone in Clinton group, above Williamson shale and below Rochester shale. Niagaran series.

D. W. Fisher, 1953, Buffalo Soc. Nat. Sci. Bull., v. 21, no. 2, p. 27 (fig. 1), 32. In Niagara Gorge, unconformably overlies lower Reynales limestone; in Genesee Gorge overlies Williamson shale.

Named for town of Irondequoit, just north of Rochester, Monroe County, N.Y.

Iron Gate facies (of Clinton Formation)

Silurian (Niagaran): Southwestern Virginia.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 238, 239, 242–243, 439b (pl. 55). Clinton formation in Virginia is composed almost entirely of shale and sandstone and varies geographically in character and proportions of its constituents. About midway of Appalachian Valley (in Virginia), where crossed by James and New Rivers, lower half of formation, which is composed of shale and sandstone, including highly ferruginous sandstone beds, has been termed Cacapon division; the upper half is composed mainly of white sandstone (closely resembling the Clinch), interbedded with shale, both constituting the Keefer member; it is proposed to designate this lithologic expression of formation the Iron Gate facies. Merges laterally into Cumberland facies (new). Well illustrated by section in the Narrows of New River, Giles County, where 157 feet of Cacapon division and 156 feet of Keefer sandstone are exposed.

Type section: Iron Gate arch in gorge of James River through Rich Patch Mountain, about 1½ miles southeast of Clifton Forge, Alleghany County.

Iron Hill Member (of Windrow Formation)

Cretaceous: Northeastern Iowa, southeastern Minnesota, and southwestern Wisconsin.

G. W. Andrews, 1958, Jour. Geology, v. 66, no. 6, p. 599, 605–607. The porous concretionary iron oxide deposit included in Windrow formation by Thwaites and Twenhofel (1921) is here designated Iron Hill member and is defined to include iron oxide deposits relatively free of coarse clastic material. Thickness about 15 feet. Unconformably underlies East Bluff member (new); unconformably overlies Cedar Valley limestone.

Named for exposure in roadcut on State Highway 9 near Iron Hill, about 1 mile north of Waukon, Allamakee County, Iowa.

Iron King Volcanics (in Alder Group)

Precambrian (Yavapai Series): Central Arizona.

C. A. Anderson and S. C. Creasey, 1958, U.S. Geol. Survey Prof. Paper 308, p. 26–28, pl. 1. Andesitic tuffaceous sedimentary rock and basaltic and perhaps andesitic flows. All but upper 500 to 1,000 feet is basalt; upper unit is andesitic tuffaceous sedimentary rock and is free of lava flows. Tuffaceous beds occur in transition zone with underlying Spud Mountain volcanics (new) and as interbeds in the flow. Basaltic flows range from grayish green to greenish black. Pillow structures in flows. Belt of Iron King volcanics ranges in width from 9,500 feet near Humboldt to 11,500 feet at south edge of map area. Because of duplication by the major syncline, formation is only about 5,500 feet thick.

Named from exposures in Iron King Gulch, Jerome area, Yavapai County.

Iron Mine Member (of Muldoon Formation)

Upper Mississippian (Chesterian): Central and eastern Idaho.

M. R. Thomasson, 1959, Dissert. Abs., v. 20, no. 3, p. 999. Composed of clastics. Thickness, 3,600 feet. Underlies Wildhorse member (new); overlies Garfield member (new).

Deposited in Muldoon trough, aligned N. 30° W.

Iron Mountain Conglomerate[1]

Upper Cambrian: Southeastern Missouri.

Original reference: A. Winslow, 1894, Missouri Geol. Survey, v. 6, p. 331, 354.

Named for Iron Mountain, St. Francois County.

Iron Mountain intrusive[1]

Cretaceous (?): Western Texas.

Original reference: C. Schuchert, 1927, Am. Jour. Sci., 5th, v. 14, p. 400.

Forms an intrusive stock north of Marathon, Brewster County, known as Iron Mountain.

Iron Mountain Porphyry[1]

Precambrian: Southeastern Missouri.

Original references: C. R. Keyes, 1894, Missouri Geol. Survey, v. 4, p. 30; 1895, Missouri Geol. Survey Sheet Rept. 4, v. 9.

Named for Iron Mountain, St. Francois County.

†Iron Mountain Series[1]

Precambrian (Llano Series): Central Texas.

Original reference: T. B. Comstock and E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., p. lvii, 274, pl. 3.

Named for Iron Mountain, northwest of Valley Spring, Llano County.

Iron Ridge ore bed[1]

Silurian: Southeastern Wisconsin.

Original reference: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, p. 561.

Iron River Iron-Formation Member (of Michigamme Slate)[1]

Precambrian (upper Huronian): Northern peninsula of Michigan and northeastern Wisconsin.

Original reference: C. K. Leith, R. J. Lund, and A. Leith, 1935, U.S. Geol. Survey Prof. Paper 184.

In Iron River, Mich., Crystal Falls, Mich., and Florence, Wis., districts.

Ironside Beds[1]

Pliocene: Northeastern Oregon.

Original reference: J. C. Merriam, 1916, California Univ. Pub. Dept. Geology Bull., v. 10, no. 9, p. 129.

H. E. Wood 2d, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 22. Clarendonian.

At Ironside, Malheur County.

Ironside Dolomite Member (of Sultan Limestone)[1]

Middle and Upper Devonian: Southeastern Nevada and Southeastern California.

Original reference: D. F. Hewett, 1931, U.S. Geol. Survey Prof. Paper 162, p. 10, 14.

D. F. Hewett, 1956, U.S. Geol. Survey Prof. Paper 275, p. 40. Sultan limestone mapper in San Bernadino County, Calif. Each of the three members of Sultan limestone recognized in Goodsprings quadrangle appear to be present throughout region in which formation is recognized. Thickness 60 to 200 feet. Underlies Valentine limestone member.

U.S. Geological Survey currently considers the Sultan Limestone and its members to be Middle and Upper Devonian in age.

Well exposed near Ironside mine, 1 mile north of Boss mine, on west side of Spring Mountain Range, Goodsprings region, Nevada.

Iron Springs Formation

Upper Cretaceous (?): Southwestern Utah.

J. H. Mackin, 1947, Utah Geol. Soc. Guidebook 2, p. 7–8, 9, fig. 4. Gradational sequence of conglomerates, limestones, sandstones, and siltstones (lettered A–F); boundaries within sequence arbitrary; individual members vary in thickness and are probably not everywhere contemporaneous. Relations indicate regional warping or gentle folding of Iron Springs, with tight folding. Rarely preserved in full thickness (4,000 to 5,000 feet); ranges generally between 1,000 and 3,000 feet. Unconformably underlies Claron formation with angular discordance commonly less than 30° but locally as much as 90°. Separated from underlying Homestake formation by sandstone-shale unit probably equivalent in part to Jurassic Entrada.

J. H. Mackin, 1954, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–14. In Granite Mountain area. Iron County, term Pinto sandstone is abandoned and the part of that formation between the Entrada and the Claron is designated Iron Springs formation. Here, formation is composed of lenticular beds of sandstone, shale, conglomerate, and fresh-water limestone; locally three stratigraphic units can be distinguished in lower part (A, B, and C). Total thickness of A, B, and C, about 400 feet; maximum thickness formation 3,000 feet.

Named for occurrence in vicinity of Iron Springs, Iron County.

Ironstone Quartz Diorite[1]

Devonian(?): Central and southern Massachusetts and northeastern Connecticut.

Original reference: B. K. Emerson, 1917, U.S. Geol. Survey Bull. 597, p. 168–170, map.

Named for exposures in railroad cut at Ironstone, in town of Blackstone, Worcester County, Mass.

Ironton Granite

Precambrian: Southeastern Missouri.

H. B. Graves, 1938, Acad. Sci. St. Louis Trans., v. 29, no. 5, p. 119. Fine-grained red granite.

Crops out in two areas west of Ironton, Iron County. Granite near Hogan, Fredericktown, and Knoblick may belong to same generation as that at Ironton.

Ironton Sandstone Member (of Franconia Sandstone)[1]

Upper Cambrian: Southwestern Wisconsin and southeastern Minnesota.

Original reference: F. T. Thwaites, 1923, Jour. Geology, v. 31, p. 550.

C R. Stauffer, G. M. Schwartz, and G. A. Thiel, 1938, (abs.) Geol. Soc. America Bull., v. 49, no. 12, pt. 2, p. 1902; 1939, v. 50, no. 8, p. 1238 (table 2), p. 1239; C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 30, 37–40 measured sections. In Minnesota, underlies Taylors Falls member (new) which name is used in preference to term Goodenough member as used by Twenhofel, Raasch, and Thwaites (1935).

R. R. Berg, 1953, Jour. Paleontology, v. 27, no. 4, p. 553, 554, 555; 1954, Geol. Soc. America Bull., v. 65, no. 9, p. 858 (fig. 1), 861–862, 863. Name abandoned. Franconia member names proposed by Twenhofel, Raasch, and Thwaites (1935) are geographic names applied to faunal zones. New member names are proposed to designate rock types, as distribution of faunal zones in formation is largely independent of natural rock units. Ironton member carries *Camaraspis* (*Elvinia*) fauna. This fauna is present in Woodhill and Birkmose members.

Type locality: Ironton, Sauk County, Wis.

Ironton slate[1]

Precambrian: Southeastern Missouri.

Original reference: C. R. Keyes, 1915, Iowa Acad. Sci. Proc., v. 22, p. 252.

Probably named for Ironton, Iron County.

Irontown Member (of Page Ranch Formation)

Oligocene, upper, or Miocene, lower: Southwestern Utah.

J. H. Mackin, 1960, Am. Jour. Sci., v. 258, no. 2, p. 90 (table 1), 97. Crudely bedded fanglomerate, made up chiefly of subangular blocks of Harmony Hills tuff (new) and other Quichapa ignimbrites. Underlies Kane Point tuff member (new); overlies Rencher formation. Zircon age of Kane tuff is 19 million years; this suggests that Rencher-Page Ranch period of extrusive-intrusive igneous activity is late Oligocene or early Miocene. Discussion of ignimbrites of area.

Exposed in east-facing scarp 2 miles northwest of Page Ranch and 1 mile southwest of Old Irontown historic site, Page Ranch quadrangle, Iron Springs district.

Ironwood Iron-Formation[1]

Precambrian (Animikie Series): Northwestern Michigan and northwestern Wisconsin.

Original reference: C. R. Van Hise, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 3, p. 338.

W. O. Hotchkiss, 1919, Eng. Mining Jour., v. 108, p. 501–505. Subdivided to include following members (ascending): Plymouth ferruginous chert, Yale, Norrie ferruginous chert, Pence ferruginous slate, and Anvil ferruginous chert.

N. K. Huber, 1959, Econ. Geology, v. 54, no. 1, p. 82–116. Detailed discussion of origin of formation. Included in Animikie series. Underlies Tyler formation; overlies Palms quartzite. Thicknesses (taken from bore holes) 421 and 513½ feet.

City of Ironwood, Mich., is partly located on formation.

Iroquois Flow or Amygdaloid (in Portage Lake Lava Series)

Precambrian (Keweenawan): Northern Michigan.

W. S. White, H. R. Cornwall, and R. W. Swanson, 1953, U.S. Geol. Survey Geol. Quad. Map GQ–27. More persistent lava flow in Portage Lake lava series, above Calumet and Hecla conglomerate and below Houghton conglomerate.

E. S. Davidson and others, 1955, U.S. Geol. Survey Geol. Quad. Map GQ–54. Amygdaloid is at top of flow in Mohawk quadrangle.

Amygdaloid is principal mineralized unit being mined in Iroquois mine, Mohawk quadrangle.

Iroquois Stage[1]

Pleistocene: Great Lakes region.

Original reference: W. Upham, 1895, Am. Geologist, v. 16, p. 106.

Irvine facies (of Brodhead Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 76, 166–177. Predominantly massive siltstones with lesser amounts of silty and argillaceous shales; no significant amount of limestone present. Thickness 150 to 195 feet. To the west-southwest, facies merges into the Liberty facies (new); to the north-northeast, merges into Morehead facies (new). Comprises Indian Fort shale, Combs Mountain siltstone, and Conway cut siltstone members (all new) of Brodhead formation (new). At type locality, underlies Floyds Knob formation and overlies New Providence formation, Boone Gap facies (new).

Type locality: Along State Highway 52 at hill west of Fitchburg Furnace Branch, Estill County, extending along highway 1½ miles northwest from bridge. Named for city of Irvine, located on lowland of Kentucky River.

Irvine Formation[1]

Pliocene or Pleistocene: Central Kentucky.

Original reference: M. R. Campbell, 1898, U.S. Geol. Survey Geol. Atlas, Folio 46, p. 3.

W. R. Jillson, 1947, Pliocene deposits of lower Kentucky River valley: Frankfort, Ky., Roberts Printing Co., p. 6–12. Occurrence in Franklin County discussed.

Named for Irvine, Estill County.

Irvine Shale (in Santiago Formation)

Eocene: Southern California.

George Lunetta, 1953, California Div. Mines Inf. Service, v. 6, no. 10, p. 4–6. Marine mudstone. Massive beds of shale from 40 to 60 feet thick alternate with thin beds of clayey sandstone and clayey limestone. Medium-grained sandstone occurs in lenticular beds up to 3 feet thick. Beds of limestone are generally 1 to 6 feet thick.

Occurs in Gypsum Canyon on Irvine Ranch, 2½ miles south of State Highway 18, in extreme northern end of Santa Ana Mountains, Orange County.

Irvineton parvafacies[1]

Upper Devonian: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 28.

Named from village of Irvineton, on Allegheny River, 4 miles west of Warren, Warren County.

Irving Greenstone[1]

Precambrian (Gunnison River Series): Southwestern Colorado.

Original reference: E. Howe, 1904, Jour. Geology, v. 12, p. 501–509.

Well exposed in southeastern part of Needle Mountains quadrangle and forms Irving Peak.

Irvington Gravels, Beds, or deposits

Pleistocene, lower: Northern California.

G. D. Louderback, 1951, California Div. Mines Bull. 154, p. 81. Southeast of Irvington, on east side of bay, a deposit of older alluvium has been cut and its eastern part elevated along a fault. Subsequent erosion has exposed gravels which have been excavated for commercial use. These Irvington beds have yielded a mammalian fauna considered to be lower Pleistocene in age.

D. E. Savage, 1951, California Univ. Dept. Geol. Sci. Bull., v. 28, no. 10, p. 219–224, 289. Terms Irvington gravels and Irvington deposits are used in this report [Late Cenozoic vertebrates, San Francisco Bay area], but terms are not formally defined. Irvington fauna was described from these gravels, and Irvingtonian stage was proposed for time of deposition of these rocks.

C. A. Hall, Jr., 1958, California Univ. Pubs. Geol. Sci., v. 34, no. 1, p. 31–33, fig. 2, geol. map. No formal naming of the formation (Irvington gravels) or type locality has been given in any publication. Savage (1951) used term Irvington gravels repeatedly throughout his report on Cenozoic vertebrates of San Francisco Bay region, and he is here considered to have named the unit. These gravels have been referred to as Santa Clara gravels by previous workers. Irvington gravels composed of crossbedded stream and, possibly in part, lake deposits. Dips 20° to 25° to the north or northeast. Unconformably overlies Briones sandstone. General appearance of formation is much like that of Livermore gravels, but mountain ridge separates Irvington and Livermore gravels; hence, the two units are mapped separately. Savage regarded Irvington fauna as "earlier Pleistocene" or post-Blancan, pre-Rancholabrean. Irvingtonian stage proposed by Savage (1951) for time of deposition of these rocks is lower Pleistocene in age.

Exposed at foot of Mission Peak (referred to by Savage as "Irvington-Mission San Jose bench"), Alameda County. Outcrop area is bounded on north by alluvium from Mission Creek and west by Hayward fault.

Irvingtonian Age

Pleistocene, early: North America.

D. E. Savage, 1951, California Univ. Pubs., Dept. Geol. Sci. Bull., v. 28, no. 10, p. 289. Provincial time term typified by Irvington (vertebrate) fauna. Irvingtonian is post-Blancan to pre-Rancholabrean.

Irwinton Sand Member (of Barnwell Formation)

Eocene, upper: East-central Georgia.

P. E. LaMoreaux, 1946, Georgia Geol. Survey Bull. 50, pt. 1, p. 3 (fig. 1), 10–11, 13, 17–18; 1946, Georgia Geol. Survey Bull. 52, p. 52, 59. At type locality and in Washington, Wilkinson, and Twiggs Counties, consists of 30 to 50 feet of light-yellow, gray, and white fine- to medium-grained micaceous quartz sand interbedded with thin gray to yellow layers, and an occasional bed of coarse white sand with carbonaceous zones. Thins updip to about 15 to 20 feet. Becomes coarse grained, and has an increasing number of clay beds so that in southern Jones, Baldwin, Hancock, and northern Washington Counties it contains about equally thick, 1- to 6-inch alternating beds of fine, medium or coarse sand and yellow and gray clay layers. May be in part equivalent to Sandersville limestone member (Cooke, 1943). Conformably overlies Twiggs clay member; underlies, with possible unconformity, a coarse red sand in upper part of formation. Believed to merge laterally with Twiggs clay into Ocala limestone in western half of Georgia.

Type locality: In gullies on Hatfield property 150 yards west of a cemetery which is 0.3 mile south of courthouse at Irwinton along Georgia Highway 29, Wilkinson County.

Isabel Sandstone[1] (in Carbondale Group)

Isabel Sandstone Member (of Spoon Formation)

Pennsylvanian: Western Illinois.

Original reference: H. R. Wanless, 1931, Illinois Geol. Survey Bull. 60, p. 192.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 50 (fig. 22), 83–84, 191, 197, 198, 199. Fairly well indurated; upper part commonly thin bedded and lower part more massive. Six inches to about 10 feet thick, reaching maximum thickness near type outcrop. Included in Abingdon cyclothem.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 33, 46 (table 1), 62, pl. 1. Rank reduced to member status in Spoon formation (new). Occurs above Greenbush coal member and below Abingdon coal member. Presentation of new rock-stratigraphic classification of Pennsylvanian strata of Illinois.

Type locality: High bank on southeast side of ravine, NW¼NE¼ sec. 16, T. 4 N., R. 3 E., Havana quadrangle, Fulton County. Named for Isabel Township.

Isabel-Firesteel facies or coal member (of Hell Creek Formation)

See **Hell Creek Formation.**

Isabella Granodiorite[1]

Upper Cretaceous: Southern California.

Original reference: W. J. Miller, 1931, California Univ. Pub. Dept. Geol. Sci. Bull., v. 20, no. 9, p. 343–352.

W. J. Miller and R. W. Webb, 1940, California Jour. Mines and Geology, v. 36, no. 4, p. 357–358, 378 (fig. 31), pl. 2. Shown on map and columnar section as Jurassic(?).

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 512, table 4. Late Mesozoic.

E. M. MacKevett, Jr., 1960, U.S. Geol. Survey Bull. 1087–F, p. 181-189, pls. Lead-alpha age determinations range from 85 to 96 million years. Average age is 90 million years, nearly equivalent to beginning of Late Cretaceous epoch. Younger than Kernville series.

Typical occurrence in vicinity of Isabella, Kernville quadrangle, Kern County.

Isabella Stage[1]

Quaternary: Puerto Rico.

Original reference: B. Hubbard, 1923, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 2, pt. 1, p. 95.

†Ischua Sandstone[1]

Upper Devonian: Western New York.

Original reference: E. N. Horsford, 1840, New York Geol. Survey 4th Ann. Rept., p. 466, 469–470.

Occurs in Ischua stone quarries, Machias, Cattaraugus County.

†Ishawooa intrusives[1]

Miocene: Yellowstone National Park, Wyoming.

Original reference: A. Hague and others, 1904, U.S. Geol. Survey Mon. 32, Atlas; Canyon, Lake Crandall, and Ishawooa sheets.

Named for exposures on west side of Ishawooa Mesa, Yellowstone National Park.

Ishpeming Basic Volcanics

†Ishpeming Formation[1]

Precambrian (Huronian): Northwestern Michigan.

Original reference: C. R. Van Hise and W. S. Bayley, 1895, U.S. Geol. Survey 15th Ann. Rept., p. 590.

W. A. Seaman, 1944, Michigan Dept. Conserv., Geol. Survey Div. Prog. Rept. 10, p. 12 (table 1), 15. Term originally used to include conglomerate, quartzite, and slates above the Negaunee, but is here restricted to the volcanics accompanying the local upheaval that stopped deposition of Negaunee iron formation. Succeeded by Goodrich conglomerate, quartzite, and slate.

Named for occurrences in vicinity of Ishpeming, Marquette County.

Isla Mona Limestone

Miocene, lower or middle: Puerto Rico.

C. A. Kaye, 1959, U.S. Geol. Survey Prof. Paper 317–C, p. 146–147, pl. 12. Thick-bedded, dense, and finely crystalline limestone and dolomite; white on fresh surface but in cliffs stained yellow. Unconformable below Lirio limestone (new). On basis of corals, age appears to be Miocene, probably early or middle.

Forms main mass of Isla Mona and Monito.

†Island Series[1]

Upper Cretaceous: Southeastern Massachusetts and southeastern New York.

Original reference: L. F. Ward, 1895, U.S. Geol. Survey 15th Ann. Rept., p. 335–336.

Extends from Staten Island to Marthas Vineyard.

Island Creek Shale[1] Member (of Wyandotte Formation)

Upper Pennsylvanian (Missouri Series): Eastern Kansas, southwestern Iowa, and southeastern Nebraska.

Original reference: R. C. Moore, 1931, Kansas Geol. Soc. Guidebook 5th Ann. Field Conf., correlation chart.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4), 2033. Island Creek shale member of Wyandotte formation; underlies Farley limestone member; overlies Argentine limestone member. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma. Previously, Missouri had classed Island Creek as basal member of Lane shale.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 35. Thickness 2 to 3 feet or more in Iowa and Nebraska, about 20 feet in northwestern Missouri, maximum 40 feet in Kansas. Additional data on type locality.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 25. As exposed in quarry in Madison County, Island Creek is a gray, platy, fossiliferous shale with limestone nodules near top. Thickness 4½ feet. Underlies Farley limestone member; overlies Argentine limestone member.

Type locality: In quarry, NW cor. sec. 11, T. 10 S., R. 23 E., near Wolcott, Wyandotte County, Kans. Named for Island Creek.

Island Hill Formation[1]

Lower Devonian: Northeastern Mississippi.

Original reference: W. C. Morse, 1928, Jour. Geology, v. 36, p. 31–43.

Fossiliferous limestone about 3 feet thick, above New Scotland limestone and below Whetstone Branch shale.

Exposed in Tishomingo County. Named for isolated hill on Yellow Creek about 3 miles above its mouth.

Island Mesa Beds[1]

Upper Devonian: Northern central Arizona.

Original reference: A. A. Stoyanow, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 500.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart above Jerome formation.

Exposed 12 miles northeast of Jerome, on Verde River, and southwest of Island Mesa.

Island Mine Conglomerate[1] (in Eagle River Group)

Precambrian (Keweenawan): Northern Michigan.

Original reference: A. C. Lane, 1898, Michigan Geol. Survey, v. 6, pt. 1, p. 99, 204, 206, 217, pl. 1.

Named for occurrence in Island mine, Isle Royale.

Isle La Motte Limestone or Formation

Isle La Motte Marble[1]

Middle Ordovician: Northwestern Vermont and northeastern New York.

Original reference: Ebenezer Emmons, 1842, Geology New York, pt. 2, div. 4, geology of 2d dist., p. 386.

G. M. Kay, 1937, Geol. Soc. America Bull., v. 48, no. 2, p. 260–261, pl. 2. Limestone assigned to Trenton group of Mohawkian series. Described at type locality as black gray-weathering medium-textured heavy-ledged limestone. Probably includes underlying blue-black limestone. Total thickness 12½ feet. Underlies Larrabee member of Glens Falls formation; overlies Lowville limestone or Amsterdam limestone. Type section designated.

Marshall Kay, 1945, (abs.) Geol. Soc. America Bull., v. 56, no. 12, pt. 2, p. 1172. Overlies Youngman formation (new) in Highgate Springs sequence, northwestern Vermont.

R. B. Erwin, 1957, Vermont Geol. Survey Bull. 9, p. 27, 61, 66, 68–69, 85–89, pl. 1. Further described on Isle La Motte and in several fault blocks on South Hero Island in Lake Champlain. Maximum thickness in latter area 40 feet.

Marshall Kay, 1958, Am. Jour. Sci., v. 256, no. 2, p. 85–87. Considered lower Trentonian by Kay (1937). This designation now considered to be in error. Isle La Motte is now classified as Blackriveran and correlated with Chaumont limestone of Black River group of northwestern New York.

Type section: In Hill quarry on east side of Isle La Motte in Lake Champlain, Grand Isle County, Vt.

Isle La Motte Sandstone[1]

Lower Ordovician: Northwestern Vermont.

Original reference: H. M. Seely, 1906, Vermont State Geologist 5th Rept., p. 174–187.

Named for Isle La Motte, northern part of Lake Champlain.

Isle Royale Amygdaloid[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: R. D. Irving, 1883, U.S. Geol. Survey Mon. 5, p. 195.

T. M. Broderick, C. D. Hohl, and H. N. Eidemiller, 1946, Econ. Geology, v. 41, no. 7, p. 678 (fig. 1). Name appears on geologic section of Michigan copper district.

Named for occurrence in Isle Royale mine, Houghton County.

Isle Royale Flow[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Copper district of Keweenaw Point.

†Isle Royale trap[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Copper district of Keweenaw Point.

Islesboro Formation[1]

Cambrian(?): Central southern Maine.

Original reference: G. O. Smith, E. S. Bastin, and C. W. Brown, 1907, U.S. Geol. Survey Geol. Atlas, Folio 149, p. 2–3.

H. W. Allen, 1951, Maine State Geologist Rept. 1949–1950, p. 79. Sequence of metamorphosed sedimentary rocks in area of Rockland quadrangle, Knox County, is (ascending) Islesboro formation containing Coombs limestone member at top; Battie quartzite; Penobscot formation; and Rockland formation consisting of Weskeag quartzite member at base, a siliceous limestone member above the quartzite, and Rockport limestone member at top.

Named for development on Islesboro, Waldo County.

Isom Formation

Eocene(?) or Oligocene, lower(?): Southwestern Utah.

J. H. Mackin, 1960, Am. Jour. Sci., v. 258, no. 2, p. 90 (table 1), 92 (fig. 2), 98–99. Chiefly ignimbrites and lava flows with intercalations of sedimentary rocks. At type locality, consists of an ignimbrite of Leach Canyon type, a few tens of feet thick, which has not been definitely identified elsewhere and needs no formal name. Lower unit is Baldhills member (new); upper is Hole-in-the-Wall member (new). Thickens greatly and is widespread in High Plateaus. Underlies Quichapa formation; at type locality, overlies Needles Range formation (new); in some areas, overlies Claron formation or on volcanic rocks of local origin. Needles-Isom sequence is probably Eocene or early Oligocene in age. Discussion of ignimbrites of area.

E. F. Cook, 1960, Utah Geol. and Mineralog. Survey Bull. 70, p. 18 (fig. 1), 36–37, geol. map. Present in Bull Valley district, Washington County, where it has maximum thickness of 170 feet and consists of andesite(?) flows overlain by two thin, highly welded, latitic, vitric ignimbrites with sparse phenocrysts. Overlies Claron formation; underlies Quichapa formation. Wedges out southward. Tertiary.

Type locality: Southern slope of east-west ridge just north of Isom Creek in northwestern part of Iron Springs district (Three Peaks quadrangle, sec. 5, T. 35 S., R. 12 W.).

Ithaca facies sub-group[1]

Upper Devonian: Central southern New York.

Original reference; K. E. Caster, 1933, Geol. Soc. America Bull., v. 44, pt. 1, p. 202. Ithaca region.

Ithaca Member (of Genesee Formation)

Ithaca Shale

Ithaca Shale Member (of Portage Formation)[1]

Upper Devonian: Central New York.

Original reference: James Hall, 1839, New York Geol. Survey 3d Rept., p. 318–325.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1743, chart 4. Ithaca shale consists of six members of uncertain relationships: Renwick shale, Six Mile shale, Cascadilla shale, Williams Bridge shale, Marathon sandstone, and Triphammer shale.

Wallace de Witt, Jr., and G. W. Colton, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2814, 2815, 2821–2822. Reallocated to member status in Genesee formation. Near Cayuga Lake is a heterogeneous sequence of fine-grained sandstone, siltstone, silty shale, and silty mudrock. This sequence, which is about 400 feet thick near Ithaca, constitutes Ithaca group of Hall (1839) and most of Ithaca shale member of Portage formation (Williams and others, 1909, U.S. Geol. Survey Geol. Atlas, Folio 169). Name Ithaca member is here restricted to rocks above Renwick shale member and below West River shale member. Term shale is dropped from member name because the Ithaca is composed largely of siltstone and other nonfissile rocks. Thickness 413 feet at reference section, herein designated. Top of member is placed at top of thick-bedded sequence of siltstone, above which the rocks consist largely of silty gray shale containing much thinner beds of siltstone, a few thin beds of black shale, and scattered silty calcareous nodules. In Coy Glen and in some lentil of coquinite about 1 foot thick is present at top of member. Mapped westward from outcrops near Ithaca to exposures at the north end of West Branch of Keuka Lake. Intertongues with lower part of West River shale member in area between Keuka Lake and valley of West River. In vicinity of Keuka and Seneca Lakes, the Ithaca member of this paper was named Starkey tongue of Sherburne formation by Grossman.

Reference section: Coy Glen, 2 miles southwest of center of Ithaca, Tompkins County. Named for occurrence at Ithaca.

Ithaca Peak Granite

Ithaca Peak Porphyry

Mesozoic(?): Northwestern Arizona.

B. E. Thomas, 1949, Econ. Geology, v. 44, no. 8, p. 667, fig. 2; 1953, Geol. Soc. America Bull., v. 64, no. 4, p. 403–405, pl. 1. Ithaca Peak porphyry comprises two intrusions of granite porphyry within the Cerbat complex (new). Intrusion in Chloride district is curved steeply dipping sill from 2,000 to 5,000 feet thick, whereas intrusion in Mineral Park district is stock that has roughly circular exposed area 3½ to 4 miles in diameter. Several thick tongues extend out from southeast side of stock, largest reaching 1½ miles through Union Basin to Golconda mine. Tertiary(?).

M. G. Dings, 1951, U.S. Geol. Survey Bull. 978–E, p. 130–132, pl. 18. Cited as Ithaca Peak granite and restricted to Mineral Park district. Granite near Chloride tentatively assigned to Precambrian and renamed Chloride granite (new). Main mass of granite stock weathers buff to reddish brown. Fresh rock typically light-gray fine- to medium-grained porphyritic granite. Outlying bodies of granite particularly abundant from Mineral Park south into Stockton and Cerbat camps, some of which grade into granite porphyry, although most are of porphyritic granite. Geographic distribution given.

Named after imposing crag in Mineral Park district. Both Ithaca Peak and Turquoise Mountain composed of the granite. All in Wallapai mining district, Mohave County.

Itkillik Glaciation

Pleistocene: Central northern Alaska.

R. L. Detterman *in* T. L. Péwé and others, 1953, U.S. Geol. Survey Circ. 289, p. 11–12, 13 (table 1). Four Quaternary glacial advances recognized in Sagavanirktok-Anaktuvuk district. Itkillik preceded Echooka glaciation (new); succeeded Sagavanirktok glaciation (new). Till covers approximately 1,000 square miles and forms thin mantle 30 to 50 feet thick over much of area. Drift forms fan-shaped deposits at mouths of major valleys. A few well-developed moraines as much as 200 feet thick. Terminal and lateral moraines as well as knob and kettle topography easily recognized. Numerous kettle lakes. Piedmont lobe formed at time of Itkillik glaciation.

Named after Itkillik River in central part of Sagavanirktok-Anaktuvuk region.

Iuka Formation[1]

Lower Mississippian: Northeastern Mississippi.

Original reference: W. C. Morse, 1928, Jour. Geology, v. 36, p. 31–43.

Named for Iuka, Tishomingo County.

Ivan Limestone Member (of Graham Formation)

Ivan Formation or Limestone (in Thrifty Group)

Ivan Limestone (in Graham Group)

Ivan Limestone Member (of Thrifty Formation)[1]

Upper Pennsylvanian: Central northern Texas.

Original reference: F. B. Plummer and R. C. Moore, 1922, Jour. Geology, v. 30, p. 24, 31.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Shown on correlation chart as Ivan formation in Thrifty group. Underlies Speck Mountain formation (Blach Ranch formation); overlies Avis sandstone.

M. G. Cheney and H. D. Eargle, 1951, Geologic map of Brown County, Texas (1:62,500): Texas Univ. Bur. Econ. Geology. Shown on columnar section as Ivan limestone in Thrifty group.

M. G. Cheney and H. D. Eargle, 1951, West Texas Geol. Soc. Guidebook Spring Field Trip, June 1–2, p. 1 (fig. 1). Listed on chart as Ivan (Rocky Mount), "*Bellerophon*" member of Thrifty formation. Occurs above Avis sandstone and below Speck Mountain (Blach Ranch member).

John Kay, 1956, North Texas Geol. Soc. Field Guidebook, May 25–26, fig. 4. Shown on generalized columnar section as Ivan limestone in Graham group. Underlies Blach Ranch limestone; overlies Avis sandstone.

D. H. Eargle, 1958, San Angelo Geol. Soc. Guidebook, Apr. 17–19, p. 50. Shown on composite section of Brown and Coleman Counties as Ivan limestone member of Graham formation. Consists of gray algal limestone that locally contains abundant horn corals and fusulinids. Thickness about 15 feet. Overlies Wayland shale; stratigraphically below Speck Mountain limestone member of Thrifty formation.

D. H. Eargle, 1960, U.S. Geol. Survey Prof. Paper 315–D, p. 71, pl. 27. Name Ivan limestone member of Graham formation extended into Brown and Coleman Counties and applied to unit that was described as *Bellerophon* bed by earlier authors (Nickell, 1938, Texas Univ. Bur. Econ. Geology Pub. 3801). Locally the Ivan changes in lithologic character from limestone to calcareous sandstone and (or) shale within short distances. Overlies Wayland shale member; separated from overlying Speck Mountain limestone member of Thrifty formation by shale unit that was called Speck Mountain clay bed by Drake (1893). Thickness as much as 18 feet.

Named for exposures in vicinity of Ivan, Stephens County.

Ivanhoe Glacial Substage

Pleistocene (Cary) : West-central Colorado.

R. L. Nelson, 1954, Jour. Geology, v. 62, no. 4, p. 331–333, fig. 2, table 4. Time of Wisconsin glaciation in Frying Pan Valley during which outwash deposits and Ivanhoe moraines were deposited. Older than Hell Gate glacial substage (new) ; younger than Biglow glacial substage (new).

Name derived from area just east of Ivanhoe. In Frying Pan River drainage just west of Continental Divide in Sawatch Range.

Ivanhoe Limestone Member (of Rome Formation)

Ivanhoe Limestone Member (of Shady Dolomite)[1]

Lower Cambrian : Southwestern Virginia.

Original reference: Charles Butts, 1933, Virginia Geol. Survey Bull. 42, p. 3, map legend.

G. W. Stose and A. I. Jonas, 1938, Virginia Geol. Survey Bull. 51–A, p. 8, 9. Reallocated to member status in Rome formation.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 41, 44–46, 52. In Wythe and Pulaski Counties, Ivanhoe is uppermost member of Shady dolomite; overlies Austinville dolomite member (new) ; underlies Rome formation. Thickness 542 to 547 feet.

Named for exposures in vicinity of Ivanhoe, Wythe County.

Iversen Basalt

"Between late Cretaceous and Oligocene" : Northern California.

C. E. Weaver, 1944, Washington [State] Univ. Pubs. in Geology, v. 6, no. 1, p. 4, 17–18, pl. 2. Dark-gray to black dense fine-grained basalt with alternating flows of vesicular and amygdaloidal rock and intercalated lenslike masses of tuffaceous sandstone; pillow structure. Thickness 800 feet. [This part of description is identical with initial description given of unit termed Skooner Gulch basalt by Weaver, 1943. In 1944, Weaver redescribed the Skooner Gulch as a sandstone formation.] Lavas stand at high angles with prevailing northwestward dip. Rests unconformably upon sandstones and shales of Gualala group and lies with erosional unconformity below Oligocene(?) or lower Miocene sediments. Stratigraphic table shows basalt underlying redescribed Skooner Gulch formation.

Exposed in sea cliffs, highway cuts, and in outcrops on hill slopes within an area approximately 100 feet wide by 3 miles long and extending from near Iversen Point northward to and beyond mouth of Skooner Gulch, Mendocino County.

Ives Breccia Member (of Houy Formation)

Ives Breccia

Ives Conglomerate Member (of Chappel Formation)

Middle(?) and Upper Devonian : Texas.

F. B. Plummer, 1939, *in* West Texas Geol. Soc. [Guidebook] Nov. 11–12, p. 15. Basal conglomerate of Chappel formation. Made up of rounded chert cobbles derived from the Ellenburger; fairly firmly cemented into layers 8 inches to 1 foot thick.

P. E. Cloud, Jr., and V. E. Barnes, 1948, Texas Univ. Bur. Econ. Geology Pub. 4621, p. 27, 42, 44 (fig. 2), 46–49. Unit raised to formational rank and designated Ives breccia because of commonly angular character of chert pebbles and granules it contains. At locality cited by Plummer (1950), the Ives overlaps beds of Honeycut formation. Considered older than Chappel limestone. Correlated with beds considered to be basal Mississippian by some and uppermost Devonian by others.

F. B. Plummer, 1950, Texas Univ. Bur. Econ. Geology Pub. 4329, p. 26, 27. Underlies Espey Creek limestone member and overlies King Creek marl member (both new). Mississippian. Exposures noted.

P. E. Cloud, Jr., V. E. Barnes, and W. H. Hass, 1958, Geol. Soc. America Bull., v. 68, no. 7, p. 810, pl. 1. Rank reduced to member status in Houy formation (new). Occurs near base of formation and below Doublehorn shale member (new). Includes lag deposits of detrital chert of varied age and source. Zesch formation of Barnes and others (1947) is a partial synonym for Ives breccia. Middle(?) and Upper Devonian. Type site designated.

Type locality: Along Ives Branch on Gibbons Ranch 2½ miles southwest of Hall, San Saba County. This is Plummer's (1950) locality 205–T–125 which he designated as best exposure of Ives conglomerate.

Ivy Point Member[1] (of Ludlowville Shale)

Middle Devonian: Central New York.

Original reference: Burnett Smith, 1935, New York State Mus. Bull. 300, p. 11, 47.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Underlies Spafford member; overlies Otisco member.

Type section: In first ravine north of Ivy (or Willow) Point on east side of Skaneateles Lake, three-fourths mile north and slightly west of Spafford Landing, Skaneateles quadrangle.

Iwana Green Schist[1]

Post-Carboniferous(?): Eastern Alabama.

Original reference: W. M. Brewer, 1896, Alabama Geol. Survey Bull. 5, p. 84, 89, 92.

Named for exposures about Iwana, Coosa County.

†Izard Limestone[1]

Lower and Middle Ordovician: Northern Arkansas.

Original reference: R. A. F. Penrose, Jr., 1891, Arkansas Geol. Survey Ann. Rept. 1890, v. 1, p. 102, 112–113, 121–124, 587–593.

Type locality: Penters Bluff, southeastern Izard County.

Izee Group

Middle Jurassic: East-central Oregon.

R. L. Lupher, 1941, Geol. Soc. America Bull., v. 52, no. 2, p. 227 (table 1), 229, 255. Consists of two noncalcareous formations, Hyde below and Snowshoe above (both new). Thickness 3,880 feet. Overlies Colpitts group (new); extends northeastward into Silvies River region, beveling both Colpitts and Mowich groups and lying discordantly upon Triassic strata; unconformably underlies Trowbridge shale (new).

Widely exposed along Ochoco anticline from western end of Jurassic rock area northeastward across South Fork Valley and into west side of Bear Valley. Named for Izee Grange and Schoolhouse near South Fork River between Poison Creek and Rosebud Creek, Crook County.

Jacaguas Group

Eocene, middle: Puerto Rico.

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm. and Princeton Univ. Dept. Geology, p. 70–103, geol. map. Includes two formations, Naranjo to east of the Río Guayo and Augustinillo to west of the Río Guayo. Thickness about 17,000 feet. Bounded on south by Cerrillos-Descalabrado fault that obscures its exact thickness.

E. A. Pessagno, Jr., 1960, Caribbean Geol. Conf., 2d, Mayagüez, Puerto Rico, 1959, Trans., p. 83. Name replaces Guayabal group, used to include Naranjo and Augustinillo formations.

Named after the Río Jacaguas near Juana Díaz.

Jacalitos Formation[1]

Jacalitos Stage

Pliocene, lower: Southern California.

Original reference: R. Arnold and R. Anderson, 1908, U.S. Geol. Survey Bull. 357.

S. S. Siegfus, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 1, p. 27 (fig. 2), 32–36. Overlies Reef Ridge shale. Confusion in defining upper contact of Reef Ridge has resulted to some extent from difference of opinion regarding lower limit of the Jacalitos. Various interpretations discussed.

W. P. Woodring, 1940, U.S. Geol. Survey Prof. Paper 195, p. 27 (table), 114–117. Underlies Etchegoin formation (restricted), although Jacalitos (as shown in table on page 27) is included in the Etchegoin by some geologists.

I. F. Wilson, 1943, California Jour. Mines and Geology, v. 39, no. 2, p. 240. Term Etchegoin group is used in this report to include Jacalitos, Etchegoin, and possibly San Joaquin formations which cannot be distinguished in field in this report [San Benito quadrangle].

B. L. Clark, 1943, California Div. Mines Bull. 118, p. 190 [preprint 1941]. Marine lower Pliocene of San Joaquin Valley area may be referred to as Jacalitos stage. This is lower part of Etchegoin formation as redefined by Nomland (1917). He recognized two faunal zones in deposits referred originally by Arnold and Anderson to the Jacalitos.

C. W. Jennings, 1953, California Jour. Mines and Geology, v. 49, no. 3, p. 279. Formation, in Kings County, consists of about 3,500 feet of marine sandstone and conglomerate. Overlies Reef Ridge shale; underlies Etchegoin formation. Crops out as wide band in Kreyenhagen Hills and in Avenal syncline on west side of Reef Ridge.

J. W. Durham, R. H. Jahns, and D. E. Savage, 1954, California Div. Mines Bull. 170, chap. 3, p. 60 (fig. 2). Chart shows Jacalitos megafaunal "stage" equivalent to the Repettian and upper part of Delmontian microfaunal stages.

Named for exposures both north and south of Jacalitos Creek, and in Jacalitos Hills, Fresno County.

Jack Creek Formation (in Pacheco Group)

Upper Cretaceous: West-central California.

N. L. Taliaferro, 1941, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 25, no. 11, p. 2095. Unconformably underlies sediments of Asuncion group.

N. L. Taliaferro, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 4, p. 474–484. Light- to dark-gray sandy clay shales and silts with thin interbeds of fine-grained silty commonly crossbedded and ripple-marked sandstone; contains lenses and thin layers of ferruginous limestone and lenses of sandstone up to 25 feet thick in places. Thickness 1,600 to 2,900 feet. Has been tilted, folded and faulted. Underlies Asuncion group. Angular discordance between the two varies from a few degrees to 70°; unconformably overlies the Franciscan. In fault contact with Lower Cretaceous Marmolejo formation (new). Type section designated.

Type section: On Jack Creek extending for 1½ miles southeast of Dover Canyon Road, in southeast part of Adelaida quadrangle, Santa Lucia Range.

Jackfork Sandstone[1]

Jackfork Group

Mississippian: Southeastern and central southern Oklahoma and southwestern Arkansas.

Original reference: J. A. Taff, 1902, U.S. Geol. Survey Geol. Atlas, Folio 79.

David White, 1937, U.S. Geol. Survey Prof. Paper 186–C, p. 43–67. Age considered to be Pennsylvanian on basis of paleobotanic evidence. Previously regarded as uppermost Mississippian.

B. H. Harlton, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 7, p. 854 (fig. 1), 856–857, 878–889. Rank raised to group. Divided into (ascending) Wildhorse Mountain, Prairie Mountain, Markham Mill, and Wesley formations (all new). Thickness as much as 8,700 feet. Overlies Chickasaw Creek formation (new) in Stanley group; underlies Union Valley sandstone. In Pushmataha (new) and Morrow series, both of which are included in the Bendian, shown as post-Chester and pre-DesMoines.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 35). Sandstone shown on correlation chart below Johns Valley shale and above Stanley shale. Morrow series.

C. L. Cooper, 1945, Jour. Geology, v. 53, no. 6, p. 390–397. Stanley and Jackfork formations have been correlated with Pennsylvanian, but their exact age is still a problem. Flora from these formations is unlike any known flora in North America and is younger than that from Wedington sandstone member of Fayetteville shale (Chester) and older than that in Baldwin coal in Bloyd shale of Morrow group (middle Pottsville).

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 106, chart 5 (column 57). Sandstone shown on correlation chart as Chesterian. Age still debatable.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped as Pennsylvanian.

L. M. Cline, 1956, Tulsa Geol. Soc. Digest, v. 24, p. 101, 102 (chart). Studies in central Ouachita Mountains revealed two complete stratigraphic sequences of Jackfork group: one southeast of Albion in eastern Pushmataha County, in Kiamichi Range, and one southeast of Big Cedar in Le Flore County. Exposures reveal Jackfork to be 5,600 and 5,700 feet thick respectively. This is much less than previous estimates. Also study reveals that upper part of type Wildhorse Mountain formation duplicates an equivalent interval in lower part of type Prairie Mountain formation. By definition Harlton's (1938) type Prairie Mountain includes type locality of Prairie Hollow maroon shale member; however, Prairie Hollow also occurs in midst of Wildhouse Mountain type section; stratigraphic overlap amounts to about 3,600 feet; hence, thickness of Jackfork group in Tuskahoma syncline should be considerably less than previously estimated. Harlton's (1938) Union Valley sandstone not equivalent to Union Valley of type locality and here considered part of Jackfork group. Age of group Chesterian or Morrowan.

B. H. Harlton, 1959, *in* The geology of the Ouachita Mountains—a symposium: Dallas, Tex., Dallas Geol. Soc. and Ardmore Geol. Soc., p. 131 (fig. 1), 135–136. Group includes (ascending) Wildhorse Mountain, Prairie Mountain, Markham Mill, Wesley, and Game Refuge (new) formations. Game Refuge replaces name Union Valley sandstone extended into area (Harlton, 1938). Overlies Chickasaw Creek formation of Stanley group; underlies unit referred to as Johns Valley shale of published reports. Pushmataha series (Carboniferous).

L. M. Cline, 1960, Oklahoma Geol. Survey Bull. 85, p. 42–58, pl. 1. Group includes (ascending) Wildhorse Mountain, Prairie Mountain, Markham Mill, Wesley, and Game Refuge formations. Thickness 5,600 to 5,800 feet. Overlies Stanley group; stratigraphically below Johns Valley shale. Meramecian and Chesterian.

H. D. Miser and T. A. Hendricks, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 11, p. 1829–1834. Mississippian. Brief summary of development of different age interpretations that have been given for Jackfork sandstone, Stanley shale, and Johns Valley shale.

O. B. Shelburne, Jr., 1960, Oklahoma Geol. Survey Bull. 88, p. 17 (fig. 2), 26–33, pl. 1. Group described in Boktukola syncline where it is 5,400 to 6,500 feet thick. Overlies Stanley group; underlies Johns Valley shale. Mississippian, Chesterian; however, on figure 2, Meramec-Chester boundary is queried.

Named for Jackfork Mountain, Pittsburg and Pushmataha Counties, Okla.

Jackman Granite

Middle Devonian: West-central Maine.

H. W. Fairbairn and P. M. Hurley, 1957, Am. Geolphys. Union Trans., v. 38, no. 1, p. 105 (table 8), 106 (table 9). Incidental mention. Intrusive into Lower Devonian sediments.

Occurs at Jackman, Somerset County.

Jackpile Ore-Bearing Bed (in Brushy Basin Member of Morrison Formation)

Upper Jurassic: Northwestern New Mexico.

V. L. Freeman and L. S. Hilpert, 1956, U.S. Geol. Survey Bull. 1030–J, p. 317, 318. Very pale orange and locally white sandstone that is dominantly fine to medium grained with minor coarse grains at base. Characterized by scour-and-fill crossbedding, but some parallel bedding, often marked by claystone partings, is present also. Ranges from knife edge, where cutout by pre-Dakota(?) erosion, to about 175 feet at Jackpile mine. Constitutes uppermost 65 feet of member at Laguna section.

Traced from Laguna section, sec. 28 T. 10 N., R. 5 W., in nearly continuous exposures, into ore-bearing sandstone at Jackpile mine of Anaconda Copper Mining Co., Valencia County.

†Jacksboro Formation (in Cisco Group)[1]

Pennsylvanian: Central northern Texas.

Original reference: F. B. Plummer, 1919, Am. Assoc. Petroleum Geologists Bull., v. 3, p. 133–145.

Occurs in sandstone hills southwest of Jacksboro, Jack County, and also in Young County.

Jacksboro Limestone Member (of Graham Formation)[1]

Upper Pennsylvanian: Central northern Texas.

Original reference: F. B. Plummer, 1919, Am. Assoc. Petroleum Geologists Bull., v. 3, p. 133–145.

Named for exposures in vicinity of Jacksboro, Jack County.

Jacksina Formation[1]

Pre-Permian: Southeastern Alaska.

Original reference: W. C. Mendenhall, 1905, U.S. Geol. Survey Prof. Paper 41, p. 26, in column of table credited to "Schrader, geologic reconn. of headwater region of Copper and Tanana Rivers, Alaska: Prof. Paper, in preparation."

†Jackson Formation[1]

Pennsylvanian: Michigan.

Original reference: A. C. Lane, as reported by M. E. Wadsworth, 1893. Michigan Geol. Survey Rept. 1891 and 1892, p. 66.

Named for exposures at Jackson, Jackson County.

Jackson Formation[1] **or Group**

Eocene, upper: Gulf Coastal Plain from Georgia to southern Texas.

Original references: T. A. Conrad, 1856, Philadelphia Acad. Nat. Sci. Proc., v. 7, p. 257–258; E. W. Hilgard, 1860, Rept. Geology and Agriculture Mississippi, p. 128–135

M. A. Hanna and Donald Gravell *in* James McGuirt, 1934, Shreveport Geol. Soc. [Guidebook] 11th Ann. Field Trip, chart facing p. 30. Correlation chart shows Jackson comprises (ascending) Moodys Branch, Yazoo, and Danville Landing (new) groups. Danville Landing group contains Danville Landing beds. [Use of term group not explained.]

B. C. Renick, 1936, Texas Univ. Bull. 3619, p. 13–55. Group comprises (ascending) Caddell (Moodys marl), Wellborn (with Bedias and Carlos sandstones), Manning (with Dilworth and Yuma sandstones), and Whitsett formations. Overlies Yegua formation of Claiborne group; underlies Catahoula formation.

H. N. Fisk, 1938, Louisiana Dept. Conserv., Geol. Bull. 10, p. 89–111. In central Louisiana, outcrop of Jackson group extends southwestward in narrow belt from Ouachita River in southern Caldwell Parish to Red River south of Montgomery. Covers most of northwestern La Salle Parish and northern third of Grant Parish. Includes (ascending) Moodys Branch marl, Yazoo clay, and Danville Landing beds. Underlies Vicksburg group; overlies Cockfield formation of Claiborne group, transition zone. Upper Eocene.

C. W. Cooke, 1939, Jour. Paleontology, v. 13, no. 3, p. 337–340. Jackson raised to group rank in Mississippi where Moodys marl is basal formation. Name Moodys replaces name Gosport. Hence, Claiborne group restricted to formations heretofore classified as lower Claiborne.

L. D. Toulmin, Jr., 1940, Alabama Geol. Survey Bull. 46, p. 40–46. Gosport sand has been transferred from Claiborne group to Jackson group (Cooke, 1939). Cooke (1939) and Gardner (1939, U.S. Geol. Survey Prof. Paper 189–F) advocate dropping name Gosport and applying name Moodys marl to deposits in Alabama heretofore known as Gosport. In present report, name Gosport sand is retained for those beds in Alabama traditionally known by that name. Formations of Jackson group west of Tombigbee River are Moodys marl and Yazoo clay. Ocala limestone in eastern Alabama, southwestern Georgia, and Florida is probably equivalent to Moodys marl and Yazoo clay. Disconformably overlies Claiborne formation; conformably underlies Red Bluff clay of Vicksburg group.

G. E. Murray, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 10, p. 1837–1839. In central Gulf Coastal Plain, sediments of Jackson age crop out in northwest-southeast-trending belt across central Mississippi and southern Alabama and in southwest-trending belt across central Louisiana. Isolated outcrops exposed in Embayment areas as far north as Kentucky. In type area, Jackson [group] consists of thin basal transgressive beach sand (Moodys formation) and an upper blue-gray fossiliferous clay (Yazoo). Yazoo is increasingly calcareous eastward and, in eastern Mississippi and western Alabama, is divisible into four members (ascending): North Creek clay (new), Cocoa sand, Pachuta marl (new), and Shubuta clay (new). In central Louisiana, Danville Landing formation is present above Yazoo clay. Farther east in Alabama entire Jackson changes to lime facies (Ocala limestone). Above Claiborne group; below Vicksburg group.

R. O. Vernon, 1951, Florida Geol. Survey Bull. 33, p. 11–172. Applin and Applin (1944) recognized in Jackson group and in Ocala limestone an upper and lower member and separated from base of Ocala limestone by about 80 feet of section that is composed of two lithologically and faunally distinct beds, about 30 and 50 feet thick. This interval is correlated with Moodys Branch formation, and names Williston and Inglis are here proposed for the two members. As used in this report [Citrus and Levy Counties], the upper Eocene, Jackson group of peninsular Florida, is composed of two formations, Ocala limestone (restricted) and Moodys Branch formation, Jackson-Claiborne contact is placed at top Avon Park limestone. Jackson group separated from older beds by disconformity.

J. F. L. Connell, 1958, Southwestern Louisiana Jour., v. 2, no. 4, p. 321–347. Discussion of Jackson group in Georgia. Outcrop area extends along inner edge of Coastal Plain from Seminole County to Savannah River Includes Ocala limestone and Barnwell formation. Cooper marl not believed to be present in Georgia.

D. H. Eargle, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 11, p. 2623–2635. Jackson group in south-central Texas consists of (ascending) Caddell, Wellborn, McElroy, and Whitsett formations. Group is used in this report only as rock unit term.

H. V. Andersen, 1960, Louisiana Dept. Conserv., Geol. Bull. 34, p. 94–102, maps. In Sabine Parish, group comprises (ascending) Moodys Branch formation, Yazoo formation, Danville Landing beds, and Mosley Hill formation (redefined). Overlies Cockfield formation of Claiborne group; underlies Sandel formation (new). Oligocene.

Named for exposures at Jackson, Miss., along Peak River and Moodys Branch.

Jackson Limestone (in Greene Formation)[1]

Permian: Southwestern Pennsylvania.

Original reference: J. J. Stevenson, 1907, Geol. Soc. America Bull., v. 18, p. 97, 110, 112.

Exposed in Center and Jackson Townships, Greene County.

Jacksonboro Limestone[1]

Miocene, lower: Eastern Georgia.

Original reference: W. H. Dall, 1892, U.S. Geol. Survey Bull. 84, p. 83–84.

Occurs near confluence of Brier Creek and Beaver Dam Creek, which together form a tributary of Savannah River, 3 miles below Jacksonboro, Screven County.

Jacksonburg Limestone[1]

Middle Ordovician: Northern New Jersey and eastern Pennsylvania.

Original reference: H. B. Kümmel, 1908, U.S. Geol. Survey Geol. Atlas, Folio 161.

R. L. Miller, 1937, Geol. Soc. America Bull., v. 48, no. 11, p. 1687–1718. At type locality, the Jacksonburg consists of 135 feet of limestone, the lower 58 feet of which contain *Leperditia fabulites* Conrad and *Doleroides* sp. cf. *D. gibbosus* Billings. These beds are probably of Rockland age. Remaining 77 feet is of Hull and Sherman Fall age. Unconformably overlies Kittatinny limestone; underlies Martinsburg shales, some disconformity. In Pennsylvania, faunas of Hull and Sherman Fall age are present. In main belt of Jacksonburg, *Leperditia* zone has not been recognized, and near Stockertown the basal beds seem to be Hull. Formation divided into two parts on basis of lithology, the lower being the "cement limestone" facies and the upper being the "cement rock" facies. "Cement rock" east of Schuylkill River, which has been called Leesport, is assigned to Jacksonburg. Underlies Martinsburg shales; overlies Beekmantown.

Carlyle Gray, 1951, Pennsylvania Geol. Survey Prog. Rept. 136, p. 15–19. Name Jacksonburg applied in this paper to all impure limestones in part formerly called Leesport lying between Annville or Beekmantown formation and Martinsburg formation in Berks County. Thickness varies. Formation is absent in at least one area due to an erosional unconformity and elsewhere due to thrust-faulting. Intense folding and faulting and lack of large exposures make it difficult to estimate thickness. West of Womelsdorf, basal conglomeratic part of formation is estimated to be about 250 feet thick where fully developed and rest of formation may be as much as 750 feet thick. Whole formation disappears abruptly east of Womelsdorf, being hidden by thrust fault. Present in anticlinal embayment of Martinsburg shale northeast of Womelsdorf where basal conglomerate is absent and rest of formation is estimated to be not more than 700 feet thick. East of Schuylkill River and in bluffs 3 miles south of West Leesport, formation is more than 270 feet thick.

J. P. Hobson, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 12, p. 2716 (fig. 3), In Berks County, Pa., overlies Ontelaunee formation (new) of Beekmantown group.

Bradford Willard, 1958, Pennsylvania Acad. Sci. Proc., v. 32, p. 177–183. In Lehigh and Delaware River valleys, overlies Coplay formation, name reinstated to replace term Beekmantown as applied to Lower and lower

Middle Ordovician beds between Upper Cambrian Allentown and Middle Ordovician Jacksonburg formations.

C. E. Prouty, 1959, Pennsylvania Geol. Survey, 4th ser., Bull. G-31, p. 28-29. Interval between Beekmantown group and Martinsburg formation, embodying essentially the Leesport in east-central Pennsylvania and in restricted sense the Jacksonburg of eastern Pennsylvania and western New Jersey, is divided into (ascending) Annville, Myerstown, and Hershey limestones. Myerstown corresponds to "cement limestone" of Jacksonburg and the Hershey to the "cement rock." Comparison of the Myerstown and Hershey to Jacksonburg of New Jersey indicates several megascopic as well as faunal differences; also, base of Jacksonburg is older than base of Myerstown. Subdivision of approximate Jacksonburg equivalents in Pennsylvania into formational units does not necessarily call for reclassification of Jacksonburg formation in New Jersey as classification in Pennsylvania does not involve typical Jacksonburg. However there is a separate problem as to status of type Jacksonburg. If Weller (1903, New Jersey Geol. Survey Rept. Paleontology, v. 3) is correct in assuming a Black River age for the lower and a Trenton age for the upper Jacksonburg, there is good cause for erecting separate formation names for upper and lower units and abandonment or redefinition of term Jacksonburg. If Miller (1937) is correct in assuming Trenton age for entire Jacksonburg (a view favored by present author), then there would be some cause to assign new names to the highly different lower and upper Jackonsburg, in which case the latter term might be elevated to group status, or alternatively, the subdivisions might be assigned formal member names with Jacksonburg maintaining its present formational status. Since a disconformity probably exists between lower and upper Jacksonburg, the choice of one name (Jacksonburg) to include units separated by a potential break might be an unfortunate one. As name Jacksonburg is deeply bedded in literature, it might best be preserved.

Named for occurrence at Jacksonburg, Warren County, N.J.

Jackson Butte Andesite

Neocene: Central California.

F. L. Ransome, 1899, U.S. Geol. Survey Geol. Atlas, Folio 63, p. 6. Massive andesite 400 to 500 feet thick. Light colored with slight reddish tint; small porphyritic crystals of dark hornblende.

Forms Jackson Butte, Amador County, Mother Lode district.

Jacksonian Stage

Eocene: Gulf and Atlantic Coastal Plain.

G. E. Murray and L. J. Wilbert, Jr., 1950, Am. Assoc. Petroleum Geologists Bull., v. 34, no. 10, p. 1990-1997. Jacksonian stage introduced as time and time-rock unit replacing Jackson formation and Jackson group as major division of Eocene sediments of Gulf and Atlantic Coastal Plain. Jacksonian stage is a time-rock unit which embraces all sediments deposited during time occupied by advance and retreat of late Eocene sea in Gulf and Atlantic coastal region. In this view, the earliest sediment which can be associated definitely with advance of this sea, or can be found to have been deposited during time sea was advancing, becomes Jacksonian; latest stratum which can be tied to retreat of this sea is included likewise. Identification of Jacksonian deposits is principally paleontological problem. Inherent in concept of Jacksonian stage is the thought that other major "lithologic" divisions of Gulf Coast Tertiary should be reconstituted in same manner. Hilgard (1860, Rept. of the geology and agriculture of State of Mississippi) used "Jackson stage;" Heilprin (1884, Philadelphia Acad. Nat. Sci. Jour., v. 9) and Dall (1898, U.S. Geol. Survey 18th Ann. Rept., pt. 2) used "Jacksonian;" most workers since then implied what we now know as "time-rock terminology" in their use of Jackson.

L. J. Wilbert, Jr., 1953, Arkansas Geol. Survey Bull. 19, p. 1–125. Discussion of Jacksonian stage in southeastern Arkansas. The outcrop areas is minimum distance of 60 miles from nearest Jacksonian exposure in coastwise belt. Jacksonian deposits include both marine and nonmarine strata. Name White Bluff formation given to marine unit and Redfield given to nonmarine unit. White Bluff formation overlies beds of Claiborne group. Paleontology of stage discussed.

Alan Cheetham, 1957, Gulf Coast Assoc. Geol. Soc. Trans., v. 7, p. 89–97. Fauna of Shubuta clay, "Red Bluff", marl, Forest Hill formation, and Bumpnose limestone has been considered intermediate between "typical Jacksonian" and "typical Vicksburgian" faunas. Cheilostome bryozans in these sediments are much more similar to those of Vicksburgian than to those of Jacksonian. Name *Spondylus dumosus* zone is proposed to designate sediments containing this fauna. Boundary between *Spondylus dumosus* zone and underlying Jacksonian is contact between what are commonly regarded as Oligocene and Eocene series in eastern Gulf Coast region. Correlation chart shows Moodys marl. Williston limestone, Inglis limestone, North Creek clay, Crystal River limestone, Cocoa sand, and Pachuta marl as Jacksonian.

C. W. Stuckey, Jr., 1960, Gulf Coast Assoc. Geol. Soc. Trans., v. 10, p. 285–298. Literature is reviewed relating to Jacksonian stage. Term Jacksonian stage is used as proposed by Murray and Wilbert (1950). All formation and member names from Rio Grande River in Texas, through Louisiana and Mississippi to western Alabama are incorporated in report.

Type section of Jackson group or Jackson formation (exposures in and around town of Jackson, Hinds County, Miss.) is designated as typical of Jacksonian stage. Outcrops in Jasper, Clarke, and Wayne Counties, Miss., and in Choctaw and Clarke Counties, Ala., are cited as alternative standard sections.

Jackson Park Shale Member (of Kanwaka Shale)[1]

Pennsylvanian (Virgil Series): Eastern Kansas and southeastern Nebraska.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. 6th Ann. Field Conf. Guidebook, p. 94, 96.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 67. Basal member of Kanwaka shale; underlies Clay Creek limestone member; overlies Kereford limestone member of Oread limestone. Thickness 16 to 52 feet.

Type locality: Jackson Park, southeastern part of Atchison, Atchison County, Kans.

Jacksonville Drift

Jacksonville Substage

Pleistocene (Illinoian): Illinois.

M. M. Leighton and H. B. Willman, 1949, *in* Itinerery of State Geologists Field Conference of late Cenozoic Geology of Mississippi Valley, p. 7

(table 1); 1950, Jour. Geology, v. 58, no. 6, p. 602 (fig. 2). Illinoian stage is divided into (ascending) Loveland, Payson, Jacksonville, and Buffalo Hart substages.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 125 (fig. 50), geol. section 46, 48, 55, 58, 59, 64, 66. At maximum advance, Jacksonville glacier formed a large lobe that extended down broad lower Illinois Valley. Jacksonville drift contains much outwash sand and gravel. Greatest thickness of gravel is 46 feet, about one-third mile northwest of Frederick, in NE¼SE¼ sec. 7, T. 1 N., R. 1 E. Derivation of name given.

Named for Jacksonville in Scott County, which is on Jacksonville moraine.

†Jacksonville Formation[1]

Miocene, upper: Northeastern Florida.

Original reference: W. H. Dall, 1892, U.S. Geol. Survey Bull. 84, p. 124–125, 157, 158, 327.

Named for exposures in excavation made for city waterworks at Jacksonville, Duval County.

Jack Valley Formation

Silurian: Western Utah.

R. W. Rush, 1956, Utah Geol. and Mineralog. Survey Bull. 53, p. 9, 12 (fig. 3), 21–25, 40–41 (fig. 9), 53 (fig. 11), 60. Prososed for argillaceous black nodular dolomite ranging up to 250 feet thick, bearing strophomenid brachiopods. Overlies Roberts Mountain [s] dolomite; unconformably underlies Decathon dolomite (new). Part of Jack Valley is exposed in fault blocks in Ibex Hills and at head of Kings Canyon; base of unit not exposed at any of these localities where Jack Valley lies in fault contact with other units. Upper part of Jack Valley is series of interbedded medium- and dark-gray dolomite beds that differ somewhat from typical nodular dolomite below. Probably unsolved facies or stratigraphic tongue problem exists in Jack Valley unit.

Well exposed on west side of Jack Valley, in Confusion Mountains, sec. 25, T. 21 S., R. 15 W., Millard County.

Jacob Sand[1]

Pleistocene: Southeastern New York and islands of southern New England.

Original reference: M. L. Fuller, 1905, Geol. Soc. America Bull., v. 16, p. 367–390.

Lawrence Weiss, 1954, U.S. Geol. Survey Prof. Paper 254–G, p. 146. Jacob sand is supposedly transition zone between interglacial Gardiners clay below and glacial Manhasset formation above. At type locality, buff fine-grained clayey sand, consisting chiefly of quartz grains, muscovite, and some dark minerals.

Named for exposures [type locality] near Jacobs Hill on north shore of Long Island, 8 miles northeast of Riverhead.

Jacobs Chapel Shale

Lower Mississippian: Indiana.

Guy Campbell, 1946, Geol. Soc. America Bull. 57, no. 9, p. 855–856. Soft greenish to dark-green glauconitic sparsely fossiliferous shale. Thickness about 9 inches. Lies between top of New Albany shale and Rockford limestone. Included in the Kinderhook and in Rockford by some workers.

Type section: One mile west of Jacobs Chapel Church, in lot 85 Clark Grant, Clark County.

Jacobsville Sandstone[1]

Jacobsville Formation

Precambrian or Cambrian; Northern Michigan.

Original reference: A. C. Lane and A. E. Seaman, 1907, Jour. Geology, v. 15, p. 680, 692.

F. T. Thwaites, 1943, Michigan Acad. Sci., Arts and Letters Papers, v. 28, p. 496–497, 501. Age of Jacobsville sandstone not yet established; quite likely Upper Keweenawan. Probably nonmarine deposits.

W. S. White, H. R. Cornwall, and R. W. Swanson, 1953, U.S. Geol. Survey Geol. Quad. Map GQ–27. Sandstone as exposed in southeast corner of Ahmeek quadrangle consists primarily of buff or salmon-colored fine- to coarse-grained sandstone with subordinate amounts of reddish-brown pebble conglomerate. Beds cropping out in quadrangle probably represent about 500 feet of formation. Drill hole records indicate thickness of at least 1,800 feet. Precambrian or Cambrian.

W. K. Hamblin, 1958, Michigan Dept. Conserv. Geol. Survey Div. Pub. 51, p. 6 (fig. 1), 15–69. Formation discussed in detail. Four lithic units recognized in formation; conglomerate facies, lenticular sandstone facies, massive sandstone facies; and red siltstone facies. Thickness varies because of relief of Precambrian surface on which formation was deposited. Underlies Munising formation; in some areas, covered by glacial drift. Along most of Lake Superior coast from Munising to Beaver Lake, the Jacobsville is below water level. Age has been matter of conjecture for many years. Discussion of factors favoring Keweenawan age and evidence opposing Keweenawan age. Unconformity between Jacobsville and Munising formations exposed at Grand Island proves that the Jacobsville is older than Upper Cambrian. It is impossible to estimate magnitude of this unconformity and to state whether the Jacobsville is Lower and Middle Cambrian or Upper Keweenawan. Evidence opposing Keweenawan age for Jacobsville appears to be quite substantial. Writer [Hamblin] concludes that the Jacobsville represents continental deposition in an enclosed basin during time marine sediments of Lower and Middle Cambrian age were being deposited in other parts of country. Formation was named by Lane and Seaman (1907). Term was applied to red sandstone east of Copper Range. It includes "lower red member" of Houghton's "Lake Superior sandstone" and most of "Eastern sandstones" of Irving (1883, U.S. Geol. Survey Mon. 5).

Named for exposures at Jacobsville, Houghton County.

Jacque Mountain Limestone Member (of Minturn Formation)

Jacque Mountain Limestone Member (of Battle Mountain Formation)

Jacque Mountain Limestone Member (of Maroon Formation)[1]

Pennsylvanian: Western central Colorado.

Original reference: S. F. Emmons, 1898, U.S. Geol. Survey Tenmile Spec. Folio 48.

K. G. Brill, Jr., 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 8, p. 1376 (fig. 1), 1378 (fig. 2), 1379–1380, 1389. Reallocated to member status in Battle Mountain formation (new). Overlies Robinson limestone member; lies near top of formation, about 120 feet below State Bridge formation (new). Thickness about 30 feet; locally splits into two limestone beds 100 feet apart.

Ogden Tweto, 1949, Colorado Sci. Soc. Proc., v. 15, no. 4, p. 152 (table 1), 204–205, 207–208. Reallocated to member status in Minturn formation. Overlies White Quail limestone member; top of member marks top of Minturn as here defined. Typically 15 to 25 feet of dark-bluish to light-gray fine-grained limestone, some parts of which are characteristically oolitic. Contains cephalopods and gastropods that might be either Pennsylvanian or Permian, but evidence slightly favors Pennsylvanian age.

First described from slopes of Jacque Mountain, Tenmile district.

Jacumba Volcanics[1]

Tertiary, upper, and Quaternary: Southern California.

Original reference: W. J. Miller, California Jour. Mines and Geology, v. 31, no. 2, p. 138–140, map.

G. B. Oakeshott, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 2, p. 258. Listed on generalized stratigraphic section as basalt and pyroclastics several hundred feet thick. Older than Saugus formation and younger than Pico formation.

Exposed in several areas north and east of Jacumba, San Diego County.

Jaeger Diorite Complex

Age not stated: Central southern Arizona.

Leonid Bryner, 1958, Dissert. Abs., v. 19, no. 6, p. 1341. With metamorphic inclusions. Comprises oldest group of rocks in mapped area. Intruded by Ko Vaya quartz monzonite (new). Older than clastic sediments of continental, fluviatile origin, which are inferred to be Lower Cretaceous.

In South Comobabi Mountains and Ko Vaya Hills, Papago Indian Reservation, Pima County.

Jagger Bend Limestone Member (of Belle Plains Formation)[1]

Jagger Bend Limestone (in Belle Plains Group)

Permian: Central Texas.

Original reference: N. F. Drake, 1893, Texas Geol. Survey 4th Ann. Rept., pt. 1, p. 421, 426.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Rank raised to formation in Belle Plains group.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheet 2. Mostly dark-blue-gray medium-grained hard even layers that contain abundant minute vermicular foraminiferal debris; lowermost limestone bed is rather conspicuous yellow-brown limestone 2 to 3 feet thick; other beds mostly weather gray; thin shales between the limestones are dark blue to brownish and clayey. Thickness about 85 feet. Underlies Valera shale member; overlies Voss shale member.

P. T. Stafford, 1960, U.S. Geol. Survey Bull. 1081–G, p. 274, pls. 11, 12. Member geographically extended into Brazos River valley. Thickness 60 to 120 feet. Overlies Voss shale member; underlies Valera shale member, boundary not distinct.

Named from westward loop of Colorado River located short distance southwest of Leaday, Coleman County.

Jake Creek Sandstone Member (of Carbondale Formation)

Jake Creek Sandstone (in Carbondale Group)

Pennsylvanian: West-central Illinois.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 89, 204. Thin-bedded fine-grained micaceous sandstone in Liverpool cyclothem. Sandstone only locally present but has maximum thickness of about 18 feet. Occurs above Francis Creek shale and below Oak Grove beds.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 35. Rank reduced to member status in Carbondale formation (redefined). Occurs above Francis Creek shale member and below Lowell coal member. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: On Jake Creek, NE¼ sec. 13, T. 4 N., R. 1 E., Vermont quadrangle, Fulton County.

Jakes Creek Formation

Pennsylvanian: Eastern Nevada and western Utah.

Grant Steele, 1960, Dissert. Abs., v. 20, no. 12, p. 4635. Incidental mention in stratigraphic interpretation of Pennsylvanian-Permian systems of eastern Great Basin. In list of formations [sequence not stated], Jakes Creek follows Strathearn and precedes Carbon Ridge.

Type locality and derivation of name not stated.

Jalama Formation

Upper Cretaceous: Southern California.

T. W. Dibblee, Jr., 1950, California Div. Mines Bull. 150, p. 23–24, 38 (fig. 2), pls. 1, 2. Consists of about 4,000 feet of clay shales and sandstones overlying Espada formation (new) and disconformably underlying Eocene Anita shale. At type locality, 2,850 feet exposed; here relationship to overlying Anita shale is accordant. In Santa Rosa hills, overlain by Anita shale and Sierra Blanca limestone with angular unconformity of about 15°.

Type locality: Divide between Santa Anita and Bulito Canyons, in the Santa Ynez Mountains, Santa Barbara County.

Jameco Gravel[1] or **Formation**[1]

Pleistocene: Southeastern New York and islands of southern New England.

Original reference: A. C. Veatch, 1903, Jour. Geology, v. 11, p. 766–776.

Lawrence Weiss, 1954, U.S. Geol. Survey Prof. Paper 254–G, p. 145–146. Thickness of gravel about 100 feet in western Long Island. Recognized in well samples by its characteristically high content of diabase fragments and its position beneath Gardiners clay. Not recognized with certainty in eastern part of island. Considered younger than Mannetto gravel on basis of degree of weathering.

Named for Jameco pumping station of Brooklyn water works, a few miles south of Jameco, N.Y., where borings first revealed the beds. Recognized on Block Island, Marthas Vineyard, and Cape Cod.

James Limestone (in Trinity Group)

James Limestone Bed (in Pine Island Member of Glen Rose Formation)

James Limestone Member (of Pearsall Formation)

Lower Cretaceous (Comanche Series): Subsurface in Louisiana, Arkansas, and Texas.

W. B. Weeks, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 8, p. 961 (fig. 4), 970. Bed in upper part of Pine Island member of Glen Rose. Oolitic coquinoid to sandy gray lime and fine sand. Apparently correlative with Dierks limestone of outcrop.

R. W. Imlay, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 3. Referred to as James limestone (in Trinity group). Underlies Rodessa formation; overlies Pine Island shale.

J. M. Forgotson, Jr., 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 10, p. 2342–2346. Member of Pearsall formation; overlies Pine Island member. For purposes of this study, defined as stratigraphic interval and its correlative rock equivalents in W. C. Feazel's Tonway Smith well No. 1, sec. 18, T. 21 N., R. 2 E., Union Parish, La., between depths of 4,255 and 4,370 feet. Separated from overlying Rodessa by variable interval referred to as Bexar shale member of its equivalent. Cow Creek member is both rock-stratigraphic and time-stratigraphic equivalent of James member.

Named for Arkansas Fuel Oil Co. James well No. 1 in sec. 14, T. 20 N., R. 1 E., Union Parish, La., from 3,827 to 3,917 feet.

†Jamesburg Formation[1]

Pleistocene: New Jersey.

Original reference: R. D. Salisbury, 1894, New Jersey Geol. Survey Ann. Rept. 1893, p. 60–72.

Well exposed in upper part of railway excavation near Jamesburg, Middlesex County.

Jameson Shale Member (of Markley Sandstone)

Eocene: Northwestern California.

C. E. Weaver, 1941, Geol. Soc. America Mem. 35, p. 17 (table 3), 62–64. Consists of light-creamy-white to tan thinly laminated siliceous and sandy shales, often paper shales. Thickness 200 to 1,200 feet. Base of shale about 1,400 feet above base of Markley; both top and base of Jameson are gradational into sandstone.

Named from Jameson Canyon in Carquinez quadrangle, north of San Francisco Bay. Occupies a single area between Elkhorn Peak and Napa Junction, Napa County.

†James River Series[1]

Lower Cretaceous: Eastern Virginia.

Original reference: L. F. Ward, 1895, U.S. Geol. Survey 15th Ann. Rept., p. 318.

Well exposed on James River from Richmond to Dutch Gap Canal, on Appomattox from below Petersburg to near its mouth, and on west bank of Potomac between Mount Vernon and Aqui Creek.

James River Shale[1]

Devonian(?): Southwestern Missouri.

Original reference: E. M. Shepard, 1905, Bradley Geol. Field Sta. Drury Coll. Bull., v. 1, pt. 2, p. 56, 67.

Occurs along and near James River.

Jamestown Coal Member (of Carbondale Formation)

Pennsylvanian: Southern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 34, 48 (table 1), pl. 1. Assigned member status in Carbondale formation (redefined). Occurs above Brereton limestone member and below Conant limestone member (new). Coal named by Bell and others (1931, Illinois Geol. Survey Ill. Pet. 19). Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: NW¼NE¼ sec. 34, T. 5 S., R. 4 W., Perry County.

Jamestown Conglomerate[1]

Upper Devonian: Western New York.

Original reference: G. D. Harris, 1891, Am. Geologist, v. 7, p. 164–174.

Occurs at Jamestown, Chautauqua County.

Jamestown cyclothem (in Carbondale Formation)

Jamestown cyclothem (in Carbondale Group)

Pennsylvanian: Southeastern Illinois.

J. M. Weller, 1942, Illinois Acad. Sci. Trans., v. 35, no. 2, p. 145 (table 1). In list of cyclothems in McLeansboro, occurs below Bankston Fork cyclothem and above Brereton cyclothem.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 10, pl. 1. Shown on correlation chart at top of Carbondale group. Includes Pokeberry limestone in western Illinois and Jamestown limestone in southern Illinois. Type locality given.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 113. Believed to be equivalent of Pokeberry cyclothem.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 52 (table 2), pl. 1. In Carbondale formation (redefined). Above Brereton cyclothem; in some areas, below Sparland cyclothem and in others below Bankston. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification independent of rock-stratigraphic classification.

Type locality: NW¼NE¼ sec. 34, T. 5 S., R. 4 W., Perry County.

Jamestown Limestone (in Carbondale Group)

Jamestown Limestone (in McLeansboro Group)

Jamestown Limestone Member (of McLeansboro Formation)[1]

Pennsylvanian: Southwestern Illinois.

Original reference: A. H. Bell, C. Ball, and L. McCabe, 1931, Illinois Geol. Survey Press Bull. 19.

J. M. Weller, L. G. Henbest, and C. O. Dunbar *in* C. O. Dunbar and L. G. Henbest, 1943, Illinois Geol. Survey Bull. 67, p. 17 (fig. 3). Shown on columnar section as limestone in McLeansboro group; stratigraphically below Anvil Rock sandstone and above Herrin limestone.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Inf. Circ. 217, p. 10. Shown on correlation chart as limestone in Jamestown cyclothem at top of Carbondale group. Type locality given.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 35, 54 (table 3). Replaced by Conant Limestone Member (new) of Carbondale Formation (redefined). Name Jamestown will be used for the coal beneath the limestone. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois; cyclical classification independent rock-stratigraphic classification.

Type locality: NW¼NE¼ sec. 34, T. 5 S., R. 4 W., in vicinity of Jamestown, Perry County.

Jamesville Limestone Member (of Manlius Limestone)

Jamesville Limestone[1] (in Manlius Group)

Lower Devonian: Central New York.

Original reference: Burnett Smith, 1929, New York State Mus. Bull. 281, p. 26, 27, 30–31.

G. H. Davis 3d, 1953, New York State Mus. Circ. 35, p. 8, 9, 10. Termed a member.

L. V. Rickard, 1955, New York State Geol. Assoc. Guidebook 27th Ann. Mtg., p. 2 (columnar section), 4–5, 7. In central New York, underlies Deansboro member (new) of Coeymans limestone. Jamesville and Clark Reservation are grouped together under heading of transitional beds between Manlius group and Helderberg group above.

U.S. Geological Survey currently classifies the Jamesville as a member of the Manlius and designates its age as Lower Devonian on the basis of a study now in progress.

Type section: At "Green Lake" State Park (Clark Reservation), west of Jamesville, town of De Witt, Onondaga County.

Jane Lew Sandstone (in Conemaugh Formation)[1]

Jane Lew Sandstone (in Pittsburgh Redbeds)

Pennsylvanian: Southwestern Pennsylvania and northern West Virginia.

Original reference: D. B. Reger, 1916, West Virginia Geol. Survey Rept. Lewis and Gilmer Counties, p. 153.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 95. Jane Lew is a thin hard sandstone, 8 to 10 feet thick; occurs at several places in Pittsburgh redbeds.

Named for exposures on Hackers Creek, just east of Jane Lew, Lewis County, W. Va.

Janesville Shale (in Admire Group)

Permian: Southeastern Kansas.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2273, 2274 (fig. 1). Defined to include strata between Foraker limestone above and Falls City limestone below. Average thickness 75 feet. Includes (ascending) West Branch shale, Five Point limestone, and Hamlin shale members.

Type section: In cut on east-west road in SW¼SE¼ sec. 23, T. 23 S., R. 10 E., Greenwood County. Name derived from Janesville Township.

Jangle Limestone Member (of Cadiz Formation)

Jangle Limestone

Middle Cambrian: Southern Nevada.

M. S. Johnson and D. E. Hibbard, 1957, U.S. Geol. Survey Bull. 1021–K, p. 339–340, pls. 32, 33. Name Jangle limestone substituted for Peasley limestone of Wheeler (1940) in Pioche and Groom districts because of differences in thickness, lithologic characteristics, and possibly in formational boundaries. Subdivided into three units each of which consists of limestone. Lower unit, 80 feet thick, consists of dark-smoky-gray to steel-gray prominent ledge-forming limestone containing buff irregular silty partings. Lower 40 feet of this unit includes some well-bedded finely crystalline limestone beds a few inches thick; remaining 40 feet dominantly resistant calcitic poorly to fairly well-bedded limestone. Middle unit, 115 feet thick, consists of dark-gray limestone containing buff to reddish-brown silty material which is distinctive for its slope-forming character. Upper unit, 80 feet thick, consists of dark-gray to smoky-gray ledge-forming limestone containing a few buff silty partings and round, concentric algal masses. Thickness 275 feet where completely exposed on Jangle Ridge. Conformably overlies Chisholm shale; conformably underlies Yucca Flat formation (new). Lower boundary is at lithologic break between shale and overlying limestone. Upper contact is at break between dark-gray limestone of Jangle and lowest, light-gray limestone bed of Yucca Flat.

U.S. Geological Survey classifies the Jangle Limestone as a member of the Cadiz Formation on the basis of a study now in progress.

Named for outcrops on Jangle Ridge, Atomic Energy Commission Nevada Proving grounds area, Nye County.

Janssen Clay Member (of Dakota Formation)

Upper Cretaceous: Central and north-central Kansas.

Norman Plummer, 1942, (abs.) Compass, v. 22, no. 4, p. 327. Dakota as defined here is subdivided into two members, Terra Cotta (lower) and Janssen (upper).

Norman Plummer and J. F. Romary, 1942, Kansas Geol. Survey Bull. 41, pt. 9, p. 336–340. Consists largely of gray to dark-gray clay and silt, some beds of fissile shale, and commonly a bed of lignite or highly lignitic clay; gray clay in lower half contains zones of siderite or limonite pellets, but no hematite. Thickness 30 to 80 feet, near minimum thickness in type area. Overlies Terra Cotta member, contact is drawn at top of marked concentration of concretionary "iron"; in places "quartzitic" silt or fine sand underlies concretionary "iron" bed; underlies Graneros shale.

Type area: Near center line sec. 3, T. 16 S., R. 9 W., near Janssen Station, Ellsworth County.

Jarbidge Rhyolite

Miocene, upper (?) : Northeastern Nevada.

R. R. Coats, 1957, U.S. Geol. Survey Trace Elements Inv. Rept. TEI–690, Book 2, p. 305–306. Quartz-rich rhyolitic rocks. Thickness at least 2,000 feet; unit sliced into number of fault blocks and reliable stratigraphic markers not recognized within it; hence, total thickness difficult to determine. Overlies Deadhorse tuff (new). In northeastern quarter of quadrangle, disconformably underlies Gods Pocket dacite (new) ; locally 30 to 50 feet of pale-gray vitric tuff separates the units.

U.S. Geological Survey currently considers the Jarbidge Rhyolite to be upper Miocene (?) in age.

Named for occurrence in Jarbidge quadrangle.

Jardine Basalt

[Pre-Paleozoic] : Southwestern Montana.

A. D. Howard, 1937, Geol. Soc. America Spec. Paper 6, p. 16–17, pl. 4. "Basalt" exposed at summit of minor peak which is composed of Precambrian schist. Exposure is weathered brown. Rock is metamorphosed. Degree of metamorphism comparable to that exhibited by the schist, so that locally the rock is true schist, and elsewhere, where intimately penetrated by silica, is fine-textured gneiss. Rock probably represents an ancient basic intrusion in old metamorphic rocks, because Paleozoic formations show no such metamorphism.

Caps mountain on east side of Bear Gulch ("Bear Creek" of Yellowstone folio), just east of town of Jardine. Lies at altitude of about 8,400 feet.

Jarita Basalt Member (of Los Pinos Formation)

Miocene(?) or Pliocene(?) : Central northern New Mexico.

Fred Barker, 1958, New Mexico Bur. Mines Mineral Resources Bull. 45, p. 3, 38 (table 5), 46–48, pl. 1. Flows of olivine basalt; widely separated, disconnected single and multiple flows. Divided into unnamed northern, central, and southern types based primarily on petrographic characteristics. Maximum thickness 50 feet. Disconformably underlies Cordito member (new) ; overlies Esquibel member (new). Name credited to Butler (unpub. dissert.).

Named from an elongate exposure along western rim of La Jarita Mesa northeast of Vallecitos; Las Tablas quadrangle.

Jarvis Church Conglomerate Member (of Konawa Formation)

Permian: East-central Oklahoma.

W. F. Tanner, 1956, Oklahoma Geol. Survey Bull. 74, p. 110–111, pl. 1. Name applied to multicolored cherts that occur about 250 feet above base of formation. Member is a single bed about 10 feet thick. Crossbedding and torrent bedding are common; uppermost horizon is clay pebble conglomerate which grades upward into thin crossbedded sandstone, thin limy sandstone, or marllike shale.

Typically developed near Jarvis Church, in sec. 23, T. 10 N., R. 5 E., Seminole County.

Jasper conglomerate[1]

Precambrian: Southwestern Minnesota and northwestern Iowa.

Original references: C. R. Keyes, 1914, Iowa Acad. Sci. Proc., v. 21, p. 187; 1914, Science, new ser., v. 40, p. 144.

Probably named for Jasper, Pipestone County, Minn.

Jasper Member (of Everton Formation)

Jasper Limestone[1]

Middle Ordovician: Northern Arkansas.

Original reference: A. H. Purdue and H. D. Miser, 1916, U.S. Geol. Survey Geol. Atlas, Folio 202.

E. E. Glick and S. E. Frezon, 1953, U.S. Geol. Survey Circ. 249, p. 3 (fig. 2), 4, 5, 6. Rank reduced to member of Everton. Separated from underlying Newton sandstone member by sequence of dolomite, sandy dolomite, and dolomitic sandstone beds about 90 feet thick; underlies St. Peter sandstone. Middle Ordovician.

Named for Jasper, Newton County.

Jasper Creek Shale (in Graford Formation)[1]

Pennsylvanian: Central northern Texas.

Original reference: G. Scott and J. M. Armstrong, 1932, Texas Univ. Bull. 3224, p. 33.

Occurs in valley of Jasper Creek, Wise County, and on slopes of escarpment to west.

Jasper Knob zone (in Negaunee Formation)[1]

Precambrian (middle Huronian) : Northern Michigan.

Original reference: J. L. Adler, 1935, Jour. Geology, v. 43, no. 2, p. 113–132.

Type locality: Southeastern part of Ishpeming, northern slope of Jasper Knob, Marquette County.

Jasper Lake Greenstone Conglomerate or Agglomerate (in Knife Lake Series)

Precambrian: Northeastern Minnesota.

J. W. Gruner, 1941, Geol. Soc. America Bull., v. 52, no. 10, p. 1583 (table 1), 1593–1594, pl. 1. Name applied to greenstone conglomerate or agglomerate that extends from Conglomerate Lake to end of map area 7 miles to east. Consists principally of two kinds of fragments: hornblende andesite with phenocrysts (metacrysts) of hornblende, and dense andesitic ones without any visible crystals. Unweathered rock is grayish or bluish green. Thickness 10,000 to 15,000 feet; this may be result of repetition of beds due to shallow asymmetric folding (pl. 1, cross section S–T). In this report, Knife Lake series is divided into 20 members. Table of approximate chronological sequence (ascending) shows Jasper Lake greenstone conglomerates as unit 4 occurring above Disappointment Mountain and Moose Lake greenstone conglomerates and below unnamed quartz porphyry conglomerates.

Extends from Conglomerate Lake in sec. 24, T. 65 N., R. 6 W., Lake County, Knife Lake area.

Java Formation

Upper Devonian: Western and central New York.

Wallace de Witt, Jr., 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 12, p. 1933–1939. Proposed for cyclically deposited Upper Devonian rocks in western and central New York that have been described previously (Pepper and de Witt, 1950) as Wiscoy sandstone and equivalent Hanover shale. Thicknesses: 94 feet at Silver Creek; 113 feet at Java village; 165 feet at Wiscoy; 185 feet in western Steuben County; more than 200 feet in central and eastern Steuben County. Comprises Pipe Creek shale, Hanover shale, and Wiscoy sandstone members. In western part of State, offshore shale and mudrock facies, Pipe Creek and Hanover members are dominant; in central part of State, near-shore siltstone and sandstone facies, Wiscoy sandstone, is dominant. Overlies West Falls formation; underlies Perrysburg formation.

Type section: Exposures along Beaver Meadow Creek above Angel Falls. Recognizable from Silver Creek, Chautauqua County eastward for more than 120 miles across parts of Cattaraugus, Erie, Wyoming, Allegany, Ontario, and Steuben Counties. Named from Java Township, Wyoming County.

Jawbone Conglomerate Member (of Kiawa Mountain Formation)

Precambrian: Central northern New Mexico.

Fred Barker, 1958, New Mexico Bur. Mines Mineral Resources Bull. 45, p. 1, 10, 25, pl. 1. Mostly quartz-pebble conglomerate with varying amounts of interlayered gray quartzite. The pebbles are light-gray, red, and black quartz, range from 4 to 25 mm in size, and are moderately well sorted, very well rounded, and mostly ovoid in shape. Granules and coarse grains of sand about as abundant as the pebbles. Matrix of conglomerate mostly blue-gray vitreous fine-grained kyanitic quartzite with hematitic layers. Crossbedding widespread. Some conglomerate is dark gray and slightly micaceous. Thickness on Jawbone Mountain at least 500 feet and perhaps as much as 2,000 feet; about 500 feet in canyon 1 mile southwest of Hopewell, and from there southeastward member appears to finger out into [lower] quartzite member. Underlies [lower] quartzite member and overlies Moppin series (new) from about 1½ miles west-northwest of Burned Mountain northwestward for several miles to west boundary of quadrangle.

Underlies Jawbone Mountain in extreme northwest corner of Las Tablas quadrangle. Also mapped in small area about 1½ miles northwest of Burned Mountain.

Jayville Granite (in Diana Syenite Complex)

Precambrian: Northeastern New York.

A. F. Buddington, 1939, Geol. Soc. America Mem. 7, p. 84, 85, 285, 286. Thought to be facies of Diana complex. Contains band of amphibolite and local masses of skarn thought to represent metamorphosed Grenville calcareous beds.

Present in Oswegatchie quadrangle. Jayville is in St. Lawrence County.

Jealousy Formation

Oligocene, upper: St. Croix, Virgin Islands (subsurface and surface).

D. J. Cederstrom, 1941, Am. Jour. Sci., v. 239, no. 8, p. 557. Name applied to gray clays and associated conglomerates that underlie Kingshill marl. Not known to crop out.

D. J. Cederstrom, 1950, U.S. Geol. Survey Water-Supply Paper 1067, p. 19–20, 68 (table 3), pl. 1. In central part of plain, test hole near Bethlehem shows that Kingshill marl is underlain by dark clayey formation known to be at least 1,938 feet thick; maximum thickness not known as base not reached. Section shows (ascending) 305 feet of dark clay with streaks of limestone, 5 feet of calcareous conglomerate, and 987 feet of greenish-gray clay. Name Jealousy formation is given to these sediments; above described section is type section. Near Jealousy estate, formation is 368 feet thick, and test drilling (well 39) shows 61 feet of hard calcareous conglomerate immediately above basement of Mount Eagle volcanics. Calcareous conglomerate that underlies Kingshill marl in stream beds near Jealousy is believed to be basal conglomerate of Jealousy formation.

Type section: Well 41, at Fredensborg.

Jeddito Formation

Pleistocene: Northeastern Arizona.

J. T. Hack, 1941, Geog. Review, v. 31, no. 2, p. 262–263; 1942, Harvard Univ. Peabody Mus. Am. Archaeology and Ethnology Papers, v. 35, no. 1, p. 48–51. Composed dominantly of russet-colored sand. Derived primarily by erosion of deposits on the mesas, sorted and transported by streams, ephemeral or perennial. Portion in lower part of valley is sandy, flood-plain deposit. In upper part of valley it is probably in places a channel deposit and in places a flood-plain deposit. Contains abundant layers of hard caliche in many places. Capped by 2 feet of fairly pure and hard limestone at one locality; more common are thin layers of sand, cemented by calcium carbonate. Recognized in most places by russet color and concretionary layers of caliche. Thickness at one measured section 9 feet. Underlies Tsegi formation (new). Contains proboscidian remains. Late Quaternary age.

C. B. Hunt, 1953, U.S. Geol. Survey Bull. 996–A, p. 4. In western Navajo country, proposed boundary between Pleistocene and Recent would be at top of Jeditto formation.

Best exposed in central part of Jeddito Valley [spelled Jadito on U.S. Geol. Survey Topog. Map or Arizona (1:500,000) for 1957] in stretch between Jeddito Trading Post and Awatovi, in western Navajo country.

Jeff Conglomerate (in Vieja Group)

Jeff Conglomerate Member (of Huelster Formation)

Tertiary: Southwestern Texas.

G. K. Eifler, Jr., 1951, Geol. Soc. America Bull., v. 62, no. 4, p. 343, pl. 1. Name applied to a sandstone and conglomerate unit constituting lowest beds of Huelster formation (new). Average thickness 25 feet. Conformably underlies volcanic tuff; lies with slight angular unconformity upon Taylor marl and Austin chalk.

R. K. DeFord, 1958, Texas Jour. Sci., v. 10, no. 1, p. 14. Usage of name extended into Rim Rock country and applied to basal conglomerate of Vieja group. In southern part of area, Gill breccia (new) intervenes between the basal conglomerate and Colmena tuff (new); northward the breccia pinches out and the conglomerate thickens, presumably as the lower part of Colmena tuff grades into conglomerate so that on north a major part of the interval between Buckshot ignimbrite (new) and base of Vieja group is occupied by conglomerate.

Type locality: In tributary ravine on left bank of Horse Thief Canyon about 3½ miles upstream from its junction with Limpia Creek near the Jeff Ranch, Barrilla Mountains, Reeves County.

Jeff Davis Granite

Precambrian(?): Northwestern Georgia.

J. W. Clarke, 1952, Georgia Geol. Survey Bull. 59, p. ix, 6 (table), 23–28, pl. 3. Garnetiferous biotite granite intrusive into metasediments overlying quartzite member of Manchester formation.

Named for exposures near Jeff Davis School, 5 miles northwest of Thomaston. Upson County. Batholith underlies large part of central and eastern parts of Thomaston quadrangle.

Jefferson Limestone,[1] Dolomite,[1] Formation, or **Group**

Upper Devonian: Montana, south-central and northern Idaho, northern Utah, and western Wyoming.

Original reference: A. C. Peale, 1893, U.S. Geol. Survey Bull. 110.

C. F. Deiss, 1933, Montana Bur. Mines and Geology Mem. 6, p. 41–45. Jefferson limestone, in northwestern Montana, subdivided into (ascending) White Ridge limestone, Glenn Creek shale, Coopers Lake limestone, Lone Butte limestone, and Spotted Bear limestone members. Middle Devonian.

G. B. Richardson, 1941, U.S. Geol. Survey Bull. 923, p. 19, pls. 1, 6. In Randolph quadrangle, Utah-Wyoming, Jefferson dolomite consists of about 1,200 feet of massive fine-grained dark-colored dolomite, which weathers to characteristic brown. Overlies Laketown dolomite and underlies Three Forks limestone; both contacts conformable. Middle Devonian.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1768–1769, chart 4. Upper Devonian.

G. W. Berry, 1943, Geol. Soc. America Bull., v. 54, no. 1, p. 9 (fig. 3), 10–14. In Three Forks area, formation consists of dark-colored limestone in lower part and dark-colored dolomite in upper part. Unconformably overlies Dry Creek shale; underlies Three Forks formation. Middle and Upper Devonian.

L. L. Sloss and W. M. Laird, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 8, p. 1407–1410, 1411–1412, 1415–1418. Formation, in central Montana, composed of an upper dolomite member, including some anhydrite or evaporite-solution breccia, and lower dense limestone member. In Three Forks area, breccia zone and overlying nonresistant shale of Three Forks formation are imperfectly exposed or entirely covered. To facilitate mapping, it would be more logical to revise Peale's (1893) classification and assign the breccias and associated shales to the Three Forks; but where the breccias are well exposed, as in type section, their genetic and lithologic relationships with main body of dolomite below are clear. Thickness 715 feet at Logan. Term Potlatch is applicable throughout Sweetgrass area subsurface and its use is recommended over Three Forks and Jefferson for that area.

C. P. Ross, 1947, Geol. Soc. America Bull., v. 58, no. 12, pt. 1, p. 1107–1108. In Borah Peak quadrangle, Idaho, Jefferson dolomite is about 1,000 feet thick, overlies Laketown dolomite and underlies Grand View dolomite.

J. S. Williams, 1948, Geol. Soc. America Bull., v. 59, no. 11, p. 1130 (table), 1139–1141. Formation, in Logan quadrangle, Utah, subdivided into (ascending) Hyrum dolomite and Beirdneau sandstone members (both new). Thickness as much as 2,120 feet. Overlies Water Canyon formation (new); underlies Madison formation.

F. D. Holland, Jr., 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 9, p. 1719. In northeastern Utah, underlies Leatham formation (new).

C. A. Sandberg and C. R. Hammond, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 10, p. 2314–2322. Sloss and Laird (1947) in effect redefined the Jefferson to include at top a breccia and shale unit that Peale (1893) described as reddish- and brownish-yellow calcareous shale and mapped at base of overlying Three Forks formation. The two units that resulted from Sloss and Laird's revision are cartographically impractical because both the breccia zone and the overlying shales of the Three Forks are rarely visible. In present report, term Jefferson formation is used as defined by Peale and not as redefined by Sloss and Laird. Jefferson is raised to group status in subsurface of Williston basin and central Montana east of 111° meridian. Includes all beds overlying Souris River and underlying the Three Forks. Divided into Duperow formation and overlying Birdbear formation (new). Upper Devonian.

Named for exposures in hills on both sides of Missouri River just below junction of Three Forks of the Missouri, and on both sides of the Jefferson a few miles above its mouth, in Three Forks quadrangle, Montana.

Jefferson City Dolomite[1]

Jefferson City Formation (in Knox Dolomite)

Jefferson City Group

Lower Ordovician: Missouri and northern Arkansas.

Original reference: A. Winslow, 1894, Missouri Geol. Survey, v. 6, p. 331, 373, 375.

C. R. L. Oder, 1934, Jour. Geology, v. 42, p. 474 (table 1), 484–486. Geographically extended into eastern Tennessee where classified as formation in Knox dolomite. Occupies interval between top of Nittany and base of Cotter-Powell beds. Consists of 55 to 400 feet of thin- to heavy-bedded, dove- and dark- to brownish-gray fine-grained limestone and extremely light- to dark-green fine-grained to dense dolomite. Thin greenish-blue siliceous shales present on some bedding planes; coarse edgewise limestone conglomerates present locally.

J. S. Cullison, 1944, Missouri Univ. School Mines and Metallurgy Bull., Tech. Ser. v. 15, no. 2, p. 15, 17–32. Term Jefferson City has had many usages in the literature since originally defined by Winslow. Term should be dropped from the literature because of this. It is retained in this report as group term for following reasons: (1) a boundary between Rich Fountain and Theodosia formations (both new) is present within those beds originally defined as Jefferson City by Winslow; (2) predominant usage of them by most writers since Winslow has been in sense of group, even though it has not been defined as such; (3) term too well established in Missouri stratigraphic literature to be disposed of especially when beds involved are essentially same as those of previous usage. Underlies Cotter formation; unconformably overlies Roubidoux formation.

O. R. Grawe, 1945, Missouri Geol. Survey and Water Resources, 2d ser., v. 30, p. 52 (fig. 2), 59–62. Term Jefferson City formation used in this report [pyrite deposits of Missouri] in its older, unrestricted sense to include all dolomite beds above top of Roubidoux formation.

T. R. Beveridge, 1951, Missouri Geol. Survey and Water Resources, 2d ser., v. 32, p. 23–27, pl. 9. In this report [Weaubleau Creek area], no attempt is made to differentiate the Cotter from the Jefferson City, and name Jefferson City formation is used in unrestricted sense. Base not exposed in area; records from two wells which penetrated formation from top to bottom give thicknesses of 200 to 205 feet. Underlies Chouteau formation and in some areas the Sylamore. Ordovician, Canadian series.

Josiah Bridge, 1956, U.S. Geol. Survey Prof. Paper 277, p. 23. Kingsport limestone replaces Jefferson City formation as used by Oder (1934). Jefferson City, Cotter, and Powell are names of formations exposed in Missouri and Arkansas, and there is no possibility that they can be traced into Appalachian Valley.

Named for exposures at Jefferson City, Cole County, Mo.

†Jefferson City Group[1]

Lower Ordovician (Beekmantown) : Missouri.

Original reference: C. L. Dake. 1921, Missouri Univ. School Mines and Metallurgy, v. 6, no. 1.

Jeffersonian Series or Stage

Ordovician (Canadian) : North America.

R. H. Flower, 1957, New Mexico Bur. Mines Mineral Resources Mem. 2, p. 18. Divisions within Canadian system favor natural division into four major units: Gasconadian, Demingian, Jeffersonian, and Cassinian. Jeffersonian (Early Upper Canadian) beds are restricted geographically. Includes Jefferson City (Rich Fountain and Theodosia), Cotter, and Powell.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 7, p. 28–32. Canadian series includes Gasconadian, Demingian, Jeffersonian, and Cassinian stages.

Jeffersonian Stage[1] or Glacial Epoch

Pleistocene: Central northern Oregon.

Original reference: E. T. Hodge, 1930, Monthly Weather Rev., v. 58, p. 405–411.

E. T. Hodge, 1938, Geol. Soc. America Bull., v. 49, no. 6, p. 841 (table 1). Fourth of five glacial epochs in area. Occurs in interval between Willamettian epoch and Hood epoch.

Jeffersonville Limestone[1]

Middle Devonian: Indiana and north-central Kentucky.

Original reference: E. M. Kindle, 1899, Bull. Am. Paleontology, v. 3, no. 12, p. 8, 23, 110.

D. G. Sutton and A. H. Sutton, 1937, Jour. Geology, v. 45, no. 3, p. 331. Term Jeffersonville is synonym of Geneva, and by custom of priority latter name should be applied to all Indiana rocks of Onondaga age.

Guy Campbell, 1942, Geol. Soc. America Bull., v. 53, no. 7, p. 1060. South of Sellersburg, Jeffersonville is overlain by Silver Creek formation; northward Speeds formation lies between Jeffersonville and Silver Creek.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Lower or Middle Devonian.

E. M. Luttrell and Ann Livesay, 1952, Kentucky Geol. Survey, ser. 9, Bull. 11, p. 8. In western Kentucky, near Kentucky Lake, overlies Camden (Clear Creek) chert.

J. B. Patton and T. A. Dawson *in* H. H. Murray, 1955, Indiana Geol. Survey Field Conf. Guidebook 8, p. 38–39, pl. 1. In type section, Jeffersonville is divided into three zones: lower is brown to gray, dense to crystalline, dolomitic, contains prolific coral fauna and is generally known as "coraline zone"; middle is lighter gray or brown, dense to crystalline, and includes *Spirifer gregarius* beds; upper is tan or light-gray crystalline thick-bedded extremely fossiliferous limestone and includes *Spirifer acuminatus* zone. Thickness 26 to 46 feet. At type locality and northward through most of Clark County, overlies Louisville limestone; from northern Clark County northward, overlies Geneva dolomite; throughout southern Indiana, overlain by rocks of Hamilton age.

Named for Jeffersonville, Clark County, Ind., where formation is well exposed in the falls of the Ohio.

Jellico Formation[1]

Pennsylvanian: Northern Tennessee.

Original reference: L. C. Glenn, 1925, Tennessee Geol. Survey Bull. 33–B, p. 14, 18–21.

C. W. Wilson, Jr., J. W. Jewell, and W. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [Folio], p. 1. As result of recent fieldwork names Briceville, Jellico, Scott, and Anderson are discontinued, and complete new classification is presented.

Named for occurrence of Jellico coal within formation.

Jelm Formation[1]

Upper Triassic: Central Wyoming and northern Colorado.

Original reference: S. H. Knight, 1917, Geol. Soc. America Bull., v. 28, no. 1, p. 168.

G. E. Condra, E. C. Reed, and O. J. Scherer, 1940, Nebraska Geol. Survey Bull. 13, p. 2 (fig. 2), 6. Stratigraphic section in vicinity of Owl Creek Canyon section, northern Colorado, shows Jelm formation, about 60 feet thick, unconformably above Spearfish (redefined) and unconformably below Sundance beds.

J. D. Love, 1948, Wyoming Geol. Assoc. Geologists Guidebook 3d Ann. Field Conf., p. 100. Name Popo Agie is used in central Wyoming in preference to Jelm. Correlation of the two units has neither been definitely established nor disproved.

G. N. Pipiringos, 1953, Wyoming Geol. Assoc. Guidebook 8th Ann. Field Conf., p. 36 (chart), 37–38 correlation chart. Restricted to exclude upper 50 feet which are included in Nugget formation. As used here, name Jelm is applied only to lower part, about 200 feet thick in type area, of original Jelm formation. Consists of two well-defined members. Overlies Alcova formation.

R. G. Hubbell, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 11, p. 2743–2748. In Freezeout Hills area, stratigraphically expanded above to include unit here named Troublesome Creek sandstone member. Underlies Sundance formation; overlies Alcova member of Chugwater.

G. N. Pipiringos, 1957, Wyoming Geol. Survey Bull. 47, p. 13, 15–17, pl. 5, strat. sections. Upper part of original Jelm formation is lithologically continuous with basal Sundance sandstone of Lee (1927, U.S. Geol. Survey Prof. Paper 149), the Entrada (Front Range, Colo.) of Baker, Dane, and Reeside (1936), and Heaton (1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 8), and Nugget(?) sandstone of Neely (1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 6). Fact that upper part of original Jelm formation (Nugget) is lithologically closely related to Sundance formation while rest of Jelm contains redbeds identical to those of underlying Chugwater, and a well-developed persistent conglomerate near its top, indicates that original Jelm straddles Triassic-Jurassic boundary. Proposed that name Jelm be applied only to part which rests disconformably on Chugwater and whose top grades into overlying Nugget sandstone within a few feet above Jelm conglomerate. Type section of Jelm (restricted) is at Red Mountain where it is 190 feet thick.

R. F. Walters, 1957, Rocky Mountain Assoc. Geologists Guidebook to geology of North and Middle Park Basins, Colorado, p. 85–86. In Independence Mountain area, North Park, Colo., formation is an 85-foot sequence consisting of basal clay gall conglomerate overlain by alternating red, pink, and white beds of fine- to coarse-grained calcareous sandstone and conglomerate interbedded with red shale. Unconformably overlies Chugwater; unconformably underlies Nugget(?).

Named for exposures near eastern base of Jelm Mountain, near southern line of Albany County, Wyo. Type section Jelm (restricted) is at Red Mountain 25 miles southwest of Laramie; section is in SW¼NW¼ sec. 16, T. 12 N., R. 76 W.

Jemez Marl[1]

Jemez Shales

Tertiary: Central northern New Mexico.

Original references: A. B. Reagan, 1903, Am. Geol., v. 31, p. 86; C. R. Keyes, 1932, Pan-Am. Geologist, v. 58, no. 4, p. 289.

Charles Keyes, 1936, Pan-Am. Geologist, v. 66, no. 1, p. 74. Puerco shale, as restricted by Mathews (1921, Am. Jour. Sci., 5th ser., v. 2, p. 220) could be properly renamed Jemez shales.

Derivation of name not given.

Jemison Chert[1]

Jemison Chert (in Talladega Series)

Lower Devonian: Eastern Alabama.

Original reference: Charles Butts, 1926, Alabama Geol. Survey Special Rept. 14, p. 57, 145–147, map.

T. N. McVay and L. D. Toulmin, 1945, Alabama Geol. Survey Bull. 55, p. 21. Jemison chert, Yellow Leaf quartz schist, Dempsey marble, and Erin shale occur in upper part of Talladega series.

Named for exposures at and near Jemison, Chilton County.

Jenkins Clay (in Cimarron Group)[1]

Jenkins Clay Member (of Cave Creek Formation)

Permian (Cimarron Series): Central-southern Kansas and western Oklahoma.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 27–28.

G. H. Norton, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 12, p. 1793, 1794, 1795. Unit formerly termed Jenkins clay is included in Nescatunga gypsum bed (new) in Blaine formation.

Named for former post office of Jenkins, Comanche County, Kans.

Jenkins Branch Chert Bed (in Cotter Dolomite)

Lower Ordovician: Northern Arkansas.

J. S. Cullison, 1944, Missouri Univ. School Mines and Metallurgy Bull., Tech. Ser., v. 15, no. 2, p. 35, pl. 2. Fossiliferous reddish- to brown chert bed that occurs stratigraphically above the Crooked Creek chert bed (new) about the middle of the Cotter; texture is open and porous and probably not more than 40 percent of the mass is chert. Readily recognizable only on partly weathered surfaces.

Well exposed in roadcut south of Jenkins Branch in NE cor. SW¼NE¼ sec. 7, T. 19 N., R. 15 W., Yellville quadrangle, Marion County.

Jenness Pond Member (of Littleton Formation)

Lower Devonian: Northern New Hampshire.

M. T. Heald, 1955, The geology of the Gilmanton quadrangle, New Hampshire: New Hampshire State Plan. Devel. Comm., p. 9, 10 (table 1), geol. map. Thin-bedded pseudoandalusite schist, pyritiferous schist, and mica schist. Underlies Durgin Brook member (new); overlies Pittsfield member (new).

Typical exposures in vicinity of Jenness Pond, Gilmanton quadrangle.

Jennings Formation[1]

Upper Devonian: Northern Virginia, western Maryland, and eastern West Virginia.

Original reference: N. H. Darton, 1892, Am. Geologist, v. 10, p. 13, 17, 18.

C. S. Prosser and C. K. Swartz, 1913, Maryland Geol. Survey, Middle and Upper Devonian Volume, p. 411–422. In Maryland, subdivided into (ascending) Genesee black shale, Woodmont shale (new), Parkhead sandstone, and Chemung sandstone members. Overlies Romney shale; upper limit not well defined, red sediments of Catskill type alternate with lighter colored fossiliferous sediments of Jennings type in upper part of Jennings.

Ernst Cloos, 1951, Maryland Dept. Geology, Mines and Water Resources Washington County [Rept. 14], p. 89–92, 99. Described in Washington County, Md. Thickness 4,000 to 4,800 feet.

Named from exposures at Jennings Gap on Jennings Branch, Augusta County, Va.

Jennings Mountain Complex

Precambrian: Northeastern New York.

A. F. Buddington, 1948, Geol. Soc. America Mem. 28, p. 25, Incidental mention in discussion of granitic rocks of the northwest Adirondacks.

Occurs in vicinity of Jennings Mountain.

Jerome Formation[1]

Upper Devonian: Central Arizona.

Original reference: A. A. Stoyanow, 1930, Pan-Am. Geologist, v. 53, no. 4, p. 316–317.

R. H. Denison, 1951, Fieldiana: Geology, v. 11, no. 5, p. 254. In upper Devonian (Chautauquan stage).

Section at Jerome, Yavapai County, described in detail.

Jeromian series

Paleozoic [Upper Devonian]: Arizona.

C. R. Keyes, 1942, Pan-Am. Geologist, v. 77, no. 3, p. 228. Jerome formation (of Stoyanow) regarded as series. Includes (ascending) Vecol limestone (new), 250 feet thick; Sycamore sandstone, 75 feet; and East Verde limestone (new), 350 feet. Older than Island Mesa limestone; younger than Tombstonian series(new).

[In Jerome region.]

Jerry Lava Flow

Recent: Southwestern Oregon.

E. T. Hodge, 1925, Oregon Univ. Pub., v. 2, no. 10, p. 37, 47, 53, 89, 101, 114, 115. Discussion of Mount Multnomah ancient ancestor of the Three Sisters. Lava flow that issued from Cinder Cone. Rests on morainic material.

Derivation of name not given. Cinder Cone is north of North Sister Mountain and south of Yapoah Crater.

Jerseyan Drift[1]

Jerseyan Glaciation[1]

Jerseyan Till

Pleistocene: New Jersey.

Original reference: T. C. Chamberlin and R. D. Salisbury, 1906, Geology, v. 3, p. 383–387.

Paul MacClintock, 1940, Geol. Soc. America Bull., v. 51, no. 1, p. 103–115. Discussion of weathering of Jerseyan till. Two pre-Wisconsin drift sheets are present in New Jersey. No evidence has come to light to modify Salisbury's and later Leverett's correlation with the Illinois and Kansan. Jerseyan, as used by Chamberlain and Salisbury, becomes group name equivalent to "pre-Wisconsin".

Named for development in New Jersey.

†Jessamine Limestone[1] (in Lexington Group)

Jessamine Limestone (in Lexington Limestone)

Middle Ordovician: Central northern Kentucky.

Original reference: A. M. Miller, 1919, Kentucky Dept. Geology and Forestry, ser. 5, Bull. 2, p. 25.

A. C. McFarlan and W. H. White, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1634–1635. Limestone in lower Lexington limestone; underlies Benson limestone; overlies Logana formation. Thickness 75 to 80 feet.

D. K. Hamilton, 1948, Econ. Geology, v. 43, no. 1, p. 41, 42; 1950, Kentucky Geol. Survey, ser. 9, Bull. 5, p. 13–14. Limestone in Lexington group. Overlies Logana formation; underlies Benson limestone.

Named for Jessamine Creek, Jessamine County.

Jessamine Series[1]

Middle Ordovician: Central northern Kentucky.

Original reference: A. F. Foerste, 1906, Kentucky Geol. Survey Bull. 7, p. 10.

Type locality not stated, but probably Jessamine, Jessamine Creek, or Jessamine County.

Jesse Sandstone Member (of Catron Formation)[1]

Middle Pennsylvanian: Southeastern Kentucky and northeastern Tennessee.

Original reference: G. H. Ashley and L. C. Glenn, 1906, U.S. Geol. Survey Prof. Paper 49, p. 31, 33, 41.

Named for Jesse Creek, Bell County, Ky.

Jessup Formation

Pleistocene: Indiana.

H. H. Gray, R. D. Jenkins, and R. M. Weidman, 1960, Indiana Geol. Survey Bull. 20, p. 19 (fig. 3). Named on diagram showing formations of Pleistocene age in Indiana. Name appears below Trafalgar formation (new). Name credited to W. J. Wayne (in preparation).

Type locality and derivation of name not given.

Jester Dolomite Member (of Blaine Formation)[1]

Permian: Southwestern Oklahoma.

Original references: G. G. Suffel, 1929, Stanford Univ. Abs. Dissert., v. 4, p. 90; 1930, Oklahoma Geol. Survey Bull. 49, p. 29, 55–57, 63.

Exposed where road from Jester, Greer County, crosses heavy gypsums at SE cor. sec. 25, T. 7 N., R. 24 W.

Jetmore Chalk Member (of Greenhorn Limestone)[1]

Upper Cretaceous: Central western Kansas.

Original reference: W. W. Rubey and N. W. Bass, 1925, Kansas Geol. Survey Bull. 10, p. 16, 46, 51.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 24, 25. Chalky shale and chalky limestone, interbedded, "Shell-rock limestone" bed at top, gray, weathers to light gray. Thickness 20 feet (Ellis and Russell Counties) to 25 feet. Overlies Hartland shale member; underlies Pfeifer shale member; in Hamilton County, Pfeifer shale and underlying Jetmore chalk are thicker than farther east; they cannot be distinguished and have been together designated the Bridge Creek limestone member.

Named for prominent exposures south and east of Jetmore, along south side of Buckner Creek, Hodgeman County.

Jewell Phyllite (in Casco Bay Group)[1]

Pennsylvanian(?): Southwestern Maine.

Original reference: F. J. Katz, 1917, Washington Acad. Sci. Jour., v. 7, p. 198.

L. W. Fisher, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 141, 142–143. Mentioned in discussion of Pejepscot correlatives. Pejepscot formation (new) extends northward from Portland toward Lewiston and Brunswick and must include formations included in Berwick, Kittery, and Casco Bay group of Katz. Hornblende-epidote-chlorite schist crops out at Bunganac Landing conformably above Pejepscot gneiss. This schist, which is lithologically same as Spring Point greenstone of Katz, appears to be southwestern continuation of hornblende-rich gneiss which overlies marble at locality C (fig. 9). Phyllites, slates, and limestone of Casco Bay group overlie Spring Point greenstone in Portland area. Jewell phyllite is characterized by its silky sheen and its metacrysts of ottrelite, garnet, and staurolite. In these features it is same as Winthrop phyllite which carries transition from Sabattus sillimanite schist into Waterville slates in Winthrop area. Katz placed Jewell phyllite above Spurwink limestone and below Mackworth slate.

Named for development on Jewell Island in Casco Bay, Cumberland County.

Jewett Silt Member[1] (of Temblor Formation)

Miocene: Southern California (subsurface and surface).

Original reference: A. Diepenbrock, 1933, California Oil Fields, Div. Oil and Gas, v. 19, no. 2, p. 16, 22, pl. 2.

A. M. Keen, 1943, San Diego Soc. Nat. History Trans., v. 10, no. 2, p. 26 (fig. 1), 28 (fig. 2), 29. Mapped as Jewett silt in Kern River area near Round Mountain. Considered member of Temblor. Underlies Olcese sand; overlies Walker formation. Also referred to as Freeman and Jewett silts, often indistinguishable and grading downward locally in Pyramid Hill sand or "grit zone".

Named in subsurface from Shell Oil Co. Well No. "Jewett" 1, sec. 29, T. 28 S., R. 29 E., Kern County.

Jicara Formation

Paleocene, upper, to Eocene, middle: Puerto Rico.

T. R. Slodowski, 1958, Dissert. Abs., v. 18, p. 200. A complex, more than 9,000 meters thick, of volcanic flows with interbedded marine limestones, mudstones, tuffs, and sedimentary rocks derived from volcanic rocks, is divided into eight formations [sequence not indicated]: Sabana Grande, El Rayo, Ensenada, Río Yauco, Río Loco, Río Blanco, San Germán, and Jicara (new), San Germán and Jicara formations are separated from underlying Ensenada and Río Yauco formations, at least locally, by unconformities. Complex ranges in age from Senorian to late Paleocene, possibly Eocene.

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm. and Princeton Univ. Dept. Geology, p. 19 (correlation chart). Paleocene, upper, to Eocene, middle.

P. H. Mattson, 1960, Geol. Soc. America Bull., v. 71, no. 3, p. 345–346. Slodowski (1956, unpub. thesis) described formation as composed of thin- to thick-bedded fine-grained siliceous and calcareous tuffs; massive limestone and massive volcanic conglomerate locally present at base; minimum thickness 1,000 meters. Formation in Mayagüez area [this report] unconformably overlies Mayagüez group. San Germán and Jicara formations form structural unit south of Sabana Grande, the only area where they occur together.

Type locality: Region around Estacion La Plata and intersection of Routes 117 and 327, about 2 kilometers east of Mayagüez area, southeast of San Germán.

Jim Creek Shale Member (of Root Shale)

Jim Creek Limestone (in Wabaunsee Group)[1]

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, southeastern Nebraska, and northeastern Oklahoma.

Original reference: R. C. Moore, 1932, Kansas Geol. Soc. 6th Ann. Field Conf. Guidebook, p. 94, 96.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 21. Jim Creek limestone is highest Pennsylvanian limestone identified in Missouri.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2274 (fig. 1), 2275. Rank reduced to member status in Root shale (new). Underlies French Creek shale member; overlies Friedrich shale member.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 11, fig. 5. Geographically extended into southwestern Iowa where it is classified as formation in Wabaunsee group. Consists of dark-blue to black argillaceous limestone that weathers red or brown; upper part commonly thin bedded and lower part massive. Thickness about 1 foot. Fossils include *Chonetes* and *Myalina*. Overlies Friedrich shale; underlies French Creek shale.

Type locality: On Jim Creek, sec. 29, T. 7 S., R 11 E., Pottawatomie County, Kans.

Jim Ned Shale Member (of Belle Plains Formation)

Jim Ned Shale (in Belle Plains Group)

Permian: Central Texas.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 96. Proposed to replace Coleman bed of Drake (1893); name Coleman preoccupied. Lower half of formation consists of channel sandstone deposits and sandstone lentils (becoming more prominent northward), sandy shales, thin lignitic coals and black shales with plant remains, and thin limestone beds; upper part green and reddish shales with thin dolomitic members. Thickness 100 to 125 feet. Underlies Elm Creek limestone and extends downward to disconformity at top of Fisk formation (new).

R. C. Moore *in* M. G. Cheney, 1948, Abilene Geol. Soc. [Guidebook] Spring Field Trip, June 11–12, sheets 3, 4; R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheet 2. Reduced to member status in

Belle Plains formation. Underlies Elm Creek limestone member; overlies Overall limestone member of Admiral formation.

Type locality: In south part of the Newschaffer Survey No. 750 just west of highway bridge over Jim Ned Creek on Coleman-Baird Highway about 10 miles north of Coleman, Coleman County.

Joachim Dolomite[1]

Middle Ordovician: Eastern Missouri, northern Arkansas, and southwestern Illinois.

Original reference: A. Winslow, 1894, Missouri Geol. Survey, v. 6, p. 331, 352.

H. S. McQueen, 1937, Missouri Geol. Survey and Water Resources 59th Bienn. Rept., app. 1, p. 11–12, pl. 3. Chiefly dolomite, magnesian limestone, and thin beds of shale and sandstone. Approximately 60 feet above base of formation is bed of fine-grained sandstone 4 to 10 feet thick. Overlies Dutchtown formation (new).

J. G. Grohskopf, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 3, p. 360, 362–364. Underlies Rock Levee formation (new). The Rock Levee includes some beds previously assigned to Joachim. Previous workers have stated that no chert occurs in the Joachim. However, in residues from well cuttings, a few fragments of light-gray to almost white chert was noted in many wells. This chert became a marker in subsurface work and has been traced for several hundred miles in eastern Missouri. It has been noted at two surface localities. Careful surface mapping will no doubt reveal its presence at many localities. It is here proposed that name Joachim be restricted to rocks overlying either the Dutchtown or St. Peter and including the chert zone at top. As thus defined, the Joachim is 175 feet thick at Cape Girardeau and gradually thins northwest until it is overlapped by the "Decorah" in vicinity of Kimmswick.

Named for exposures along Joachim Creek, Jefferson County, Mo.

Joana Limestone[1]

Joana Limestone Member (of White Pine Shale)

Lower Mississippian: Eastern Nevada and western Utah.

Original reference: A. C. Spencer, 1917, U.S. Geol. Survey Prof. Paper 96, p. 24, 26, map.

G. S. Campbell, 1951, Utah Geol. Soc. Guidebook 6, p. 21 (fig. 4), 23. Joanna [Joana] limestone geographically extended into House and Confusion Ranges, Utah, where it is 100 to 300 feet thick, underlies Chainman shale and overlies Pilot shale.

W. H. Easton and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 1, p. 147 (fig. 2). Shown as member of White Pine shale on correlation chart of recommended revision of stratigraphic units in Great Basin.

T. B. Nolan, C. W. Merriam, and J. S. Williams, 1956, U.S. Geol. Survey Prof. Paper 276, p. 4 (fig. 1), 54–56. Described in stratigraphic section in vicinity of Eureka where it is as much as 125 feet thick; overlies Pilot shale and underlies Chainman shale. Early Mississippian.

R. L. Langenheim, Jr., and Herbert Tischler, 1960, California Univ. Pub. Geol. Sci., v. 38, no. 2, p. 108 (fig. 5), 110. Discussion of Quartz Spring area, Inyo County, Calif. Formations Tin Mountain limestone, Perdido formation, and Rest Spring shale, as defined by McAllister (1952), are utilized in this discussion and description of rocks in area. On other hand, Joana limestone, Peers Spring formation, and Chainman shale, with somewhat different limits, are the formations to which these same rocks would be assigned in regional discussion of Mississippian stratigraphy in Great Basin.

Named for Joana mine, on south side of Robinson Canyon, 2 miles above Ely, White Pine County, Nev.

Joaquin Ridge Sandstone Member (of Panoche Formation)

Upper Cretaceous: Central California.

P. P. Goudkoff, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 7, p. 962 (fig. 2), 989. Mentioned in discussion of Weldonian stage (new). Shown on chart as underlying Ragged Valley shale and overlying Alcade shale (new). Name credited to J. Q. Anderson.

A. S. Huey, 1948, California Div. Mines Bull. 140, p. 31. Referred to as member of Panoche in discussion of Moreno Grande formation (new) and Moreno formation.

Occurs in San Joaquin Valley in Coalinga-Ortigalito area.

Joe Lott Tuff

Pliocene(?): Southwest-central Utah.

Eugene Callaghan, 1939, Am. Geophys. Union Trans. 20th Ann. Mtg., pt. 3, p. 439 (fig. 2), 440 (fig. 3), 449–450. Several discrete areas of white to light-yellow or brownish tuff are grouped as Joe Lott tuff. Thickness of outcrops highly variable; in Clear Creek basin aggregate thickness more than 1,000 feet; here tuff is in massive beds, in places between 50 and 100 feet thick; these beds show no lamination, but thin pinkish interbeds are commonly laminated. Upper part of tuff, exposed in northwestern part of region, interbedded with abundantly porphyritic latite and quartz-latite flows of Dry Hollow latite (new). Commonly overlies Dry Hollow latite; locally overlies Mount Belknap rhyolite (new) and Bullion Canyon volcanics (new). Tertiary.

U.S. Geological Survey currently considers the Joe Lott tuff to be Pliocene (?). This designation made on the basis of a restudy of units in area.

Named for exposures on Joe Lott Creek in northern part of Marysvale region. Largest exposures are in Clear Creek basin west of Sevier and in Beaver River basin southwest of Delano Peak.

Joes Canyon Formation

Ordovician: Central Nevada.

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 12, p. 97 (fig. 3). Discussion of Paleozoic continental margin in central Nevada. Clipper Canyon sequence comprises (ascending) Charcoal Canyon, Petes Summit, Sams Spring, and Joes Canyon formations (all new). Clipper Canyon sequence isolated by surrounding Tertiary volcanic rocks.

Clipper Canyon, Toquima Range, Nye and Lander Counties.

†Joes Rock Granite[1]

Devonian(?): Southeastern Massachusetts.

Original reference: C. H. Warren and S. Powers, 1914, Geol. Soc. America Bull., v. 25, p. 456, map.

Mapped at Joes Rock, west of Sheldonville, Norfolk County.

Joes Valley Member (of North Horn Formation)

Paleocene: Central Utah.

C. L. Gazin, 1941, U.S. Natl. Mus. Proc., v. 91, no. 3121, p. 6. Proposed for Paleocene part of North Horn formation. Defined as beginning with the highly colored clay and sandy clay, locally black carbonaceous shales, resting abruptly but without apparent disconformity on massive sandstones capping dinosaur-bearing North Horn beds. Upper part includes greater quantity of buff sandstone, with thicker zones of more uniformly colored sandy clay, ending abruptly beneath Flagstaff limestone. Estimated thickness several hundred feet.

Well exposed on mountain slopes adjacent to Joes Valley, Emery County. Also exposed in Dragon Canyon and on North Horn Mountain.

Johannesburg Gneiss[1]

Precambrian: Southern California.

Original reference: C. D. Hulin, 1925, California State Mining Bur. Bull. 95, p. 21–23, 28, map.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 509, table 4. Older Precambrian; older than Rand schist.

Named for exposures 2 miles north of Johannesburg, Kern County.

John Day Formation[1]

Oligocene, upper, and Miocene, lower: Central northern Oregon.

Original reference: O. C. Marsh, 1875, Am. Jour. Sci., 3d, v. 9, p. 52.

Morton Green, 1950, (abs.) Geol. Soc. America Bull., v. 61, no. 12, pt. 2, p. 1538–1539. Since 1902, formation has been considered divisible into three parts: lower reddish trachytic tuffs, middle blue-green, and upper buff andesitic tuffs. Early studies indicated that a rhyolitic flow separates middle and upper beds. Plant remains from lower beds have been determined as upper Oligocene in character, and mammal remains in middle and upper divisions as lower Miocene. Recent studies indicate that the rhyolite is welded tuff, ignimbrite, and this grades into andesitic tuff of upper division. Since characteristics for middle and upper beds are the same, separated only by local extrusive variant, it seems evident that any division is artificial.

Howel Williams, 1957, A geologic map of the Bend quardangle, Oregon, and a reconnaissance geologic map of the central portion of the High Cascade Mountains (1:125,000): Oregon Dept. Geology and Mineral Industries. Oldest rocks in Bend quadrangle. Consists principally of flows and domes of rhyolite, welded rhyolite tuffs, bedded rhyolite tuffs, and varicolored fluviatile and lacustrine tuffaceous sediments; flows of andesite and basalt subordinate. Maximum thickness not over 5,000 feet and may be less. Underlies Columbia River basalt. Upper Oligocene and lower Miocene.

R. V. Fisher and R. E. Wilcox, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B302–B304. Formation exposed mainly in southern part of Monument quadrangle. Aggregate thickness about 950 feet. Tentatively divided into three unnamed members, which do not strictly conform to those proposed by Merriam (1901, Geol. Soc. America Bull., v. 12, p. 496–497) for section at Picture Gorge. Lower member consists of deep-red friable mudstones and siltstones, 67 feet thick. Middle member, 530 feet thick, divided into two parts: lower dominantly reddish and upper colored in light shades of red, yellow, gray, and green, welded tuff present locally. Upper member, 346 feet thick, characterized by light-gray or buff colors and weathers to silty powdery soil. Late Oligocene and early Miocene.

Typical localities are along John Day River. Well exposed in Picture Gorge.

Johnnie Formation[1]

Precambrian: Eastern California and southeastern Nevada.

Original reference: T. B. Nolan, 1928, Am. Jour. Sci., 5th, v. 17, p. 461–472.

L. F. Noble, 1941, Geol. Soc. America Bull., v. 52, no. 7, p. 952–953. Geographically extended into southern Death Valley region, where it overlies Noonday dolomite and underlies Stirling quartzite. Hazzard (1937, California Jour. Mines and Geology, v. 33, no. 4) described Johnnie(?) formation in Resting Springs and Nopah region, California. Name Johnnie used here without query with the understanding that not all of type Johnnie is represented in Death Valley.

C. R. Longwell, 1952, Washington Acad. Sci. Jour., v. 42, no. 7, p. 212. Suggestion made that Johnnie formation, Noonday dolomite, Deep Springs formation, and Reed dolomite of Inyo region be carried under "age unknown" because there is no firm basis for drawing lower boundary of Cambrian in Death Valley region.

B. K. Johnson, 1957, California Univ. Pubs. Geol. Sci., v. 30, no. 5, p. 372–375, figs. 1, 3. Described in Manly Peak quadrangle, California, where it it 2,000 to 2,500 feet thick; underlies Stirling quartzite and overlies Noonday dolomite. Nonfossiliferous. In this report, beds below *Olenellus* zone are referred to the Precambrian. In Nopah-Resting Springs Ranges, top of Johnnie formation is 4,500 feet below lowest occurrence of *Olenellus*; hence, formation is well within late Precambrian as defined in this report.

First described in Johnnie Wash, north of Johnnie mine, Spring Mountains region, Nevada.

Johnny Bull Sandstone (in Bisbee Group)

Lower Cretaceous: Southwestern New Mexico.

Elliot Gillerman, 1958, New Mexico Bur. Mines Mineral Resources Bull. 57, p. 52–53, table 1, pl. 1. Interbedded light-colored fine-grained well-sorted well-cemented orthoquartzite, dark-grayish-brown fine-grained well-cemented subgraywacke, and brown shale. Sandstone and interbedded shale comprise major part of formation. Shale beds typically thin bedded. No complete section observed. Thickness at type locality 1,047 feet. Conformably overlies Still Ridge formation (new).

Type section: Central part is about a mile due west of Johnny Bull mine, from which unit is named. Section measured along south side of prominent hill just north of road to Silver Hill mine, in SE¼ sec. 4, T. 25 S., R. 21 W., Peloncillo Mountains, Hidalgo County.

Johnny Lyon Granodiorite

Precambrian: Southeastern Arizona.

P. E. Damon, 1959, Arizona Geol. Soc. Guidebook 2, p. 19 (table 3), 20. Briefly mentioned in paper on geochemical dating of igneous and metamorphic rocks. Alpha-lead dates for zircon separates given as 615 and 815 million years.

In Johnny Lyon Hills, about 50 miles east of Tucson.

Johnsburg Limestone[1]

Precambrian: Northeastern New York.

Original reference: H. L. Alling, 1918, New York State Mus. Bull. 199.

Type locality: Johnsburg, Warren County.

Johnson Granite Porphyry[1] (in Tuolumne Intrusive Series)

Cretaceous: Eastern California.

Original reference: F. C. Calkins, 1930, U.S. Geol. Survey Prof. Paper 160, p. 127–128, map.

J. F. Evernden, G. H. Curtis, and J. Lipson, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 9, p. 2121, 2122, 2123 (fig. 1). Discussed in paper dealing with potassium-argon dating of igneous rocks. Age given as 82.4 millions of years. Younger than Cathedral Peak granite and Hoffman quartz monzonite (new).

Named for fact it forms Johnson Peak in Yosemite National Park.

Johnson Gravels[1]

Miocene: Northern California.

Original reference: J. S. Diller, 1892, Geol. Soc. America Bull., v. 3, p. 371–394.

Extend south of 40th parallel, through Cascade mine to vicinity of Haskell Peak, Taylorsville region.

Johnson Shale[1] (in Council Grove Group)

Permian: Southeastern Nebraska, northeastern Kansas, and northern Oklahoma.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 84, 86, 88.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 168; R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 48. Gray shale that locally, in northern Kansas, contains thin beds of argillaceous limestone; dark carbonaceous material occurs in upper part of shale in north; lower and middle parts are commonly somewhat sandy. Thickness ranges from about 16 feet in northern part of Kansas to about 25 feet in southern part. Underlies Long Creek limestone member of Foraker limestone. Wolfcamp series.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 85–86. In Kansas and Nebraska, rocks of interval above Long Creek limestone and below Glenrock limestone member of Red Eagle limestone are known as Johnson shale. In Pawnee County, Red Eagle limestone has not been subdivided, and it is not certain that Glenrock member is present. Name Johnson shale has been retained and applied to beds between Eagle Rock and Long Creek limestone member of Foraker limestone. Unit extends southward into Lincoln County. Thickness 35 to 60 feet in Pawnee County.

Named for exposures 1½ miles north of Johnson County, Nebr.

Johnsonburg Sandstone[1]

Mississippian: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 139–140.

Occurs in southern suburb of Johnsonburg, Elk County.

†Johnson Creek Conglomerate[1]

Precambrian (Keweenawan) : Northern Michigan.

Original reference: A. C. Lane, 1911, Michigan Geol. and Biol. Survey Pub. 6, geol. ser. 4, p. 527, 546, 554, 555.

Probably named for exposures on Johnson Creek, Houghton County.

Johnson Gap Formation

Triassic(?) : Southeastern Colorado and northeastern New Mexico.

R. B. Johnson and E. H. Baltz, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 12, p. 1896 (fig. 1), 1897–1899. Sequence of thin to thick beds of gray silty siliceous limestone conglomerate that contains pebbles and cobbles of gray finely crystalline limestone. Conglomerate interbedded with gray and light-red silty and siliceous limestone; red, siliceous, thin-bedded siltstone; greenish gray and brown plastic shale; and gray and red, fine-grained quartzose sandstone. Thickness at type locality about 90 feet. Thickens southward from wedge-edge about 2 miles north of Johnson Creek to about 100 feet at State line, and about 110 feet at Gold Creek, about 8 miles south of Johnson Creek and 3 miles into New Mexico. Rests with apparent unconformity on Sangre de Cristo formation. Upper beds truncated by erosion surface at base of overlying Entrada sandstone.

Type locality: Johnson Creek, secs. 19 and 20, T. 34 S., R. 69 W., Sangre de Cristo Mountains, Colo. Named for exposures in gap of Johnson Creek, locally known as Johnson Gap, 3 miles west of Tores, Las Animas County, Colo.

Johnson Gulch Porphyry[1] (in Gray Porphyry Group)

Early Tertiary: Northern central Colorado.

Original reference: S. F. Emmons, J. D. Irving, and G. F. Loughlin, 1927, U.S. Geol. Survey Prof. Paper 148.

C. H. Behre, Jr., 1953, U.S. Geol. Survey Prof. Paper 235, p. 53–54, 57, pl. 1. Younger than Iowa Gulch porphyry. Intrusion of Johnson Gulch porphyry was latest event in igneous sequence in area [west slope of Mosquito Range]. Igneous rocks younger than Precambrian in area of this report are either wholly or mainly Tertiary and only possibly in part late Cretaceous or early Pleistocene.

U.S. Geological Survey currently designates the age of the Johnson Gulch Porphyry as early Tertiary on basis of a study now in progress.

Named for development in Johnson Gulch, Leadville district, Lake County.

Johnson Mill Graphite Schist

[Precambrian] : Western Virginia.

W. A. Nelson, 1949, (abs.) Virginia Acad. Sci. Proc. 1948–49, p. 140. Overlies Lynchburg gneiss; underlies Charlottesville formation (new).

Report discusses structure and stratigraphy of the Blue Ridge in Albemarle and adjacent counties. Main Blue Ridge mountain is an overturned anticline, with axial plane dipping 28° to southeast, and thrust fault bordering it on its western edge.

Johnson Peak Formation

Upper Cretaceous: Southern California.

O. T. Marsh, 1956, Dissert. Abs., v. 16, no. 1, p. 101; 1960, California Div. Mines Spec. Rept. 62, p. 7 (fig. 3), 16–18, pls. 1, 2. Approximately 65 percent of formation at Johnson Peak consists of pale- to dark-green silty shale which weathers light brown; locally shale contains fine carbonaceous particles; limestone nodules and thin limestone beds common throughout shale; some thin layers of yellowish-green siltstone present; thinly bedded arkosic sandstones make up the remaining 35 percent. About 200 to 300 feet below top of formation is a prominent lens of massive thinly bedded concretionary graywacke which attains maximum thickness of about 380 feet northeast of Orchard Peak; this lens is named Enebro sandstone member (Spanish for "juniper") in reference to numerous junipers that thrive on its sandy soil. [Enebro not considered formal name.] Thickness at type section 2,250 feet; about 800 feet near western limit of outcrop; about 950 feet at eastern limit, near Devil's Den. Except where faulted, conformably overlies Risco formation (new); conformably underlies Aguila sandstone (new). Presence of single *Baculites* sp. indicates Late Cretaceous age.

Type locality: Section through Johnson Peak, Three Peaks anticline, Tent Hills quadrangle, Kern County. Crops out mainly east and northwest of Orchard Peak and in Three Peaks anticline.

Johnson Run Sandstone

†Johnson Run Sandstone (in Pottsville Formation)[1]

Pennsylvanian (Pottsville Series): Central northern Pennsylvania.

Original reference: C. A. Ashburner, 1879, Geol. map of McKean County: Pennsylvania 2d Geol. Survey.

Henry Leighton, 1941, Pennsylvania Geol. Survey, 4th ser., Bull. M–23, p. 57, 103. Johnson Run sandstone (Pottsville series) is separated from underlying Kinzua Creek sandstone by Alton coal group. Forms top of Pottsville in many areas.

First described in McKean County. Also noted in Cameron and Clinton Counties.

Johnson Spring Formation

Johnson Spring Formation (in Eureka Group)

Middle Ordovician: East-central California.

H. R. Pestana, 1960, Jour. Paleontology, v. 34, no. 5, p. 862–873. Interbedded limestone, dolomite, and quartzite. Thickness 163 to 384 feet; 208 feet at type section. Conformably overlies Barrel Spring formation; conformably underlies Ely Springs dolomite. This is unit referred to as undifferentiated upper part of Eureka group by Langenheim and others (1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9).

Type section: Lead Canyon Trail section, Independence quadrangle, Inyo Mountains. Outcrops of formation parallel outcrops of other Paleozoic formations along eastern side of Mazourka Canyon.

Johns Pond Formation

Silurian(?): Central western Maine.

R. J. Willard, 1959, Dissert. Abs., v. 19, no. 11, p. 2918. Passes from low-grade greenstones in north through hornblende-epidote-(albite or oligoclase) amphibolites to middle-high-grade almandite-hypersthene-biotite-andesine granulites in the south. Thickness about 1,600 feet. Underlies Perry Mountain formation; overlies Lost Brook formation (new).

In Kennebago Lake quadrangle.

Johnstone Peak Tuff Breccia (in Glendora Volcanics)

Miocene, middle or older: Southern California.

J. S. Shelton, 1955, Geol. Soc. America Bull., v. 66, no. 1, p. 65–67, pls. 1, 4. Name applied to accumulations of tuff that occur at various horizons in volcanics in foothills area. Contains numerous scattered subangular fragments and blocks ranging in diameter from fraction of inch to over 10 feet. Proportion of blocks to tuff matrix ranges from about 10 to over 50 percent. In most outcrops, deposit is chaotic with no sign of bedding; locally contains lenses and thin streaks of bedded tuff matrix. Breccias lie between and upon the three lava members of volcanic series and range in thickness from about 100 to 700 feet.

Typically exposed south of Johnstone Peak, in San Gabriel Mountains, Los Angeles County.

Johnston Hill Glaciation

Pleistocene: Southwestern Alaska.

E. H. Muller, 1953, *in* T. L. Péwé and others, U.S. Geol. Survey Circ. 289, p. 2, 13 (table 1). Four major glaciations tentatively recognized in northern part of Alaska Peninsula. Johnston Hill was second early ice advance, or major recessional phase of preceding (unnamed) glaciation. Includes bouldery outwash in shore bluffs west of Johnston Hill and till in bluffs at mouth of Naknek River. Characteristic topographic expressions of glaciation largely destroyed by succeeding glaciations. Succeeded by Mak Hill glaciation (new). Name credited to Abrahamson (unpub. dissert.).

Named for prominent till ridge 12 miles southwest of Naknek, northern Alaska Peninsula.

Johnstown Limestone Member (of Allegheny Formation)[1]

Johnstown Limestone (in Allegheny Group)

Upper Pennsylvanian: Western Pennsylvania.

Original reference: H. M. Chance, 1880, Pennsylvania 2d Geol. Survey Rept. V_2.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 60 (table), 74, fig. 21. Included in Kittanning subdivision of Allegheny group. Thickness as much as 10 feet. Separated from overlying Freeport sandstone by Upper Kittanning coal; overlies Upper Westernport sandstone.

Named for occurrence at Johnstown, Cambria County.

Johns Valley Shale[1]

Mississippian and Pennsylvanian: Southeastern Oklahoma and central and western Arkansas.

Original reference: E. O. Ulrich, 1927, Oklahoma Geol. Survey Bull. 45, p. 6, 21–23, 30, 36–37.

B. H. Harlton, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 7, p. 896. Name abandoned. Replaced by Round Prairie formation (new).

R. C. Rea, 1947, Tulsa Geol. Soc. Guidebook Field Conf., May 8, 9, 10, p. 47–49. Johns Valley shale of Pennsylvanian age (some say Bendian) lies conformably between Jackfork sandstone below and Atoka formation above in normal sequence at all localities where it was observed in western Ouachita Mountains. Measured sections indicate minimum of

300 feet and maximum thickness of 900 feet. Characterized by presence of erratic and exotic boulders ranging from Cambrian to Mississippian in age.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped as Pennsylvanian.

L. M. Cline, 1956, Tulsa Geol. Soc. Digest, v. 24, p. 103–106. Upper part of Johns Valley shale is partial equivalent of Mississippian Caney formation of Arbuckle province. Type locality of the Johns Valley is in bowl-shaped Johns Valley in trough of Tuskahoma syncline. Also type locality of Caney shale is along Caney Creek (originally Cane Creek) which is also in Johns Valley topographic basin. Many Mississippian fossils illustrated by Girty (1909, U.S. Geol. Survey Bull. 377) were collected in Johns Valley. With recognition of exotic boulders of Arbuckle and (or) Ozark facies that are embedded in the shale, Ulrich (1927) proposed name Johns Valley for the boulder-bearing shale. He acknowledged the Mississippian age of rocks containing Caney fauna, but held that they were erratics which had been transported to Johns Valley in early Pennsylvanian time. The pre-Mississippian boulders and blocks in Johns Valley are foreign to Ouachita province, but it is now believed that the so-called "Caney boulders" are sideritic concretions indigenous to Caney, that the Caney "blocks" are substantially where the shale was deposited, and that the type Caney is in reality the lower part of the type Johns Valley as defined by Ulrich.

L. M. Cline and O. B. Shelburne, 1959, *in* The geology of the Ouachita Mountains—a symposium: Dallas Geol. Soc. and Ardmore Geol. Soc., p. 193–204. Formation discussed in detail. Harlton's (1938) name Round Prairie not accepted by later workers. Overlies Game Refuge sandstone; underlies Atoka formation. Thickness 425 to 900 feet. Mississippian-Pennsylvanian.

H. D. Miser and T. A. Hendricks, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 11, p. 1829–1832. Discussion of age of Johns Valley shale, Jackfork sandstone, and Stanley shale. Geologic evidence establishes presence of both Pennsylvanian and Mississippian beds in Johns Valley shale.

Typically exposed in center of Tuskahoma syncline, particularly in north half of T. 1 S., R. 16 E. Named for settlement (on Cane Creek, in northwest part of Pushmataha County, about 6 miles north of Eubanks) which is now called Johns Valley, but which, at time Taff named Caney shale, was locally known as Caney and which Taff in 1925 stated was type locality of Caney shale.

Johns Wash Limestone

Upper Cambrian: East-central Nevada.

Harald Drewes and A. R. Palmer, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 1, p. 106 (fig. 2), 108 (fig. 3), 115, 117; Harald Drewes, 1958, Geol. Soc. America Bull., v. 69, no. 2, p. 224 (fig. 2), 226, pl. 1. Name applied to 250-foot unit of coarsely crystalline and clastic, light- to dark-gray limestones that commonly makes cliff above Lincoln Peak formation (new). Underlies Corset Spring shale (new).

Type section: Head of Johns Wash, Mount Washington-Lincoln Peak area, Snake Range.

Joins Formation[1] (in Simpson Group)

Middle Ordovician: Central southern Oklahoma.

Original references: E. O. Ulrich, 1928, Manuscript chart exhibited at New York meeting of Geol. Soc. America; C. E. Decker, 1930, Am. Assoc. Petroleum Geologists Bull., v. 14, no. 12, p. 1495.

R. W. Harris, 1957, Oklahoma Geol. Survey Bull. 75, p. 55–61. Consists of thin limestones and shales with several intraformational conglomerates near base; limestones are light to dark gray and vary from fine grained and resistant to coarsely crystalline and crumbling; shales are characteristically green and less abundant and thinner bedded than those of overlying Simpson formations. Thickness at type locality approximately 300 feet; thins to 160 feet in southeastern end of Arbuckle Mountains; ranges from 200 feet at northwestern end to zero at northeastern end. Overlapped by Oil Creek formation; unconformably overlies Arbuckle dolomitic limestone. Ostracoda indicate more indirectly than directly Chazyan age; none of the Ostracoda in the Joins has been recorded from Chazyan strata outside Oklahoma; similarity of Joins and Oil Creek (Chazyan) Ostracoda is indirect evidence of Chazyan age.

Type locality: Exposures along Spring Creek on Johns Ranch, in Carter County, T. 2 S., R. 1 W., northwest of Woodford, near western end of Arbuckle Mountains.

Joins Ranch Formation[1]

Lower Ordovician (Chazy): Central southern Oklahoma.

Original reference: E. O. Ulrich *in* C. E. Decker, Dec. 1930, Am. Assoc. Petroleum Geologists Bull., v. 14, no. 12, p. 1495.

Arbuckle and Wichita Mountains.

Joliet Conglomerate[1]

Pleistocene: Northeastern Illinois.

Original reference: J. W. Goldthwait, 1909, Illinois Geol. Survey Bull. 11, p. 42.

Named for Joliet, Will County.

Joilet Limestone[1]

Joliet Dolomite

Joliet stage

Middle Silurian: Northeastern and western Illinois.

Original reference: G. A. Shufeldt, Jr., 1865, Am. Jour. Sci., 2d, v. 40, p. 389.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Correlation chart shows Joliet dolomite (restricted) as underlying Cordova dolomite (new) and overlying Rockdale dolomite (new).

J. N. Payne, 1942, Illinois Geol. Survey Bull. 66, p. 191 (table 8). Shown on table of general classification of geologic time as Joliet stage in Niagaran epoch.

Well exposed in quarry of National Stone Co., Joliet, Will County.

Jolliff Conglomerate Member (of Golf Course Formation)

Jolliff Limestone Member (of Dornick Hills Formation)[1]

Pennsylvanian (Morrow Series): South-central Oklahoma.

Original reference: J. A. Waters, 1927, Jour. Paleontology, v. 1, p. 129.

B. H. Harlton, 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 7, p. 854 (fig. 1). Correlation chart shows Jolliff below Otterville and above Limestone Gap shale (new).

B. H. Harlton, 1956, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium v. 1: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 137 (fig. 2), 138. Member of Golf Course formation (new). Overlies Primrose sandstone member; underlies Otterville limestone member. South of Ardmore the Jolliff conglomerate is lowest unit of Morrowan age.

C. W. Tomlinson and William McBee, Jr., 1959, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 2: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 20. Jolliff limestones and conglomerates occur south of Ardmore where they were described by Tomlinson (1929, Oklahoma Geol. Survey Bull. 46) as basal member of Dornick Hills formation, now regarded as group. Along much of its 15-mile outcrop, consists of two coarse conglomerates, each 10 to 30 feet thick. Conglomerates locally disappear or grade into thin tan limestones. Where these occur, they are the first extensive limestones above the Sycamore (Mississippian). They are also lowest conglomerates in sedimentary section here, above Cambrian arkosic conglomerates at base of Reagan sandstone—except for intraformational flat-pebble conglomerates in the Joins and upper Arbuckle beds (Ordovician) and the very local 4-inch bed in Lake Ardmore formation. Tan to black shales fill the varying interval (50 to 200 feet) between major competent strata of Jolliff unit. South of Ardmore, about 800 feet of black shale with sideritic layers intervene between Jolliff conglomerates and Otterville limestone—next higher resistant member of Dornick Hills group.

Named for outcrops in Jolliff Prairie, on allotment of Norman Criner Jolliff, in sec. 24, T. 5 S., R. 1 E., Carter County, east of axis of Overbrook anticline.

Jolly Limestone (in McLeansboro Formation)[1]

Pennsylvanian: Western Kentucky.

Original reference: F. M. Hutchinson, 1912, Kentucky Geol. Survey Bull. 19, p. 30–125.

Probably named for Jolly, Webster County.

Jolly Limestone Member (of Savanna Sandstone)[1]

Pennsylvanian: Central southern Oklahoma.

Original reference: G. D. Morgan, 1924, [Oklahoma] Bur. Geology Bull. 2, p. 74–75.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 108. Rejected by Oklahoma Geological Survey. Name preoccupied.

Well exposed in road in front of J. S. Jolly's house, 300 yards east of NW cor. sec. 8, T. 1 N., R. 7 E., Pontotoc County.

Jollytown Limestone Member (of Washington Formation)[1]

Jollytown Limestone (in Washington Group)

Permian: Southwestern Pennsylvania, western Maryland, and northern West Virginia.

Original reference: I. C. White, 1891, U.S. Geol. Survey Bull. 65, p. 22, 23, 24, 29, 34.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 151. Included in Washington group, although not exposed in Fayette County.

Named for exposures in vicinity of Jollytown, Greene County, Pa.

Jollytown Sandstone (in Washington Formation)[1]

Jollytown Sandstone Member (of Greene Formation)

Permian: Southwestern Pennsylvania, eastern Ohio, and western West Virginia.

Original reference: E. V. d'Invilliers, 1895, Pennsylvania 2d Geol. Survey Summ. Final Rept., v. 3, pt. 2, p. 2573.

Wilber Stout, 1943, Ohio Geol. Survey, 4th ser., Bull. 44, p. 154, chart facing p. 108. In Ohio, termed sandstone member of Greene formation, Dunkard series.

R. L. Nace and P. P. Bieber, 1958, West Virginia Geol. Survey Bull. 14, p. 17 (table 2). In Harrison County, W. Va., Jollytown sandstone is shown as underlying unnamed shale below Dunkard coal and overlying Jollytown coal and (or) slate and shale. Included in Greene formation, Dunkard group.

Thomas Arkle, Jr., 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 118 (table 1). Shown on table of classification of Greene series. Above Jollytown coal and below Dunkard coal.

First described near mouth of Hoover Run on Dunkard Creek, Washington County, Pa.

Jonesboro Limestone[1]

Mississippian: Southwestern Illinois.

Original reference: H. Engelmann, 1868, Illinois Geol. Survey, v. 3, p. 43.

Well exposed one-half mile west of Jonesboro, Union County.

Jonesboro Limestone[1] (in Knox Group)

Lower Ordovician: Northeastern Tennessee and southwestern Virginia.

Original reference: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, p. 564, 637, 671–674, pl. 27.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, p. 62, 63–64, pl. 11. In proposing term Jonesboro limestone, Ulrich included within it virtually whole southeastern phase of Knox group, as exposed in Jockey Creek section, and at same time included in his Copper Ridge virtually whole northwestern phase as exposed in Thorn Hill section, because he believed rocks in Knox group in Thorn Hill section were almost entirely older than those in Jockey Creek section. Later studies have shown that the rocks in the two sections cover almost the same span. The Jonesboro is restricted, in Jockey Creek section and elsewhere, to the Ordovician part of Knox group (southeastern phase). On present map, this phase of Knox group is divided into Jonesboro limestone above and Conococheague limestone below. The Jonesboro consists largely of dark-blue-weathering limestone some of which is "ribboned" with thin layers of silty dolomite; fairly thick sandstone beds occur in lower 400 feet or so. Thickness about 2,000 feet.

P. B. King and H. W. Ferguson, 1960, U.S. Geol. Survey Prof. Paper 311, p. 28 (tables), 56–57, 126, pl. 1. Thickness 1,700 feet in Denton Valley, north-central Shady Valley quadrangle. Overlies Conochocheague limestone. Top formation in Knox group in this area. Underlies Lenoir limestone. Lower Ordovician.

First described in vicinity of Jonesboro, Washington County, Tenn.

Jonesburg Sandstone Member (of Vamoosa Formation)

Jonesburg Sandstone Member (of Nelagony Formation)[1]

Pennsylvanian (Virgil Series): Southern Kansas and central northern Oklahoma.

Original reference: M. I. Goldman, 1920, U.S. Geol. Survey Bull. 686–W, p. 329–330.

W. F. Tanner, 1956, Oklahoma Geol. Survey Circ. 40, p. 48–50, pl. 1. Reallocated to Vamoosa formation in Oklahoma. Thickness 38 to 54 feet. Upper part consists of buff fine-grained sandstone, middle part of alternating flaggy siltstones and shales, and lower part of contorted buff sandstone and greenish-gray siltstone. Lower part lies at about same stratigraphic position of Bowhan sandstone member; top lies about 100 feet below Middle Oread limestone. The 100-foot interval from the Jonesburg to the Middle Oread is primarily shale, with many lenses of sandstone and a few lenses of limestone; south of southern limit of the Jonesburg, this lenticular zone extends from Labadie limestone member to the Middle Oread, a thickness of about 170 feet; that is, the Jonesburg sandstone is a named member in lower part of an otherwise unsystematized sequence of lenses.

Named for exposure on top of ridge west of Jonesburg, Chautauqua County, Kans.

Jones Point Shale Member (of Topeka Limestone)

Jones Point Shale (in Calhoun Shale)[1]

Pennsylvanian (Virgil Series): Southeastern Nebraska, southwestern Iowa, eastern Kansas, and northwestern Missouri.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 40, 43, 51.

G. E. Condra and E. C. Reed, 1937, Nebraska Geol. Survey Bull. 11, 2d ser., p. 15, 46, 49–50. Reallocated to member status in Topeka limestone; underlies Sheldon limestone member; overlies Curzen [Curzon] limestone member. Occurrences in Missouri noted.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2035. Member of Topeka formation. Overlies Iowa Point shale member; underlies Sheldon limestone member. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 16, fig. 5. Light- to dark-gray argillaceous to calcareous fossiliferous shale with some beds of thin fossiliferous limestone. Thins to northeast; thickness 7 feet near Thurman, Fremont County; 2.3 feet west of Macedonia, Pottawatamie County; 0.7 foot near Howe, Adair County. Member of Topeka limestone; underlies Sheldon limestone member; overlies Curzon limestone member.

Named for Jones Point, spur in Missouri River bluffs east of Union, Cass County, Nebr.

Jones Ranch Beds

Pleistocene: Southwestern Kansas.

H. T. U. Smith, 1940, Kansas Geol. Survey Bull. 34, p. 110–111, pl. 15B. Name applied provisionally to deposits from which Jones Ranch fauna was described by Hibbard (1940, Kansas Acad. Sci. Trans., v. 43). Consist of poorly consolidated sand, silt, and clay. Thickness 34 to 60 feet. Vertebrate faunas indicate Pleistocene age, probably early.

J. C. Frye and C. W. Hibbard, 1941, Kansas Geol. Survey Bull. 38, p. 411, 416. Included in Meade formation (redefined).

T. G. McLaughlin, 1946, Kansas Geol. Survey Bull. 61, p. 123. Considered part of Kingsdown silt.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 110. Listed among units classed at least in part as Sanborn formation.

Occur along headwaters of Sand Creek, in southern part of T. 32 S. and northern part of T. 33 S., R. 27 W., southeast of Meade, Meade County.

Jonestown Beds or Formation (in Martinsburg Formation or Group)

Ordovician: East-central and central Pennsylvania.

Bradford Willard, 1939, Pennsylvania Acad. Sci. Proc., v. 13, p. 129, 131. Name proposed for beds or formation in upper part of Martinsburg "formation." Described as basically dark shale weathering to buff chips; also includes many red shale bands and lenticular bodies of platy or brecciated, rarely massive, limestone. This alternation of dark shale, red shale, and limestone is not sharply defined below but passes over into nonred limestone-poor older Martinsburg shales. Maximum thickness 500 feet. Underlies Shochary sandstone.

Bradford Willard, 1943, Geol. Soc. America Bull., v. 54, no. 8, p. 1068, 1074, 1075, 1090, 1116 (fig. 8), 1118. Beds further described as including cross-bedded sandy layers, oolite, and an abundance of limestone breccia or edgewise conglomerate associated with the limestones and red beds. Continental quivalent of marine Martinsburg with which it intergrades. In eastern outcrops of Martinsburg group, unit lies stratigraphically near base of sandstones ("Fairview" and Shochary) and extends down into underlying shale (Dauphin).

Named for exposure along Swatara Creek north of Jonestown, Lebanon County.

Jonestown Volcanics

Ordovician: Central Pennsylvania.

Owen Bricker, 1960, Pennsylvania Geologists Guidebook 25th Ann. Field Conf., p. 92–99. Consists of volcanics interbedded with series of shales, sandstones, and limestone. Section shows (ascending) dark-gray shale, green arkosic sandstone, thin beds of red shale; red basalt breccia, massive basalt and some porphyritic basalt, about 600 feet; dark-gray shale containing beds of red and purple shale, green arkosic sandstone, and thin limestone, about 125 feet; hard white sandstone with angular fragments of green clay, about 150 feet; dark-gray shale with thin beds of red, purple, and green shale; about 50 feet; dark-greenish-gray basalt breccia, massive basalt, and amygdaloidal basalt, about 500 feet; fine- to medium-grained blue-gray limestone, about 150 feet; dark-gray to black fissile shale. Stratigraphic position of volcanics is within main belt of Martinsburg formation.

Volcanics are south of Jonestown, Lebanon County. Form topographic high known locally as Bunker Hill.

Jordan Limestone Member (of Bingham Quartzite)[1]

Pennsylvanian: Central northern Utah.

Original reference: A. Keith, 1905, U.S. Geol. Survey Prof. Paper 38, p. 38, map, sections.

Named for occurrence in Old Jordan mine, Bingham district.

Jordan Sandstone[1]

Jordan Sandstone Member (of Trempealeau Formation)

Upper Cambrian: Southern Minnesota, northern Illinois, Iowa, and Wisconsin.

Original reference: A. Winchell, 1872, Rept. of geol. survey of Belle Plaine, Scott County, Minn., 16 p.

G. O. Raasch, 1939, Geol. Soc. America Spec. Paper 19, p. 97–105. Trempealeau formation subdivided into (ascending) St. Lawrence, Lodi, and Jordan members.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 46–49, measured sections. Described in southeastern Minnesota where it includes Norwalk member below and Van Oser member above. Overlies Lodi member of St. Lawrence formation; underlies Oneota dolomite; in some areas, separated from Oneota by Kasota sandstone and Blue Earth siltstone. St. Croixian series.

J. N. Payne *in* H. B. Willman and J. N. Payne, 1942, Illinois Geol. Survey Bull. 66, p. 191 (table 8), 192. Jordan stage of Cambrian period mentioned in discussion of geologic history of pre-Pennsylvanian in Illinois.

B. F. Howell and others, 1944, Geol. Soc. America Bull., v. 55, no. 4, chart 1 (column 61). Shown on correlation chart as member of Trempealeau formation.

G. O. Raasch, 1951, Illinois Acad. Sci. Trans., v. 44, p. 150. Uppermost member of Trempealeau formation. Overlies Lodi member; underlies Sunset Point formation (new) which name replaces term Madison formation as previously used in Wisconsin.

G. O. Raasch, 1952, Illinois Acad. Sci. Trans., v. 45, p. 94. Includes Van Oser submember.

C. A. Nelson, 1956, Geol. Soc. America Bull., v. 67, no. 2, p. 165–184. Discussion of Upper Croixan stratigraphy of Upper Mississippi Valley. Terminology adopted represents return to early lithologic classifications in which St. Lawrence and Jordan formations are recognized as dolomitic strata and massive sandstone, respectively. Urged that term Trempealeau, previously employed as formation name to include all these strata and also as stage name, be restricted to Trempealeauan stage.

R. R. Berg, C. A. Nelson, and W. C. Bell, 1956, Geol. Soc. America Guidebook Minneapolis Mtg. Field Trip 2, p. 13–20. Formation consists of massive- to well-bedded fine- to coarse-grained sandstone lying above Lodi member of the St. Lawrence. Contact with St. Lawrence generally sharp and drawn above highest siltstone and at base of continuous sandstone. Thickness 20 to 150 feet; average about 100 feet. Trowbridge and Atwater (1934) suggested member terminology, Norwalk and overlying Van Oser. This subdivision officially adopted for Minnesota classification by Stauffer and others (1939, Geol. Soc. America Bull., v. 50, no. 8). These units are of limited applicability and have been used in few published measured sections of Jordan. They serve to emphasize general upward gradation of the Jordan from fine- to coarse-grained sandstone. Relation of Jordan sandstone to Madison (Irving, 1875) or Sunset Point (Raasch, 1951) sandstone of eastern Wisconsin not clear. Twenhofel, Raasch, and Thwaites (1935, Geol. Soc. America Bull., v. 46, no. 11) appear to be only workers who have applied term Madison away from type section at Madison, Wis., and their usage is ambiguous; unit not recognized in Minnesota. Difficulty that various workers have experienced in clearly differentiating Jordan from Madison in a single section suggests that they represent lateral facies of one another. The Madison (Sunset Point) may bear same relation to the Jordan as does the Kasota sandstone. These strata lie between true Jordan and true Oneota dolomite deposits. Disconformity commonly suggested at top of Jordan is based on catastrophic concept that Jordan sandstone cannot contain post-Cambrian fossils (as does the Kasota) and has yet to be clearly demonstrated on physical evidence. Croixan series.

Named for exposures in Sand Creek at Jordan, Scott County, Minn.

Jordan Narrows unit (in Salt Lake Group)

Oligocene, middle, to Miocene, middle: North-central Utah.

L. W. Slentz, 1955, Utah Geol. Soc. Guidebook 10, p. 23, 24 (fig. 6), 25–26. Salt Lake group, in Lower Jordan Valley, is divided into (ascending) Traverse volcanics, Jordan Narrows unit, Camp Williams unit, Harkers fanglomerate, and Travertine unit. Jordan Narrows unit is chiefly white marlstone with oolitic argillaceous and cherty limestone, sandstone, clays, and rhyolitic tuffs, all fresh-water lacustrine deposits. Total thickness unknown but exceeds 300 and perhaps 2,000 feet. Interfingering relationships with Traverse volcanics.

Type locality: Jordan Narrows and Beef Hollow. Areal extent of unit not definitely known but may underlie entire Jordan Valley. Lower Jordan Valley is defined as that part of Jordan Valley northward from Traverse Mountains to Great Salt Lake.

Jornada Basalt

Quaternary: Central southern New Mexico.

F. E. Kottlowski and others, 1956, New Mexico Bur. Mines Mineral Resources Mem. 1, p. 72. Vesicular basalt. Thickness from 50 to 100 feet. Partly covered by thin sheet of Recent windblown sand and clay.

Occupies rectangular-shaped area, about 20 miles from east to west and 11 miles from north to south on northwest side of Jornada del Muerto, Socorro County.

Jornada Gravels

Age not given: Southwestern New Mexico.

F. E. Kottlowski, 1958, Roswell Geol. Soc. Guidebook, 11th Field Conf., p. 109. Gravels are of angular pebbles typical of alluvial fan gravels and dissimilar to rounded gravels now found along the Rio Grande.

Exposed along Highway U.S. 70, 65 miles southwest of Alamogordo.

Jornada Limestone (in Montoya Group)

Upper Ordovician: Southwestern New Mexico.

V. C. Kelley, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 10, p. 2201 (table), fig. 2. Thickness ranges from fraction of a foot to 400 feet. Underlies Fusselman limestone; overlies Cable Canyon sandstone.

Exposed in Caballo Mountains.

Jornadan series[1]

Quaternary: New Mexico.

Original reference: C. R. Keyes, 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 8.

Jose Butte Basalt or Flow (in Clayton Basalt)

Late Cenozoic: Northeastern New Mexico.

Brewster Baldwin and W. R. Muehlberger, 1959, New Mexico Bur. Mines Mineral Resources Bull. 63, p. 122, pl. 1–b. Ten basalt flows in what is termed Folsom sequence of Clayton basalt are named and mapped. Stratigraphic position of six of these basalts has been determined. Jose Butte is youngest in known sequence. Overlies Robinson Mountain basalt. Thickness unknown although topographic breaks along margin indicate at least 20 feet. Rock is medium-gray holocrystalline porphyritic olivine basalt.

Jose Butte lies along Colfax-Union County line, and basalt from it covers several square miles northwest of Capulin Mountain.

Jose Shale Member (of Yegua Formation)

Eocene (Claiborne): Western Texas, and Tamaulipas, Mexico.

J. M. Patterson, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 2, p. 259 (fig. 2), 265. Name applied to predominantly red and green bentonitic shales above Mier sandstone tongue and below Loma Blanca sandstone tongue of Yegua formation. Thickness 70 to 130 feet.

Named from Jose ranchhouse located 1¾ miles northeast of village of Falcon, Falcon quadrangle, Texas.

Jose Creek Member (of McRae Formation)

Upper Cretaceous: Southwestern New Mexico.

H. P. Bushnell, 1955, Compass, v. 33, no. 1, p. 11 (table), 12–14. Lower part of member at type locality consists of green shale and siltstone beds interbedded with coarse-grained tan to dark-brown or greenish andesitic sandstone beds. Upper part distinguished by coarse-grained andesitic sandstone beds that weather dark brown and by tan to cream-colored bedded chert. Conglomerate interspersed with sandstone beds at type locality. Contains sequence of coarse volcanic conglomerate beds in vicinity of Elephant Butte Dam. Thickness at type locality 394 feet. Conformably underlies Hall Lake member (new); unconformably overlies Mesaverde formation.

Type locality: Immediately east of Elephant Butte Reservoir, north of McRae Canyon, Sierra County. Outcrops of member observed only near Elephant Butte Reservoir in McRae Canyon, and at south end of Fra Cristobal Mountains.

Joserita Member (of Lowell Formation)

Lower Cretaceous: Southeastern Arizona.

A. A. Stoyanow, 1949, Geol. Soc. America Mem. 38, p. 11–12, 15, pl. 27. Consists of following units (ascending): soft sandstone and arenaceous shale, gray shaly limestone, soft shale and sandstone, Baga shale and limestone (new), yellow dolomite, Espinal grit (new), Corta sandstone (new), and Quimbo dolomite (new). Thickness 123 feet. Underlies Saavedra member (new); overlies Pacheta member (new).

In standard section of Lowell formation in Ninety One Hills. Type locality of formation also designated as Ninety One Hills area, immediately north of international border in vicinity of international monument No. 91, southeast of Bisbee Junction in Southern Pacific Railway, Cochise County.

Joshua Schist

Pre-Triassic: Western Massachusetts.

M. E. Willard, 1951, Bedrock geology of the Mount Toby quadrangle, Massachusetts: U.S. Geol. Survey Geol. Quad. Map [GQ–8]. Name proposed for well-foliated, coarse-grained muscovite-quartz-biotite schist and gneiss. Large iron-stained flakes of muscovite cause gilded appearance. Partly pegmatized; cut by granite dikes and sills. Overlies Erving hornblende schist. Mapped previously as part of Amherst schist; new name introduced since unit can not be traced to other areas of the Amherst and latter at its type locality underlies the Erving. Gneissic beds were formerly mapped as Williamsburg granodiorite. Pre-Triassic.

Named for Joshua Hill, east of Mount Toby, Mount Toby quadrangle.

Joshua Schist (in Evington Group)

Lower Paleozoic(?): South-central Virginia.

W. R. Brown, 1951, (abs.) Geol. Soc. America Bull., v. 62, no. 12, pt. 2, p. 1547. Incidental mention.

W. R. Brown, 1953, Kentucky Geol. Survey, ser. 9, Spec. Pub. 1, p. 91 (fig. 1). Blue-gray phyllite and fine-grained schists. Biotite porphyroblasts common. Calcareous in part. Thickness from a fraction of a foot to 500 feet. Overlies Candler formation (new); underlies Arch marble (new), all in Evington group (new). Type locality designated. Paleozoic(?).

G. H. Espenshade, 1954, U.S. Geol. Survey Bull. 1008, p. 16. Included in Archer Creek formation (new).

W. R. Brown, 1958, Virginia Div. Mineral Resources Bull. 74, p. 8 (fig. 2). Age shown on columnar section as Lower Paleozoic(?).

Type locality: Along parts of Joshua Creek 6½ miles east of Lynchburg, Campbell County. Lynchburg quadrangle.

Joshua Submember (of Otisco Member of Ludlowville Formation)

Middle Devonian: Central New York.

W. A. Oliver, Jr., 1951, Am. Jour. Sci., v. 249, no. 10, p. 709–713, 716–717, fig. 6 (facing p. 724). Name proposed for upper coral bed in Otisco member. Consists of mass of closely packed rugose coral skeletons; interstices filled with same shaly sediments as that constituting body of Otisco. Maximum thickness 50 feet. Thins laterally and marked at edges by thin fingers extending into shale of the Otisco. Base lies in sharp contact with shale without sandstone platform. Interval between base and Centerfield limestone member of Ludlowville 90 to 100 feet. Lower coral bed is Staghorn Point submember (Smith, 1935).

Named for exposures at Lord's Hill near Joshua, Onondaga County. Areal extent northeast-southwest is 9 miles.

Joyita Sandstone Member (of Yeso Formation)

Permian: Central New Mexico.

C. E. Needham and R. L. Bates, 1943, Geol. Soc. America Bull., v. 54, no. 11, p. 1660. Name applied to soft crossbedded sandstone that forms uppermost unit of formation. In Joyita Hills, 160 feet thick and consists of pink, orange, and yellow thin-bedded sandstone that weathers to rounded ledges; orange color and manner of weathering distinguish member.

Thickness 185 feet at Yeso type section; 120 feet at Chupadera Mesa; 105 feet at Bend. Overlies limestones of middle evaporites or Canas gypsum member (new); underlies Glorieta sandstone.

Named from section in canyon of west-flowing tributary of Rio Grande in La Joyita Hills 18 miles north of Socorro and about 4½ miles south of village of La Joya, Socorro County.

Juab Limestone (in Pogonip Group)

Lower Ordovician (Chazyan): Western Utah.

L. F. Hintze, 1951, Utah Geol. and Mineralog. Survey Bull. 39, p. 17–18, 57, 58. Proposed for the fine sandy calcisiltite limestone that overlies Wahwah limestone (new) and underlies Kanosh shale (new). Thickness at type locality 139 feet.

R. E. Cohenour, 1959, Utah Geol. and Mineralog. Survey Bull. 63, p. 12 (table 1), 73–74, pl. 1. Described in Sheeprock Mountains where it is 161 to 204 feet thick; conformably overlies Wahwah (Wah Wah) limestone and conformably underlies Kanosh shale. Included in Pogonip group.

Type locality: NE¼ sec. 31, T. 22 S., R. 14 W., Millard County. Name derived from Juab County.

Jualin Diorite[1]

Lower Cretaceous (?): Southeastern Alaska.

Original reference: A. Knopf, 1911, U.S. Geol. Survey Bull. 446, p. 24–25, map.

Exposed at Jualin and in Jualin mine, Berners Bay region.

Juan Ascencio Chert Beds[1]

Cretaceous (?): Puerto Rico.

Original reference: D. R. Semmes, 1919, New York Acad. Sci., Scientific survey of Porto Rico and Virgin Islands, v. 1, p. 65.

Juan Ascencio Member (of Fajardo Shale)[1]

Upper Cretaceous: Eastern Puerto Rico.

Original reference: H. A. Meyerhoff, 1931, New York Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, v. 2, pt. 3, p. 288.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 36 (table 2). Thickness of Fajardo shale with Juan Ascencio member 1,100 feet. Upper Cretaceous.

Occurs in Fajardo district.

Juana Díaz Formation

Juana Díaz Marls[1] or Shales[1]

Oligocene, middle: Puerto Rico.

Original reference: C. P. Berkey, 1915, New York Acad. Sci. Annals, v. 26, p. 10, 17.

A. D. Zapp, H. R. Bergquist, and C. R. Thomas, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 85. Formation includes about 655 meters of middle Oligocene conglomerate, sandy limestone, and shales. Roughly divided into three members: upper shale 140 meters; middle sandy limestone and limy shale 375 meters; and lower sandy conglomerate 140 meters. Basal Tertiary in south Coastal Plain; underlies Ponce formation.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech. Paper 13, p. 36 (table 2), 57. Northeast of town of Juana Díaz, formation rests unconformably upon rocks believed to be the Cañas Arriba formation (new).

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm. and Princeton Univ. Dept. Geology, p. 103–107. In area north of Juana Díaz, formation rests unconformably on rocks of lower middle Eocene Jacaguas group (new). Underlies Oligocene-Miocene Ponce formation.

Named for exposures east of village of Juana Díaz and along the Río Jacaguas to west.

Juana Lopez Member (of Mancos Shale)

Juana Lopez Sandstone Member (of Carlile Shale)

Upper Cretaceous: Northern New Mexico and western Colorado.

C. H. Rankin, 1944, New Mexico Bur. Mines Mineral Resources Bull. 20, p. 7, 12, 19–20, fig. 3. Very calcareous thin-bedded sandstone near top of Carlile; weathers brown; grades into shale at base. Thickness 10 feet. Contains abundant Frontier fauna. For mapping purposes in northern New Mexico, top of Juana Lopez could well be used as top of Carlile.

C. E. Stearns, 1953, Geol. Soc. America Bull., v. 64, no. 4, p. 463, 466, pl. 1. In Galisteo-Tonque area, New Mexico, Carlile-Niobrara contact not marked by mappable lithologic horizon, but Juana Lopez member is close approximation. This member, about 6 feet of interbedded arenaceous shale and very thin-bedded arenaceous fetid limestone, forms low persistent hog-back 300 to 475 feet above Greenhorn limestone and marks break between "lower Mancos shale" and "middle Mancos shale." Juana Lopez is overlain by about 500 feet of argillaceous shale ("middle Mancos shale").

C. E. Stearns, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 5, p. 967–968. Persistent horizon marker, but since lithology varies it seems advisable to retain name but avoid lithologic designation.

U.S. Geological Survey currently classifies the Juana Lopez as a member of Mancos Shale on the basis of a study now in progress.

Type section: In sec. 32, T. 15 N., R. 7 E., on Mesita Juana Lopez Grant, 6 miles northwest of Cerrillos, Santa Fe County, N. Mex. Widespread in New Mexico and Colorado.

Jubilee phase (of Amargosa chaos)

Post-Miocene(?): Southern California.

L. F. Noble, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 1936. Listed as a phase of the Amargosa chaos, an assemblage of blocks on overthrust plate of Amargosa thrust.

L. F. Noble, 1941, Geol. Soc. America Bull., v. 52, no. 7, p. 965, 972–977. Mosaic of fault blocks composed mostly of sedimentary and volcanic rocks and breccias of granitic, sedimentary, and metamorphic rocks ranging in age from Precambrian to Tertiary. Maximum thickness not over 1,000 feet. Jubilee phase lies at one place on Virgin Spring phase and at another place forms the sole of the thrust. Calico and Jubilee phases not in contact in the area, and their relative position is not known. Unconformably overlain by Pliocene(?) Funeral fanglomerate.

Occurs in Virgin Spring area near Death Valley. Name derived from Jubilee Wash, where mosaic is exposed on both sides of Shoshone-Death Valley Highway at Chaos Ridge.

Judd Shale Member (of Frontier Formation)

Upper Cretaceous: Northeastern Utah.

L. A. Hale, 1960, Wyoming Geol. Assoc. Guidebook 15th Ann. Field Conf., p. 136 (chart 1), 139 (fig. 1), 140, 141–142, 143 (fig. 2), 145 (fig. 3). Where well exposed, consists of gray marine shale 690 to 760 feet thick. Apparently thins to west because it is not recognized in section along Echo Reservoir north of Coalville. Represents a tongue of Hilliard shale of southwestern Wyoming. Lies between Grass Creek member (new) below and Upton sandstone member (new) above. Name credited to D. W. Trexler (unpub. thesis).

Exposed in Judd Canyon, 6 miles east of Coalville, Summit County.

Judd Creek Latite

Tertiary: Western Utah.

G. H. Thomas, 1958, Brigham Young Univ. Research Studies, Geology Ser., v. 5, no. 4, p. 13–14, pl. 1. Fine-grained aphanite with porphyritic texture; locally reddish color.

Named from exposures near Judd Creek, Tooele County. Covers about 3 square miles in and around sections 16 and 17, T. 10 S., R. 7 W.

Judith River Formation (in Montana Group)[1]

Upper Cretaceous: Central, northern, southeastern, and southern Montana and northwestern Wyoming.

Original references: F. B. Meek and F. V. Hayden, 1856, Philadelphia Acad. Sci. Proc., v. 8, p. 267; 1858, v. 9, p. 123; 1862, v. 13, p. 418; 1862, Am. Philos. Soc. Trans., new ser., v. 12.

J. D. Love, J. L. Weitz, and R. K. Hose, 1955, Geologic map of Wyoming (1:500,000): U.S. Geol. Survey. As mapped, Montana group includes Telegraph Creek and Eagle sandstones, Claggett shale, and Judith River formation along north margin of Yellowstone National Park.

W. J. McMannis, 1955, Geol. Soc. America Bull., v. 66, no. 11, pl. 7. Plate 7 shows Livingston formation intertongues with Claggett, Judith River, Bearpaw, Lennep, Hell Creek, Tullock, and Lebo formations.

M. M. Knechtel and S. H. Patterson, 1956, U.S. Geol. Survey Bull. 1023, p. 12 (fig. 3), 34–36, pls. 1, 2. Formation, as mapped near Montana-Wyoming boundary, comprises two members: Parkman sandstone and an upper unnamed member. Thickness about 255 feet as exposed east of Hardin, Mont. Overlies Claggett shale member of Cody shale; underlies Bearpaw shale.

Named for occurrence near mouth of Judith River, Mont.

Judkins Formation

Quaternary: Western Texas.

R. M. Huffington and C. C. Albritton, Jr., 1941, Am. Jour. Sci., v. 239, no. 5, p. 327–329. An aeolian deposit consisting of reddish-brown massive sandstone with interstitial clay and fine silt. At type locality, maximum thickness 6 feet; base not exposed. Underlies Monahans formation (new); surface of contact sharply defined and irregular in profile; in different places, rests on rock of Triassic, Cretaceous, and older Quaternary age.

Type locality: South side of Highway 80, 6½ miles northeast of Monahans, near Sand Hills, Ward County. Probably named from nearby village of Judkins [also spelled Judkin].

Judson Member (of St. Lawrence Formation)

Upper Cambrian (St. Croixian): Minnesota.

C. R. Stauffer, G. M. Schwartz, and G. M. Thiel, 1938, (abs.) Geol. Soc. America Bull., v. 49, no. 12, pt. 2, p. 1902. Named as lower member of formation. Underlies Lodi member; overlies Franconia formation. [Probably replaced by Nicollet Creek member.]

Type locality of St. Lawrence formation is in Scott County.

Jueyes Lens (in Ildefonso Formation)

Upper Cretaceous: Puerto Rico.

E. A. Pessagno, Jr., 1960, Geology of the Ponce-Coamo area, Puerto Rico: Puerto Rico Econ. Devel. Adm. and Princeton Univ. Dept. Geology, p. 34. Massive limestone lens in upper part of formation.

Named from village of Río Jueyes near which it is located.

Julian Group[1]

Triassic or older: Southern California.

Original reference: F. J. H. Merrill, 1914, Geology and Mining Resources San Diego and Imperial Counties; California State Mining Bur., p. 11–12.

Named for village of Julian, San Diego County.

†Julian limestone[1]

Middle Ordovician: Iowa.

Original reference: C. R. Keyes, 1922, Pan-Am. Geologist, v. 37, p. 252–255.

Named for Julian Township.

Julian Schist[1]

Triassic(?) or older: Southern California.

Original reference: F. J. H. Merrill, 1914, Geology and mineral resources of San Diego and Imperial Counties: California State Mining Bur., p. 11–12.

D. L. Everhart, 1951, California Div. Mines Bull. 159, p. 58–60, pls. 2, 3, 4, 5. Consists essentially of quartz-mica schist and quartzite; the former far more abundant. Older than other intrusive rocks in area. Shown on map as Triassic(?). Previous workers have assigned various ages to the schist, and in one instance age is given as Jura-Triassic.

Richard Merriam, 1958, California Div. Mines Bull. 177, p. 9–11, pl. 1. Described and mapped in Santa Ysabel quadrangle. Older than Stonewall quartz diorite.

Named for village of Julian, Santa Ysabel quadrangle, San Diego County, which occurs in midst of mass.

†Julian series[1]

Middle Ordovician: Iowa.

Original reference: C. R. Keyes, 1927, Pan-Am. Geologist, v. 47, p. 146–148.

Dubuque region.

Juliand Member[1] (of Enfield Formation)

Juliand zone

Upper Devonian: Southeastern New York.

Original reference: G. H. Chadwick, 1933, Pan-Am. Geologist, v. 60, p. 99, 285.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart as Juliand zone, below Van Etten zone and above Kattel shale.

Named from exposures in Juliand Hill just east of village of Greene, Greene County.

Jumbo Dolomite Member (of Talladega Slate)[1]

Jumbo Dolomite (in Talladega Series)

Paleozoic(?): Eastern Alabama.

Original reference: Charles Butts, 1926, Alabama Geol. Survey Spec. Rept. 14, p. 53, map.

T. N. McVay and L. D. Toulmin, 1945, Alabama Geol. Survey Bull. 55, p. 20. Included in lower part of Talladega series.

Named for exposures and quarries at and near Jumbo, Chilton County.

Jumbo Volcanics[1]

Late Paleozoic or Mesozoic: Northeastern Washington.

Original reference: C. E. Weaver, 1920, Washington Geol. Survey Bull. 20, p. 95, map.

Occurs at headwaters of Fifteen Mile Creek, at east end of Jumbo Mountain, Stevens County.

Jumonville Sandstone

Upper Devonian (Conewango): Southwestern Pennsylvania.

W. M. Laird, 1941, Pennsylvania Topog. and Geol. Survey Prog. Rept. 126, p. 11, 12. Name will probably be used, following more definitive study of area, for unit here termed Sandstone D in Riceville stage and described as interbedded gray-brown sandstones and shales with some lenses of white quartz-pebble and clay-gall conglomerate. More sandy than underlying shale. Thickness 135–152 feet. Disconformably underlies Mississippian beds; conformably overlies Shale C (Watering Trough shale).

Type locality: Along the National Pike at Watering Trough Inn below crest of Chestnut Ridge, Fayette County. Longer section exposed in Youghiogheny Gorge through Chestnut Ridge in vicinity of mouth of Indian Creek.

Juncal Formation

Eocene, middle: Southern California.

B. M. Page, J. G. Marks, and G. W. Walker, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 8, p. 1730 (fig. 2), 1733 (fig. 3), 1734 (fig. 4), 1747, 1749–1756. In type area, north of Santa Ynez fault, separable into three members: lower shale with lenticular sandstone, middle sandstone, and upper shale and sandstone. Changes in facies are pronounced, and threefold division not always recognizable in other areas. South of the fault, formation is sandstone and shale as in type section, but composition and thickness of the three members are quite different and none of members mapped in type section can be identified with certainty. Thickness at type locality 3,360 feet; south of fault where formation includes Camino Cielo sandstone member (new), thickness is 5,520 feet. In and near type locality, Juncal lies with angular unconformity on Upper Cretaceous strata (Pendola shale) and is conformably overlain by upper Eocene Matilija sandstone; south of fault, Juncal disconformably(?) overlies Upper Cretaceous Debris Dam sandstone (new) and the Romero conglomerate lentils (new). In vicinity of Mono Debris Dam, conformably overlies Sierra Blanca limestone; 1½ miles southwest of Pendola Guard Station, where strata are exposed in core of an anticline, Debris Dam sandstone is missing, and Juncal unconformably overlies undifferentiated Cretaceous shale.

W. R. Merrill, 1952, *in* Am. Assoc. Petroleum Geologists, Soc. Econ. Paleontologists Mineralogists, Soc. Explor. Geophysicists Joint Ann. Mtg. Guidebook, p. 17. Includes Wheeler sandstone member in area from Ojai to Ozena.

Type locality: In crestal region of Agua Caliente anticline, Santa Barbara County. Section extends from point in small canyon 10,200 feet N. 55° E. of Pendola Guard Station to point 9,500 feet N. 21° E. of Juncal CCC Camp. Extends northward beyond limits of mapped area where it is involved in structural complexities; south of type section, it is truncated by Santa Ynez fault, reappears south of Santa Ynez River valley, and is traceable entire lateral extent of map area on crest and flanks of Santa Ynez Mountains. Nelson (1925, Bull. California Univ. Geol. Sci., v. 15, no. 10) mapped unit as "undifferentiated Eocene" in upper India and Mono Creeks area; there it conformably overlies Sierra Blanca limestone.

Juncos Gabbro[1]

Age(?) Puerto Rico.

Original references: C. R. Fettke, 1924, New York Acad. Sci., Scientific survey of Porto Rico and Virgin Islands, v. 2, pt. 2, p. 153; 1924, Am. Inst. Mining and Metall. Trans., v. 70, p. 1026–1042.

Junction limestone[1]

Upper Jurassic: Utah.

Original reference: C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 36, 301.

Derivation of name not stated.

Junction City facies (of New Providence Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 76, 115–117. Soft argillaceous shale, blue gray, olive gray, to drab. "Clayey character is outstanding". Foerste (1905) named the unit Linietta clay. Thickness 70 to 125 feet; thinnest along axis of Cincinnati Arch in Casey County. Merges with Keith Knob facies (new) westward and with Dicks River facies (new) eastward. Underlies New Albany black shale.

Named for Junction City, located at edge of Lexington Plain, at foot of Plateau escarpment in southeastern Boyle County. Good outcrops occur along the fairly even line of escarpment westward across southern Boyle County along irregular belt southward into Lincoln County.

Junction City Quartzite[1]

Precambrian (middle Huronian): Central northern Wisconsin.

Original reference: S. Weidman, 1907, Wisconsin Geol. Nat. History Survey Bull. 16, p. 91.

Exposed in vicinity of Junction City, Portage County.

Junction Creek Sandstone (in San Rafael Group)

Junction Creek Sandstone Member (of Morrison Formation)

Junction Creek Sandstone Member (of Wanakah Formation)

Upper Jurassic: Southwestern Colorado.

M. I. Goldman and A. C. Spencer, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 9, p. 1748 (fig. 2), 1750–1751, 1753 (table 1). Proposed for uppermost member of Morrison formation. Estimated thickness 300 feet. Overlies Wanakah marl member. [See La Plata sandstone.]

E. G. Eckel, 1949, U.S. Geol. Survey Prof. Paper 219, p. 27 (table), 29–30, pl. 2. Rank raised to formation. Predominantly massive white to light-buff friable crossbedded sandstone; thin partings of greenish-gray or light-red shale partings numerous. Thickness 200 to 500 feet. Overlies Wanakah formation (redefined); underlies Morrison formation.

L. C. Craig and C. N. Holmes, 1951, New Mexico Geol. Soc. Guidebook 2d Field Conf., p. 94. Reallocated to member status in Wanakah formation. Similar to and appears to occupy same stratigraphic position as Bluff sandstone. Relation of Junction Creek to Morrison formation not definitely established; upper part may have been deposited synchronously with lower bed of Morrison in southwestern Colorado.

L. W. Kilgore, 1955, Four Corners Geol. Soc. Guidebook [1st] Field Conf., p. 120, fig. 2. Suggested that Eckel's interpretation of Junction Creek as separate formation be followed and its age relationship placed with San Rafael group. Generalized cross section of Animas River valley shows Junction Creek sandstone overlying Summerville formation and underlying Salt Wash sandstone of Morrison group.

E. B. Ekren and F. N. Houser, 1959, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–221. Mapped in Moqui SE quadrangle, Colorado, where it is 250 to 300 feet thick and consists of three gradational units. Upper unit, 20 to 50 feet thick, is argillaceous fine-grained reddish sandstone with obscure flat stratification. Middle unit, about 150 feet thick, of fine- to coarse-grained poorly sorted sandstone, cross-stratified at high angle; weathers to a "slick rim." Lower unit, 30 to 50 feet thick, has same general lithology as middle unit but with low-angle cross-stratification and numerous horizontal truncations. Overlies Summerville formation, contact gradational; underlies Salt Wash sandstone member of Morrison formation. San Rafael group. Upper Jurassic.

Named from exposures opposite Animas City Mountain between Junction Creek and Animas River, La Plata County.

June Bell Rhyolite[1]

Tertiary: Central northern Nevada.

Original reference: E. H. Rott, Jr., 1931, Nevada Univ. Bull., v. 25, no. 5.

Occurs in small area on June Bell claim in Gold Circle or Midas mining district, western part of Elko County.

June Lake Basalt

Pleistocene: Eastern California.

W. C. Putnam, 1940, (abs.) Geol. Soc. America Bull., v. 51, no. 12, pt. 2, p. 1939. Basalt flow from small cinder cone in floor of June Lake glacial trough.

Occurs in region about June Lake in east-central Sierra Nevada.

Juniata coal measures[1]

Devonian: Pennsylvania.

Original reference: F. Platt, 1877, Pennsylvania 2d Geol. Survey H_2, p. xxiii–xxx.

Juniata Formation[1]

Upper Ordovician: Central southern and eastern Pennsylvania, western Maryland eastern Tennessee, western Virginia, and eastern West Virginia.

Original reference: N. H. Darton, 1896, U.S. Geol. Survey Geol. Atlas, Folios 28 and 32.

Bradford Willard and A. B. Cleaves, 1939, Geol. Soc. America Bull., v. 50, no. 7, p. 1165–1198. Discussion of Ordovician-Silurian relations in Pennsylvania. Term Oswego has been misapplied in Pennsylvania. For beds commonly referred to by that name, Bald Eagle is revived and treated as basal Juniata. Overlies Martinsburg formation; underlies Tuscarora formation. There is a disconformity between Bald Eagle and Tuscarora east of Susquehanna River and either a disconformity or unconformity below Bald Eagle or Tuscarora or Shawangunk from Susquehanna River to southeastern New York. Either hiatus might be used as Ordovician-Silurian line of separation. If lower is accepted, Juniata is Silurian; if upper is used, then Juniata is Ordovician.

Charles Butts, 1940, Virginia Geol. Survey Bull. 52, pt. 1, p. 203, 205, 207, 221–229. Occupies space between Oswego sandstone below and Tuscarora sandstone above in northern end of Appalachian Valley in Virginia; farther southwest, it is overlain by Clinch sandstone and rests everywhere upon *Orthorhynchula* zone of Martinsburg shale. In Lee County, the equivalent Sequatchie formation also succeeds *Orthorhynchula* zone. Maximum thickness about 725 feet, northwest of Monterey, Highland County.

F. M. Swartz, 1948, Pennsylvania Geologists Guidebook 14th Ann. Field Conf., supp., diagram (following p. 4), fig. 3. Underlies unit termed Run Gap sandstone.

H. P. Woodward, 1951, West Virginia Geol. Survey, v. 21, p. 387–408. Juniata formation, as herein defined, is uppermost member of Ordovician in West Virginia. Directly underlies Tuscarora sandstone. Overlies Oswego sandstone, or where Oswego is absent, Martinsburg formation. Thickness 150 to 800 feet. In previous West Virginia Geological Survey reports, the Juniata has been called "Red Medina" and regarded as a Silurian formation.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, p. 97–98, pls. Mapped in eastern Tennessee. Juniata and Sequatchie formations form sheet of red or maroon sediments similar in lithology to older sheet represented by Bays and Moccasin formations and long confused with it. The Juniata and Sequatchie, like Bays and Moccasin formations, are respectively the less and more calcareous parts of the sedimentary sheet; they intergrade laterally and boundary between them is arbitrary. For present map, it has been taken along line of Hunter Valley and Whiteoak Mountain faults, but belts northwest of these faults as far as Powell River anticline and Kingston fault are transitional and, though shown on map as Sequatchie, could equally well have been mapped as Juniata.

F. M. Swartz, 1957, Pennsylvania State Univ., Dept. Geology Contr. 3, 58 p. Formation, from Tyrone Gap to Susquehanna Gap, includes (ascending) East Waterford red sandstone member (new), Plummer Hollow red mudstone and sandstone member (new), and Run Gap red sandstone member. Overlies Bald Eagle sandstone (Spring Mount sandstone member, new, in western part of area) and Lost Run conglomerate in eastern part.

L. D. Harris and R. L. Miller, 1958, U.S. Geol. Survey Geol. Quad. Map GQ-111. Name Juniata abandoned in Clinch Mountain area of Duffield quadrangle, Virginia, and term Sequatchie extended into area.

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 6-7, pl. 1. Juniata is the Red Medina of Pennsylvania Second Geologic Survey and is presently correlated with Queenston of New York. Thickness varies from 85 feet at Susquehanna Gap to 2,000 feet near Lewistown. Overlies Bald Eagle formation; underlies Tuscarora formation, transitional.

Named for typical occurrence on Juniata River in Pennsylvania.

Juniata River Series[1]

Devonian: Pennsylvania.

Original reference: F. Platt, 1877, Pennsylvania 2d Geol. Survey Rept. H., p. 6, 8.

Juniper Andesites[1]

Cenozoic: Northern California.

Original reference: Howel Williams, 1932, California Univ. Pub., Dept. Geol. Sci. Bull., v. 21, no. 8, geol. map.

O. P. Jenkins, 1943, California Div. Mines Bull. 118, p. 678. Cenozoic. Overlie Willow Lake basalts.

Occur in Lassen National Park.

†Juniperan Stage

Eocene, early: California.

V. S. Mallory, 1953, (abs.) Jour. Paleontology, v. 27, no. 6, p. 903. Named as one of six stages, based on foraminiferal assemblages, in lower Tertiary of California. Includes interval between Ulatisian above, and Paleocene Bulitan [Bulitian] stage.

V. S. Mallory, 1959, Lower Tertiary biostratigraphy of the California Coast Ranges: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 34. Replaced by Penutian stage (new).

Juniper Flat Granite

Triassic or Jurassic: Southeastern Arizona.

W. G. Hogue and E. D. Wilson, 1950, Arizona Bur. Mines Bull. 156, Geol. Ser. 18, p. 21, fig. 7. Intrudes Precambrian schist and is overlain by basal conglomerate of Cretaceous, but its relation to Paleozoic not clear.

James Gilluly, 1956, U.S. Geol. Survey Prof. Paper 281, p. 53-55, pl. 5. Light reddish brown in outcrop and pinkish gray on fresh fracture. Most of it is porphyritic within central Cochise County, although much of it along Tombstone Canyon is equigranular. Considerable range in grain size. Forms discordant intrusive masses that cut all formations up to and including Horquilla limestone. Rough tendency to form sills beneath

Bolsa quartzite; all other contacts appear to be clean cut and without regard to preexisting structures. Older than Glance formation. Triassic or Jurassic. Type locality designated.

Type locality: Juniper Flat on west side of Mule Mountains, where granite is well exposed. Also well exposed on northeast wall of Tombstone Canyon. In west-central Cochise County.

Juniper Hill Formation[1]

Juniper Hill Shale Member (of Lime Creek Formation)

Upper Devonian: Central northern Iowa.

Original reference: A. O. Thomas, 1925, Iowa Geol. Survey, v. 30, p. 116, footnote.

M. A. Stainbrook, 1944, Illinois Geol. Survey Bull. 68, pt. 1, p. 182, 187. Rank reduced to member status in Lime Creek formation. Basal member of formation; comprises about 45 feet of sparsely fossiliferous blue shale. Underlies Cerro Gordo member; overlies Nora member of Shellrock formation.

Named for exposures on Juniper Hill, about 1 mile northwest of Rockford Brick and Tile Plant, Floyd County.

Junipero Sandstone

Eocene: West-central California.

R. R. Thorup, 1941, (abs.) Geol. Soc. America Bull., v. 52, no. 12, pt. 2, p. 1958. Listed as underlying Lucia shale (new) and unconformably overlying basement complex. Thickness as much as 125 feet.

R. R. Thorup, 1943, California Div. Mines Bull. 118, pt. 3, p. 463–465. Described as white to light-gray, coarse to pebbly, feldspathic sandstone. Lies unconformably on basement complex (Sur "series" and Santa Lucia quartz-diorite) and has basal conglomerate which averages 8 feet in thickness. Conformably underlies Lucia shale. Formerly considered part of Vaqueros which is herein stratigraphically restricted in its type area.

Type locality: NE¼ sec. 34, T. 20 S., R. 6 E., Junipero Serra quadrangle, Monterey County.

Juniper Ridge Sandstone (in Panoche Formation or Group)

Upper Cretaceous: Central western California.

P. P. Goudkoff, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 7, p. 962 (fig. 2). Panoche group (or formation) is subdivided into 10 units. Juniper Ridge sandstone is fourth in sequence (ascending). Occurs between units termed Lower Waltham shale and Upper Waltham shale. Assigned to Delevanian stage (new). Name credited to J. Q. Anderson.

Occurs in Coalinga-Ortigalito area, San Joaquin Valley.

Jupiter shales

Precambrian (Chuaran series): Northern Arizona.

Charles Keyes, 1938, Pan-Am. Geologist, v. 70, no. 2, p. 107 (chart), 112. Shales mainly dark colored, often black. Thickness 1,700 feet. Underlie Oso beds (new); overlie Gunther dolomite (new).

Best developed in valleys paralleling west rim of Marble Canyon. Particularly conspicuous and complete under the cliff ruins known as Jupiter's Temple, situated a few miles below mouth of Little Colorado River; Grand Canyon region.

Jurupa Series[1]

Paleozoic and Paleozoic(?) : Southern California.

Original reference: J. W. Daly, 1935, Am. Mineralogist, v. 20, no. 9, p. 638–647, map.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 475–476, table 4. Paleozoic and probable Paleozoic. Series includes undifferentiated complex (metasedimentary), Chino crystalline limestone, quartzite and schist, and Sky Blue crystalline limestone.

Occurs in Jurupa Mountains, Riverside County.

Kaaterskill Formation[1] or Sandstone

Middle Devonian: Southeastern New York.

Original reference: Bradford Willard, 1933, Geol. Soc. America Bull., v. 44, no. 3, p. 498.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart as Kaaterskill sandstone, Middle Devonian.

G. H. Chadwick, 1944, New York State Mus. Bull. 336, p. 121, 122–125, 127, geol. map. Referred to as Kaaterskill sandstones and mapped with overlying Kiskatom redbeds in Catskill and Kaaterskill quadrangles. Underlies Onteora red beds. Thickness 250 to 300 feet. Middle Devonian.

Ledges make the falls of the Kaaterskill [Greene County].

Kaaterskillian series

Devonian (Devonic) : Eastern North America.

[C. R.] Keyes, 1941, Pan-Am. Geologist, v. 75, no. 4, p. 157 (chart), 311. Name proposed for the eastern Devonic; Linnian series applied to western Devonic. The two series overlap at the Mississippi River in Missouri. In Missouri, includes (ascending) Bailey limestone, Clear Creek limestones, Grand Tower limestones, and Wittenberg shales.

Kaau Basalt or Tuff

See **Kaau Volcanics** (in Honolulu Volcanic Series).

Kaau Mud Flow

Pleistocene: Oahu Island, Hawaii.

H. T. Stearns, 1940, Hawaii Div. Hydrography Bull. 5, p. 51–52. Consists chiefly of small nodules of Kaau basalt, a few bombs and olivine segregations, and numerous fragments of Koolau basalt set in gray dirty matrix. No bedding present. Deposit reaches height of about 60 feet above adjacent Kaau basalt. Also referred to as Palolo Valley mud flow.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 93. Probably correlative with Kaau volcanics in lower part of Honolulu volcanic series. Locally rests on tuff of Kaau volcanics.

Well exposed over small area in Palolo Valley, 1 mile above mouth of Waiomoa Stream, on south side of Koolau Range, about 9 miles west of Makapuu Head.

Kaau Volcanics[1] (in Honolulu Volcanic Series)

Pleistocene, upper: Oahu Island, Hawaii.

Original reference: H. T. Stearns, 1935, Hawaii Div. Hydrography Bull. 1.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 93–94. Tuff and melilite-nepheline basalt lava erupted from Kaau Crater; tuff was formed in part by phreatic explosions; secondary deposits of tuff occur below crater along Pukele, Waiomo, and Palolo Valleys. At least two flows are present, separated by tuff. Upper flow averages about 20 feet thick. Rests in part on Koolau volcanic series and in part on older alluvium. Volcanics erupted during high stand of sea preceding minus 60-foot (Waipio) stand, and probably the plus 95-foot (Kaena) stand. Terms Kaau basalt and Kaau tuff have been used for parts of the volcanics. Pleistocene.

Named for Kaau Crater, which is believed to have been its source. Covers fraction of square mile in upper part of Palolo Valley and its tributaries, on south side of Koolau Range about 9 miles west of Makapuu Head.

Kachess Rhyolite[1]

Eocene: Central Washington.

Original reference: G. O. Smith and F. C. Calkins, 1906, U.S. Geol. Survey Geol. Atlas, Folio 139.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 45, 51. Kachess rhyolite consists of numerous flows intercalated within Naches formation. On eastern side of Lake Kachess the rhyolites unconformably overlies Swauk formation and unconformably underlies Teanaway basalts. Swauk, Naches, and Kachess are probably in part contemporaneous.

R. J. Foster, 1960, Geol. Soc. America Bull., v. 71, no. 2, p. 105. Silver Pass volcanic rocks (new) include type area for Smith and Calkins' Kachess rhyolite. Mapping for present study has shown that rhyolites of many different ages were included in Kachess rhyolite by Smith and Calkins. They were aware of these inconsistencies and described relationships of the Kachess as peculiar, noting that it was interbedded with the Swauk, Teanaway, and Naches formations and occurred between the Naches and Teanaway formations. These relationships would require extrusion of the Kachess to have begun in Swauk time, to have extended across the unconformity between the Swauk and Teanaway, and to have continued until post-Teanaway time. In mapped area, rocks called Kachess by Smith and Calkins can be separated into two groups, presumably of different ages, the Silver Pass volcanic rocks of post-Swauk and pre-Teanaway age and the rhyolite within Naches formation.

Well exposed on northeast side of Kachess Lake [Kittitas County], Snoqualmie quadrangle.

Kagel Fanglomerate[1]

Pleistocene or Recent: Southern California.

Original reference: M. L. Hill, 1930, California Univ. Pub., Dept. Geol. Sci. Bull., v. 19, no. 6, p. 141, 144.

B. F. Howell, 1954, California Div. Mines Bull. 170, map sheet 10. Referred to as Kagel alluvium. May be same age as Beehive Mesa alluvium (new). Pleistocene or Recent.

Named for exposures in Kagel Canyon, Los Angeles.

Kagman Andesite

See **Hagman Formation.**

Kaguyak Formation

Upper Cretaceous: Central southern Alaska.

A. S. Keller and H. N. Reiser, 1959, U.S. Geol. Survey Bull. 1058–G, p. 273–278, pls. 29, 32. Divided into three informal members: lower fossiliferous siltstone member, 2,000 feet thick at type locality; middle massive locally crossbedded concretionary sandstone and interbedded siltstone and silty shale member, 1,090 feet; and upper thin-bedded sandstone and siltstone member, 1,460 feet. Total measured thickness 4,550 feet. Overlies Naknek formation; upper contact of formation not seen.

Type section: Includes exposures at Kaguyak and the sequence exposed in the sea cliffs from mouth of Big River to Swikshak River, Mount Katmai area, Alaska Peninsula.

Kaguyak Formation

Upper Cretaceous: Southern Alaska.

T. C. Hiestand, 1957, Oil and Gas Jour., v. 55, no. 49, p. 194 (table 1). Listed on chart only. Marine. Thickness 10,000 feet.

Under heading—Alaska Peninsula, Kenai Peninsula, Sustina district, and Copper River district.

Kahuku Volcanic Series

Pleistocene: Hawaii Island, Hawaii.

H. T. Stearns and G. A. Macdonald, 1946, Hawaii Div. Hydrography Bull. 9, p. 64 (chart), 67 (table), 68–71. Comprises all basalt flows and interbedded ash beds that are unconformable on Ninole volcanic series and that were laid down before end of deposition of ash member (Pahala) at its top. Unit is the Pahala basalt renamed, name Pahala being here restricted to top ash member. At type locality, consists of about 600 feet of interbedded aa and pahoehoe flows overlain by 40 feet of yellow ash; one massive flow 100 feet above base is about 100 feet thick; other flows average about 15 feet in thickness. Underlies Kau volcanic series (new).

D. A. Davis and G. A. Macdonald *in* Jacques Avias and others, 1956. Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 94. Pleistocene.

Type locality: Kahuku Pali, a fault scarp running north from South Point. Exposed intermittently in windows in Kau and Puna volcanic series around eastern and southern sides of Mauna Loa from Hilo Point and at Kealakekua Bay on west side of island.

Kaibab Limestone (in Aubrey Group)[1]

Kaibab Limestone (in Park City Group)

Kaibab Formation

Permian: Western Utah, northern Arizona, southeastern California, and southeastern Nevada.

Original reference: N. H. Darton, 1910, U.S. Geol. Survey Bull. 435, p. 21, 28, 32.

E. D. McKee, 1937, Carnegie Inst. Washington Year Book 36, p. 341–343. In typical exposure, Kaibab consists of two massive limestone members, above and below each of which are units composed of red beds, gypsum, and impure thin-bedded limestones; unconformity present at top of middle red-bed member. Proposed that name Kaibab be restricted to upper massive limestone together with associated members above and below and that these be termed Kaibab formation. Members below unconformity are here named Toroweap formation.

E. D. McKee, 1938, Carnegie Inst. Washington Pub. 492, p. 12, 35–61, strat. sections. Based on approximately 50 measured sections, classification has been developed embodying principal divisions of the Kaibab. Formation used in restricted sense is divided vertically into three members, designated as α, β, and γ, from top to bottom. These members are characterized as (α) time of receding sea, (β) time of most extended sea, and (γ) time of advancing sea. The α or uppermost has been referred to variously as the A member, the Super Aubrey, Bellerophon limestone, and Harrisburg gypsiferous member; middle division, commonly termed "cherty limestone" is B member of most earlier writers. The γ or lowermost is local in distribution and is recognized only on Mogollon Plateau; it is unrecorded in earlier literature. Facies of members discussed in detail. Underlies Moenkopi. Overlies Toroweap formation or in areas where Toroweap is absent, as on Mogollon Plateau south of Flagstaff, the Kaibab overlies Coconino sandstone.

N. D. Newell, 1948, Geol. Soc. America Bull., v. 59, no. 10, p. 1045 (fig. 2), 1057. Geographically extended into Confusion Range, Utah, where it is about 2,000 feet thick and consists of cherty drab to dark-gray relatively unfossiliferous limestone. Underlies Phosphoria formation; overlies Supai equivalents.

H. E. Gregory, 1948, Geol. Soc. America Bull., v. 59, no. 3, p. 226, 227; 1950, U.S. Geol. Survey Prof. Paper 220, p. 50–55. Unconformably underlies underlies Timpoweap member (new) of Moenkopi formation.

C. R. Longwell, 1949, Geol. Soc. America Bull., v. 60, 5, p. 930 (table 1), 931. In Muddy Mountains, Nev., consists of upper and lower limestone members separated by middle member, chiefly gypsum. An additional upper unit, Harrisburg member of Reeside and Bassler, present locally. Lower limestone unit and overlying gypseous beds may correspond to McKee's (1938) Toroweap formation of the Plateau. Thickness 600 to 800 feet. Overlies unnamed red beds; unconformably underlies Moenkopi formation.

C. B. Hunt, Paul Averitt, and R. L. Miller, 1953, U.S. Geol. Survey Prof. Paper 228, p. 38 (table), 46–47, pl. 1. Described in Henry Mountains region where it is restricted to steep flanks of San Rafael Swell and Circle Cliffs. Consists of white, buff, light-gray limestone and limy sandstone containing siliceous concretions. Thickness commonly 50 to 100 feet. Overlies Coconino sandstone; underlies Moenkopi formation.

D. F. Hewett, 1956, U.S. Geol. Survey Prof. Paper 275, p. 45–46, pl. 1. Mapped in San Bernardino County, Calif.

R. K. Hose and C. A. Repenning, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 9, p. 2178–2180. In Confusion Range, basal formation of Park City group. Consists of 480 feet of somewhat cherty bioclastic limestone. Underlies Plympton formation (new); overlies Arcturus formation.

H. J. Bissell, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 8, p. 1427 (fig. 3), 1433 (fig. 9), 1434–1435 (fig. 10). In Spring Mountains area, Nevada, overlies Spring Mountain formation (new).

Grant Steele, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 109–112. West of Gold Hill mining district, Nevada, a sequence of thin- to thick-bedded cherty limestones overlies Loray formation (upper beds of Nolan's Oquirrh formation). Nolan (1935) named this sequence Gerster formation. Nolan placed lower contact of Gerster at top of "Oquirrh formation" and upper contact at base of overlying Triassic limestones and shales. Present study shows that lower 170 feet of Nolan's Gerster is lithologically equivalent to Kaibab formation. Seems appropriate to restrict Gerster to those limestones above the light-gray cherty carbonates of the Kaibab.

Type locality: Kaibab Gulch, a deep canyon cut entirely across northern part of Kaibab Plateau, about 8 miles southwest of abandoned settlement of Paria, Utah, about 6 miles north of Arizona line. Caps Kaibab Plateau on north side of Grand Canyon. At type locality, overlies Hermit shale.

Kailua Volcanic Series[1]

Pliocene(?) : Oahu Island, Hawaii.

Original reference: H. T. Stearns, 1935, Hawaii Div. Hydrog. Bull. 1.

H. T. Stearns, 1940, Hawaii Div. Hydrog. Bull. 5, p. 48–50. Kailau amygdaloidal basalts, formerly regarded as part of an independent volcano older than Koolau volcano, are believed to represent caldera complex of Koolau volcano.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 95. Composed of amygdaloidal flows of basalt and olivine basalt pahoehoe and aa accumulated in caldera of Koolau volcano, and the dike complex cutting them. Flows as much as 60 feet thick. Total exposed thickness about 1,650 feet; rocks extend below sea level. Probably separated from adjacent extra-caldera Koolau lavas by faults and buried fault scarps. Formerly considered older than Koolau lavas, they are now believed probably contemporaneous with, or even younger than, lavas of Koolau volcanic series in crest region of Koolau Range.

Named for occurrence near town of Kailau. Crop out over about 15 square miles in Kailau area on northeast side of Koolau Range, 6 to 12 miles northwest of Makapuu Head.

Kaimuki Basalt (in Honolulu Volcanic Series)

Kaimuki Volcanics[1]

Pleistocene, upper: Oahu Island, Hawaii.

Original reference: C. K. Wentworth, 1926, Bernice P. Bishop Mus. Bull. 30, p. 40, 42, 44.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie. fasc. 2, p. 95–96. Referred to as Kaimuki basalt. Consists of nepheline basanite lava flows with some cinder and spatter composing small lava shield. Lava varies from dense to very scoriaceous. Maximum thickness about 400 feet. Overlies Diamond Head tuff; underlies marine limestone of plus 25-foot (Waimanalo) stand of sea, and lithified calcareous sand dunes of minus 60-foot (Waipio) stand.

Type locality: Kaimuku Hill. Covers about 2 square miles on south side of Koolau Range about 10 miles west of Makapuu Head.

Kaiparowits Formation[1]

Upper Cretaceous: Central southern Utah.

Original reference: H. E. Gregory and R. C. Moore, 1931, U.S. Geol. Survey Prof. Paper 164.

H. E. Gregory, 1950, U.S. Geol. Survey Prof. Paper 220, p. 51 (table), 109–110, 128, 130–131. In Zion Park region, consists of bluish-drab fine- to moderately coarse-grained arkosic sandstone and sandy shale, with weak calcareous cement; forms slopes and badlands; plants, vertebrates, and fresh- and brackish-water shells. Thickness 600 to 750 feet. Unconformably underlies Wasatch formation; unconformably overlies Wahweap and Straight Cliffs sandstones. Forms part of Gray Cliffs and is continuously exposed across Kolob and Skutumpah terraces.

E. F. Cook, 1952, Utah Geol. Soc. Guidebook 7, p. 96. In Pine Valley Mountains, unconformably underlies Claron conglomerate. Thickness about 1,200 feet.

First described in Kaiparowits Plateau region. Occurs on Kaiparowits Peak.

Kalama Volcanics[1] (in Honolulu Volcanic Series)

Recent: Oahu Island, Hawaii.

Original reference: H. T. Stearns, 1935, Hawaii Div. Hydrography Bull. 1.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 96. Lava flow of nepheline basanite with spatter and cinder at its source. Thickness unknown; at least 10 feet, base not exposed. Underlies Koko tuff. No reef of plus 25-foot (Waimanalo) stand of sea present on lava; hence, eruption is believed to be later than Waimanalo stand (last high stand of sea during Pleistocene).

Named for Kalama Crater, a symmetrical crater about 500 feet across and 50 feet deep, at source of flow. Covers about three-fourths square mile on south side of Koolau Range 1 to 2 miles southwest of Makapuu Head.

Kalama River Mud Flow

Recent: Western Washington.

Don Mullineaux, 1960, Oregon Country Geol. Soc. Newsletter, v. 26, no. 5, p. 40. Hot mud flow; contains charred logs as much as 3 feet in diameter. Radiocarbon dating on wood gave age of 2,000 years ± 250.

Came down west side of Mount St. Helens and flowed down Kalama River valley to Merrill Lake, distance about 8 miles.

Kalamazoo Volcanics

Tertiary: Eastern Nevada.

J. C. Young, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 160, 164–165. Flows, volcanic breccias, conglomerates, and lapilli, and subordinate ignimbrites. Thickness approximately 2,000 to 3,500 feet. Overlies Kinsey Canyon formation (new); unconformably underlies North Creek formation (new).

Named for exposures at Kalamazoo Pass-upper Kalamazoo Canyon, Schell Creek Range area, Ely quadrangle.

Kalaupapa Basalt

Pleistocene(?): Molokai Island, Hawaii.

H. T. Stearns, 1946, Hawaii Div. Hydrography Bull. 8, p. 69 (table), 73; H. T. Stearns and G. A. Macdonald, 1947, Hawaii Div. Hydrography Bull. 11, p. 25–26, 109, table facing p. 16; G. A. Macdonald, and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 96–97. Porphyritic olivine basalt pahoehoe. Maximum thickness 405 feet; base not exposed. Separated from East Molokai volcanic series (new) by erosional unconformity.

Type locality: Kalaupapa Peninsula. Covers about 6¼ square miles, comprising all Kalaupapa Peninsula.

774–954—vol. 2—66——33

Kalihi Volcanics[1] (in Honolulu Volcanic Series)

Pleistocene, upper: Oahu Island, Hawaii.

Original reference: H. T. Stearns, 1935, Hawaii Div. Hydrography Bull. 1.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 97. Lava flow of melilite-nepheline basalt and associated cinder cone remnant. Cone more than 100 feet thick. Lava about 50 feet thick. Rest with erosional unconformity on Koolau volcanic series. Extent noted.

Exposed in area of about 1.7 square miles along Kalihi Valley, from crest of Koolau Range southwestward to sea, about 14 miles west of Makapuu Head.

Kalkberg Limestone[1] (in Helderberg Group)

Kalkberg Limestone Member (of Coeymans Limestone)

Kalkberg Limestone Member (of New Scotland Formation)

Lower Devonian: Eastern and east-central New York and northern Pennsylvania.

Original reference: G. H. Chadwick, 1908, Science, new ser., v. 28, p. 346–348.

F. M. Swartz, 1939, *in* Bradford Willard, F. M. Swartz, and A. B. Cleaves, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 55–56, 60, 88. Rank reduced to member status in New Scotland formation. Geographically extended into Pennsylvania.

Rudolf Ruedemann, J. H. Cook, and D. H. Newland, 1942, New York State Mus. Bull. 331, p. 128. Referred to as Kalkberg member of Coeymans limestone.

G. H. Chadwick, 1944, New York State Mus. Bull. 336, p. 64, 67–71 [1946]. Member of New Scotland; underlies Catskill shaly limestone member.

Winifred Goldring, 1946, New York State Mus. Bull. 332, p. 159–161. Member of New Scotland; underlies Catskill shaly limestone member. Thickness 40 feet in type area; about 20 feet in Capital district (Helderberg area).

Theodore Arnow, 1949, New York State Water Power and Control Comm. Bull. GW–20, p. 8 (table 1), 15. Kalkberg is transition formation between underlying Coeymans limestone and overlying New Scotland limestone. Thickness about 25 feet in Albany County. Lower Devonian.

L. V. Rickard, 1955, New York State Geol. Assoc. Guidebook 27th Ann. Mtg., p. 7–8, 9. Kalkberg cherty limestone is considered to be a distinct mappable formation separated from the Coeymans below and the shaly New Scotland above. Extends as far west as Oriskany Falls where it is represented by uppermost 6 feet of limestone just beneath Oriskany sandstone in Oriskany Falls quarry where it is much younger than it is in eastern New York. Helderbergian series.

Well exposed on Catskill Creek, Greene County N.Y. Name Kalkberg (lime hill) is local Dutch designation for Helderbergian Ridge, and is pronounced Collak-barrakh.

Kalorama Member[1] (of Santa Barbara Formation)

Pleistocene: Southern California.

Original reference: E. D. Pressler, 1929, California Univ. Pub. Bull. Dept. Geol. Sci., v. 18, no. 13, p. 325–345.

T. L. Bailey, 1943, Geol. Soc. America Bull., v. 54, no. 10, p. 1557, 1560. Pleistocene.

Occurs in vicinity of Santa Barbara, Ventura County.

Kaltag Formation[1] (in Shaktolik Group)

Lower Cretaceous: Central western and central Alaska.

Original reference: G. C. Martin, 1926, U.S. Geol. Survey Bull. 776, p. 395–412, chart opp. p. 474.

R. W. Imlay and J. B. Reeside, Jr., 1954, Geol. Soc. America Bull., v. 65, no. 3, pl. 1 (facing p. 246). Lower Cretaceous.

T. G. Payne, 1955, U.S.. Geol. Survey Misc. Geol. Inv. Map I–84. Nonmarine formation included in Shaktolik group in Koyukuk geosyncline and Hogatza uplift areas.

Named from exposures on northwest bank of Yukon River between Kaltag and the Williams mine. In Nulato-Norton Bay district, Lower Yukon River region, and Koyukuk River region.

Kalua O Lapa Flow

Recent: Maui Island, Hawaii.

Grote Reber, 1959, Geol. Soc. America Bull., v. 70, no. 9, p. 1245, 1246. pl. 1 (fig. 1). Consists of a single flow. Radiocarbon dating gives age about 200 years. Overlies part of Kamahena flow (new).

On southwest side of Haleakala.

Kamahena Flow

Recent: Maui Island, Hawaii.

Grote Reber, 1959, Geol. Soc. America Bull., v. 70, no. 9, p. 1245, 1246, pl. 1 (fig. 1). Consists of a single flow. Lower part of flow buried by Kalua O Lapa flow (new). Radiocarbon dating gives age about 890 years.

On southwest side of Haleakala.

Kamanaiki Basalt[1] (in Honolulu Volcanic Series)

Pleistocene, upper: Oahu Island, Hawaii.

Original reference: H. T. Stearns, 1935, Hawaii Div. Hydrography Bull. 1.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 97–98. Fresh dark-gray slightly vesicular basalt. Shows well developed columnar jointing. Unconformably overlies Koolau volcanic series and sediments laid down during stand of sea higher than present one; underlies limestone of the plus 25-foot (Waimanalo) stand of sea. Extent noted.

Named for occurrence in Kamanaiki Valley where it forms a 40-foot V-shaped fill in a waterfall at 750 feet altitude. Occurs as patches at other localities in valley and adjacent valleys.

Kamehame Basalt[1]

Pleistocene, upper (?) and Recent: Hawaii Island, Hawaii.

Original reference: H. T. Stearns, 1926, Geol. Soc. America Bull., v. 37, p. 151; 1930, U.S. Geol. Survey Water-Supply Paper 616, p. 69.

H. T. Stearns and G. A. Macdonald, 1946, Hawaii Div. Hydrography Bull. 9, p. 103. Rocks on western and southern slopes of Kilauea were mapped as Kamehame basalt; because this name included both lavas from Mauna Loa and Kilauea, it is herein replaced by new name, Puna volcanic series.

Named for Kamehame Hill, 3½ miles south of town of Pahala.

Kameset Agglomerate

See Gamsetu Agglomerate.

Kamiah Volcanics[1]

Tertiary : Northern Idaho.

Original reference: A. L. Anderson, 1930, Idaho Bur. Mines and Geology Pamph. 34.

C. P. Ross and J. D. Forrester, 1958, Idaho Bur. Mines and Geology Bull. 15, p. 13. Report is an expansion of map explanation of Geologic map of Idaho, 1947. North of westward flowing stretch of Salmon River, rocks that resemble Challis volcanics are rare. The only rocks there grouped with Challis volcanics are Kamiah volcanics of Anderson (1930). These rocks are andestic and latitic flows, erosion remnants of which constitute buttes in small area in Idaho County. They are surrounded and overlapped by Columbia River basalt.

Represented in outline and area by Kamiah Buttes, about 12 miles south of town of Kamiah, Lewis County.

Kamishak Formation

Kamishak Chert[1]

Upper Triassic : Central southern Alaska.

Original reference: G. C. Martin and F. J. Katz, 1912, U.S. Geol. Survey Bull. 485, p. 47, table facing p. 30, map.

L. B. Kellum, 1945, New York Acad. Sci. Trans., ser. 2, v. 7, no. 8. p. 203 (table 1), 204. Kamishak formation exposed at Cold Bay is dominantly limestones. Underlies Bidarka formation (new).

Typically exposed on west shore of Kamishak Bay, especially in vicinity of Bruin Bay ; Cook Inlet region.

Kanab limestone[1]

Carbonic : Northern Arizona.

Original reference: C. R. Keyes, 1936, Pan-Am. Geologist, v. 66, p. 216.

Named from Kanab plateau bordering the Kanab side-canyon opposite Cataract Canyon, in Grand Canyon region.

†Kanab Sandstone[1]

Upper Triassic and Jurassic (?) : Southwestern Utah.

Original reference: E. Huntington and J. W. Goldthwait, 1903, Jour. Geol. ogy, v. 11, p. 46–63.

Kane County.

Kanab Canyon Member (of Muav Formation)

Lower and (or) Middle Cambrian : Northwestern Arizona.

E. D. McKee, 1945, Carnegie Inst. Washington Pub. 563, p. 14 (fig. 1), 29, 102–105. Changes in lithology considerably from east to west. At type locality consists of single massive cliff of uniform lithology composed of mottled limestone; 25 miles to southeast at Bass trail it includes sandy shale in basal 10 feet, and 8 miles farther in the same direction, it is divisible, on basis of lithology, into two parts of about equal thickness. Thickness increases westward and northward as far as Granite Park, and ranges from 62 to 143 feet. Underlies Gateway Canyon member (new) ; overlies Peach Springs member (new).

Type locality: At mouth of Kanab Canyon, where it is lowest massive cliff-forming unit, not far above level of Colorado River, Lowest subdivision of Muav formation throughout eastern part of Grand Canyon.

Kanaka Formation[1]

Mississippian: Northern California.

Original reference: H. G. Ferguson, 1929, Am. Inst. Mining Metall. Engineers Pub. 211, p. 4.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 58, no. 2, chart 5 (column 15). Shown on correlation chart above Tightner formation and below Relief quartzite.

Named for exposures in valley of Kanaka Creek, Sierra County.

Kanapou Volcanic Series

Pliocene(?): Kahoolawe Island, Hawaii.

H. T. Stearns, 1946, Hawaii Div. Hydrography Bull. 8, p. 63, 65 (fig. 1). Name applied to thin-bedded pahoehoe and aa basalt together with few thin beds of firefountain debris and cinder cones and associated intrusives that make up Kahoolawe volcanic dome. Two groups of lavas distinguished in series: pre-caldera lavas and the caldera-filling lavas some of upper members of which are slightly differentiated. Five post-erosional lavas and pyroclastics of Recent age lie unconformably on cliff at Kanapou Bay.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 98–99. Pliocene(?).

Type section: Cliffs in Kanapou Bay.

Kanawha Black Flint (in Allegheny Formation or Group)

Kanawha Black Flint (in Kanawha Formation[1] or Group)

Pennsylvanian: Northern West Virginia.

Original reference: I. C. White, 1891, U.S. Geol. Survey Bull. 65, p. 98.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 88. Marine chert previously considered near top of Kanawha group but here placed in lower Allegheny.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 12). Shown on correlation chart below Roaring Creek sandstone and above Buffalo Creek limestone and coal.

Exposed along Great Kanawha River, on Elk River, and at other places in Kanawha County.

Kanawha Formation (in Pottsville Group)[1]

Kanawha Group

Kanawha Series

Middle Pennsylvanian: West Virginia, Kentucky, and Virginia.

Original reference: M. R. Campbell and W. C. Mendenhall, 1896, U.S. Geol. Survey 17th Ann. Rept., pt. 2.

P. H. Price and E. T. Heck, 1939, West Virginia Geol. Survey [Rept.] Greenbrier County, p. 214, 215, 220–222. Kanawha group comprising upper part of Pottsville series, is youngest group of stratified rocks in Greenbrier County: only basal part represented; maximum thickness 250 feet. Overlies New River group.

M. G. Cheney, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 2, p. 140 (chart 2), 142, 146. Pennsylvanian system divided into six series in standard Appalachian section and in standard Midcontinent section. Kanawha series of Appalachian section is correlated with Lampasas series of Midcontinent section. Succeeds New River series and is followed by Allegheny series.

C. B. Read and S. H. Mamay, 1960, U.S. Geol. Survey Prof. Paper 400–B p. B381. Middle Pennsylvanian on basis of fossil plants.

U.S. Geological Survey currently classifies the Kanawha as a formation in the Pottsville Group in West Virginia.

Complete section exposed in hills north of Kanawha Falls, W. Va.

Kanawha volcanic zone (in Eagleford Formation)

Cretaceous: Northeastern Texas.

R. T. Hazzard, 1939, Shreveport Geol. Soc. Guidebook 14th Ann. Field Trip, p. 138–140, 143. Ferruginous sands, clayey tuffaceous sands, tuffaceous sands with fossil casts; characterized by development of fossiliferous sandy limestone lenses and fossiliferous, calcareous sandstone lenses. Thickness 15 to 20 feet. Separated from overlying Medill volcanic zone by an interval of 80 to 90 feet of bluish-gray bedded clay shales; separated from underlying Pine Bluff volcanic zone by shale interval that varies from 158 to 212 feet in thickness.

Named from exposures near Kanawha, Red River County.

Kanayut Conglomerate

Upper Devonian: Northern Alaska.

A. L. Bowsher and J. T. Dutro, Jr., 1957, U.S. Geol. Survey Prof. Paper 303–A, p. 3, 5, 7–13, figs. 2–4, pl. 2. Probable nonmarine conglomerate, sandstone, and shale. Comprises three members (ascending): lower, about 1,400 feet thick; middle, of massive chert-pebble conglomerate, 1,030 feet thick; and Stuver member at top, about 860 feet of orthoquartzite, gray, red, and green shale, and conglomerate. Composite section 3,300 feet thick. Disconformably underlies Kayak shale (new); overlies unnamed shale and sandstone.

Type locality: On ridge south of Mount Wachsmuth, Shainin Lake area, central Brooks Range. Typically exposed along east side of Alapah Creek upstream from Shainin Lake. Named from Kanayut River which originates at north end of Shainin Lake.

Kandik Formation[1]

Lower Cretaceous: Northeastern Alaska.

Original reference: J. B. Mertie, Jr., 1930, U.S. Geol. Survey Bull. 816, p. 136.

J. T. Dutro, Jr., and T. G. Payne, 1957 Geologic map of Alaska (1:2,500,000): U.S. Geol. Survey. Appears on map legend.

Typically exposed in valley of Kandik River from the Yukon northeast probably to boundary [international], in Eagle-Circle district.

Kane Limestone (in Allegheny Formation)[1]

Pennsylvanian: Central northern Pennsylvania.

Original reference: C. A. Ashburner, 1885, Pennsylvania 2d Geol. Survey Rept. R_2, p. 72, 73.

Quarried at Gen. Kane's quarry, west of road leading from Catholic Church to J. Pistner's, Elk County.

Kanektok Silts and Gravels[1]

Pleistocene: Central southern Alaska.

Original reference: J. E. Spurr, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 7, p. 177.

Extend along lower course of Kanektok River to Oklune Mountains and farther up Kanektok River.

Kaneohe Volcanics[1] (in Honolulu Volcanic Series)

Pleistocene: Oahu Island, Hawaii.

Original reference: H. T. Stearns, 1935, Hawaii Div. Hydrography Bull. 1.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2 ,p. 99. Cinder cones and lava flow of nepheline basalt and melilite-nepheline basalt. Pleistocene.

Type locality: Main highway 2 miles south of Kaneohe village. Covers about 1½ square miles on northeast side of Koolau Range, 11½ miles northwest of Makapuu Head.

Kane Point Tuff Member (of Page Ranch Formation)

Oligocene, upper, or Miocene, lower: Southwestern Utah.

J. H. Mackin, 1960, Am. Jour. Sci., v. 258, no. 2, p. 90 (table 1), 97, 98. Consists of vitric ignimbrite of rhyolite composition. Overlies Irontown member (new). Zircon age 19 million years; this indicates that Rencher-Page Ranch period of extensive-intrusive igneous activity is late Oligocene or early Miocene. Discussion of ignimbrites of area.

Named for peak several miles southwest of east-facing scarp near Page Ranch, Page Ranch quadrangle, Iron Springs district.

Kangaroo Formation[1]

Pennsylvanian(?) and Permian: Central Colorado.

Original reference: R. D. Crawford, 1913, Colorado Geol. Survey Bull. 4, p. 70.

J. W. Gabelman, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 8, p. 1588. Sangre de Cristo formation is probably correlative with Maroon formation of Mosquito Range and has some counterpart in the Kangaroo of the Sawatch Range.

Named for Kangaroo Gulch, Monarch district.

Kankakee Limestone[1] or **Formation**

Kankakee stage

Lower Silurian: Northeastern, central, and western Illinois and eastern Missouri.

Original reference: T. E. Savage, 1916, Geol. Soc. America Bull., v. 27, p. 305–324.

J. N. Payne, 1942, Illinois Geol. Survey Bull. 66, p. 191 (table 8), 194. Shown on table of general classification of geologic time as Kankakee stage of Alexandrian epoch. Younger than Edgewood stage. During Kankakee stage, seas became clear and little or no clastic material was deposited.

E. C. Brown and J. W. Whitlow, 1960, U.S. Geol. Survey Bull. 1123–A, p. 40–42, pl. 3. Described in Dubuque South quadrangle, Iowa-Illinois. Ranges in thickness from 50 feet where it overlies Edgewood dolomite in southeastern part of quadrangle to 45 feet northwest of Dubuque airport.

Comprises grayish-yellow dense fine-grained dolomite and as much as 50 percent bedded chert in upper 40 feet. Overlies Tete des Morts member (new) of Edgewood dolomite; underlies Hopkinton dolomite.

Well exposed along Kankakee River about 5 miles south of Richey, Macon County, Ill.

Kanosh Shale (in Pogonip Group)

Lower or Middle Ordovician: West-central Utah and eastern Nevada.

L. F. Hintze, 1951, Utah Geol. and Mineralog. Survey Bull. 39, p. 9 (fig. 2) 18–19, 29 (fig. 4), 57–58, 64–66. Predominantly yellowish-brown, olive-gray, or pink fissile shale with intercalated thin-bedded limestones; several thin-bedded orange-weathering siltstones and fine sandstones in upper part. Fossiliferous. Thickness about 500 feet in Ibex area, Utah; about 370 feet at Scipio. Overlies Juab limestone (new); underlies Lehman formation (new). Lower Ordovician.

R. E. Cohenour, 1959, Utah Geol. and Mineralog, Survey Bull. 63, p. 74–75. Described in Sheeprock Mountains area where it is present in East and West Lookout Hills as narrow band dipping beneath cliff-forming Swan Peak quartzite. Conformably overlies Juab formation. Thickness 205 feet; neither top nor base exposed. Kanosh shale is approximate age equivalent of lower part of Swan Peak formation of Ross (1949, Am. Jour. Sci., v. 247, no. 7) in northwestern Utah, of upper half of Antelope Valley limestone of Eureka, Nev., and of Orient shale member of Orient formation in West Tintic mining district on eastern edge of Sheeprock Range (Stringham, 1942, Geol. Soc. America Bull., v. 53, no. 2). Proposed that names Orient formation and its subdivision Orient shale and Orient quartzite be supplanted by Kanosh shale and Swan Peak quartzite.

J. A. Teichert, 1959, Utah Geol. and Mineralog. Survey Bull. 65, p. 12 (fig. 2), 25, 29–31, fig. 3. Described in southern Stansbury Range, Utah, where it is about 162 feet thick, overlies Garden City formation, and underlies Fish Haven dolomite. Middle Ordovician.

Type locality: Flank of Fossil Mountain, W¼ cor. sec. 19–30, T. 22 S., R. 14 W., Millard County, Utah. Named for village of Kanosh. Extends westward to Snake Range in Nevada.

Kanouse Sandstone[1]

Kanouse Sandstone and Conglomerate (in Onondaga Formation or Group)

Middle Devonian: Northern New Jersey and southeastern New York.

Original reference: H. B. Kummel, 1908, U.S. Geol. Survey Geol. Atlas, Folio 161.

Bradford Willard, 1937, Am. Jour. Sci., 5th ser., v. 33, no. 196, p. 271, 272. In proposed succession in Green Pond Mountain area, New Jersey, Kanouse sandstone and conglomerate is assigned to Onondaga formation. Occurs below Cornwall shale and above Decker limestone (basal Helderberg) Lower Devonian.

Bradford Willard, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 138. Referred to as Kanouse member of Onondaga group.

G. A. Cooper, 1942, Geol. Soc. America Bull. v. 53, no. 12, pt. 1, chart 4, Age of Kanouse sandstone given as Lower or Middle Devonian.

C. H. Kindle and S. H. Eidman, 1955, Jour. Paleontology, v. 29, no. 1, p. 183–185. At Highland Mills, N.Y., overlies Schoharie grit. Contains fauna that is distinct from the Schoharie-Esopus. Apparently represents a near-shore facies of Onondaga sea, deposited contemporaneously with Onondaga limestone of Catskill and Schoharie regions.

A. J. Boucot, 1959, Jour. Paleontology, v. 33, no. 5, p. 734–735. In Highland Mills area, New York, overlies Woodbury Creek member (new) of Esopus formation. Upper contact with overlying Cornwall shale, of Hamilton age, not exposed. Minimum thickness 50 feet. Contains fauna of Onondaga age. Lower Devonian.

Well exposed in Valley west of Kanouse Mountain, Passaic County, N.J.

Kansan Glaciation

Kansan Drift[1]

Kansan stage of deglaciation[1]

Pleistocene : Mississippi Valley.

Original references: T. C. Chamberlain, 1894, *in* James Geikie, The Great Ice Age, 3d ed.: London, Edward Stanford, p. 724–775; 1895, Jour. Geology, v. 3, p. 270–277; 1896, Jour. Geology, v. 4, p. 872–876.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 38, 52 (fig. 2), 70–104. Kansan age (stage) is interval between Aftonian and Yarmouthian. It is assumed that Kansas is type region for this stage. Kansan stage contains Atchison formation, Kansas till, and Meade formation which includes Grand Island sand and gravel member at base and Sappa member with Pearlette volcanic ash bed. In Nebraska, stage contains Red Cloud formation, Atchison formation, Kansan till, Grand Island formation, and Sappa formation. In Iowa and Illinois, term Ottumwan is used to include the Kansan and Yarmouthian.

H. R. Wanless, 1957, Illinois Geol. Survey Bull. 82, p. 130–132. Kansan deposits include early Kansan calcareous laminated silt, pro-Kansan loess and peat soil, till, and sand and gravel. Kansan drift is present in each of quadrangles, Beardstown, Glasford, Havana, and Vermont, of this report, in exposures generally limited to bedrock valleys or places of moderately low altitude. In many exposures, silt or loess of early Kansan, Yarmouth, or Aftonian age is directly overlain by Illinoian till. Because Kansan till is missing in these exposures, it seems likely that Kansas glacier did not entirely cover this area.

Name amended to Kansan Glaciation to comply with Stratigraphic Code adopted 1961.

Named for development in Kansas.

Kansan Period[1]

Pennsylvanian: Kansas.

Original reference: L. C. Wooster, 1906, Kansas Acad. Sci. Trans., v. 20, pt. 1, p. 75–82.

Kansas Till

Pleistocene (Kansan) : Kansas.

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 24, 36, 37, 44, 52, 123, 128. Kansas till, used here as stratigraphic unit of formation rank, includes deposits made directly by Kansas glacier and some water-laid sediments interstratified with the till. Does not include pro-glacial silts, sands, and gravels deposited in front of advancing glacier (Atchison formation) or outwash deposits from retreating glacier (Meade formation). No type section specified since term has been accepted for more than 50 years, but reference sections designated. Thickness as much as 300 feet; 9 feet at Iowa Point section, Doniphan County, where it overlies Nebraska till and underlies Loveland silt member (Illinoian stage).

Reference sections: Exposures in cut banks about one-half mile southwest of type locality of Atchison formation, NE¼ sec. 10, T. 6 S., R. 20 E., Atchison County. Exposures north of Atchison along Missouri River bluffs. Iowa Point section, NE¼SE¼ sec. 6, T. 2 S., R. 20 E., Doniphan County.

Kansas City Group[1]

Kansas City Formation[1]

Pennsylvanian (Missouri Series): Northwestern Missouri, southwestern Iowa, eastern Kansas, and southeastern Nebraska.

Original reference: H. Hinds, 1912, Missouri Bur. Geol. and Mines, v. 11, p. 7.

H. S. McQueen and F. C. Greene, 1938, Missouri Geological Survey and Water Resources, 2d ser., v. 25, p. 27, pl. 5. Term Kansas City group, as used in this report [northwestern Missouri], includes all beds between base of Hertha limestone and top of "Iola" limestone. It appears that bed designated Iola at Kansas City by early geologists is a higher bed than that which was named Iola limestone at Iola, Kans. According to Kansas Geological Survey, the true Iola can be traced into the Raytown at Kansas City. Left thus without a name, the "Iola" in the vicinity of Kansas City has been given name Argentine for upper gray part and name Frisbie for basal yellowish beds by Kansas Geological Survey. Outcrops upon which changes in nomenclature have been based are in Kansas and the field work was done in that State. Overlies Pleasanton group; underlies Lansing group, basal formation of which is Lane shale according to Missouri Survey usage.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2028–2033; 1949, Kansas Geol. Survey Bull. 83, p. 68 (fig. 14), 74–111; F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. vi, 10–14; H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 24–28, fig. 5. At conference, May 1947, revised definition of Kansas City group was agreed to by State Geological Surveys of Iowa, Kansas, Missouri, and Nebraska; this term not applicable to Missourian deposits in Oklahoma. Lower boundary of group placed at base of Hertha formation, and upper boundary at base of Plattsburg formation of Lansing group. This modifies originally designated limits (Hinds, 1912) by addition of "Lane shale" of Missouri usage (Island Creek shale, Farley limestone, and Bonner Springs shale) at top of group and to same extent changes usage that has been followed by Missouri Geological Survey since 1912. Newly agreed upper boundary coincides with definition of this line that has been employed for past 15 years in Kansas (Moore, 1932) and Nebraska (Condra, 1935, Nebraska Geol. Survey Paper 8), but lower limit of group (top of Dennis formation) used by Kansas and Nebraska Geological Surveys in recent years differs from definition accepted by the conference, which follows original Missouri Survey usage and that followed in Iowa. Group is subdivided into (ascending) Bronson, Linn (new), and Zarah (new) subgroups. Redefined group thus comprises (ascending) Hertha limestone, Ladore shale, Swope limestone, Galesburg shale, Dennis limestone, Cherryvale shale, Drum limestone, Chanute shale, Iola limestone, Lane shale, Wyandotte limestone, and Bonner Springs shale.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 34–42. Group in Nebraska includes (ascending) Hertha, Ladore, Swope, Galesburg, Dennis, Fontana, Sarpy (new), Drum, Chanute, Iola, Lane, Wyandotte, and Bonner Springs formations.

Named for exposures at Kansas City, Mo.

†Kansas City Limestone[1]

Pennsylvanian: Northwestern Missouri.

Original references: J. A. Gallaher, 1898, Missouri Geol. Survey Bienn. Rept., p. 51; 1900, Missouri Geol. Survey, v. 13, p. 206.

†Kansas City Oolite[1]

Pennsylvanian: Northwestern Missouri.

Original reference: G. C. Broadhead, 1886, St. Louis Acad. Sci. Trans., v. 4, p. 483.

Kanuti Group[1]

Paleozoic: Northern central Alaska.

Original reference: W. C. Mendenhall, 1902, U.S. Geol. Survey Prof. Paper 10, p. 37, pl. 5.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000): U.S. Geol. Survey. Mapped with Mississippian volcanic rocks.

Kanuti River flows for 30 miles through canyon cut in these rocks.

Kanwaka Shale (in Shawnee Group)[1]

Kanwaka Shale Member (of Shawnee Formation)[1]

Kanwaka Shale Member (of Vamoosa Formation)

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: J. W. Beede, 1902, Kansas Univ. Sci. Bull., v. 1, p. 163.

R. C. Moore, 1949, Kansas Geol. Survey Bull. 83, p. 142 (fig. 29), 150–151; R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 62 (fig. 23), 67. Name applied to beds between top of Oread formation and base of Lecompton formation. Includes both marine and nonmarine deposits. Thickness 40 to 145 feet. Divisible into three members recognized from central Kansas northward (ascending): Jackson Park shale, Clay Creek limestone, and Stull shale. A few feet below the Lecompton is a persistent sandstone which thickens southward to form main part of Elgin sandstone in Oklahoma.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 24. Thickness 7 to 9 feet in Weeping Water Valley, Cass County.

T. L. Welp, L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 64, p. 419. Thickness about 10 feet in measured section near Winterset, Madison County.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 30–32. Referred to as shale member of Vamoosa formation. Beds limiting Kanwaka formation of Kansas not present in Pawnee County section. Most southerly outcrops of Oread limestone are in Osage County, and only top limestone member of Lecompton formation extends as far south as Pawnee County. Hence, true Kanwaka as defined in Kansas cannot be delimited. However, interval between Wynona sandstone and Lecompton limestone in Pawnee County contains unit lithologically similar to Kanwaka formation, and, because it occupies essentially same stratigraphic position, name

Kanwaka will be applied in this report. Elgin sandstone wedges into section as member within Kanwaka interval. Thickness about 265 feet. Overlies Wynona member; underlies Lecompton limestone member of Pawhuska.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 20–21, fig. 5. At type locality, Kanwaka consists of two shale members separated by limestone member. In Iowa, where it is thin, the limestone member is not well defined and is undifferentiated. Between Griswold and Lewis, the Kanwaka is gray to buff fossiliferous shale commonly containing nodular limestone beds. Clay Creek limestone member not recognized, and Kereford limestone member of Oread does not appear to be present; therefore, this shale interval probably includes equivalents of Kereford and Heumader intervals of the Oread. Thickness here about 10 feet. Near Stennett, Kereford limestone has been recognized, and it is possible to distinguish between Kanwaka and upper Oread, although Kanwaka members are undifferentiated; thickness here 6½ to 7 feet. Thickness about 10 feet east of Greenfield. Underlies Lecompton limestone; overlies Oread limestone. Shawnee group.

Type locality: Exposures east of Stull, in Kanwaka Township, about 9 miles due west of Lawrence, Douglas County, Kans.

Kaohikaipu Volcanics[1] (in Honolulu Volcanic Series)

Pleistocene, upper, or Recent: Oahu Island, Hawaii.

Original reference: H. T. Stearns, 1935, Hawaii Div. Hydrography Bull. 1.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc, 2, p. 99. Red cinder, bombs, and spatter and associated black pahoehoe olivine basalt lava flow containing many phenocrysts of olivine. Volcanics are isolated, and relationships to other units of Honolulu series not known. Partly overlain by lithified calcareous sand dunes. Includes Kaohikaipu lava (Winchell, 1947, Geol. Soc. America Bull., v. 58, no. 1, p. 21).

Named for Kaohikaipu Island which consists largely of these volcanics.

Kapaula Basaltic Andesite (in Hana Volcanic Series)

Pleistocene(?): Maui Island, Hawaii.

G. A. Macdonald *in* H. T. Stearns and G. A. Macdonald, 1942, Hawaii Div. Hydrography Bull. 7, p. 230 (table), 244–246, pl. 1. Single flow of aa; interflow clinker present locally and in such there may be more than one flow but elsewhere above basal clinker entire thickness is composed of dense rock. Columnar jointing not prominent; platy jointing rare; phenocrysts seldom present. Resembles Makaino flow (new) and occupies approximately same stratigraphic position; the two may be branches of same flow or separate flows erupted simultaneously from different points on same fissure. Exposed thickness 40 to 50 feet; 140 feet in test hole 20. Overlies Waiaaka lava (new). Each member in series is underlain by local erosional unconformity.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 100. Pleistocene(?).

Occurs as a narrow valley-filling flow which followed valley of ancient Kapaula Stream, Haleakala (East Maui) volcano. Exposed from coast to 2,000 feet south of Koolau ditch, where it disappears beneath later Paakea lava.

Kara Bentonitic Member (of Pierre Shale)

Upper Cretaceous: Northeastern Wyoming.

C. S. Robinson, W. J. Mapel, and W. A. Cobban, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 1, p. 103 (fig. 2), 111–113. Sequence of gray shale and gray bentonite. Thickness about 100 feet. At type section, top of member is about 300 feet stratigraphically below base of Fox Hills sandstone, and base of member is estimated to be about 2,100 feet above base of Pierre shale and about 1,000 feet above Mitten black shale member of Pierre. In northwestern Crook County, Wyo., and in Carter County, Mont., rocks of same age as Kara bentonitic member apparently are represented either by upper part of black shale unit that overlies Monument Hill bentonitic member, or possibly by Fox Hills sandstone.

Type section: NW¼ sec. 2, T. 48 N., R. 67 W., 1½ miles south of Kara, Weston County.

Karla Kay Conglomerate Member (of Burro Canyon Formation)

Lower Cretaceous: Southwestern Colorado and southeastern Utah.

E. B. Ekren and F. N. Houser, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 1, p. 195–199. Lowest conglomerate in Burro Canyon formation. Part of a system of shoestring channel-filling conglomerate and conglomeratic sandstone lenses. Lenses thin sharply toward sides of channel, but a thin gently cross-laminated fine-grained sandstone of the channel-fill commonly extends laterally, beyond channel edge, several tens to hundreds of feet. Rarely are channel fills more than 2,000 feet wide or more than 65 feet thick; commonly 500 to 800 feet wide.

Named from an exposure at the Karla Kay mine in McElmo Canyon, Montezuma County, Colo., where one of the channel-fills is well exposed.

†Kasaan Greenstone[1]

Lower Cretaceous (?) : Southeastern Alaska.

Original reference: A. H. Brooks, 1902, U.S. Geol. Survey Prof. Paper 1, p. 40–52, map.

C. W. Wright, 1915, U.S. Geol. Survey Prof. Paper 87, p. 68. Kasaan greenstone, as used by Brooks (1902) not used in this report.

E. N. Goddard, L. A. Warner, and M. S. Walton, Jr., 1944, Copper-bearing iron deposits of the Mount Andrew-Mamie area, Kasaan Peninsula, Prince of Wales Island, southeastern Alaska: U.S. Geol. Survey [Mineral deposits of Alaska-Short Prelim. Repts.]. p. 3–4, fig. 3. Made up of metamorphosed interlayered volcanic rocks, pyroclastics, limestones, and poorly sorted sediments in Mount Andrew-Mamie area. Volcanics predominate in lower part of section, and sediments predominate in upper part.

Occurs in peninsula lying between Clarence Strait and Kasaan Bay: Ketchikan region.

Kashong Member (of Moscow Shale)[1]

Middle Devonian: Central New York.

Original reference: G. A. Cooper, 1930, Am. Jour. Sci., 5th, v. 19, p. 218, 231.

R. G. Sutton, 1951, Rochester Acad. Sci. Proc., v. 9, nos. 5–6, p. 375–377, pl. 1. Name proposed by Cooper for shale sequence above Portland Point member and Windom shale member. Thickness about 38 feet in Batavia quadrangle [this report]. Overlies Menteth limestone member; underlies Windom shale member.

Type section: On Kashong Creek, Seneca Lake.

†Kaskaskia Limestone,[1] Formation,[1] or Group[1]

Mississippian: Western Illinois, western Kentucky, and eastern Missouri.

Original reference: J. Hall, 1857, Am. Assoc. Adv. Sci. Proc., v. 10, p. 55–56.

Named for Kaskaskia, Ill., near mouth of Kaskaskia River.

Kaskaskia sequence

Devonian (Chautauquan) to Mississippian (Osagean): Central and western United States.

L. L. Sloss, W. C. Krumbein, and E. C. Dapples *in* C. R. Longwell, chm., 1949, Geol. Soc. America Mem. 39, p. 112 (table 2), 115–121. "Operational unit" for use in interregional facies analysis. Named for Kaskaskia River in south-central Illinois. Limits of sequence in Illinois are Ste. Genevieve limestone-Wapsipinicon limestone; in Kansas, Ste. Genevieve limestone-"Chattanooga shale"; in Wyoming, Madison limestone-Darby formation.

Kasota Sandstone[1]

Lower Ordovician (Beekmantown): Southeastern Minnesota.

Original reference: L. H. Powell, 1935, St. Paul Inst. Sci. Mus., Sci. Bull. 1, p. 2–16.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 7 (geol. column), 50 (fig. 13), 54–55. Lies at base of Ordovician. Varies from a few inches to 6½ feet in thickness. White sandstone with medium to coarse well-rounded grains. Bedding slightly irregular; occasionally contact with underlying Jordan is uneven, indicating disconformity. Separated from overlying Oneota dolomite by thin Blue Earth siltstone.

Known only at Kasota and at St. Peter along Minnesota River, Le Sueur County.

Kassler Sandstone Member (of South Platte Formation)

Lower Cretaceous: North-central Colorado.

K. M. Waagé, 1955, U.S. Geol. Survey Prof. Paper 274–B, p. 31, figs. 10, 17, 19. Throughout most of nonmarine phase of South Platte formation (new) in southern part of northern foothills area, the first sandstone subunit at top of South Platte lies on dip slope of hogback, and crest of hogback is formed by second sandstone subunit. Latter is here named Kassler sandstone member. It is dominant ledge-forming sandstone of formation from Golden quadrangle, where it is about 30 feet thick, south to Kassler quadrangle, where it is between 75 and 100 feet thick. North of Golden quadrangle, too thin to be mapped. Can be traced as far as El Dorado Springs quadrangle, where it is about 10 feet thick. To the north appears to grade gradually into marine siltstone and shale member.

Type section: At end of hogback 0.5 mile north of South Platte River at Kassler. Named for exposure in Kassler quadrangle. It is part of composite type section of South Platte formation. In northern Front Range foothills.

Kasutesyo (Kasuteshio) Limestone

See Castiyo Limestone.

Katahdin Granite[1]

Post-Lower Devonian: Central Maine.

Original reference: C. H. Hitchcock, 1861, Maine Bd. Agric. 6th Ann. Rept., p. 259.

A. J. Boucot, 1954, Am. Jour. Sci., v. 252, no. 3, p. 144–148. Probably post-Lower Devonian. Discussion of stratigraphic relationships of Katahdin granite with Toppan's Ripogenous [Ripogenus] series, and Fisher's [in Willard, 1945] Chesuncook limestone and Ripogenus volcanics

Exposed in Mount Katahdin area in eastern Piscataquis and western Penobscot Counties.

Katalla Formation[1]

Oligocene and Miocene: Southeastern Alaska.

Original reference: G. C. Martin, 1905, U.S. Geol. Survey Bull. 250, p. 13.

D. J. Miller, D. L. Rossman, and C. A. Hickcox, 1945, Preliminary report on petroleum possibilities in the Katalla area, Alaska: U.S. Geol. Survey, p. 6–8; 1945, Geologic and topographic map and sections of the Katalla area, Alaska: U.S. Geol. Survey War-Minerals Inv. Prelim. Map. Consists of about 8,600 feet of marine shale, sandstone, and conglomerate in Katalla area. Compiled from continuous, apparently conformable, section measured from Split Creek southward along Redwood Creek-Burls Creek divide and Redwood Creek-Puffy Creek divide to point near southern end of latter divide. Divided into seven members (ascending): unnamed shale, Split Creek sandstone, Basin Creek member (new), Burls Creek shale, organic shale, Point Hey member, and Puffy member. Measured section in many respects representative of average thickness and lithology of formation as exposed in Katalla area. Oligocene(?).

W. Waloweek and W. L. Norem, 1957, Jour. Paleontology, v. 31, no. 3, p. 674–675. Oligocene and Miocene.

Typically exposed in region northeast of Katalla, along banks of whole of peninsula between Bering Lake and Controller Bay and cropping out in most of hills south and east of Bering River.

†Katemcy Series[1]

Upper Cambrian: Central Texas.

Original reference: T. B. Comstock and E. T. Dumble, 1890, Texas Geol. Survey 1st Ann. Rept., p. lxi, 289–293, pl. 3.

Named for Katemcy Creek, Mason County.

Kate Peak Formation

Kate Peak Andesite or Andesite Series

Miocene or Pliocene, lower: Western Nevada.

V. P. Gianella, 1936, Nevada Univ. Bull., v. 30, no. 9, p. 68–73, pl. 1. Pyroxene andesites, glassy lavas, tuffs, breccias, and agglomerates. Some flows with prominent biotite and hornblende phenocrysts. Estimated thickness about 1,200 feet. Plate shows age as early Pliocene; text states that fossil evidence places upper part of andesites in lower Pliocene and lower part of series possibly extruded in late Miocene time.

G. A. Thompson, 1956, U.S. Geol. Survey Bull. 1042–C, p. 54–55, pl. 3. Formation described in Virginia City quadrangle. Most abundant rock in formation is coarse agglomerate that contains blocks of andesite of contrasting color and texture; flows and flow breccias also present. Contains vitrophyre member in northeastern part of quadrangle. Maximum thickness more than 2,000 feet. Vitrophyre member at least 1,000 feet thick and probably nearly 2,000 feet in thickest part. Top of formation intertongues with overlying Truckee formation. Miocene or early Pliocene.

D. I. Axelrod, 1956, California Univ. Pubs. Geol. Sci., v. 33, p. 32, 64. Underlies Coal Valley formation (new).

D. I. Axelrod, 1958, California Univ. Pubs. Geol. Sci., v. 34, no. 2, p. 97, map 1. From type area in Silver City region, andesite can be traced almost continuously into Verdi basin where it is exposed chiefly in Carson Range south of Truckee River. Section largely one of interbedded agglomerates; mudflow breccias, and lavas. Thickness 1,500 to 2,500 feet. Underlies Coal Valley formation. Rests on all older rocks in area; near Fleish lies on granodiorite or on metamorphic rocks. Outside mapped area rests on Alta andesite; on basis of interfingering relationships with Mehrten formation of Sierra Nevada, Kate Peak andesites were erupted chiefly during span of time ranging from Mio-Pliocene transition to later part of early Pliocene with a few episodes extending into early middle Pliocene.

D. I. Axelrod and W. S. Ting, 1960, California Univ. Pubs. Geol. Sci., v. 39, no. 1, p. 3. In fault contact with upper Pliocene Wichman formation (new).

Named for Kate Peak in Flowery Range, east of Silver City. Covers an extensive area in Virginia City quadrangle.

Katherine Granite[1]

Precambrian: Northwestern Arizona.

Original reference: C. Lausen, 1931, Arizona Bur. Mines Bull. 131, p. 22–27, pl. 2.

Katherine district, Mohave County.

†Katmai Series[1]

Jurassic: Central southern Alaska.

Original reference: W. C. Mendenhall, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 7, p. 317 (table).

Katmai, Katmai Point and on Katmai River.

Katsberg Red Beds[1]

Upper Devonian: Eastern New York.

Original reference: G. H. Chadwick, 1933, Am. Jour. Sci., 5th, v. 26, p. 480, 482–483, 484.

G. H. Chadwick, 1944, New York State Mus. Bull. 336, p. 135–139, geol. map. Described in Catskill and Kaaterskill quadrangles. Thickness about 3,000 feet where complete. Although formation is here called redbeds (which it actually is farther west) it contains very little red in this area. This absence of abundant red color has puzzled many observers and has been one of reasons for their thinking that later rocks here supervened upon the Catskill. Include Stony Clove sandstone member at base and Wittenberg conglomerate member in upper part. Overlies Onteora redbeds; underlie Slide Mountain conglomerate.

Type section: On steep slopes of highest peak, Slide Mountain in Catskill Mountains. Katsberg is old Dutch name for mountains miscalled "Catskills" by the English.

Kattel Shale[1]

Upper Devonian: Southeastern New York.

Original reference: G. H. Chadwick, 1932, Eastern States Oil and Gas Weekly, v. 1, no. 17, p. 7.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 52, no. 12, pt. 1, chart 4. Shown on correlation chart above Cincinnatus shale and sandstone and below Juliand "zone" of Enfield shale.

Type locality: Kattel Hill, especially the long Lackawanna Railway cut around its east base, between Chenango Bridge and Chenango Forks, Broome County.

Kau Volcanic Series

Pleistocene, upper(?), and Recent: Hawaii Island, Hawaii.

H. T. Stearns and G. A. Macdonald, 1946, Hawaii Div. Hydrography Bull. 9, p. 38 (fig. 12), 62 (table), 64 (table), 65 (fig. 17), 67 (table), 76–78. Assemblage of Recent and latest Pleistocene rocks laid down by Mauna Loa volcano. Separated into lower or prehistoric member and upper or historic member. Lavas form thin veneer, commonly one flow thick, on lower slopes of Mauna Loa but thicken toward summit and in walls of Mokuaweoweo exceed 600 feet. Chiefly porphyritic or nonporphyritic aa and pahoehoe basalts; flows average about 15 feet in thickness. Rocks of Ninole and Kahuku volcanic series form kipukas in Kau lavas. One of latest prehistoric lavas is Keamuku lava flow. Overlapped by Puna lavas (new) between Kilauea caldera and Keaau. Overlies Kahuku volcanic series (new) and Pahola ash. Kau and Puna volcanics formerly included in Kamehame basalt.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 100. Late Pleistocene(?) and Recent.

Type locality: In wall of Mokuaweoweo caldera. Named from Kau district where rocks are well exposed.

Kauai Lavas.

Pliocene(?): Kauai Island, Hawaii.

N. E. A. Hinds, 1930, Bernice P. Bishop Mus. Bull. 71, p. 56–57. Basaltic lava flows; make up main cone of Kauai volcano. Consist of lower and upper lavas separated by Waimea conglomerate (new). Thickness of lower lavas about 4,000 feet. Unconformable below lavas and pyroclastics of late Kolea volcanic episode.

D. A. Davis and G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 100–101. Included in what is now known as Waimea Canyon volcanic series. Pliocene(?).

Distributed over most of island.

Kauffman Member (of Mercersburg Formation)

Middle Ordovician (Trentonian): South-central Pennsylvania.

L. C. Craig, 1949, Geol. Soc. America Bull., v. 60, no. 4, p. 715 (fig. 1), 734–738. Name proposed for upper member of formation. Described at type section as dark-gray fine- to medium-grained, thin crinkly to slabby gray-weathering limestone. Thick slabby or thin cobbly beds developed locally in eastern belts of outcrop; usually platy bedded in western belts. Four metabentonites present at type section; each is immediately succeeded by several feet of olive-drab to green shale or blocky siltstone. Maximum thickness 168 feet; thins northeastward. Conformably overlies Housum member (new); disconformably underlies Oranda formation.

Type section: In fields adjacent to Cumberland Valley Railroad, 2.1 miles southwest of Marion, Franklin County. Named for village of Kauffman, 1.6 miles southeast of type section.

Kaupo Basalt[1] (in Honolulu Volcanic Series)

Pleistocene, upper, or Recent: Oahu Island, Hawaii.

Original reference: H. T. Stearns, 1935, Hawaii Div. Hydrography Bull. 1.

G. A. Macdonald and D. A. Davies *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 101. Flow of olivine basalt pahoehoe that issued from talus at foot of windward cliff (Pali) of Koolau Range 200 feet above sea level and flowed to ocean. Surface only sparsely soil covered, and neither Manana tuff nor reef of the plus 25-foot (Waimanalo) stand of sea is present on it. Extent noted.

Named for abandoned Kaupo village situated on flow. Forms small peninsula, with area of about 0.1 square mile, 1 mile northwest of Makapuu Head.

Kaupo Mud Flow (in Hana Volcanic Series)

Pleistocene: Maui Island, Hawaii.

H. T. Stearns *in* H. T. Stearns and G. A. Macdonald, 1942, Hawaii Div. Hydrography Bull. 7, p. 65 (table), 67 (table), 107–108, pls. 1, 21B. Coarse breccia with blocks reaching 50 feet across. Forms hills that project through later Hana lavas (new) and cliffs 300 feet high along coast. Exposed thickness 355 feet in sea cliff at Puu Maneoneo; extends below sea level.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 101. Included in Hana volcanic series. Pleistocene.

Named for exposures at mouth of Kaupo Valley, Haleakala (East Maui) volcano.

†Kaupulehu Flow

Recent: Hawaii Island, Hawaii.

G. A. Macdonald, 1949, U.S. Geol. Survey Prof. Paper 214–D, p. 75. Several flows were extruded from Hualalai Volcano probably during years 1800 and 1801. Kaupulehu flow originated at vent between 5,500 and 6,000 feet above sea level on northwest flank. Another flow, Huehue, originated at row of cones at 1.500 feet altitude shortly after Kaupulehu flow. Kaupulehu is largely aa and Huehue flow is largely pahoehoe.

Kaweah Series

Triassic(?) : Southern California.

Cordell Durrell, 1940, California Univ. Dept. Geol. Sci., v. 25, no. 1, p. 13, 116, fig. 29, geol. map. Metamorphic series made up of great variety of sedimentary and intrusive and extrusive rocks. Divided into four stratigraphic units (ascending) : Yokohl amphibolite, Lemon Cove schist, Homer quartzite, and Three Rivers schist. Age of series unknown, but Triassic age is suggested by comparison with Mineral King beds and rocks of Inyo Range.

Occurs in southern Sierra Nevada in north-central part of Tulare County.

†Kawishiwin Agglomerate,[1] Greenstones,[1] or Series[1]

Precambrian (Keewatin) : Northeastern Minnesota.

Original reference: N. H. Winchell, 1889, Minnesota Geol. Survey 17th Ann Rept. 1888, p. 41–42, 45–46, 68, 70.

Probably named for Kawishiwi River, Vermilion district.

Kawvian Series or Epoch

Upper Pennsylvanian: North America.

R. C. Moore and M. L. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 3, p. 284–285, 286, 288–289 (fig. 1), 297–300. Analysis of physical characters and paleontological features of Pennsylvanian rocks in North America leads to conclusion that stratigraphic cleavage at two positions within system has paramount significance. Three series recognized: Ardian-Lower Pennsylvanian, Oklan-Middle Pennsylvanian, and Kawvian-Upper Pennsylvanian. Approximately upper one-third of Pennsylvanian system belongs to Kawvian series which includes formations from oldest Missourian to base of Permian. Kawvian rocks divided into Missourian stage below and Virgilian stage above. Time equivalent is Kawvian epoch.

Typically displayed in valley of Kaw (Kansas) River in northeastern Kansas. Name derived from commonly used alternative designation of Kansas (or Kaw) River which joins the Missouri at Kansas City.

Kayak Shale

Lower Mississippian: Northern Alaska.

A. L. Bowsher and T. J. Dutro, Jr., 1957, U.S. Geol. Survey Prof. Paper 303–A, p. 4, 6, 14–15, figs. 2–4, pl. 2. At type locality composed of five unnamed members (ascending): sandstone, 130 feet thick; lower black shale, 595 feet; argillaceous limestone, 80 feet; upper black shale, 140 feet; and red limestone, 10–15 feet. Total thickness approximately 960 feet. Disconformably underlies Wachsmuth limestone (new); disconformably overlies Kanayut conglomerate (new).

Type locality: In saddle near foot of south slope of Mount Wachsmuth, Shainin Lake area, central Brooks Range. Name taken from Kayak Creek, which joins Alapah Creek south of Shainin Lake.

Kaycee Formation

Recent: Eastern Wyoming.

L. B. Leopold and J. P. Miller, 1954, U.S. Geol. Survey Water-Supply Paper 1261, p. 10–11. Described as uniform tan or light-brown silt consisting of moderately well sorted grains, predominantly quartz. Grains subrounded but not pitted. Lenses of sand or fine gravel locally present. In places there is a thin basal gravel. Unconformably overlies Ucross formation (new).

Type locality: Left bank in the reach of Powder River from Kaycee to Sussex.

Kayenta Formation (in Glen Canyon Group)[1]

Upper Triassic(?): Northeastern Arizona, southwestern Colorado, and southeastern and southern Utah.

Original reference: A. A. Baker, C. H. Dane, and E. T. McKnight, 1931, U.S. Geol. Survey Prelim. map showing structure of parts of Grand and San Juan Counties, Utah.

A. A. Baker, C. H. Dane, and J. B Reeside, Jr, 1936, U.S. Geol. Survey Prof. Paper 183, p. 5. pls. Name Kayenta here used for beds in northern Arizona and southeastern Utah that have been previously designated "Todilto" and "Todilto(?)" formation. Overlies Wingate sandstones; underlies Navajo sandstone. Middle formation of Glen Canyon group which is herein classified as Jurassic(?). Type locality stated.

H. E. Gregory, 1950, U.S. Geol. Survey Prof. Paper 220, p. 51 (table), 79–81, pl. 2, geol. sections. Described in Zion Park region where it is 75 to 100 feet thick in Johnson Canyon, 118 to 200 feet in Kanab Canyon, 130 to 165 feet in Sand Canyon, 0 to 180 feet in Zion Park, and 25 to 310 feet east of Paria. Underlies Navajo sandstone; overlies Wingate sandstone.

Paul Averitt and others, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no. 12, p. 2520–2523. As redefined in southwestern Utah and along Echo Cliffs of northern Arizona, includes sequence of beds between top of Springdale sandstone member of Moenave formation and base of Navajo sandstone. Sequence 1,190 feet thick at Cedar City, Utah; 714 feet at Zion Canyon; 680 feet at Kanab; and 150 to 500 feet in Echo Cliffs area. At Cedar City, includes Cedar City tongue (new); in Kanab area includes Tenney Canyon tongue (new). Divided locally into two parts by Shurtz and Lamb Point tongues (both new) of Navajo sandstone, but elsewhere is single unit with fairly well-defined boundaries. Jurassic(?).

J. W. Harshbarger, C. A. Repenning, and J. H. Irwin, 1957, U.S. Geol. Survey Prof. Paper 291, p. 3 (table), 17–19, pl. 2. At type locality, is represented by sandstone facies typical of unit throughout most of Colorado Plateau; to southwest of type locality, increases in silt content. Thickness: 55 feet at Rock Point near its eastern limit; 144 feet at Kayenta; 466 feet at Gap where it includes many silty units that are tongues of silty facies; 678 feet along Ward Terrace. In eastern half of Navajo country, conformably overlies Wingate sandstone (Lukachukai member); in western half of country, conformably overlies Moenave formation. Intertongues with basal part of overlying Navajo sandstone. Contains *Tritylodontoids*; study of these fossils is incomplete, but they seem to be closest to Old World forms generally referred to Upper Triassic.

U.S. Geological Survey currently designates the age of the Kayenta Formation as Upper Triassic(?) on the basis of a study now in progress.

Type locality: In Comb Ridge, 1 mile northeast of Kayenta, Navajo County, Ariz.

Keanae Basalt (in Hana Volcanic Series)

Pleistocene(?): Maui Island, Hawaii.

H. T. Stearns *in* H. T. Stearns and G. A. Macdonald, 1942, Hawaii Div. Hydrography Bull. 7, p. 95 (table), 96. Dark-gray olivine basalt containing phenocrysts of olivine and augite. Last lava flow to reach lower part of Keanae Valley.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 102. Pleistocene(?).

Named for exposures at Keanae village, Haleakala (East Maui) volcano. At an altitude of 1,300 feet, lava covers entire floor of Keanae Valley, but farther north it divided into two branches, one followed eastern wall of valley to altitude of 500 feet and the other followed gulch of present Piinaau Stream at foot of western wall. At the coast, western branch spread out to form lava delta on which village of Keanae is located.

Keanakakoi Formation

Recent: Hawaii Island, Hawaii.

C. K. Wentworth, 1938, Hawaiian Volcano Observatory 3d Spec. Rept., p. 92–102. Applied to whole series of surface ash layers which appear to have resulted from successive explosions of Kilauea during present physiographic epoch; as thus defined, includes not only 1790 ash but also that of 1924 as component members. Includes variety of materials; some parts largely lapilli and dust produced by phreatic explosions; other parts reticulite and pyroclastics thrown out by magmatic explosions. Maximum thickness over 30 feet, on tongue of caldera rim.

H. T. Stearns and G. A. Macdonald, 1946, Hawaii Div. Hydrography Bull. 9, p. 108. Treated as aa member of Puna volcanic series (new).

Type locality: Surface in vicinity of Keanakakoi Crater.

Kearny Formation

Pennsylvanian (Morrow): Southwestern Kansas (subsurface).

M. L. Thompson, 1944, Kansas Geol. Survey Bull. 52, pt. 7, p. 414–417. Name proposed for 127 feet of rocks encountered between base of producing sand at depth of 4,752 feet and top of highly oolitic limestone, believed to be of Mississippian age, at depth of 4,879 feet in type well. Type section composed of greenish-gray, bluish-gray, and dark-gray coarsely crystalline to dense glauconitic fossiliferous limestones interbedded with dark-gray and green fossiliferous shales. Subordinate amount of sandstone and sandy glauconitic fossiliferous limestone occurs in lower part. Four different although gradational lithologic zones can be recognized.

Type well: Stanolind Oil and Gas Co. No. 1 Patterson well, SE cor. sec. 23, T. 22 S., R. 38 W., Kearny County.

Kearsarge Amygdaloid[1] (in Portage Lake Lava Series)

Precambrian (Keweenawan): Northern Michigan

Original reference: L. L. Hubbard, 1895, Michigan Geol. Survey, v. 5, pt. 1, p. 117, footnote.

H. R. Cornwall, 1954, U.S. Geol. Survey Geol. Quad. Map GQ–51. Included in Portage Lake lava series.

At Kearsarge [mining] location, Houghton County.

Kearsarge Andalusite Group[1]

Paleozoic(?): Central southern New Hampshire.

Original reference: C. H. Hitchcock, 1877, Geology of New Hampshire, pt. 2, p. 585–588, 674, pl. 24.

Occurs on Mounts Kearsarge and Ragged, constituting a band 12 miles long and from 3 to 4 miles wide in towns of Warner, Sutton, Andover, and Salisbury, Merrimack County.

Kearsarge Conglomerate[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: A. R. Marvine, 1873, Michigan Geol. Survey, v. 1, pt 2, p. 114, chart.

H. R. Cornwall, 1951, Geol. Soc. America Bull., v. 62, no 2, p. 161. Incidental mention in report on Keweenawan lavas.

Named for occurrence in old Kearsarge mine, Houghton County.

Kearsarge Flow[1] (in Portage Lake Lava Series)

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

W. S. White, H. R. Cornwall, and R. W. Swanson, 1953, U.S. Geol. Survey Geol. Quad. Map GQ–27. Included in Portage Lake lava series.

At the Kearsarge [mining] location, Houghton County

Kearsarge West Amygdaloid[1]

Precambrian (Keweenawan) : Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Named for fact that it lies west of Kearsarge amygdaloid.

Kearsarge West Flow[1]

Precambrian (Keweenawan) : Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Copper district of Keweenaw Point.

Keasey Shale[1] or **Formation**

Keasey Stage

Eocene, upper, and Oligocene, lower: Northwestern Oregon and southwestern Washington, and British Columbia, Canada.

Original reference: H. G. Schenck, 1927, California Univ. Pub., Dept. Geol. Sci. Bull., v. 16, no. 12, p. 457, 459.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v 4, p. 104, 105. Thickness of formation in Rock Creek area, near Keasey, about 1,200 feet. Lower part composed of dark-grayish-brown somewhat stratified medium-grained tuffaceous sandy shales containing several species of fossil mollusca; upper two-thirds composed of medium to dark-brownish-gray rather massive medium- to coarse-grained shaly sandstone within which fossils are scarce. Underlies Pittsburg Bluff formation; basal contact not observed. Lower Oligocene.

C. E. Weaver and others, 1944, Geol. Soc. America Bull., v. 55, no. 5, p. 592, chart 11. In southwestern Washington, a section consisting of Metchosin volcanics and Keasey, Lincoln, and Astoria formations has been folded and deeply eroded so as to expose over 3,000 feet of the Metchosin. Keasey rests unconformably on the volcanics; also present on Vancouver Island. Eocene and Oligocene.

W. C. Warren, Hans Norbisrath, and R. M. Grivetti, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 42. Shale described west of Willamette River. Thickness about 1,800 feet in vicinity of Sunset Tunnel on Wolf Creek Highway. Overlies Cowlitz formation; disconformably underlies Pittsburg Bluff formation. Upper Eocene or lower Oligocene.

W. C. Warren and Hans Norbisrath, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 2, p. 220 (table 1), 225–228. Formation described in upper Nehalem River basin. Thickness 1,800 to 2,000 feet. Overlies Cowlitz formation; underlies Pittsburg Bluff formation.

J. W. Durham, 1950, Geol. Soc. America Bull., v. 61, no. 11, p. 1254–1255. A stage based on faunal assemblages.

M. L. Steere, 1955, Geol. Soc. Oregon Country News Letter, v. 21, no. 10, p. 85. In Sunset Tunnel area, Columbia County, Oreg., overlies Nehalem formation (new).

Typically exposed on railroad at Keasey Station, Columbia County, Oreg.

†Keddie Formation[1]

Pennsylvanian: Northern California.

Original reference: J. S. Diller, 1892, Prelim, proof-sheet ed. U.S. Geol. Survey Lassen Peak Folio.

Forms narrow belt on northeast slope of Keddie-Dyer Ridge, Plumas County.

†Keechelus Andesitic Series[1]

Keechelus Andesite or Formation

Eocene to Miocene: Central Washington.

Original reference: G. O. Smith and F. C. Calkins, 1906, U.S. Geol. Survey Geol. Atlas, Folio 139.

H. A. Coombs, 1936, Washington [State] Univ. Pubs. in Geology, v. 3, no. 2, p. 150–171. Series described in Mount Rainier National Park. Includes rock types referred to as Mineral Mountain andesite porphyry, Sheepskull Gap tuffs, Sourdough Mountain breccias, Chinook Pass diorite porphyry, Longmire acid breccias, Starbo altered tuffs, Cayuse Pass acid hornfels, and Mowich hypersthene basalt. Overlies rocks of Puget group with angular unconformity; intruded by Snoqualmie granodiorite. Exact upper age limit of Keechelus unknown. Only materials definitely overlying the younger capping flows in vicinity of park are [Mount] Rainier volcanics; elsewhere volcanic activity in Keechelus may have extended into Pliocene and judging from freshness of flows, may be equivalent to [Mount] Rainier lavas in age.

G. E. Goodspeed and H. A. Coombs, 1937, Am. Jour. Sci., v. 34, 5th ser., no. 199, p. 12–15. Miocene age of Keechelus is in doubt. "Type locality" given.

W. C. Warren, 1941, Jour. Geology, v. 49, no. 8, p. 795–802. In Mount Aix quadrangle, upper part of Keechelus andesitic series is mapped as separate unit—Fifes Peak andesite. Marginal flows of Yakima basalt overlap Fifes Peak andesite and are clearly younger than the andesite. Snoqualmie granodiorite probably intermediate in age between lower part of Keechelus and Fifes Peak andesite. Overlies undifferentiated rocks considered to be pre-Oligocene. Map bracket shows Keechelus Oligocene(?) to Miocene.

R. V. Fisher, 1954, (abs.) Geol. Soc. America Bull., v. 65, no. 12, pt. 2, p. 1340. Formation, covering hundreds of square miles in southern Washington Cascades, is thick sequence of andesitic volcanic breccias, tuffs, flows, and interbedded continental sediments. It is gently folded and intruded by small dioritic stocks and diabasic dikes. Age variously regarded as Miocene and (or) Oligocene. On basis of single oreodont, it is now thought to be mainly Oligocene. Immediately south of Mount Rainier, lower part of Keechelus is interbedded with upper part of the probable upper Eocene Puget group. Keechelus, therefore, appears to belong in part to upper Eocene.

D. R. Crandell and L. M. Hard, Jr., 1959, U.S. Geol. Survey Geol. Quad. Map GQ–125. Series described in Buckley quadrangle where it conformably overlies Puget group. Eocene to Miocene.

R. J. Foster, 1960, Geol. Soc. America Bull., v. 71, no. 2, p. 118–121, pl. 1. Referred to as Keechelus andesite. Term andesitic series considered inappropriate. Type area designated because none was stated by Smith and Calkins. Most workers have considered east shore of Lake Keechelus as the type. Relationship of Keechelus of various workers to new type area must be established by further mapping. Section along Lake Keechelus is metamorphosed; at newly designated type area, Keechelus consists of sequence of bedded andesites with minimum of 3,500 feet exposed. Here, overlies Naches formation and is intruded by Snoqualmie granodiorite.

At Denny Mountain, Keechelus is andesite breccia; appears to overlie Guye formation unconformably. In area of this report, base of Keechelus may be as old as Eocene; no younger rocks are in stratigraphic contact with Keechelus.

Type locality (Goodspeed and Coombs): Along eastern shore of Lake Keechelus, about 70 miles southeast of Seattle on Sunset Highway which connects Puget Sound region with eastern Washington. Type area (Foster): West face to Rampart Ridge at altitude of Rachel Lake which drains into south branch of Box Creek, Kittitas County.

Keechi Creek Formation (in Whitt Group)

Keechi Creek Shale and Sandstone (in Mineral Wells Formation)[1]

Pennsylvanian (Canyon): Central northern Texas.

Original references. F. B. Plummer and R. C. Moore, 1922, Jour. Geology, v. 30, p. 25, 31; Texas Univ. Bull. 2132, p. 78.

M. G. Cheney, 1940, Am Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 88. Rank raised to formation in Whitt group (new). Expanded below to base of Turkey Creek sandstone. Underlies Palo Pinto formation; overlies Salesville formation. Name Mineral Wells dropped in this report.

Leo Hendricks, 1957, Texas Univ. Bur. Econ. Geology Pub. 5724, p. 25, fig. 3, pl. 1. This report [Parker County] follows Cheney's (1940) definition of Keechi Creek. However, objection is raised to Cheney's procedure of reclassification. Group terminology not used in this report.

Typically exposed along Keechi Creek west of Mineral Wells, Palo Pinto County.

Keefer Sandstone Member (of Clinton Formation)[1]

Keefer Member (of Mifflin Formation)

Keefer Sandstone (in Clinton Group)

Middle Silurian: Western Maryland, central Pennsylvania to northeastern West Virginia.

Original reference: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, p. 522, 545, 591, pl. 28.

H. P. Woodward, 1941, West Virginia Geol. Survey, v. 18, p. 8, 92–106, measured sections. Keefer sandstone described in West Virginia. Thickness 5 to 30 feet. Overlies Rose Hill formation; underlies Rochester shale. Included in Clinton group. Middle Silurian, Niagaran series.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Correlation chart shows that Clinton—central Pennsylvania to northeastern Tennessee—comprises (ascending) Rose Hill shale, Keefer sandstone, and Rochester shale. Niagaran series.

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 5, 6, 21, 23. Rank reduced to member status in Mifflin formation (new). Underlies Rochester member; overlies Rose Hill formation. Thickness commonly 40 to 50 feet; locally absent. At Mount Union section referred to as Keefer formation; thickness 47 feet. The Keefer is the "Ore sandstone" of Pennsylvania Second Geological Survey Reports.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1:250,000): Pennsylvania Geol. Survey, 4th ser. Clinton group, as mapped, includes Rose Hill formation, Keefer sandstone, and Rochester shale.

Named for Keefer Mountain a few miles northeast of Hancock, Washington County, Md.

Keel Limestone Member (of Chimneyhill Limestone)

Lower Silurian: South-central Oklahoma.

R. A. Maxwell, 1936, Northwestern Univ. Summ. of Doctoral Dissert., v. 4, p. 132, 134. An oolitic limestone 6 to 8 feet thick. Underlies Cochrane member (new); unconformably overlies Hawkins member (new).

T. W. Amsden, 1957, Oklahoma Geol. Survey Circ. 44, p. 4 (fig. 2), 6 (fig. 3), 11–16, fig. 4. Unconformably overlies Ideal Quarry member (replaces Hawkins limestone member); unconformably underlies Cochrane member. Type locality designated.

Type locality: NW¼NE¼NE¼ sec. 36, T. 3 N., R. 5 E., Pontotoc County. Name taken from allottee who originally owned land.

Keeler Canyon Formation

Pennsylvanian to Lower Permian: Eastern California.

C. W. Merriam and W. E. Hall, 1957, U.S. Geol. Survey Bull. 1061–A, p. 4–7. Consists of thin-bedded medium- to dark-gray impure silty and arenaceous to pebbly limestones and limy siltstones, with intercalations of pinkish or maroon fissile shale. Silicified fusulinids are sometimes an important constituent of the pebbly limestones. All rocks show clastic texture, and bedding is inclined to be platy or flaggy with few layers as much as 3 feet thick. Formation highly folded; section overturned in Darwin Hills. Thickness averages 2,200 feet; in Darwin quadrangle, formation thickens to about 4,000 feet. Where section is greatly thinned, there is evidence that segments have been cutout by faulting. Conformably overlies Chainman shale in New York Butte quadrangle; in Darwin quadrangle, overlies an unnamed limestone which seemingly overlies the Chainman; unconformably underlies Owens Valley formation (new) with angular discordance of about 15° in some places.

W. E. Hall and E. M. MacKevett, 1958, California Div. Mines Spec. Rept. 51, p. 7 (table 1), 9–10, pl. 1. In Darwin quadrangle, consists of a lower member, about 2,300 feet thick, of thin-bedded limestone with intercalated limestone-pebble conglomerate and an upper member, about 1,700 feet thick of calcilutite and fine-grained calcarenite with lesser shale and limestone-pebble conglomerate. Underlies Owens Valley formation; overlies Rest Spring shale. Ranges in age from probable Atoka or Des Moines (Pennsylvanian) to probable late Wolfcamp (Permian).

Type locality: East of the Estelle Tunnel portal and 2 miles southwest of Cerro Gordo Peak, southern Inyo Mountains.

Keen Conglomerate

Pennsylvanian (Strawn): Central Texas.

Robert Pavlovic, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 4, p. 891–892. Massive coarse green chert conglomerate with wavy closely banded black and white chert common. Thickness about 25 feet. Occurs approximately in middle(?) of the Strawn.

Named from Keen Creek in southeast corner of Zephyr quadrangle, Mills County. Traced about 6 miles along strike from Pompey Creek on Mullin topographic sheet to head of Rough Creek where it is hidden by the Cretaceous.

Keene Gneiss[1]

Precambrian : Northern New York.

Original reference: W. J. Miller, 1918, Geol. Soc. America Bull., v. 29, p. 400–462, geol. map.

M. H. Krieger, 1937, New York State Mus. Bull. 308, p. 15, 41–42, 43, 47, geol. map. Keene gneiss included in discussion of anorthosites in Thirteenth Lake quadrangle.

Named for exposures along State road just north of village of Keene, Lake Placid quadrangle, Essex County.

Keene Limestone[1]

Upper Cambrian and Middle Devonian : Western central Montana.

Original reference: W. H. Weed, 1901, U.S. Geol. Survey 22d Ann. Rept., pt. 2, p. 434, 438, 505, map.

Named for Keene mine, Elkhorn region.

Keeseville Sandstone[1]

Upper Cambrian (?) : Northern New York.

Original reference: E. Emmons, 1841, New York Geol. Survey 5th Rept., p. 130, 131.

D. W. Fisher, 1956, Internat. Geol. Cong., 20th, Mexico, Cambrian Symposium, pt. 2, p. 333. Although Emmons (1841) treated Keeseville sandstone as variety of Potsdam sandstone, name was later revived for upper predominantly white part of the Potsdam, and name Potsdam was restricted to lower, largely red, part (Chadwick, 1920, New York State Mus. Bull. 217–218). Because reddish and white sandstone interfinger, advisability of using two names is questioned. Not considered valid name.

A. W. Postel, A. E. Nelson, and D. R. Wiesnet, 1959, U.S. Geol. Survey Geol. Quad. Map GQ–123. Potsdam sandstone in Nicholville quadrangle is divided into two members. Nicholville conglomerate (new) below and upper unnamed orthoquartzite member. Unnamed upper member corresponds to Keeseville sandstone of Emmons.

Extends from Keeseville to Hopkinton, St. Lawrence County.

Keetley Volcanics

Tertiary, lower (?) : North-central Utah.

M. B. Kildale, 1958, Utah Mineralog. Soc. Field Trip, Aug. 17, 1958, p. 8. Series of volcanic rocks largely of andesitic flows, agglomerates, and tuffs. Unconformably overlie older folded sedimentary rocks. Probably early Tertiary in age. Altered by hydrothermal solutions southeast of Keetley.

In eastern and northeastern parts of Park City mining district. Well exposed in cuts along new highway between Silver Fork junction and Hailstone, and occur in vicinity of Keetley.

Keewatin Group, Volcanics

Precambrian : Northern Minnesota and Canada.

Original reference: A. C. Lawson. 1885, Report on the geology of the Lake of the Woods region with special reference to the Keewatin (Huronian?) belt of the Archaean rocks: Canada Geol. and Nat. History Survey, 1885, the same being part CC of Canada Geol. and Nat. History Survey Ann. Rept., new ser., v. 1, 1886, p. 10CC–13CC, 14CC–15CC.

F. F. Grout and others, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1023–1029, 1074. Lawson (1885) named the Keewatin from exposures on

Lake of the Woods, most of which are in Canada. No doubt the series is equivalent to outcrops south of the boundary. Outcrops run east on Canadian side nearly to Port Arthur and almost connect with the Minnesota belt from Saganaga Lake to Cass County. West of that, drift cover is thick. Hays and others (1905, Jour. Geology, v. 13, no. 2) found original Keewatin a fairly well developed unit and approved name to cover greenstone, green schist, and the iron-formation of basement complex, apparently considering it below Knife Lake (Seine) group. Keewatin group in Minnesota divided into Ely greenstone and Soudan iron-bearing formation. Keewatin having been named from outcrops on Lake of the Woods has its type locality in Minnesota. Widespread use of term is based on evidence (not all equally good) that other rocks can be correlated with those near Lake of the Woods. Possible that greenstones resembling those at type locality may be of different ages. Pettijohn (1937, Geol. Soc. America Bull., v. 48, no. 2) reported greenstones of two ages north of type locality. He would restrict the Keewatin to the older of the two series. Cooke and others (1931, Canada Geol. Survey Mem. 166) suggest that there are larger, well-exposed, and less-metamorphosed greenstones in northern Ontario and Quebec, which have so long been agreed upon as Keewatin that it would be well to substitute that as type locality. Term Earlier Precambrian System as used in this report includes Keewatin Period.

Type locality: Keewatin district, Lake of the Woods area, northern Minnesota.

Keewatin Series[1]

Precambrian: Lake Superior region.

Original reference: A. C. Lawson, 1885, Report on the geology of the Lake of the Woods region with special reference to the Keewatin (Huronian?) belt of the Archaean rocks: Canada Geol. and Nat. History Survey, 1885, the same being part CC of Canada Geol. and Nat. History Survey Ann. Rept., new ser., v. 1, 1886, p. 10CC–13CC, 14CC–15CC.

F. F. Grout and others, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1023. Early Precambrian System, as used in this report [Precambrian of Minnesota], includes Keewatin Period and the time of the following period of invasion, orogeny, and erosin. Rocks include (1) Keewatin flows and associated Soudan iron formation and minor sediments, and (2) pre-Knife Lake granite, usually designated Laurentian.

Name derived from Keewatin district.

†Keg Creek Sand[1]

Eocene, upper: Eastern Georgia.

Original reference: S. W. McCallie, 1919, Jour. Geology, v. 27, p. 176.

Named for exposures on Keg Creek, Washington County.

Keith Knob facies (of New Providence Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 76, 112–114. Predominantly a gray, blue-gray, olive-gray to drab argillaceous shale with local siltstone layers in lower part. Thickness 125 to 175 feet, in harmony with general southward thinning of formation. Merges with Silver Hills facies (new) to north and west and with Junction City facies (new) to east. Underlies Culver Springs shale member of Brodhead formation, Pilot Knob facies (all new); overlies New Albany shale.

Well exposed along U.S. Highway 62, one-half mile southwest of Boston, Nelson County. Named for Keith Knob, westernmost prominence in Nelson County.

Kekekabic Granite[1]

Precambrian: Northeastern Minnesota.

Original reference: N. H. Winchell, 1900, Minnesota Geol. Survey Final Rept., v. 5, pt. 1, p. 32.

J. T. Stark and V. G. Sleight, 1939, Geol. Soc. America Bull., v. 50, no. 7, p. 1032 (table 2), 1036. Intrudes Knife Lake series in Kekequabic area. Presumably contemporaneous with Vermilion granite (batholith).

Occurs along south side of Kekekabie [Kekequabic] Lake, Vermilion district, Lake County.

Kekekabic Tuffs, Agglomerates, Slates, and Andesite Porphyry (in Knife Lake Series)

Precambrian: Northern Minnesota.

J. W. Gruner, 1941, Geol. Soc. America Bull., v. 52, no. 10, p. 1583 (table 1), 1606–1608, 1624. Overlies Amoeba Lake graywackes, slates, and tuffs. Porphyry is interstratified with tuffs, agglomerates, and slates in vicinity of Kekekabic Lake; near Eddy Lake, lies on top of other sediments. Thickness 2,000 to 4,000 feet. Difficult to limit series upward because transition is gradual. In this report, Knife Lake series is divided into 20 members. Table of approximate chronologial sequence (ascending) shows Kekekabic tuffs as member 11.

Type locality not stated. Probably named for occurrence at Kekekabic Lake.

Kekekabic Lake Tuffs, Agglomerates, Slates, and Andesite Porphyry

See Kekekabic Tuffs, Agglomerates, Slates, and Andesite Porphyry.

Keller Group

Pennsylvanian (Virgil Series): Central and southern New Mexico.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 27 (table 2), 69–71. Proposed for group of rocks between top of Hansonburg group (new) of Missouri series below and the base of the Fresnal group (new). Includes Moya (top) and Del Cuerto formations (both new). At type locality, group is about 132 feet thick and is composed largely of limestone; several thick beds of arkosic sandstone, conglomerate and shale occur in lower two-thirds of group. Lithology varies markedly among some localities.

Carel Otte, Jr., 1959, New Mexico Bur. Mines Mineral Resources Bull. 50, p. 19. Holder formation includes Fresnal and Keller groups in the classification of Thompson (1942).

Type locality: At north end of Oscura Mountains on northeast bluff of canyon that cuts across northern part of mountains. Located mainly in NE¼ sec. 31, T. 5 S., R. 6 E., but extends a short distance into west-central part of sec. 32, Socorro County. Name derived from Keller Spring on east slope of Oscura Mountains about 2 miles east of South Oscura Peak.

Kellogg Shale

Eocene, upper: Northern California.

B. L. Clark and A. S. Campbell, 1942, Geol. Soc. America Spec. Paper 39, p. 1, 4 (fig. 3), 5–9. Name applied to 130-foot shale unit lying stratigraphically below Markley formation, and in western part of area forms upper part of series of sands and shales which have been known locally as "Nortonville" shales. Shale is uniform; some layers are thin-bedded paper shales and others more massive; unweathered rock, buff to light-chocolate; weathered surface almost pure white. In type area, underlies San Pablo formation.

Type section: On bank of road between Kellogg Creek and Byron Hot Springs, northeast of Mount Diablo.

Kelly Formation

Pennsylvanian: North-central Utah.

H. J. Bissell, 1936, Iowa Acad. Sci. Proc., v. 43, p. 240, 241. Predominantly sandstone and limestone interbedded; minor amounts of conglomerate and shale. Thickness 1,885 feet. Underlies Hobble formation (new). Rocks have been referred to Oquirrh formation. Proposed in this report to elevate Oquirrh to rank of series in this region.

Type section: In Hobble Creek Canyon, central part T. 7 S., R. 3 E., east of Springville, Utah County.

Kelly Limestone

Kelly Formation[1]

Mississippian: Southwestern New Mexico.

Original reference: G. L. Herrick, 1904, Am. Geol., v. 13, p. 310–312. [See Graphic-Kelly limestone.]

S. B. Talmage and T. P. Wootton, 1937, New Mexico Bur. Mines Mineral Resources Bull. 12, p. 27. Since its definite correlation with the Lake Valley limestone has been established, it seems preferable to discontinue use of local term, Kelly limestone, in Magdalena Mountains.

V. T. Stringfield, A. H. Koschmann, and G. F. Loughlin, 1942, U.S. Geol. Survey Prof. Paper 200, p. 14–16, pl. 2. In Magdalena district, for most part it is light bluish-gray medium- to coarse-grained thick-bedded high-calcium limestone with persistent bed of dense argillaceous limestone in middle part known as "silver pipe" or "indicator." Thickness ranges from 90 to 135 feet; exceeds 110 feet in most places.

A. K. Armstrong, 1958, New Mexico Bur. Mines Mineral Resources Mem. 5, p. 3, 5, 11, figs. 6, 8, 9. Formation ranges in thickness from 0 to 75 feet in Magdalena, Lemitar, and Ladron Mountains. Disconformably overlies Caloso formation. Keokuk (Osage) age.

Named for Kelly, Magdalena district, Socorro County.

Kelly Hill facies[1] (of Carwood Formation)

Lower Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv., Div. Geology Pub. 98, p. 77, 186–191.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 127–128, pl. 2. Mississippian facies nomenclature discussed. Correlation chart lists Kelly Hill facies of Carwood formation.

Name taken from hill 2 miles southwest of Nashville which is crossed by State Highway 46, NE¼NW¼ sec. 35 and SW¼SE¼ sec. 26, T. 9 N., R. 2 E., Brown County.

Kelso Shale

Lower Cambrian : Southern California.

J. C. Hazzard, 1938, (abs.) Geol. Soc. America Proc. 1937, p. 241. Listed as underlying Chambless limestone and overlying Tough Nut quartzite (new). Thickness 55–57 feet.

J. C. Hazzard, 1954, California Div. Mines Bull. 170, chap. 4, p. 30, 32. Name preoccupied ; unit renamed Latham shale.

Area is in Providence Mountains, San Bernardino County.

Kelvin Formation

Kelvin Conglomerate[1]

Lower Cretaceous : Central northern Utah.

Original reference: A. A. L. Mathews, 1931, Oberlin Coll. Lab. Bull., new ser., no. 1.

W. L. Stokes, 1944, Geol. Soc. America Bull., v. 55, no. 8, p. 970. Considered to be equivalent to Cedar Mountain group (new).

D. A. Andrews and C. B. Hunt, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 70. Shown on map legend as Kelvin formation.

A. E. Granger and others, 1952, Utah Geol. Soc. Guidebook 8, p. 15, pl. 1. Formation discussed in geology of central Wasatch Mountains. Conglomerates form its most prominent outcrops, but formation consists in greater part of pale reddish-brown to purple siltstone with smaller amounts of sandstone. Thickness in Parleys Canyon about 1,500 feet. Conformably overlies Morrison (?) formation ; underlies Frontier formation.

L. A. Hale, 1960, Wyoming Geol. Assoc. Guidebook 15th Ann. Field Conf., p. 138. Frontier formation, in Coalville anticline, contains a middle red-bed sequence 3,150 feet thick considered by some writers as belonging to Kelvin formation. This sequence is here named Chalk Creek member of Frontier.

Named for exposures at Kelvins Grove, Emigration Canyon, about 8 miles east of Salt Lake City.

Kemp Clay (in Navarro Group)[1]

Upper Cretaceous (Gulf Series) : Northeastern Texas.

Original reference: R. T. Hill, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 7, p. 342–344.

L. W. Stephenson, 1941, Texas Univ. Bur. Econ. Geology Pub. 4101, p. 27–30. Youngest formation in group. Unconformably underlies Midway group; overlies Corsicana marl; in Bexar County, merges westward along strike into Escondido formation. Maximum thickness not determined; well records in Limestone County show thickness of about 370 feet, but that figure may be exceeded in places. Locally formation appears to be no more than 160 feet.

D. L. Frizzell, 1954, Texas Univ. Bur. Econ. Geology Rept. Inv. 22, p. 52–53. Foraminifera described.

Presumable type locality is faulted inlier near Kemp, Kaufman County.

Kemper Member (of Naheola Formation)

[Paleocene] : West-central Alabama and east-central Mississippi.

W. F. Roux, Jr., 1958, Dissert. Abs., v. 19, no. 5, p. 1056. Upper Midway Naheola formation composed of Matthews Landing, Oakhill, and Kemper members.

Type locality and derivation of name not given.

Kenai Formation[1]

Eocene(?) and Oligocene: Central southern Alaska.

Original reference: W. H. Dall and G. D. Harris, 1892, U.S. Geol. Survey Bull. 84, p. 234.

F. H. Moffit, 1954, U.S. Geol. Survey Bull. 989–D, p. 143. In recent years, formation has been restricted to rocks of the type locality on Kenai Peninsula.

F. F. Barnes and E. H. Cobb, 1959, U.S. Geol. Survey Bull. 1058–F, p. 224–229, pls. Only known bedrock in Homer district. Consists of moderately indurated sand, silt, and clay in generally thin and intergrading beds and lenses, interbedded with a few lenses of fine conglomerate and many beds of subbituminous and lignitic coal ranging from a few inches to 7 feet in thickness. Total thickness of formation not known, because neither top nor base has been recognized, but probably exceeds 4,700 feet; this figure is aggregate thickness of sections measured along northwest shore of Kachemak Bay.

Type locality: Homer district, Kenai Peninsula.

Kendall Sandstone Member (of Gypsum Spring Formation)

Jurassic: Western Wyoming.

R. E. Skinner, 1960, Wyoming Geol. Assoc. Guidebook 15th Ann. Field Conf., p. 129–130. Marine type clastics including sandstone, siltstone, and some thin limestones; buff, tan, and red. Thickness in outcrop about 20 to 25 feet. Basal member of formation. Unit has been termed "Nugget Pay" and included in Nugget formation.

Well exposed in southwest part of sec. 25, T. 38 N., R. 110 W., Sublette County. Name derived from nearby Kendall Ranger station and local name for valley in which station is located and sandstone exposed.

Kendall Tuff[1]

Tertiary: Southwestern Nevada.

Original reference: F. L. Ransome, 1909, U.S. Geol. Survey Prof. Paper 66, p. 28, 41.

Named for Kendall mine, Goldfield district.

Kendall Green Slate[1]

Precambrian: Eastern Massachusetts.

Original reference: W. E. Hobbs, 1899, Am. Geologist, v. 23, p. 109–115.

Occurs in Kendall Green area, Middlesex County.

Kendrick Shale (in Breathitt Formation)

Kendrick Shale (in Pottsville Group)[1]

Pennsylvanian: Southeastern Kentucky.

Original reference: W. R. Jillson, 1919, Kentucky Dept. Geology and Forestry, ser. 5, v. 1, p. 96–104.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 88. Marine shale in Breathitt formation; directly overlies Amburgy coal.

R. E. Hauser, 1953, Kentucky Geol. Survey Bull. 13, p. 11, 17. Thickness at type locality 50 feet.

Type locality: (Morse, 1931) On Cow Creek in Floyd County, approximately 15 miles east of Paintsville.

Kenilworth Member (of Blackhawk Formation)

Upper Cretaceous (Montana): Central eastern Utah.

R. G. Young, 1955, Geol. Soc. America Bull., v. 66, no. 2, p. 183, 184–185, figs. 2, 3, pl. 3. Consists of massive cliff-forming basal sandstone, an overlying series of coal-bearing rocks, and offshore bar sandstones behind which they were deposited. Basal sandstone grades into underlying tongue of Mancos shale, has sharply defined top, is white capped, and is medium grained, thick bedded, and buff colored with maximum thickness of 85 feet; crossbedding common in more massive beds. Coal-bearing rocks of about 160 feet of gray to black shale with lenses of white and buff sandstone and four minable coal beds which are (ascending): Kenilworth or Castlegate "D", Gilson, Fish Creek, and Rock Canyon. Separated from Sunnyside member (new) above and Aberdeen member (new) below by tongues of Mancos shale.

Named from exposures near Kenilworth, Carbon County. In Book Cliffs.

Kennebec Formation

Age not stated: West-central Maine.

A. R. Cariani, 1959, Dissert. Abs., v. 19, no. 10, p. 2577. Thinly bedded black sulfide-rich limestones, phyllites, and quartzites. Position and formational status of Kennebec still in doubt.

In Anson quadrangle.

†Kennedy Gravels,[1] Drift

Pleistocene (pre-Wisconsin): Northwestern Montana, and Alberta, Canada.

Original reference: B. Willis, 1902, Geol. Soc. America Bull., v. 13, p. 315, 328–330.

Leland Horberg, 1954, Geol. Soc. America Bull., v. 65, no. 11, p. 1102. Pre-Wisconsin Mountain drift of Glacier Park was described by Willis (1902) as Kennedy gravels and considered a fluvial deposit. Alden (1932, U.S. Geol. Survey Prof. Paper 174) determined its glacial origin and included it in his pre-Wisconsin Mountain drift. Inasmuch as references are clearly to same deposits, original name should be retained. Kennedy drift, which is at least 100 feet thick, includes both till and outwash and in places is cemented by calcium carbonate into tillite and conglomerate. Upper 20 feet in places is weathered and leached, so that residue of insoluble pebbles occur in yellow-brown, limonitic, clayey matrix.

G. M. Richmond, 1960, U.S. Geol. Survey Prof. Paper 400–B, p. B223. Discussion of correlation of alpine and continental glacial deposits of Glacier National Park and adjacent high plains, Montana. Three alpine glaciations occurred. Tills of these three ancient glaciers are all included in Kennedy drift of Horberg (1954). They have no continental counterparts in this region but are correlated with Nebraskan, Kansan, and Illinoian tills of central interior.

Type locality: Gravel mesa, 5,800 feet high, 5 miles east of Chief Mountain, north of Kennedy Creek and 900 feet above it, in northwestern part of Teton County, Mont.

Kenneth Limestone[1]

Upper Silurian or Lower Devonian: North-central Indiana.

Original reference: E. R. Cumings and R. R. Schrock, 1927, Indiana Acad. Sci. Proc., v. 36, p. 76–77.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown on correlation chart in Cayugan series, but may be Devonian.

D. J. McGregor, 1958, Indiana Geol. Survey Bull. 15, p. 37–39. Gray to tan dense cherty and irregularly bedded limestone 30 to 40 feet thick. Overlies Kokomo limestone; underlies Pendleton sandstone. Lower Devonian.

Exposed in quarries at Kenneth Station and vicinity, Cass County.

Kennett Formation[1]

Middle Devonian: Northern California.

Original reference: J. P. Smith, 1894, Jour. Geology, v. 2, p. 591–593, 598.

A. R. Kinkel, Jr., W. E. Hall, and J. P. Albers, 1956, U.S. Geol. Survey Prof. Paper 285, p. 1, 32–38, pl. 1. Composed almost entirely of shale and limestone, but minor beds of shaley tuff and crystal tuff are interbedded with shale near base. Black shale forms lower part; it is commonly a black siliceous, thinly bedded rock which is locally crumpled and cut by a network of tiny quartz veins. Limestone forms upper part and is largely a coral reef. Maximum thickness probably not more than 400 feet; folding and repetition by faulting make it impossible to obtain exact thickness. Overlies Balaklala rhyolite; rhyolitic tuff of Kennett is interbedded with shale and grades downward through transition zone to rhyolitic tuff beds that are part of Balaklala rhyolite; conformably underlies Mississippian Bragdon within mapped area [West Shasta copper-zinc district]; outside area, Kennett has been uplifted by warping and erosional unconformity separates the two formations.

Exposed between Squaw and Backbone Creeks, about 4 miles west of Kennett, on Sacramento River. Exposed in northern part of West Shasta district as discontinuous erosion remnants on present topography of a much more continuous formation. Also exposed in southern part of Behemotosh Mountain quadrangle.

Kennett Limestone[1]

Precambrian: Southeastern Pennsylvania.

Original reference: T. D. Rand, 1900, Philadelphia Acad. Nat. Sci. Proc. 1900, pt. 1, p. 235–242.

Probably named for Kennett Square Station, Chester County.

Kenney Formation

Oligocene, upper, or Miocene, lower: Eastern central Idaho.

A. L. Anderson, 1957, Idaho Bur. Mines and Geology Pamph. 112, p. 13, 14, 16–17, pl. 1. Composed of beds of shale and to lesser extent of sandstone, conglomerate, and locally tuff and bentonite. Conglomerate beds are generally thin and not very persistent and are scattered here and there throughout formation. Much of the shale is light colored and generally somewhat sandy. Beds of sandstone are white or pale buff. Inferred thickness is several hundreds of feet. Passes beneath beds of Geertson and Carmen formations and unconformably overlies Challis volcanics in Baker quadrangle. Underlies Kirtley formation (new name to replace preoccupied Carmen). Thickness about 500 feet in North Fork quadrangle. Late Oligocene or early Miocene.

Named for Kenney Creek along which more or less typical exposures are to be found. Confined to Lemhi Valley, Lemhi County.

Kennicott Formation[1]

Lower Cretaceous: Central Alaska.

Original reference: O. Rohn, 1900, U.S. Geol. Survey 21st Ann. Rept., pt. 2, p. 424–440, pl. 52.

F. H. Moffit, 1938, U.S. Geol. Survey Bull. 894, p. 70–71. Rocks of type locality of Rohn's Kennicott formation in Fourth of July Pass now considered Lower Cretaceous. Those that overlie Upper Triassic rocks and, on paleontologic grounds, properly belong to Kennicott formation include conglomerate, brown sandstone, crumbly gray shale, and black shale.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000): U.S. Geol. Survey. Appears on map legend.

Type locality: In Fourth of July Pass, Copper River region. Occurs on Bear and Fourth of July Creeks between Fohlin Creek and Kennicott Glacier.

Kenosha Shale Member (of Tecumseh Shale)[1]

Pennsylvanian (Virgil Series): Southeastern Nebraska, southwestern Iowa, and northeastern Kansas.

Original reference: G. E. Condra, 1930, Nebraska Geol. Survey Bull. 3, 2d ser., p. 47, 52.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 23. Underlies Ost limestone member; overlies Avoca limestone member of Lecompton formation.

R. C. Moore, 1949, Kansas Geol. Survey Bull. 83, p. 156. Not distinct enough to be treated as subdivision of Tecumseh in Kansas.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 19, fig. 5. Bluish argillaceous shale with *Crurithyris* near base. Thickness about 6½ feet near Thurman, Fremont County. Underlies Ost limestone member; overlies Avoca limestone member of Lecompton limestone.

Type locality: In Missouri River bluffs near mouth of Kenosha Valley, south of King Hill, Cass County, Nebr.

Kensington Granite-Gneiss

Age unknown: Eastern Maryland and District of Columbia.

Ernst Cloos *in* C. W. Cooke and Ernst Cloos, 1951, Geologic map of Prince Georges County and the District of Columbia (1:62,500): Maryland Dept. Geology, Mines and Water Resources. Highly foliated; coarse biotite granite. This youngest crystalline rock is a discordant granodiorite invading the schist in bodies which are too small to be shown on map. The granodiorite may be responsible for a great deal of the metamorphism of this area. Mapped in District of Columbia west of Rock Creek Park.

Ernst Cloos *in* C. W. Cooke and Ernst Cloos, 1953, Geologic map of Montgomery County and District of Columbia (1:62,500): Maryland Dept. Geology, Mines and Water Resources. Mapped in Montgomery County, northward from District of Columbia through Kensington to vicinity of Norwood.

Derivation of name not given, but probably named for occurrence at Kensington, Md.

Kent Bed[1]

Lower Cretaceous (Comanche Series): Southern Kansas.

Original reference: F. W. Cragin, 1895, Am. Geologist, v. 16, p. 383.

Derivation of name not stated.

Kent Till

Pleistocene (Wisconsin) : Northern Ohio and northwestern Pennsylvania.

V. C. Shepps and others, 1959, Pennsylvania Geol. Survey, 4th ser., Bull. G–32, p. 10 (fig. 3), 13 (fig. 4), 31–35, pl. 1. Bluish-gray moderately pebbly to pebbly calcareous loam to sandy loam till deposited during Kent advance in early Cary time. Kent advance followed Mogadore advance and preceded Lavery advance. Name credited to G. W. White (in press).

G. W. White, 1960, U.S. Geol. Survey Bull. 1121–A, p. 2 (table 1), 3 (fig. 1), 5–6. Thickness about 17 feet. Where base is exposed, lies unconformably upon bedrock or Mogadore till. Where Kent does not form surface material, it is commonly overlain unconformably by Hiram till; in places, Windham sand (new) lies between the tills. Locally overlain by Lavery till.

Named for exposures in vicinity of Kent, Portage County, Ohio.

Kentucky Shale[1]

Mississippian : Eastern Kentucky.

Original reference: N. S. Shaler, 1877, Kentucky Geol. Survey, new ser., v. 3, p. 183–186.

Kenwood Beds[1]

Kenwood Member (of Wapsipinicon Formation)

Middle Devonian : Eastern Iowa.

Original reference: W. H. Norton, 1894, Iowa Acad. Sci. Proc., v. 1, pt. 4, p. 23.

E. H. Scobey, 1940, Jour. Sed. Petrology, v 10, no. 1, p. 38 (fig. 1), p. 40. Composed chiefly of interbedded thinly laminated impure limestones and shales. Maximum thickness about 20 feet attained near Cedar Rapids. Underlies Spring Grove member; bluish shale at base rests with sharp lithologic break on Otis member. Kenwood here considered good member name as Independence shale with which it has been correlated is believed to be Lime Creek in age and therefore occupies much higher stratigraphic position. Middle Devonian (?). Type section designated.

Type section: Exposure along Indian Creek in Kenwood Park in northern Cedar Rapids, Linn County.

Kenwood Sandstone[1]

Kenwood Sandstone Member (of New Providence Formation)

Lower Mississippian: Western and northern Kentucky, southern Indiana, and southeastern Wisconsin.

Original reference: C. Butts, 1915, Kentucky Geol. Survey, 4th ser., v. 3, pt. 2, p. 148.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 79, 108, 109–111. Rank reduced to member status in New Providence formation; occurs in Silver Hills facies of formation. Reasons for change are: areal extent is quite limited, it is a local facies feature of what both to north and to south is shale undifferentiated from that beneath; sandstone layers constitute minor part of interval; interbedded shale is of nature of shale below.

F. T. Thwaites, 1947, Michigan Acad. Sci., Arts, and Letters Papers, v. 33, p. 249 [1949]. Kenwood formation at Milwaukee, known only from fossils collected from dump of tunnel, believed to be Misssissippian.

Named for Kenwood Hill, near Louisville, Jefferson County, Ky.

Kenyon Member (of Mount Simon Formation)

Upper Cambrian: Northern Illinois (subsurface).

J. S. Templeton, Jr., 1950, Illinois Acad. Sci. Trans., v. 43, p. 153 (fig. 2), 154–155. Name proposed for thin conglomeratic sandstone overlying Crane member (new). Type section extends from depths of 2,975 to 3,105 feet. Thickness 34 to 130 feet. Where less than 80 feet thick is composed chiefly of coarse-grained sandstone containing quartz granules; where thicker, consists of conglomeratic sandstone interbedded with nonconglomeratic layers. Underlies Lowell member (new).

Type well: Wyman No. 1 (well 7), in NE¼NE¼SE¼ sec. 35, T. 41 N., R. 5 E., Dekalb County. Name derived from Kenyon School, 3¼ miles southeast of type well.

Keokuk Limestone

Keokuk Limestone (in Osage Group)[1]

Lower Mississippian (Osage Series): Iowa, Illinois, western Kentucky, and eastern Missouri.

Original reference: D. D. Owen, 1852, Rept. Geol. Survey Wisconsin, Iowa, and Minnesota, p. 91, 92., Philadelphia.

J. M. Weller, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 131, 132–133. Keokuk limestone listed in Osage group, Valmeyer series. Burlington and Keokuk limestones not readily separable in southwestern Illinois and southeastern Missouri.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 766 (fig. 1), 771, 795. Limestone in Osage group, Iowa series. Classification follows Illinois Geological Survey. Consists of 60 to 80 feet of interbedded limestone and chert with minor amounts of shaly material. Lower 30 feet is very cherty limestone known as Montrose member. In Ste. Genevieve County, Mo., is separated into two parts by unconformity, below which beds are lithologically indistinguishable from Burlington limestone.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 150–156, chart 5. In standard Mississippian section, Keokuk limestone is uppermost formation of Osagean series. Occurs above Burlington limestone and below Warsaw limestone of Meramecian series.

G. G. Huffman and others, 1958, Oklahoma Geol. Survey Bull. 77, p. 14 (fig. 2), 44–46, pls. Described on southwestern flank of Ozark uplift where it consists of massive white to buff and gray-mottled fossiliferous chert; locally interbedded with irregular stringers of blue-gray dense fine-grained limestone. Crinoidal reefs or bioherms present locally. Thickness 0 to 250 feet; average thickness between 60 and 80 feet. Overlies Reeds Spring formation with unconformity. This hiatus represents most or all of Burlington time. Succeeded unconformably by various facies of Moorefield formation, the Hindsville, or locally by Fayetteville shale. Osagean.

Charles Collinson and D. H. Swann, 1958, Geol. Soc. America Guidebook St. Louis Mtg., Field Trip 3, p. 1, 4 (fig. 3). Generalized geologic column for field trip area [western Illinois] shows the Keokuk in Valmeyer series above the Burlington and below the Warsaw.

Named for exposures at Keokuk, Iowa. Well exposed along Soap Creek in quarry in Mississippi River bluff near mouth of creek.

Keonehunehune flow

Recent: Maui Island, Hawaii.

Grote Reber, 1959, Geol. Soc. America Bull., v. 70, no. 9, p. 1245, 1246, pl. 1 (fig. 3). Consists of single flow. Radiocarbon dating gives age of about 650 years.

On southwest side of Haleakala.

Keosauqua Sandstone[1]

Mississippian: Southeastern Iowa.

Original reference: C. H. Gordon, 1895, Jour. Geology, v. 3, p. 304–305.

Named for exposures in southern bank of Des Moines River about 2½ miles below Keosauqua, Van Buren County.

Keota Sandstone Member (of McAlester Formation)

Keota Sandstone Member (of Savanna Sandstone)[1]

Pennsylvanian (Des Moines Series): Eastern Oklahoma.

Original reference: C. W. Wilson, Jr., 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 4, p. 503–520.

M. C. Oakes and M. M. Knechtel, 1948, Oklahoma Geol. Survey Bull. 67, p. 42–44, pl. 1. Reallocated to member status in McAlester formation. Sequence of lenticular sandstone and arenaceous shale beds, locally including one or more thin coal seams. Within town limits of Keota are two sandstone units, each comparable to that described as Keota sandstone member in Muskogee County; these two units and the intervening shale are considered as constituting the Keota within the Cowlington syncline in Haskell County; in the Sanbois and Stigler synclines, only one sandstone unit seems to be present at this horizon. Conformably overlies an unnamed shale that lies above Tamaha sandstone or above the horizon of the Tamaha where the Tamaha is not present; conformably underlies an unnamed shale in upper part of formation.

Type locality: Comprises town of Keota and area immediately adjacent to northwest, Haskell County.

†Keownville Limestone Member (of Ripley Formation)

Upper Cretaceous: Northeastern and east-central Mississippi.

N. F. Sohl, 1960, U.S. Geol. Survey Prof. Paper 331–A, p. 18–20. Commonly less than 100 feet thick and consists of yellowish-brown sandy limestone beds which are no more than 5 feet thick and are interbedded with yellow to dark-blue-gray fossiliferous sand units. At type section, 47 feet of yellow-brown sandy sideritic fossiliferous limestone in beds 1 to 3 feet thick alternate with yellow to gray micaceous fossiliferous layers of sand and represents full thickness of member. These beds are unconformably overlain by 8½ feet of fossiliferous sand and clay of Prairie Bluff chalk; below limestone sequence is about 120 feet of fossiliferous sand and sandstone beds of upper part of Ripley.

Type section: Roadcuts on Mississippi State Route 30, 1.4 to 2.1 miles south of Keownville, Union County, on north-facing slope of Willhite Creek valley and parallel to Daniel Creek, a north-flowing tributary of Willhite Creek, in E½ sec. 31, T. 6 S., R. 4 E.

Kerber Formation[1]

Pennsylvanian: Southern Colorado.

Original reference: W. S. Burbank, 1932, U.S. Geol. Survey Prof. Paper 169.

L. R. Litsey, 1958, Geol. Soc. America Bull., v. 69, no. 9, p. 1147 (fig. 2), 1159–1160. Composite Paleozoic section in northern Sangre de Cristo

Range shows Kerber formation, 0 to 150 feet thick, between Leadville limestone below and Minturn formation above. No fossil or plant remains. On basis of stratigraphic position, may be Morrowan or Atokan.

D. R. Williamson and Lorraine Burgin, 1960, Colorado School Mines Mineral Industries Bull., v. 3, no. 1, p. 11. Correlation chart shows Kerber formation underlying Sharpsdale formation (new).

Named for exposures along Kerber Creek, Bonanza district, Saguache County.

Kereford Limestone Member (of Oread Limestone)[1]

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 45.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2035 (fig. 5). Kereford limestone member of Oread limestone; overlies Heumader shale member; underlies Kanwaka formation. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

T. L. Welp, L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 64, p. 418 (fig. 1), 419. Thickness 7 feet in section measured near Winterset, Madison County.

H. G. O'Connor, 1960, Kansas Geol. Survey Bull. 148, p. 40–41, pl. 1. In Douglas County, consists of 2½ to 9 feet of gray limestone and a calcareous shale beds, which weather light gray to tan. Underlies Jackson Park shale member of Kanwaka shale.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 21, fig. 5. Commonly light to medium gray, fine grained and dense; occurs as one massive bed. Near Red Oak, Montgomery County, it is a 2-foot massive finely oolitic bed with *Osagia* in upper part, and fusulinids throughout. Overlies Heumader shale member; underlies Kanwaka shale. Absent in some areas.

Type locality: Kereford quarry at south edge of Atchison, Atchison County, Kans.

Kerens Member (of Wills Point Formation)[1]

Paleocene: Northeastern Texas.

Original reference: F. B. Plummer, 1933, Texas Univ. Bull. 3232, p. 530, 535, 559, 562.

Mackenzie Gordon, Jr., J. I. Tracey, Jr., and M. W. Ellis, 1958, U.S. Geol. Survey Prof. Paper 299, p. 25. Upper member of Wills Point formation. Includes Wortham aragonite lentil. Overlies Mexia member.

Type locality: Exposures along Trinity River north of St. Louis & Southwestern Railroad, east of Kerens, Navarro County.

Kern Park Formation

See Mon Bluff Formation.

Kern River Group,[1] Formation,[1] or Series[1]

Miocene, upper, to Pliocene, middle: Southern California.

Original reference: F. M. Anderson, 1905, California Acad. Sci. Proc., 3d ser., v. 2, p. 187–188, 191.

R. W. Wilson, 1937, Carnegie Inst. Washington Pub. 487, p. 13, 34. Middle Pliocene on the basis of vertebrate fauna.

C. C. Church, 1958, San Joaquin Geol. Soc. [Guidebook] Spring Field Trip May 17, p. 15. Formation in outcrop unconformably overlies Mon Bluff formation (new) in vicinity of Kern River. Unconformably overlies lower part of Round Mountain silt north of Poso Creek fault. There is evidence from downdip well sections that formation rests with transitional contact on Santa Margarita sand indicating transgression of upper part of unit onto its lower members and then onto middle Miocene rocks. Such relation indicates upper Miocene age for unit in downdip areas. Upper Miocene-Pliocene.

Exposed on Kern River, 2 to 6 miles east of Oil City, Kern County.

Kernville Series[1]

Pre-Cretaceous: Southern California.

Original reference: W. J. Miller, 1931, California Univ. Pub., Bull. Dept. Geol. Sci., v. 20, no. 9, p. 335–343.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 512, table 4. Age not certain; probably Carboniferous. Intruded by Summit gabbro.

T W. Dibblee, Jr., and C. W. Chesterman, 1953, California Div. Mines Bull. 168, p. 18. Pampa schist (new) may be phase of Kernville series, but its relationship to Kernville is obscured by granitic intrusions.

E. M. MacKevett, Jr., 1960, U.S. Geol. Survey Bull. 1087–F, p. 176–180, 195, pl. 1. Consists mainly of mica schist and impure quartzite but includes some calc-hornfels and marble Older than Isabella granodiorite that is considered Late Cretaceous on basis of lead-alpha determinations.

Named for exposures in vicinity of Kernville, Kern County.

Kerr Ranch Schist

Pre-Franciscan (pre-Devonian?): Northwestern California.

G. A. Manning and B. A. Ogle, 1950, California Div. Mines Bull. 148, p. 7, 13–18, pls. 1, 2. Series of quartz-muscovite schists, green schists, semischists, and slates; only slightly metamorphosed. In fault contact with overlying Franciscan. Thickness undetermined. Name replaces term Redwood Creek schist, used by authors in unpublished theses.

Type locality: Near Kerr Ranch in southeastern part of Blue Lake quadrangle, Humboldt County.

Kerton Creek Coal Member (of Carbondale Formation)

Pennsylvanian: Northern and western Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 35, 47 (table 1), pl. 1. Assigned member status in Carbondale formation (redefined). Occurs above Pleasantview sandstone member and below Summum coal (No. 4) member. Coal named by Ekblaw (1930, Illinois Acad Sci. Trans., v. 23, no. 3); Wanless (1957, Illinois Geol. Survey Bull. 82) credited name to W. V. Searight, unpublished manuscript. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: North side of Kerton Creek, NE¼NE¼ sec. 15, T. 3 N., R. 2 E., Fulton County.

Kessler Limestone Member (of Bloyd Shale)[1]

Kessler Limestone Lentil (in Bloyd Shale)

Lower Pennsylvanian (Morrow Series) : Northwestern Arkansas and northeastern Oklahoma.

Original reference: F. W. Simonds, 1891, Arkansas Geol. Survey Ann. Rept. 1888, v. 4, p. 26, 103-105.

C A. Moore, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 3, p. 430–432. Geographically extended into Adair County, Okla., where its maximum thickness is less than 10 or 12 feet. Lies immediately below the Atoka sandstone.

W. H. Easton, 1942, Arkansas Geol. Survey Bull. 8, p. 25–26. Referred to as a lentil within Bloyd shale.

L. G. Henbest, 1953, Am Assoc. Petroleum Geologists Bull., v. 37, no. 8, p. 1942. Bloyd shale consists of (ascending) Brentwood limestone member, Woolsey member (new), and an unnamed shale division which includes the Kessler limestone lentil and which represents upper half to two-thirds of formation. Kessler underlies Greenland sandstone member (new) of Atoka formation.

Named for Kessler Mountain, Washington County, Ark.

†Ketchikan Series[1]

Carboniferous and Upper Triassic: Southeastern Alaska.

Original reference: A. H. Brooks, 1902, U.S. Geol. Survey Prof. Paper 1, p 40–52, map.

Occurs along east margin of Gravina Island, west margin of Revillagigedo Island, and in vicinity of Ketchikan, on both sides of Tongass Narrows, on Cleveland Peninsula, along George Inlet, on east arm of Behm Canal, Ketchikan region.

Ketchum Bluff Conglomerate[1]

Pennsylvanian : Central southern Oklahoma.

Original reference: J. R. Bunn, 1930, Oklahoma Geol. Survey Bull. 4OPP, p. 11.

Exposed on Ketchum's Bluff along Red River, in sec. 24, T. 7 S., R. 6 W., and adjoining sections to the east in Jefferson County

Ketona Dolomite[1]

Upper Cambrian: Northern central Alabama.

Original references: C. Butts, 1910, U.S. Geol. Survey Bull. 400, p. 14; U.S. Geol. Survey Geol. Atlas, Folio 175, p. 3.

C. E. Resser, 1938, Geol. Soc. America Spec. Paper 15, p. 17. Coarsely crystalline light-gray thick-bedded dolomite 200 to 250 feet thick. Overlies Brierfield dolomite in Sixmile Creek; in western Alabama overlies *Blountia* zone of Nolichucky, here it is 400 to 600 feet thick. Underlies Bibb dolomite.

T. N. McVay and L. D. Toulmin, 1945, Alabama Geol. Survey Bull. 55, p. 23. Listed with formations of Cambrian or Ordovician age.

Named for exposures at Ketona, Jefferson County

Kettle Meta-Andesite[1]

Kettle Formation

Pennsylvanian: Northern California.

Original reference: J. S. Diller, 1908, U.S. Geol. Survey Bull. 353.

P. A. Lydon, T. E. Gay, Jr., and C W. Jennings, 1960, Geologic map of California Westwood sheet (1:250.000): California Div. Mines. Formation consists of fossiliferous andesite and dacite breccia, tuff, conglomerate, and sills or flows. Mapped with Jurassic and (or) Triassic metavolcanic rocks.

Named for development around Kettle Rock, northeast of Taylorsville, Plumas County.

Kettleman Lake Bed[1]

Pliocene(?): Southern California.

Original reference: J. G. Cooper, 1894, California Acad. Sci Proc., 2d ser., v. 4, p. 167.

Type locality not stated, but beds are probably the fresh-water deposits mentioned as occurring on west border of Kettleman Plains.

Kettle River Formation[1]

Oligocene(?): Southern British Columbia, Canada, and northeastern Washington.

Original reference: R. A. Daly, 1912, Canada Geol. Survey Rept. Mines Mem. 38, maps.

Mapped along Kettle River, British Columbia, north of 49th parallel.

Keuka Flagstone[1] (in Standish Formation)

Keuka Flagstone Lentil (in Starkey Tongue of Sherburne Formation)

Upper Devonian: West-central New York.

Original reference: I. W. Fox, 1932, Am. Assoc. Petroleum Geologists Bull., v. 16, no. 7, p. 677, 683, 687.

W. L. Grossman, 1944, Geol. Soc. America Bull., v. 55, no. 1, p. 67, pl. 1. Reallocated. Lentil occurs at top of Starkey tongue of Sherburne formation. Described as cross-laminated coarse quartz siltstone with considerable calcite.

Wallace de Witt, Jr., and G. W. Colton, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2825. A highly cross-laminated, ripple-marked layer of siltstone 1 to 2 inches thick is present at base of upper third of West River shale member of Genesee in most exposures of member between Lake Erie and Canandaigua Lake. This key bed, which is present in more than 500 square miles in western and west-central New York, was traced eastward to Keuka Lake where it was found to be the 3- to 4-inch Bluff Point flagstone of Torrey (Torrey and others, 1932, Am. Petroleum Inst. Div. Production Paper 826–4A), the same bed that was named Keuka flagstone by Fox (1932).

Named for excellent exposures on all shores of Keuka Lake.

Kevin Shale Member (of Marias River Shale)

Upper Cretaceous: Northwestern Montana.

W. A. Cobban and others, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2792 (fig. 3), 2795–2796; 1959, Billings Geol. Soc. [Guidebook] 10th Ann. Field Conf., p. 89 (fig. 1), 91–92. Subdivided into three units on basis of relative abundance of bentonite beds and on lithology of concretions. Lowest unit characterized by many beds of bentonite, grey limestone concretions and concretionary limestone, and some brown prismatic calcite having cone-in-cone structure. Middle unit has numerous concretionary layers of ferruginous limestone and dolostone that weather dark reddish brown to very dusky red. Also contains thin but very widespread conglomerate bed—MacGowan concretionary bed (new). Top unit contains several concretionary limestones that weather yellowish gray, some beds of concretionary dolostone that weather reddish brown, and a few thin layers of bentonite and shaly sandstone; upper half of unit locally calcareous. Thickness of member about 620 feet at type section. Top marked by thin persistent layer of gray bentonite on north side of Kevin-Sunburst dome. Disconformably overlies Ferdig shale member (new); underlies Telegraph Creek formation.

Type section: Composite from outcrops a few miles north and northwest of Kevin in secs. 3, 4, 12, 15, and 17, T. 35 N., R. 3 W., Toole County. Named from town of Kevin on Shelby-Sweetgrass branch of Great Northern Railway in SW¼ sec. 35, T. 35 N., R. 3 W., Toole County, Shelby quadrangle, northwest flank of Kevin-Sunburst dome.

Kewanee Group

Middle Pennsylvanian: Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 8 (fig. 1), 26 (fig. 4), 31–36, 45–46 (table 1), pl. 1, geol. sections. Middle group of Pennsylvanian formations. Comprises Spoon (new) and Carbondale formations. Overlies McCormick group (new); underlies McLeansboro group. Characterized by widespread development of minable coals. Sandstones compose about 25 percent of group. Limestones commonly 1 to 5 feet thick. Presentation of new rock-stratigraphic classification of Pennsylvanian in Illinois. Cyclical classification is retained but is independent of rock-stratigrapic classification.

Type locality: Vicinity of Kewanee, Henry County.

Keweenawan Series[1]

Keweenawan Group

Precambrian: Michigan, Minnesota, and Wisconsin, and Canada.

Original references: T. B. Brooks, 1876, Am. Jour. Sci., 3d ser., v. 11, p. 206–211; F. D. Adams and others, 1905, Jour. Geology, v. 13, no. 2, p. 102.

F. F. Grout and G. M. Schwartz, 1939, Minnesota Geol. Survey Bull. 28, p. 12–15. Lower Keweenawan includes Puckwunge formation (as used by Winchell, 1897); middle Keweenawan includes Keweenaw Point volcanics (new) and Beaver Bay complex.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 10, 11–23. Geological column shows upper Keweenawan includes Lake Superior series, made up of Fond du Lac beds (Orienta) and Hinckley sandstone (Devils Island). The Keweenawan underlies St. Croixian series and occurs above the Huronian.

F. F. Grout and others, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1017–1078. Keweenawan group overlies Animikie group. Group in Minnesota includes Puckwunge formation in lower part; Keweenaw Point volcanics, Beaver Bay complex and Logan intrusives, Duluth gabbro, and scattered intrusives in middle part; Fond du Lac beds and Hinckley sandstone in upper part. Unconformably underlies Cambrian (Upper Cambrian in Minnesota). Upper Keweenawan of Minnesota correlates with Oronto and Bayfield groups of Wisconsin and Michigan.

H. M. Gehman, 1958, Minnesota Univ. Center for Continuation Study, Gen. Ext. Div., Inst. of Lake Superior, Geology, Apr. 21–22, p. 1. Three gabbroic intrusions (Beaver River, Beaver Bay ferrogabbro, and Black Bay) with minor associated rock types form Beaver Bay complex in southeastern Lake County, Minn. The gabbros intrude middle Keweenawan North Shore volcanic group (new).

Named for occurrence on Keweenaw Peninsula, northern Michigan.

Keweenaw Point Volcanics

Precambrian (middle Keweenawan): Northern Michigan and eastern Minnesota.

F. F. Grout and G. M. Schwartz, 1939, Minnesota Geol. Survey Bull. 28, p. 12, 13. Term applied to series of Middle Keweenawan flows and associated sediments which are best known as they appear on Keweenaw Point (Michigan) in Lake Superior. Irving (1883, U.S. Geol. Survey Mon. 5) used term Keweenaw series, and Van Hise and Leith (1911, U.S. Geol. Survey Mon. 52) used phrase Keweenawan series for rocks here named Keweenaw Point volcanics. Irving limited his Keweenaw series to the volcanic and associated rocks and some sediments conformably above, using term Keweenawan series for all Keweenawan rocks, including sediments above, below, and interbedded with volcanics. Term Keweenaw Point volcanics should therefore be applied as a formation to flows and associated fragmental rocks included by Irving in lower division of Keweenaw series and by Van Hise and Leith in middle divisions of Keweenawan series. Table of formations shows Keweenaw Point volcanics above Puckwunge formation and below Beaver Bay complex.

G. M. Schwartz, 1949, Minnesota Geol. Survey Bull. 33, p. 18, 37. Estimated thickness 20,800 feet. Overlies Puckwunge formation.

F. F. Grout and others, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1021 (table 3), 1053–1054. Included in middle part of Keweenawan group. Also referred to as Keweenawan Point volcanics.

Named for occurrence at Keweenaw Point (Michigan) in Lake Superior.

†Key Sandstone[1]

Lower Ordovician: Northern Arkansas.

Original reference: G. I. Adams and E. O. Ulrich, 1904, U.S. Geol. Survey Prof. Paper 24, p. 20, 95–97.

Named for Key, near Rogers, Benton County.

Keyhole Sandstone Member (of Fall River Formation)

Lower Cretaceous: Western South Dakota and northeastern Wyoming.

R. E. Davis and G. A. Izett, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 11, p. 2745–2750. Generally light-brown to medium-brown very fine grained massively bedded cross-stratified sandstone, commonly containing iron-cemented concretions ranging from less than an inch to about 1 foot in diameter and, less commonly, gray calcareous concretions ranging from a few inches to nearly 4 feet in diameter. Thickness ranges from 15 to about 80 feet and averages about 30 feet; at type section 31.6 feet. Underlies upper silty unit of Fall River formation with sharp contact; overlies lower silty unit with gradational contact.

Type section: In NE¼SE¼ sec. 21, T. 51 N., R. 66 W., Crook County, Wyo., about one-fourth mile north of Keyhole Dam on Belle Fourche River. Carlile quadrangle. Traced throughout large part of northern Black Hills.

Key Largo Limestone[1]

Pleistocene: Southern Florida.

Original reference: S. Sanford, 1909, Florida Geol. Survey 2d Ann. Rept., p. 209, 214–218, table.

M. C. Schroeder and E. W. Bishop, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 9, p. 2183. Pleistocene deposits older than Pamlico sand (which represents youngest Pleistocene) include Miami oolite, Fort Thompson formation, Anastasia formation and Key Largo limestone, all more or less contemporaneous in age.

Named for exposures in cuts and borrow pits on Key Largo, at frequent intervals from south shore of Lake Surprise to west end of island at Tavernier Creek, a distance of 15 miles.

Keyser Limestone

Keyser Group

Keyser Limestone (in Cayugan Group)

Keyser Limestone Member (of Helderberg Limestone)[1]

Upper Silurian and Lower Devonian(?): Northern West Virginia, western Maryland, Pennsylvania, and western Virginia.

Original reference: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, p. 563, 590, 591, pl. 28.

F. M. Swartz, 1929, U.S. Geol. Survey Prof. Paper 158–C, p. 29–38. In West Virginia, formation includes Big Mountain shale member (new); near Clifton Forge, Va., includes Clifton Forge sandstone member (new). Lower Devonian.

F. M. Swartz, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 29–91. Keyser limestone separated from Helderberg group and tentatively assigned to Silurian.

C. K. Swartz and F. M. Swartz, 1941, Geol. Soc. America Bull., v. 52, no. 8, p. 1182–1184. Term Keyser group proposed for three formations of Keyser age: Decker sandstone, Rondout limestone, and Manlius limestone. Group, as thus defined, extends from southeastern Pennsylvania to southeastern New York. Bossardville limestone immediately underlying Keyser group is uppermost formation of undoubted Silurian in area. Keyser limestone presents both Silurian and Devonian aspects. It is tentatively assigned to Silurian.

J. R. Mills and R. N. Taylor, 1949, Pennsylvania Acad. Sci. Proc., v. 23, p. 49–57. Silurian-Devonian relationships discussed in Schuylkill County. Keyser limestone (Silurian, Cayugan group) overlies Bossardville limestone; underlies Ridgeley sandstone (Devonian, Oriskany group).

F. G. Lesure, 1957, Virginia Polytech. Inst. Bull., Engineering Expt. Sta. Ser. 118, p. 19 (table 1), 20 (table 2), 42–45, pls. Formation described in Clifton Forge area where it includes Clifton Forge sandstone member in lower part. Thickness about 116 feet. Overlies Tonoloway limestone; underlies Coeymans limestone. Upper Silurian.

H. H. Arndt and others, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 4–5, 13–14, 28. Keyser formation lies immediately above and is transitional with Tonoloway formation throughout most of Pennsylvania. Underlies Helderberg. Thickness 125 to 200 feet.

W. A. Oliver, Jr., 1960, U.S. Geol. Survey Bull. 1111–A, p. 4. Corals comparable to Beck Pond species are found in Coeymans limestone, Helderberg age, in New York, and in Keyser limestone. Late Silurian and Early Devonian(?) age, in Maryland and West Virginia. *Halysites* indicates Late Silurian age for at least part of the formation.

Named for exposures at Keyser, Mineral County, W. Va.

Keystone Sandstone (in Pocahontas Group)

Keystone Sandstone (in Pottsville Group)[1]

Pennsylvanian: Southern West Virginia.

Original reference: R. V. Hennen and R. M. Gawthrop, 1915, West Virginia Geol. Survey Rept. Wyoming and McDowell Counties, p. 237.

H. R. Wanless, 1939, Geol. Soc. America Special Paper 17, p. 88. Included in lower part of Pocahontas group.

Exposed at Keystone, McDowell County.

†Key West Oolite[1]

Pleistocene: Southern Florida.

Original reference: E. Sanford, 1909, Florida Geol. Survey 2d Ann. Rept., p. 209, 218–221, table opposite p. 50.

Crops out on shores of Harbor Key and Content Key, and on most of keys to south and southwest, and forms surface of Boca Grande, 10 miles west of Key West.

Kialagvik Formation[1]

Middle Jurassic: Southwestern Alaska.

Original reference: S. R. Capps, 1923, U.S. Geol. Survey Bull. 739, p. 90, 91, 94, map.

L. B. Kellum, 1945, New York Acad. Sci. Trans., ser. 2, v. 7, no. 8, p. 203 (table 1), 205, 208 (table 2). Subdivided into (ascending) Aleuts and Kolosh members (new). Thickness 1,600 feet. Underlies Tuxedni formation; overlies Bidarka formation (new). Lower Jurassic.

C. E. Kirschner and D. L. Minard, 1948, U.S. Geol. Survey Oil and Gas Inv Prelim. Map 95 [1949]. Oldest Jurassic marine strata exposed on Iniskin Peninsula. Consists of about 2,500 feet of siltstone, sandstone, and conglomerate. Divided into lower unnamed sandy shale member and upper unit, the Gaikema sandstone member (new). Siltstone member predominantly of dark-gray arenaceous siltstone which weathers light brown: fine-grained sandstone beds present throughout; approximately 1,600 feet thick.

R. W. Imlay, 1953, U.S. Geol. Survey Prof. Paper 249–B, table 5, facing p. 60. Age given as Middle Jurassic for exposures at Wide Bay. Underlies Shelikof formation. Gaikema sandstone and unnamed underlying members reassigned to Tuxedni formation.

Forms bluffs along beach of northwest shore of Kialagvik Bay from near mouth of Pass Creek to southwest end of bay. Recognized at least as far south along Alaska Peninsula as Wide Bay.

Kiamichi Formation (in Fredericksburg Group)

Kiamichi Clay Member (of Georgetown Formation)

Kiamichi Formation (in Washita Group)[1]

Lower Cretaceous (Comanche Series): Central southern and southeastern Oklahoma and northeastern Texas.

Original reference: R. T. Hill, 1891, Geol. Soc. America Bull., v. 2, p. 504, 515.

J. F. Smith, Jr., 1940, Geol. Soc. America Bull., v. 51, no. 4, p. 601 (fig. 2). Geologic map of Sierra Blanca area, Texas, shows Kiamichi as upper formation of Fredericksburg group. Overlies Finlay formation; underlies Washita group.

F. E. Lozo, Jr., 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 8, p. 1060–1080. Discussion of bearing of Foraminifera and Ostracoda on Lower Cretaceous Fredericksburg-Washita boundary of north Texas. On the basis of ostracode affinities, Kiamichi is uppermost formation of Fredericksburg group. At exposure studied, there is no conclusive physical evidence of hiatus between Kiamichi and overlying Duck Creek formation. Contact with underlying Goodland not exposed.

E. R. Leggat, 1957, Texas Board of Water Engineers Bull. 5709, p. 13 (table 2), 27–31, pls. In Tarrant County, Tex., the Kiamichi, uppermost formation of Fredericksburg group, crops out in narrow sloping band in bluffs overlooking Clear Fork and West Fork of Trinity River. Consists of dark-blue to brownish-yellow marl, thin limestone, and flaggy sandstone. Lower half is marly, contains thin limestone and sandstone layers, overlain by 8 feet of thin limestone ledges alternating with marl in which *Gryphaea navia* is abundant and distinctive. Upper part is marly and less fossiliferous. Thickness 0 to 40 feet; thins southward. Overlies Goodland limestone; underlies Duck Creek formation.

O. B. Shelburne, 1959, Texas Univ. Bur. Econ. Geology Pub. 5905, p. 105–130. Described in central Texas where it is uppermost formation in Fredericksburg group. Enclosed by Edwards limestone below and Georgetown limestone above. Thickness 25 feet near Blum in Hill County; thins southward along outcrop and disappears in southern McLennan County. Twenty stratigraphic sections measured and described from surface exposures in southern Fort Worth Prairie in Hill, Bosque, Coryell, McLennan, and Bell Counties.

B. F. Perkins, 1960, Geol. Soc. America Mem. 83, p. 9 (fig. 3), 12 (fig. 4), 22–24, pls. 1, 2. In this report [Fort Worth-Weatherford area], Kiamichi is considered basal formation in Washita group. Consists chiefly of yellow and bluish-gray calcareous and arenacous marls, flaggy limestone, and fissile sandstones. Thickness 25 to 35 feet. Underlies Duck Creek formation, possible unconformity; overlies Benbrook limestone member (new) of Goodland formation.

W. J. Fox and O. N. Hopkins, Jr., 1960, Baylor Geol. Soc. Guidebook 5th Field Conf., p. 88, 90, pl. 14. In this report [Grand and Black Prairies, east-central Texas], Kiamichi clay is considered basal member of Georgetown limestone; underlies Duck Creek member. Generally found in outcrops on streams that have cut into underlying Edwards and Comanche Peak formations. Thickness as much as 10 feet; consists of black to dark-gray clays with several 6- to 10-inch limestone beds.

Named for historic plains of Kiamitia (correctly spelled Kiamichi) River near Fort Towson, Choctaw County, Okla.

Kiawa Mountain Formation

Precambrian: Central northern New Mexico.

Fred Barker, 1958, New Mexico Bur. Mines Mineral Resources Bull. 45, p. 1, 10, 24, pl. 1. Defined as the quartzite including and overlying the Big Rock conglomerate and overlying the Moppin metavolcanic series from

Cleveland Gulch to Jawbone Mountain. Consists of (ascending) Big Rock (new) conglomerate member, lower quartzite member, amphibolite member, Jawbone (new) conglomerate member, and upper quartzite member, Several thousand feet thick.

Exposed on Kiawa Mountain and in other areas of Las Tablas quadrangle.

Kibbey Sandstone (in Big Snowy Group)

Kibbey Sandstone Member (of Quadrant Formation)[1]

Upper Mississippian: Central northern Montana.

Original reference: W. H. Weed, 1899, U.S. Geol. Survey Geol. Atlas, Folio 55.

W. H. Scott, 1935, Geol. Soc. America Proc. 1934, p. 367; 1935, Jour. Geology, v. 43, no. 8, pt. 2, p. 1026–1027. Included in Big Snowy group (new).

E. S. Perry, 1937, Montana Bur. Mines and Geology Mem. 3, p. 16. In type locality, Big Snowy group comprises (ascending) Kibbey, Otter, and Heath formations. Kibbey, 130 feet thick, consists of red to brown shaly or calcareous fine-grained sandstone.

O. A. Seager, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 5, p. 863. In subsurface in Cedar Creek anticline, southeastern Montana, overlies Charles formation (new).

L. R. Laudon, 1955, Billings Geol. Soc. Guidebook 6th Ann. Field Conf., p. 210. Kibbey, Heath, Otter, and Amsden are believed to represent shore facies of various parts of early Pennsylvanian seas.

L. S. Gardner, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 2, p. 333 (fig. 2), 334 (fig. 3), 341–342, 346–347. Thickness 220 feet in composite standard section of revised Big Snowy group. Underlies Otter formation; unconformably overlies Mission Canyon limestone of Madison group.

Named from Kibbey post office, Fort Benton region, central Montana.

Kickapoo Beds[1]

Pleistocene (Wisconsin): Central western Illinois.

Original reference: C. O. Sauer, 1916, Illinois Geol. Survey Bull. 27.

Well developed about mouth of North Kickapoo Creek, Illinois Valley.

†Kickapoo Limestone[1]

Pennsylvanian: Eastern Kansas.

Original reference: E. Haworth and J. Bennett, 1908, Kansas Acad. Sci. Trans., v. 21, pt. 1, p. 81.

Named for Kickapoo, Leavenworth County, Kans., 5 miles south of Iatan, Platte County, Mo.

†Kickapoo Marl[1]

Upper Cretaceous (Gulf Series): Northeastern Texas.

Original reference: R. T. Hill, 1894, Geol. Soc. America Bull., v. 5, p. 308.

Derivation of name not stated.

Kickapoo Creek Group

Pennsylvanian (Lampasas): North-central Texas (subsurface and surface).

M. G. Cheney, 1947, Jour. Geology, v. 55, pt. 2, p. 209–210. Proposed for section between Millsap Lake group (restricted) and Bend group; that is, from disconformity at or near top of Dennis Bridge limestone down to top of Smithwick. Upper 200 feet of group crops out between villages of Dennis and Lipan, but for the most part group must be studied from well samples. Well data indicate that approximately 2,600 feet of section should be assigned to group in southwestern Parker County and 3,500 feet or more in Fort Worth basin. Stratigraphic section assigned to group includes Rayville (new), Parks, and Caddo Pool formations which extend from depths of 380–1,350, 1,350–2,125, and 2,125–3,000 feet, respectively, in type wells. Kickapoo Creek group proposed in preference to elevation of Parks formation to group status as suggested in 1945.

Some reports place Kickapoo Creek group in Strawn series.

Type section: Logs of Gilbert No. 1 and Wheeler No. 1 wells of southeastern Parker County, 5 miles northeast of Lipan. Name derived from Kickapoo Creek of southwestern Parker and northwestern Hood Counties.

Kickapoo Falls Limestone (in Millsap Lake Formation)[1]

Kickapoo Falls Limestone Member (of Dickerson Formation)

Kickapoo Falls Limestone Member (of Lazy Bend Formation)

Pennsylvanian (Strawn): Central northern Texas.

Original reference: F. B. Plummer, 1919, Am. Assoc. Petroleum Geologists Bull., v. 3, p. 138.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Shown on correlation chart as Kickapoo Falls limestone member of Lazy Bend formation. Occurs below Dennis Bridge limestone member; occurs above Dickerson formation.

M. G. Cheney and others, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 2. p. 163. Kickapoo Falls limestone may be classified as top member of Dickerson formation in harmony with common practice in this region [Texas] of placing important limestone at top of formation.

Leo Hendricks, 1957, Texas Univ. Bur. Econ. Geology Pub. 5724, p. 12–13. On basis of studies in Kickapoo Creek valley and Dennis area on Brazos River, Kickapoo Falls limestone believed to occupy slightly higher stratigraphic position than Dennis Bridge limestone.

Named for prominent exposures at Kickapoo Falls on Kickapoo Creek, in northern edge of Hood County.

Kidd Member (of Salem Limestone)

Mississippian (Valmeyer Series): Southwestern Illinois.

J. W. Baxter, 1959, Dissert. Abs., v. 19, no. 11, p. 2910. Salem limestone subdivided into four members [sequence not indicated] to which names Kidd, Fults, Chalfin, and Rocher are assigned. Kidd member is skeletal calcarenite composed of medium- to coarse-grained crinoid columnals and fine bryozoan debris.

J. W. Baxter, 1960, Illinois Geol. Survey Circ. 284, p. 2, 6–7, 12, 19–22, pl. 1. Typically consists of gray or brownish-gray, fine- to coarse-grained limestone composed of fragmented fossils, chiefly crinoid columnals and bryozoan detritus. In most outcrops in Monroe County, only upper part of member can be observed because lower contact is either below level of bottomland or covered by faults. East of village of Kidd, Warsaw-Salem contact rises above talus slopes where an anticline intersects bluff southwest of Renault. At this location, the Kidd is about 90 feet thick. Underlies Fults member; overlies Warsaw formation.

Type section: NE¼ sec. 1, T. 5 S., R. 10 W., Monroe County. Named from village of Kidd.

Kiddville Limestone[1]

Lower or Middle Devonian: East-central Kentucky.

Original reference: A. F. Foerste, 1906, Kentucky Geol. Survey Bull. 7, p. 92, 93.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart below Boyle limestone. Lower or Middle Devonian.

Named for hamlet 1 mile north of Indian Fields, Clark County.

Kiekie Volcanic Series

Pleistocene: Niihau Island, Hawaii.

H. T. Stearns, 1946, Hawaii Div. Hydrography Bull. 8, p. 91; H. T. Stearns and G. A. Macdonald, 1947, Hawaii Div. Hydrography Bull. 12, p. 14–15 (table), 19–24, 45–49; D. A. Davis and G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 102–103. Olivine basalts and vitric-lithic tuff cones. Thickness above sea level as much as 290 feet; believed to rest on bench cut into Paniau lavas (new) 300 feet below sea level.

Form low coastal plain of Niihau.

Kiewitz shale zone (in Stoner Limestone Member of Stanton Formation)[1]

Pennsylvanian (Missouri Series): Southeastern Nebraska.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 42, 55.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 32. Zone consisting of grayish calcareous fossiliferous shale 3 feet thick. Underlies unnamed limestone unit; overlies Dyson Hollow limestone zone or member (new).

Named for exposures in Kiewitz quarry located in Platte Valley bluffs west of Meadow Station, Sarpy County.

Kiger Group (in Cimarron Series)

Kiger division (in Cimarron Group[1] or Series)

Permian: Central southern Kansas and northwestern Oklahoma.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 3, 39.

G. H. Norton, 1939, Am. Assoc. Petroleum Geologists Bull., v. 23, no. 12, p. 1803–1813. Cimarron series in Kansas includes all Permian redbeds overlying salt-bearing and gypsum-bearing gray shales of Wellington formation. These redbeds were earlier divided by Cragin into Salt Fork and Kiger divisions. The Kiger includes strata from base of Whitehorse sandstone to base of Big Basin formation.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 25, 26. Referred to as group in Cimarron series. Data in this report are from subsurface records.

Named for Kiger Creek, Clark County, Kans.

Kigluaik Group[1]

Lower Paleozoic or older: Northwestern Alaska.

Original reference: A. H. Brooks, G. B. Richardson, and A. J. Collier, 1901, Reconn. in Cape Nome and Norton Bay regions, Alaska, in 1900: U.S. Geol. Survey Spec. Pub., p. 27, map.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000): U.S. Geol. Survey. Appears on map legend.

First found in heart of Kigluaik Mountains, Seward Peninsula.

Kiheki Sandstone Member (of Vamoosa Formation)

Pennsylvanian (Virgil Series): Northeastern Oklahoma.

W. F. Tanner, 1956, Oklahoma Geol. Survey Circ. 40, p. 45, pl. 1. Name applied to single, more-or-less continuous sandstone ledge, 5 to 25 feet thick, that occurs in the shale interval between the Cheshewalla and the Labadie members. Commonly occurs within 30 feet below the Labadie, or within 50 to 75 feet above the Cheshewalla sandstone.

Type section: Along road in sec. 25, T. 26 N., R. 10 E., Osage County. Named for siding and cattle loading platform on Missouri, Kansas and Texas Railroad in sec. 3, T. 25 N., R. 10 E.

Kii Point Limestone

Pleistocene or Recent: Oahu Island, Hawaii.

C. K. Wentworth and J. E. Hoffmeister, 1939, Geol. Soc. America Bull., v. 50, no. 10, p. 1560–1561. Wedge-shaped mass of limestone composed chiefly of oyster and barnacle shells. Maximum thickness 30 feet; thickness 20 feet at sea level; pinches out at height of 45 feet. Basal 6 feet consists of irregularly imbricated oyster shells and large number of barnacle shells; in next 2 to 4 feet oysters become less numerous and barnacles more numerous; formation grades to calcareous sandstone composed of beach detritus.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6 Océanie, fasc. 2, p. 103. Rests on eroded surface of Ulupau tuff; overlain by old alluvium. Pleistocene or Recent.

Type locality: Kii Point. Crops out as two small patches on east side of Ulupau Peninsula, one at Kii Point and the other about 1,000 feet to south; also small exposure on northwest side of peninsula.

Kilbeck Granite Gneiss

Precambrian: Southern California.

J. C. Hazzard and E. F. Dosch, 1937, (abs.) Geol. Soc. America Proc. 1936, p. 309. Defined as being younger than Fenner gneiss (new). In contact with lower member of Essex series (new).

Occurs in southern end of Old Woman Mountains, San Bernardino County.

Kilby Formation

Pleistocene: Eastern Virginia.

W. E. Moore, 1956, Virginia Acad. Sci., Geology sec., Field Trip Guidebook, no pagination. Composed of clayey sands and gravels; base characterized over wide areas by thin cobble and boulder zone which contains boulders of exceptional size. Plates and concretions of limonite occur at contact with Sedley formation (new). Overlies Sedley and directly underlies both Sunderland and Wicomico terrace surfaces. New formation names necessary because names Sunderland formation and Wicomico formation are meaningless. Both of these terraces are underlain by same formation, not two different formations as previously believed. Terrace as used here refers to land form only and does not refer to nor imply existence of any deposits genetically related to them.

Area discussed is south of James River.

Kilea Volcanics (in Lahaina Volcanic Series)

Pleistocene(?) : Maui Island, Hawaii.

H. T. Stearns *in* H. T. Stearns and G. A. Macdonald, 1942, Hawaii Div. Hydrography Bull. 7, p. 158 (table), 181. Fine-grained nepheline basanite flow 15 feet thick. Rests on consolidated older alluvial fan of Olowalu Stream.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 103–104. Pleistocene(?).

Originated from cinder cone, Puu Kilea, one-half mile north of Olowalu on south bank of Olowalu Stream, West Maui Mountains.

Killarney Granite[1]

Precambrian: Western Ontario, Canada, and northern Michigan.

Original reference: W. G. Miller and C. W. Knight, 1914, Ontario Bur. Mines Report, v. 22, pt. 2, p. 125.

W. T. Stuart, E. A. Brown, and E. C. Rhodehamel, 1954, Michigan Dept. Conserv., Geol. Survey Div. Tech. Rept. 3, p. 11 (table 3). Table of geologic formations in Marquette district shows Killarney granite above Keweenawan, but footnote states stratigraphic position doubtful.

First described on north shore of Lake Huron, Ontario, Canada.

Killbuck Conglomerate Lentil (of Cattaraugus Formation)[1]

Devonian or Carboniferous: Southwestern New York.

Original references: L. C. Glenn, 1903, New York State Mus. Bull. 69, p. 977; 1904, Geol. Soc. America Bull., v. 14, p. 522–531.

Well exposed northeast and east of Kilbuck [Kill Buck], Cattaraugus County.

Killbuck shale facies (of Cuyahoga Formation)

Mississippian (Kinderhook) : Northeastern Ohio.

F. T. Holden, 1941, Illinois Acad. Sci. Trans., v. 34, no. 2, p. 172; 1942, Jour. Geology, v. 50, no. 1, p. 43 (fig. 2), 49–50. One of seven facies in the formation. Includes Black Hand shale member, Armstrong sandstone member, and Burbank member. Lies between River Styx conglomerate facies (new) to the northeast and Tobosa conglomerate facies to the southwest.

Occurs in Huron, Lorain, Medina, Ashland, and Wayne Counties.

Killians Member (of Genshaw Formation)

Killians Limestone[1]

Middle Devonian: Northeastern Michigan.

Original reference: A. S. Warthin, Jr., and G. A. Cooper, 1935, Washington Acad. Sci. Jour., v. 25, no. 12, p. 524–526.

A. S. Warthin, Jr., and G. A. Cooper, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 5, p. 583–584. Rank reduced to member status in Genshaw formation (redefined).

G. V. Cohee, 1947, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 28, footnote 22. Michigan Geological Survey considers Killians limestone a formation.

Type locality: Exposures along French Road, one-half mile south of Killians resort, Long Lake, Alpena County.

Killik Tongue (of Chandler Formation)

Lower Cretaceous: Northern Alaska.

R. L. Detterman *in* George Gryc and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 2, p. 237–239, figs. 4, 5. Lower and thickest tongue of formation, formerly called the Hatbox tongue. Renamed and type locality changed because sequence is better exposed along Killik River than at Hatbox Mesa. Nonmarine in origin with some marginal facies. Separated into upper and lower part in southernmost exposures. Lower part at type locality is 1,095 feet thick and comprises abundance of thick-bedded bluff-forming sandstones. Above base, sandstones tend toward varous shades of yellow red in addition to "salt-and-pepper" appearance; also includes grayish micaceous carbonaceous siltstone and silt-shale with numerous thick coal seams. Upper part at type locality 1,720 feet thick and characterized by series of massive white quartz conglomerate ledges; rest of constituents quite similar to those of lower part. Overall thickness at type locality 2,815 feet. In most exposures, tongue underlies marine Ninuluk formation (new), overlies marine Tuktu formation (revised), and overlies and interfingers with marine Grandstand formation (new). Age shown on chart as Lower (?) and Upper(?) Cretaceous.

F. R. Collins, 1958, U.S. Geol. Survey Prof. Paper 305–F, p. 343. Lower Cretaceous.

Type locality: Along east bank of Killik River between lat 68°52′ N. and 68°55′ N., and long 153°26′W.

Killingworth Leucotonalite

Carboniferous(?), middle: South-central Connecticut.

W. G. Foye, 1949, Connecticut Geol. Nat. History Survey Bull. 74, p. 52–53, 54, pl. 1. Bluish-gray medium- to coarse-grained igneous rock with little foliation. Occurs at core of large batholithic area of Monson orthogneiss.

H. M. Mikami and R. E. Digman, 1959, Connecticut Geol. Nat. History Survey Bull. 86, p. 25–26. Present study shows that entire Killingworth dome should be mapped as one tonalite mass with peripheral zone of mixed rocks. Entire formation here designated Haddam tonalite.

Mapped in towns of Killingworth, Middlesex County, and Madison, New Haven County.

Kimball Formation (in Ogallala Group)

Kimball Member (of Ogallala Formation)

Pliocene, upper: Southwestern Nebraska, northern Colorado, and northwestern Kansas.

A. L. Lugn, 1938, Am. Jour. Sci., 5th ser., v. 36, no. 213, p. 224, 227; 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1262–1264. 1266 (table 2). Uppermost formation in group. Consists of silt, clay, and fine sand more or less cemented with caliche, with 1 or 2 algal limestone beds at top; pinkish to reddish. Thickness 25 to 50 feet. Overlies Sidney gravel (new). Very late Pliocene.

C. B. Schultz and T. M. Stout, 1948, Geol. Soc. America Bull., v. 59, no. 6, p. 553–588. Formation includes Sidney gravel and silt member. Discussion of Pleistocene mammals and terraces in Great Plains. Unconformity between Kimball and Broadwater formations is most significant stratigraphic break in upper Tertiary and Pleistocene deposits of western Nebraska and Great Plains in general. Faunal break between Kimball and

Broadwater is most important one paleontologically in same area. This break believed to be Pliocene-Pleistocene boundary.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 20. Member of Ogallala formation in Kansas.

Typical exposure: At the High Plains level about 2 miles south of Kimball, Kimball County, Nebr., in vicinity of adjoining corners of secs. 5, 6, 7, and 8, T. 14 N., R. 55 W.

Kimberling Shale[1]

Upper Devonian: Southwestern Virginia and southeastern West Virginia.

Original reference: M. R. Campbell, 1894, Geol. Soc. America Bull., v. 5, p. 171, 177, pl. 4.

Named for Kimberling Creek, Bland County, Va.

Kimbrel Bed[1]

Eocene, upper: Northwestern Louisiana.

Original reference: T. L. Casey, 1902, Science, new ser., v. 15, p. 716.

Named for outcrops on estate of T. W. Kimbrel, south of Montgomery, Grant County.

Kimmswick Limestone[1]

Middle Ordovician: Eastern Missouri, northern Arkansas, and southwestern Illinois.

Original reference: E. O. Ulrich, 1904, Missouri Bur. Geology and Mines, v. 2, 2d ser., p. 111.

E. O. Ulrich, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 106 (correlation table), 107. In Cape Girardeau sections, overlies Plattin limestone. Decorah absent.

J. M. Weller *in* Stuart Weller and J. M. Weller, 1939, Illinois Geol. Survey Rept. Inv. 59, p. 7, pl. 1. Exposed in limited area in Kimmswick quadrangle where Ordovician rocks have been brought to surface in Mississippi River bluff at crest of Valmeyer anticline. Consists of pure white to flesh-colored crystalline limestone free from chert except in a zone about 8 feet thick near middle of formation. Thickness about 100 feet. Overlies Decorah limestone; underlies Maquoketa shale.

C. J. Wells, 1949, Arkansas Div. Geology Bull. 15, p. 9. In Independence County, Ark., formation is chiefly an even-bedded massive light-gray medium- to coarse-grained limestone with characteristic surgary texture. Overlies Plattin limestone; underlies Fernvale limestone.

E. R. Larson, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 9, p. 2044 (fig. 2), 2064, 2066. In southeastern Missouri, disconformably overlies Decorah formation.

G. A. Cooper, 1956, Smithsonian Misc. Colln., v. 127, pt. 1, p. 116. Overlies Barnhart formation (new).

T. J. Laswell, 1957, Missouri Geol. Survey and Water Resources Rept. Inv. 22, p. 8–13. Described in Bowling Green quadrangle where it consists predominantly of limestone beds 3 feet thick; thinner beds of dolomitic limestone and shaly to silty limestone present near top. Thickness 80 feet, base not exposed. Unconformably underlies Maquoketa formation. On basis of fauna and stratigraphic position, considered to be Middle Ordovician (Trenton) in age and approximately correlative with lower part of Galena formation.

Named for exposures at Kimmswick, Jefferson County, Mo.

Kincaid Formation (in Midway Group)[1]

Paleocene: Eastern Texas and southern Arkansas.

Original reference: Julia Gardner, 1933, Am. Assoc. Petroleum Geologists Bull., v. 17, no. 6, p. 744.

C. W. Cooke and others, 1943, Geol. Soc America Bull., v. 54 no. 11, chart 12. Shown on correlation chart as underlying Wills Point formation. Paleocene.

Mackenzie Gordon, Jr., J. I. Tracey, Jr., and M. W. Ellis, 1958, U.S. Geol. Survey Prof. Paper 299, p. 11 (fig. 4), 13–25, pls. In Texas, comprises (ascending) Littig glauconitic, Pisgah, and Tehuacana members. Geographically extended into bauxite region of Arkansas where it is as much as 185 feet thick and consists of greenish- and dark-gray clay, sandy in places, interbedded with fossiliferous marl, sandy glauconite limestone, and calcareous sandstone. Not differentiated although equivalents of the Texas members are present. Underlies Wills Point formation Overlies Late Cretaceous (in some areas Arkadelphia marl). Paleocene.

Type exposure: On old Kincaid Ranch (Lewis Ranch), three-fourths mile above Bob Evan's apiary to one-quarter mile below it [Uvalde County], Tex.

Kinchloe Limestone[1]

Pennsylvanian: Western Kentucky.

Original reference: F. M. Hutchinson, 1912, Kentucky Geol. Survey Bull. 19, fig. 28.

Derivation of name not stated, but probably named for Kinchloes Bluff, Muhlenberg County.

Kindblade Formation (in Arbuckle Group)

Lower Ordovician: Southwestern Oklahoma.

C E. Decker, 1939, Oklahoma Geol. Survey Circ. 22, p. 15, 16 (table 1), 25–26, 47–48; 1939, Geol. Soc. America Bull., v. 50, no. 8, p. 1313, 1320, table 1. Name proposed to replace preoccupied Alden (Decker, 1933). Chiefly dark-gray limestones in groups of beds in which one or two thick ones alternate with zones of thinner beds. Thickness near type section about 956 feet; in Arbuckle Mountains aggregates 1,216 to 1,536 feet. Grades into Cool Creek formation below and West Spring Creek formation above.

Type section: Outcrop on Kindblade Ranch, E½ sec. 26, T. 6 N., R. 14 W., 10½ miles southwest of Carnegie, Comanche County. Well exposed along east side of ranch.

Kinderhook Series

Kinderhook Group[1]

Lower Mississippian: Mississippi Valley.

Original reference: F. B. Meek and A. H. Worthen, 1861, Am. Jour. Sci., 2d, v. 32, p. 288.

E. B. Branson, 1938, Missouri Univ. Studies, v. 13, no. 3, pt. 1, p. 5–6. Term Lower Mississippian used here as name for division of Mississippian to take place of term Kinderhook. Because several Devonian formations have been included in the Kinderhook, the name is not suitable for Mississippian division.

J. M. Weller, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 131, 132. Basal series of Mississippian in Mississippi Valley. Varies greatly from place to place, and no standard section can be set up for it. Unconformable below Valmeyer series. Some units included are: Sulphur Springs formation in Missouri, Mountain Glen, and Springville shales in Illinois.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 766 (fig. 1), 771, 777–793. Basal group of Iowa series. In standard section, includes (ascending) Grassy-Saverton shale, Louisiana limestone, Hannibal shale and sandstone, and Chouteau limestone. Underlies Osage group. This report follows classification of Illinois Geological Survey. Authors believe, however, that Mississippian should have threefold division, that Kinderhook should be raised to rank of series, and that Valmeyer series should be recognized.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 100–101, chart 5. Series subdivided into two groups. Easley includes all Kinderhookian strata which are almost universally recognized to be of Mississippian age. Fabius consists of Kinderhookian strata which are believed by some to be Mississippian but by others to be Devonian. Standard section comprises (ascending) Grassy Creek shale, Saverton shale, Louisiana limestone, Maple Mill shale, Chouteau limestone, Sedalia limestone, and Gilmore City limestone. Underlies Osage (Osagean) series.

T. R. Beveridge and E. L. Clark, 1952, Missouri Geol. Survey and Water Resources Rept. Inv. 13, p. 71–79. Kinderhookian-Osagean boundary defined as being contact of Northview and the overlying Pierson formation. Both formations here considered co-extensive throughout western Missouri. Northview has commonly been considered Kinderhookian, but Pierson has been assigned to either Osagean or Kinderhookian by various writers.

L. E. Workman and Tracey [Tracy] Gillette, 1956, Illinois Geol. Survey Rept. Inv. 189, p. 8 (fig. 1), 12–38. In previous Illinois Geological Survey reports, Kinderhook strata have been considered a group in Iowa series. In this report, Kinderhook raised to series rank. Name Iowa dropped, following usage of Mississippian correlation chart (Weller and others, 1948). Series in northwestern, western, and central Illinois divided into three groups: North Hill above, Hannibal middle, and the Champ Clark (new) below. In eastern and southern Illinois, series is divided into two formations: Chouteau above and New Albany below. Name Valmeyer is accepted by Illinois Survey as a series name to include Osage and Meramec groups.

M. G. Mehl, 1960, Denison Univ. Jour. Sci. Lab., v. 45, art, 5, p. 92–94. Use of term Kinderhook discussed. If Louisiana limestone is Devonian, as believed by some stratigraphers, and is equivalent to McCraney, as is maintained by some, there is possibility that no strata of Mississippian Kinderhook age are exposed at Kinderhook. If term is interpreted in broad sense in which it was originally proposed, there is no necessity for new name or designation of type locality. Proposed here that Kinderhook be used to designate all strata of Mississippian age that are older than Osage. Recommended that terms Easley and Fabius groups be dropped from list of stratigraphic designations in Missouri. If there is no doubt of Mississippian age of a unit that is older than Osage, it may be called Kinderhook in age and, with somewhat more refinement, it may be designated as early of late Kinderhookian.

Named for exposures at Kinderhook, Pike County, Ill.

Kineo Rhyolite[1]

Devonian : West-central Maine.

Original reference: W. H. Perkins, 1925, Am. Jour. Sci., 5th ser., v. 10, p. 371

H. W. Fairbairn and P. M. Hurley, 1957, Am. Geophys. Union Trans., v. 38, no. 1, p. 104 (table 7), 106. Enclosed by Lower Devonian strata; age designated Lower Devonian.

Forms Mount Kineo and several other hills in Moosehead Lake quadrangle.

King Limestone[1]

Lower Ordovician (Beekmantown) : Southwestern Missouri.

Original reference: E. M. Shepard, 1898, Missouri Geol. Survey, v. 12, pt. 1, p. 49, 71–74.

Named for outcrops on King Branch and King Mound, Greene County.

Kingak Shale[1]

Lower-Upper Jurassic : Northeastern Alaska.

Original reference: E. D. Leffingwell, 1919, U.S. Geol. Survey Prof. Paper 109, p. 103, 119, map.

George Gryc and others, 1951, Washington Acad. Sci. Jour., v. 41, no. 5, p. 163 (fig. 2). Lower, Middle, and Upper Jurassic. Underlies Okpikruak formation (new).

Identified at Kingak Cliff, near Camp 263, at southeast end of Sadlerochit Mountains.

King City Formation

Pliocene: Southern California.

B. L. Clark, 1940, (abs.) Geol. Soc. America Bull., v. 51, no 12, pt. 2, p. 1956–1957. Name applied to series of deposits at base of Pliocene in Salinas Valley area. Unconformably overlies basement complex; underlies Poncho Rico formation.

B. L. Clark, 1943, California Div. Mines Bull. 118, pt. 2, p. 190 [preprint 1941]. Has basal arkosic sand which, in places, is more than 100 feet thick, overlain by series of white shale, in turn overlain by Poncho Rico formation.

Type area: East and southeast of King City between Peach Valley and Salinas Valley.

King Creek Marl Member (of Chappel Formation)

Mississippian : Central Texas.

F. B. Plummer, 1950, Texas Univ. Bur. Econ. Geology Pub. 4329, p. 26. Dark-gray colloidal nonlaminated fossiliferous partially cemented hard marl that fills depressions, cavities, and holes in Ellenburger surface on which Chappel formation was deposited. Commonly less than 1 foot thick and quite erratic in its distribution. Chappel comprises [ascending] King Creek marl, Ives conglomerate, Espey Creek limestone, and Whites Crossing coquina members.

P. E. Cloud, Jr., V. E. Barnes, and W. H. Hass, 1957, Geol. Soc. America Bull., v. 68, no. 7, p. 810–811 (footnote). "King Creek marl member" of Plummer's Chappel formation is argillaceous limestone surely identified only at its type site where it constitutes a few inches of Houy formation (new). Although it contains conodonts and megafossils of early Kinderhook sorts, type "King Creek marl" occurs beneath Ives breccia (here reallocated to member status in newly defined Houy formation) which has yielded only Devonian types of conodonts.

Typically exposed on King Branch on Sloan Ranch one-quarter mile northwest of King Spring and 300 feet east of road crossing, Lampasas County.

Kingdom Formation (in Ancell Group)

Middle Ordovician : Northern Illinois.

J. S. Templeton and H. B. Willman, 1952, Tri-State Geol. Soc. Guidebook 16th Ann. Field Conf., figs. 3, 12. Consists of argillaceous silty fine and coarse-grained sandstone about 9 feet thick. Shown on columnar section as underlying Daysville formation (new) and unconformably overlying St. Peter sandstone.

Occurs in Dixon-Oregon area.

King Ferry Shale Member (of Ludlowville Shale)[1]

Middle Devonian : Central New York.

Original reference: G. A. Cooper, 1930, Am. Jour. Sci., 5th ser., v. 19, p. 219, 228.

R. S. Boardman, 1960, U.S. Geol.. Survey Prof. Paper 340, p. 6–7. Generally considered lateral equivalent of Wanakah shale, Tichenor limestone, and Deep Run members. Trepostomatous Bryozoa discussed.

Type locality: At Clearview, King Ferry, Cayuga County, near Cayuga Lake.

†Kingfisher Formation (in Cimarron Group)[1]

Permian : Southern Kansas and central Oklahoma.

Original reference : F. W. Cragin, 1897, Am. Geologist, v. 19, p. 352–355.

C. C. Branson, 1957, Oklahoma Geology Notes, v. 17, no. 11, p. 101 Abandoned by Oklahoma Geological Survey.

Named for Kingfisher Creek and town in Kingfisher County, Okla.

King Hill Shale Member (of Lecompton Limestone)[1]

Pennsylvanian (Virgil Series) : Southeastern Nebraska, southwestern Iowa, northeastern Kansas, and northwestern Missouri.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p 44, 45, 47.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 23; R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 66. Thickness 4 to 6 feet in Nebraska, about 20 feet in northwestern Missouri, and 5 to 20 feet in Kansas. Underlies Avoca limestone member; overlies Beil limestone member.

H G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 19, fig. 5. Dark- to greenish-gray massive shale with seams of nodular limestone. Thickness 6 to 7½ feet. Underlies Avoca limestone member; overlies Beil limestone member.

Type locality: One and one-half miles south and 1 mile east of Rock Bluff, Cass County, Nebr. Name derived from King Hill, a high point in Missouri River bluffs.

King Lear Formation

Lower Cretaceous : Northwestern Nevada.

Ronald Willden, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 10, p. 2381 (table 1), 2382–2391, 2394. Consists of clastic rocks, including pebble to boulder conglomerate with interbedded siltstone and graywacke and lenses of limestone. Basal part invariably poorly sorted conglomerate composed almost entirely of subrounded to rounded clasts of subjacent rock type overlain by pebble to cobble conglomerate with some interbedded red siltstone. Conglomerates typically bimodal. Basal conglomerate 200 to 300 feet thick and overlain by 300 to 500 feet of dusky-red and greenish-gray to brown siltstone interbedded with greenish-gray to brown sandstone and graywacke. Lenticular bodies of light- to dark-gray finely crystalline dense limestone occurs locally in basal conglomerate and overlying siltstone-sandstone unit. Siltstone-sandstone unit overlain by about 200 feet of pebble to cobble conglomerate interbedded with sandstone, graywacke, and siltstone which is in turn overlain by upper unit of uncertain thickness consisting of interbedded siltstone, graywacke, and sandstone. Total thickness 200 to 3,000 feet. Overlies pre-Cretaceous volcanic series at most localities where exposed. Unconformably underlies Pansy Lee conglomerate (new).

Type section: Along road south of DeLong mine, Jackson Mountains, Humboldt County. Named from exposures on southeast side of King Lear Peak. Also exposed west of crest of range in vicinity of Deer Creek Peak, Parrot Peak, and DeLong Peak.

Kingman Sandstone Member (of Harper Sandstone)

Permian (Leonard Series): Southern Kansas and northern Oklahoma.

G. H. Norton, 1937, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 21, no. 12, p. 1557; 1939, v. 23, no. 12, p. 1785–1786. An 80-foot unit of silty red sandstone containing a 3-foot white sandstone at base. Overlies Chikaskia sandstone member (new). Top not distinct, but placed arbitrarily at bed of maroon shale at base of Salt Plain measures of Cragin.

Named for exposures in and around Kingman, Kingman County, Kans. U.S. Highway 54 cuts through ridge of the sandstone about three-fourths mile east of Kingman; here basal bed and lower part of member are exposed.

Kingman Series

Tertiary: Northwestern Arizona.

B. E. Thomas, 1949, Econ. Geology, v. 44, no. 8, p. 667, fig. 2. Comprises rhyolite tuffs, breccias, and flows. Disconformably overlies Bull Mountain series (new); unconformably underlies Big Wash andesite (new).

B. E. Thomas, 1953, Geol. Soc. America Bull., v. 64, no. 4, p. 408, pl. 1. Two northernmost mapped exposures contain visible section approximately 700 feet thick of coarse reddish breccias. Rocks distinctly stratified and well consolidated. In three exposures to the south, several hundred feet of strata must be represented, but maximum thickness of any one section is about 80 feet. Rock types present are (ascending) loosely consolidated grayish-yellow to light-brown tuff; welded tuff, 10 to 15 feet thick; and reddish-brown tuffaceous breccia, about 30 feet thick.

Best exposed in and around Kingman, Mohave County. Occurs discontinuously along east flank of Cerbat Mountains.

King Peak Rhyolite

Precambrian: West-central Arizona.

C. A Anderson, E. A. Scholz, and J. D. Strobell, Jr., 1955, U.S. Geol. Survey Prof. Paper 278, p. 12, pl. 3. Fine-grained nonporphyritic rock containing quartz and feldspar. Generally massive, and foliation is rare. White and sugary in appearance on unweathered surfaces, but outcrops typically are tan in western belt near Niagara Creek. Eastern exposures are brown. Distinguished from Dick rhyolite (new) by its nonporphyritic texture. Oldest intrusive in area. Mass of King Peak rhyolite exposed west of Niagara Creek is essentially concordant with southwestern belt of Bridle formation (new), but evidence proves that the rhyolite is intrusive. Pattern of outcrops indicates that the King Peak also intrudes Dick rhyolite.

Exposed on King Peak, for which the rock has been named, in southern part of Bagdad area, Yavapai County

Kings Limestone[1]

Devonian: Missouri.

Original reference: E. M. Shepard, 1904, Drury Coll., Bradley Geol. Field Sta. Bull., v. 1, p. 41.

Kings Branch Limestone[1]

Age (?) : Southwestern Missouri.

Original reference: E. M. Shepard, 1905, Drury Coll., Bradley Geol. Field Sta. Bull., v. 1.

Greene County.

Kingsbridge Marble[1]

Precambrian: Southeastern New York.

Original reference: L. D. Gale, 1839, New York Geol. Survey 3d Ann. Rept., p. 183.

Probably named for Kingsbridge on Manhattan Island.

Kingsbury Conglomerate Member (of Wasatch Formation)[1]

Eocene, lower: Northern Wyoming.

Original reference: N. H. Darton, 1906, U.S. Geol. Survey Prof. Paper 51, p. 13, 60.

R. P. Sharp, 1948, Jour. Geology, v. 56, no. 1, p. 1–14. Underlies Moncrief gravel (new).

J. D. Love and J. L. Weitz, 1951, U.S. Geol. Survey Oil and Gas Inv. Map OM–122. Underlies Moncrief gravel herein allocated to member status in Wasatch formation.

R. K. Hose, 1956, U.S. Geol. Survey Bull. 1027–B, p. 67–70. Described in Crazy Woman Creek area, Johnson County, where it unconformably overlaps Fort Union formation. North of mapped area, successively overlaps Lance formation, Bearpaw shale, and Parkman sandstone. Four miles north of mapped area, unconformably underlies Moncrief member. Thickness 400 to 600 feet in vicinity of Kingsbury Ridge.

W. J. Mapel, 1959, U.S. Geol. Survey Bull. 1078, p. 63–64. Described in Buffalo-Lake De Smet area where it is as much as 800 feet thick. Underlies Moncrief member with angular discordance near Bighorn Mountains; eastward both members grade laterally into conformable nonconglomerate sequence of sandstone, shale, and coal that makes up Wasatch formation east of area. Overlies Fort Union formation with angular unconformity.

Named for Kingsbury Ridge, 6 miles southwest of Buffalo, Johnson County

Kings Canyon Dolomite

Devonian (?) : Western Utah.

R. W. Rush, 1956, Utah Geol. and Mineralog. Survey Bull. 53, p. 12 (fig. 3), 23 (fig. 5), 26–27, 31 (fig. 6), 35 (fig. 7), 37 (fig. 8), 41 (fig. 9), 53 (fig.

11), 60. Proposed for light-gray microcrystalline dense laminated dolomite 460 feet thick that conformably overlies Decathon dolomite (new) and conformably underlies Simonson dolomite. No fossils. Considered Devonian because of stratigraphic position below Simonson and lithologic similarity to Sevy dolomite.

Type locality: Fantastic Canyon, sec. 13, T. 21 S., R. 15 W., 5 miles south of Kings Canyon in Confusion Mountains, Millard County. Also well exposed in eastern front of Confusion Mountains between Kings Canyon and Ibex.

†Kings Creek phase[1] or silex[1]

Eocene, upper, or Oligocene: Western South Carolina and southeastern Georgia.

Original references: E. Sloan, 1905, South Carolina Geol. Survey geognostic map of South Carolina, advance copies, published in 1908, in South Carolina Geol. Survey, ser. 4, Bull. 2; 1907, Summary of mineral resources of South Carolina, p. 12, 18, name only, not defined; 1908, South Carolina Geol. Survey, ser. 4, Bull. 2, p. 435, 464–465.

Occurs between Johnson's Landing, near mouth of Lower 3 Runs, Barnwell County, S.C., to point immediately south of King's Creek and about 1 mile west of river road.

Kingsdown Silt or **Formation** (in Sanborn Group)

Kingsdown Marl[1]

Pleistocene: Southwestern Kansas.

Original reference: F. W. Cragin, 1896, Colorado Coll. Studies, v. 6, p. 53–54.

H. T. U. Smith, 1940, Kansas Geol. Survey Bull. 34, p. 111–116. Cragin's loosely defined Kingsdown marl of supposed late Pliocene age, redefined as Kingsdown formation to include beds of Pleistocene age only. It was included in Tertiary marl as mapped by Hay (1890, U.S. Geol. Survey Bull. 57). Formation consists of light-colored sand and gravel grading upward into characteristically light-buff even-bedded silt and clay containing some small and scattered calcareous concretions. Thickness 64 feet at section measured in Clark County. Here the Kingsdown overlies Rexroad formation (new). Overlain by loess and seems locally to grade upward into loess from which it differs little except in its bedding.

J. C. Frye and C. W. Hibbard, 1941, Kansas Geol. Survey Bull. 38, pt. 13. p. 410–411. Redefined to include overlying loess. Overlies Meade formation (redefined).

C. W. Hibbard, 1944, Geol. Soc. America Bull., v. 55, no. 6, p. 745–752. Kingsdown marl apparently referred to by Cragin is divisible into an upper and lower part separated by a disconformity. Lower Kingsdown consists of light-buff silt and some sand and caliche pebbles, unconformable upon Meade formation and unconformably overlain by upper Kingsdown silt. Where well exposed in SE¼ sec. 17, T. 30 S., R. 23 W., Clark County, the lower Kingsdown is 25 feet thick. Here the Kingsdown is channelled into the Meade formation. Upper Kingsdown silt consists of light-tan silt and fine sand, thin-bedded at base grading upward into massive silt and loess. Well exposed in NE¼ sec. 13, T. 30 S., R. 23 W., Clark County (section measured by Smith, 1940).

C. W. Hibbard, 1949, Michigan Univ. Mus. Paleontology Contr., v. 7, no 4, p. 80–84. Formation redefined to include sands and gravels at base of silt not recognized by Cragin but included by Hibbard (1944) in lower Kingsdown silt. Term formation used here instead of marls because unit here defined as formation consists both of channel sands and gravels and flood-plain silts containing large amounts of calcium carbonate. Use of formation as here restricted and redefined, is not use of term as defined by Smith (1940). Typical section given by Smith is of beds younger than those described by Cragin as Kingsdown marls and belongs to later cycle of erosion and deposition named and defined in this paper as Vanhem formation. In some areas, overlies Meade formation; in others, Crooked Creek formation (new). Type locality designated

J. C. Frye and A. B. Leonard, 1952, Kansas Geol. Survey Bull. 99, p. 110. Kingsdown marl or formation listed among units that consist in part or entirely of deposits known to be of Illinoian or younger age, and which are properly classed at least in part as Sanborn formation.

C. W. Hibbard, 1958, Am. Jour. Sci., v. 256, no. 1, p. 55 (fig. 1). Lower formation in Sanborn group. Overlies Crooked Creek formation; underlies Vanhem formation.

Named for Kingsdown, Ford County.

Kingshill Marl

Kingshill Series

Oligocene and Miocene: St. Croix, Virgin Islands.

J. F. Kemp, 1926, New York Acad. Sci. Scientific Survey of Porto Rico and the Virgin Islands, v. 4, pt. 1, p. 49 (reprinted? from J. F. Kemp, 1923, Report to H. H. Hough, Captain, U.S.N., Governor, Virgin Islands. Printed at the Naval Station, St. Thomas [not seen]). Kingshill series consists of white or cream-colored soft limestones, chalky beds and marls. Thickness may be 500 or 600 feet. Rests on upturned edges of older Mount Eagle series.

D. J Cederstrom, 1941, Am. Jour. Sci., v. 239, no. 8, p. 556–557. Referred to as Kingshill marl. In test wells, overlies Jealousy formation (new). Oligocene to lower Miocene.

D. J. Cederstrom, 1950, U.S. Geol. Survey Water-Supply Paper 1067, p. 20–27, pl. 1. Exposed thickness of marl may be more than 600 feet. Subsurface thickness as much as 180 feet. In some areas directly overlies Mount Eagle volcanics. Calcareous conglomerate underlying Kingshill is exposed in stream beds near Jealousy. This is believed to be basal conglomerate of Jealousy formation. Oligocene-Miocene contact is within Kingshill marl and is at least 108 feet above base of formation in test well at Fair Plain.

Probably named for Kings Hill in western part of island.

Kingsley Red Shale Member (of New Milford Formation)[1]

Kingsley shale member (of Wellsburg monothem)

Upper Devonian: Northeastern Pennsylvania.

Original reference: Bradford Willard, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 571–589.

K E. Caster, 1938, Jour. Paleontology, v. 12, no. 1, p. 44, 45 (fig. 7), 46–47, 49–50, Reallocated to lower part of Wellsburg monothem and described in vicinity of Lanesboro. Not properly termed "red" shale. Stratigraphically restricted; basal 105 feet of shale in original definition included by inference in Starruca shale member. Underlies Lanesboro formational suite of Wellsburg monothem; overlies Starrucca shale member of Cayuta monothem.

Well exposed in railroad cut at Kingsley, Susquehanna County.

Kings Mill Sandstone[1]

Upper Devonian: Central Pennsylvania.

Original reference: E. W. Claypole, 1885, 2d Pennsylvania Geol. Survey Rept. F2, p. 73–77.

Bradford Willard, 1937, Pennsylvania Acad. Sci. Proc., v. 11, p. 33. Described as marine unit intercalated with Catskill continental facies in Perry County.

Exposed near King's Mill 2 miles northwest of Duncannon, Perry County.

Kings Mill Shale[1] and Sandstones

Upper Devonian: Central Pennsylvania.

Original reference: E. W. Claypole, 1885, Pennsylvania 2d Geol. Survey Rept. F–2, p. 77.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Kings Mill shales and sandstones shown on correlation chart below Dellville sandstone.

Named for King's Mill, 2 miles northwest of Duncannon, Perry County.

†Kings Mountain Group,[1] Series,[1] or Slates[1]

Precambrian and Cambrian: Western North Carolina and northwestern South Carolina.

Original reference: O. M. Lieber, 1858, Rept. of survey of South Carolina for 1856, p. 23, 30.

Named for development on Kings Mountain, in Cleveland and Gaston Counties, N C.

Kings Mountain Quartzite[1]

Kings Mountain Group

Ordovician to Mississippian: Southern North Carolina and northwestern South Carolina.

Original reference: A. Keith and D. B. Sterrett, 1931, U.S. Geol. Survey Geol. Atlas, Folio 222.

J. L. Stuckey and S. G. Conrad, 1958, North Carolina Div. Mineral Resources Bull. 71, p. 30–31; J. L. Stuckey, 1958, Geologic map of North Carolina (1:500,000): North Carolina Div. Mineral Resources. Rocks of Kings Mountain group consist of two parts, one of highly siliceous rock and the other largely calcareous. They are mapped as Stokes County and Kings Mountain belts. Precambrian(?) or Lower Paleozoic(?).

U S. Geological Survey currently designates the age of the Kings Mountain Quartzite as Ordovician to Mississippian on the basis of a study now in progress.

Named for development in Kings Mountain, in Cleveland and Gaston Counties. N.C.

Kingsport Formation or **Dolomite** (in Knox Group)

Lower Ordovician: Eastern Tennessee and southwestern Virginia.

John Rodgers, 1943, Geologic map of Copper Ridge district, Hancock and Grainger Counties, Tennessee (1:24,000): U.S. Geol. Survey Strategic

Minerals Inv. Prelim. Map. Name appears on map legend. Occurs below Mascot dolomite (new).

C. R. L. Oder and H. W. Miller, 1945, Am. Inst. Mining Metall. Engineers Tech. Pub 1818, p. 1, 2–9. In Mascot-Jefferson City zinc district, Kingsport formation consists of four divisions: upper, 101 to 135 feet, fairly light to dark fine-grained dolomite with some interbedded brown limestone; underlying 44 to 50 feet, light-brownish-gray to nearly white fine-grained dolomite, some of which is lithographic in texture; variable zone 33 to 38 feet, light- to dark-gray to brownish fine-grained to finely crystalline dolomite and some brown limestone; lower 178 to 216 feet, mainly brown limestone locally altered to crystalline dolomite; interbedded with limestone is light- to dark-gray fine-grained dolomite; cherty layers numerous. Includes Grasselli dolomite (new) near top. Separated from overlying Mascot formation by chert matrix sand about 6 inches thick; overlies Longview formation. Name chosen, jointly by Josiah Bridge and Oder. [Description based on mine sections.]

John Rodgers and D. F. Kent, 1948, Tennessee Div. Geology Bull. 55, p. 25–27. Described in Lee Valley, Hawkins County, where it is 218 feet thick. Consists typically of thick-bedded compact blue to brown limestone below interbedded with and grading up into light- to dark-gray finely crystalline well-bedded dolomite. Thickness 218 feet. Underlies Mascot dolomite; overlies Longview dolomite

R. L. Miller and W. P. Brosgé, 1954, U.S. Geol. Survey Bull. 990, p. 26–28, pl. 1. Described in Jonesville district, southwestern Virginia, where it underlies Mascot dolomite and overlies Longview dolomite. Thickness 119 to 272 feet.

Josiah Bridge, 1956. U.S. Geol. Survey Prof. Paper 277, p. 49–54, pl. 1. Kingsport limestone replaces names Jefferson City formation (Oder, 1934, Jour. Geology, v. 42) and Forked Deer formation (Hall and Amick, 1934). As defined here, Kingsport includes units 459 to 519 of Thorn Hills section (Hall and Amick, 1934) and units 240 to 256 of Lee Valley section (Rodgers and Kent, 1948). Thickness at type locality, here designated, 280 feet. Discussion of boundaries of Kingsport as used here with boundaries drawn by Oder and Miller (1945).

Type section: On east side of U.S. Highway 23 just northwest of Kingsport, Sullivan County, Tenn. Top of formation is 0.55 mile north of traffic light at intersection of U.S. Highways 23 and 11W; base is 0.23 mile farther north.

Kings River Sandstone Member (of Everton Formation)[1]

Middle Ordovician: Northwestern Arkansas.

Original reference: A. H. Purdue and H. D. Miser, 1916, U.S. Geol. Survey Geol. Atlas, Folio 202.

U.S. Geological Survey currently considers the Everton Formation and its members Middle Ordovician in age.

Named for exposures along Kings River, Eureka Springs quadrangle, [Carroll County].

†Kingston Beds[1]

Lower Devonian: Eastern New York.

Original reference: J. M. Clarke and C. Schuchert, 1899, Science, new ser., v. 10, p. 874–878.

Typically exposed in vicinity of Kingston, Ulster County.

Kingston Conglomerate[1] (in Portage Lake Lava Series)

†Kingston Conglomerate (in Central Mine Group)

Precambrian (middle Keweenawan) : Northern Michigan.

Original reference: A. R. Marvine, 1873, Michigan Geol. Survey, v. 1, pt. 2, p. 114, chart.

W. S. White, H. C. Cornwall, and R. W. Swanson, 1953, U.S. Geol. Survey Geol. Quad. Map GQ–27. Shown on map legend as one of 16 units included in newly defined Portage Lake lava series

Named for occurrence on Kingston Farm, on Keweenaw Point.

Kingston Peak Formation

Precambrian (Pahrump Series) : Southern California.

D. F. Hewett, 1940, Washington Acad. Sci. Jour., v. 30, no. 6, p. 240; 1956, U.S. Geol. Survey Prof. Paper 275, p. 27, 28, pl. 1. Consists of sandstone and limestone with thick coarse conglomerate in middle. Conglomerate made up largely of subangular cobbles of limestone up to 12 inches in diameter with quartzite and granite cobbles predominating near base. Resembles debris, called fanglomerate, that forms fans on border of present valleys. About 1,900 feet thick along western part of outcrop belt but thickens toward east. Conformably overlies Beck Spring dolomite (new) ; underlies Paleozoic rocks that are Lower Cambrian in age.

D. F. Hewett, 1948, California Div. Mines Bull. 129, p. 199. In Kingston Range, San Bernardino County, underlies Cambrian Noonday dolomite.

L. A. Wright, 1952, California Div. Mines Spec. Rept. 20, p. 12. In Superior talc area, southern Death Valley-Kingston Range region, formation, at least 1,900 feet thick, consists of a lower one-fourth of quartzite and shale and an upper three-fourths of conglomeratic quartzite locally containing much diabase debris.

B. K. Johnson, 1957, California Univ. Pub. Geol. Sci., v. 30, no. 5, p. 360–369, fig. 3, 378 (fig. 7). Described in Manly Peak quadrangle, Death Valley region. In northern part of quadrangle, divided into three members (ascending) : Surprise (conglomerate subgraywacke), Sour Dough limestone, and South Park member (new) consisting of conglomerate, sandstone, and shale. Key to subdivision was Sour Dough limestone which forms prominent escarpments and hogbacks that contrast with smoother weathering members. Separation into members in southern part of area not possible, mostly because of insufficient time to trace outcrops of thinner and topographically less well defined Sour Dough in this rather inaccessible part of quadrangle. Base of thickest part of section not exposed, but it has minimum thickness of 2,700 feet in northern part of quadrangle; thickness decreases to a few tens of feet near Lotus mine. Base of formation exposed on west limb of anticline in Coyote Canyon and in Goler Wash; in both places, it rests unconformably on Archean gneiss or Archean metaconglomerate; throughout region, underlies Noonday dolomite with slight angular discordance; also pronounced color contrast marks contact—Noonday buff, Kingston Peak dark. Widely distributed over much of southern Death Valley region and exposed over more of western side of southern Panamint Range than any of other sedimentary formations; crops out discontinuously from Goler Wash at least as far north as Wildrose Canyon and Harrisburg Flat

Crops out in belt 20 miles long around north and east slopes of Kingston Range, Ivanpah quadrangle. Formation is interrupted by several faults. Name derived from Kingston Peak, highest point in range.

Kingston Range Monzonite Porphyry

Upper Cretaceous or Tertiary, lower: Southern California.

D. F. Hewett, 1948, California Div. Mines Bull. 129, p. 199–200; 1956, U.S. Geol. Survey Prof. Paper 275, p. 24, 26, 67–68, pl. 1. Uniform in composition and texture. In Kingston Range, Precambrian Pahrump series forms large dome in center of which is core of igneous rock, the Kingston Range monzonite porphyry.

Kingston Range, about 10 miles in diameter, lies near northeast corner of San Bernardino County.

†Kingstown Series[1]

Carboniferous: Central southern Rhode Island.

Original reference: A. F. Foerste, 1899, U.S. Geol. Survey Mon. 33, p. 331–347, pl. 31, map.

Typically exposed in South and North Kingstown, Washington County.

Kings Valley Siltstone Member (of Siletz River Volcanic Series)

Eocene, lower: West-central Oregon.

H. E. Vokes, D. A. Myers, and Linn Hoover, 1954, U.S. Geol. Survey Oil and Gas Inv. Map OM–150. Thin-bedded tuffaceous siltstone and water-laid tuffs that interfinger with volcanic rocks in upper part of Siletz River volcanic series. Thickness about 3,000 feet in vicinity of Kings Valley. Underlies Tyee formation.

Extensively exposed along east and south edges of Kings Valley in northwestern part of Corvallis quadrangle. No complete sequence exposed in map area.

Kinishba Beds (in Supai Formation)[1]

Permian: Southeastern Arizona.

Original reference: A. A. Stoyanow, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 533–536.

Named for occurrence in walls of old Indian pueblo, known as Kinishba, on bank of dry wash, southwest of White River settlement and northwest of Fort Apache, at foot of Kelly Butte, Navajo County.

Kinkaid Limestone[1]

Kinkaid Limestone (in Elvira Group)

Upper Mississippian (Chester Series): Southern and western Illinois, southern Indiana, and western Kentucky.

Original reference: S. Weller, 1920, Jour. Geology, v. 28, no. 4, p. 281–290; no. 5, p. 395–416.

J. M. Weller, 1939, Kansas Geol. Soc. Guidebook 13th Ann. Field Conf., p. 131, 136, 137; J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 5, p. 766 (fig. 1), 839–841. Assigned to Elvira group (new). Youngest formation of Chester series. In standard Mississippian section, overlies Degonia sandstone. In southwestern Indiana, Negli Creek limestone and the underlying shale are probably equivalent of Kinkaid formation.

C. A. Malott, 1952, Stratigraphy of the Ste. Genevieve and Chester formations of southern Indiana: Ann Arbor, Mich., The Edwards Letter Shop, p. 6. Name Kinkaid limestone extended into southern Indiana where it replaces term Negli Creek limestone. Local Indiana names of upper

Chester are dropped, and formations given names of standard Chester column.

T. G. Perry and N. M. Smith, 1958, Indiana Geol. Survey Bull. 12, pl. 1. Kinkaid limestone shown on stratigraphic column of upper Chester in Indiana as 20 to 35 feet of gray lithographic to medium-grained crystalline fossiliferous limestone and gray platy shale. Unconformable below Pennsylvanian Mansfield formation. Term Elvira group not used in Indiana.

Named for exposures along Kinkaid Creek and some of its tributaries in Jackson County, Ill.

Kinney Limestone Member (of Matfield Shale)

Kinney Limestone (in Chase Group)[1]

Permian: Southeastern Nebraska and eastern Kansas.

Original reference: G. E. Condra and J. E. Upp, 1931, Nebraska Geol. Survey Bull. 6, 2d ser., p. 37.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 45. Member of Matfield shale. Limestone and shale; generally an upper and lower gray fossiliferous limestone separated by gray fossiliferous shale. Thickness 1 to 24 feet. Underlies Blue Springs shale member; overlies Wymore shale member. Wolfcamp series.

M. R. Mudge and R. H. Burton, 1959, U.S. Geol. Survey Bull. 1068, p. 12 (table 2), 93–94, pls. Thickness 1 to 15 feet in Wabaunsee County, Kans. Overlies Wymore shale member; underlies Blue Springs shale.

Type locality: Burlington Railroad cut just east of Kinney, Gage County, Nebr.

Kinnick Formation[1]

Miocene, middle: Southern California.

Original reference: J. P. Buwalda, 1934, Pan-Am. Geologist, v. 61, no. 4, p. 310.

H. E. Wood, 2d, and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 23, pl. 1. Included in Hemingfordian and Barstovian ages.

J. P. Buwalda and G. E. Lewis, 1955, U.S. Geol. Survey Prof. Paper 264–G, p. 147–148. Described as consisting mainly of stratified green basic volcanic tuffs, largely ash beds with some coarse agglomerates; upper part gray sandy shale with, locally, white freshwater diatomaceous beds and cherts; some basic lava flows. Thickness not less than 1,500 feet. Strata moderately deformed with dips generally not more than 30°. Lies with strong angular unconformity across edges of Witnet formation; probably conformable with overlying Bopesta. Type locality designated; derivation of name given.

Type section: Base at unconformity north of confluence off Cache, Oil and Sand Creeks (SW cor. sec. 11, T. 32 S., R. 34 E.), thence northward through California Institute of Technology locality 503 in saddle west of Hill 5,015, Mojave quadrangle, in NW¼ sec. 34, T. 31 S., R. 34 E., M D B and M, Kern County. Named from Kinnick Ridge, north of Cache, Oil and Sand Creeks.

Kinnikinic Quartzite[1]

Upper Ordovician: Southern central Idaho and extreme southwestern Montana.

Original reference: C. P. Ross, 1932, Idaho correlation chart compiled by M. G. Wilmarth.

C. P. Ross, 1947, Geol. Soc. America Bull., v. 58, no. 12, pt. 1, p. 1102–1104, 1195, pl. 1. Described in Borah Peak quadrangle, Idaho, where it is about 3,000 feet thick, underlies Saturday Mountain formation and overlies Ramshorn(?) slate. Early part of Upper Ordovician.

L. L. Sloss and C. A. Moritz, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 10, p. 2148. Described in extreme southwestern Montana along crest of Beaverhead Range where it is a few tens of feet thick. Exposed above Beltian quartzites.

Named for exposures along Kinnikinic Creek, which reaches the Salmon River at Clayton, Idaho.

Kinnison Shale Member (of Cherokee Formation)

Kinnison Shale Member (of Mulky Formation)

Kinnison Shale Member (of Senora Formation)

Pennsylvanian (Des Moines Series): Northeastern Oklahoma.

W. B. Howe, 1951, Am. Assoc. Petroleum Geologists Bull., v. 35, no. 9, p. 2092. Member of Cherokee formation. Shale, dark gray at base, lighter above; upper 2 feet calcareous, fossiliferous, containing nonpersistent rough limestone in which crinoid fragments and *Chonetes* are most abundant fossils; includes a dark- to medium-gray conglomeratic limestone about 6 inches thick at base. Thickness a little more than 6 feet. Underlies Breezy Hill limestone member; overlies Iron Post coal.

C. C. Branson, 1954, Oklahoma Geol. Survey Guidebook 2, p. 5. Listed as Kinnison shale member of Mulky coal cycle in Senora formation.

W. B. Howe, 1956, Kansas Geol. Survey Bull. 123, p. 84. Reallocated to member status in Mulky formation. Kinnison shale and underlying Iron Post coal pinch out abruptly approximately at latitude of Oklahoma-Kansas line.

Well exposed in W½SW¼ sec. 36, T. 29 N., R. 19 E., Craig County.

Kinsey Canyon Formation

Tertiary: Eastern Nevada.

J. C. Young, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 160, 163–164. Conglomerate and lacustrine beds. Oldest Tertiary unit in area. Underlies Kalamazoo volcanics (new). Rests with slight angular unconformity on underlying upper Paleozoic rocks, locally contact is conglomerate-filled channels in Ely limestone. Tentatively correlated with the Eocene and early Oligocene(?) Sheep Pass formation.

Named for exposures in Kinsey Canyon, Schell Creek Range area, Ely quadrangle.

Kinsman Quartz Monzonite (in New Hampshire Plutonic Series)

Kinsman Granodiorite[1]

Upper Devonian(?): Southwestern and west-central New Hampshire.

Original reference: C. R. Williams, 1934, Appalachia, v. 20, no. 4, p. 69–78.

M. P. Billings, 1937, Geol. Soc. America Bull., v. 48, no. 4, p. 506–507. Described as quartz monzonite.

M. P. Billings, 1955, Geologic map of New Hampshire (1:250,000): U.S. Geol. Survey. Includes Meredith granite of Lake Winnipesaukee region, also "Franconia" breccia. Belongs to New Hampshire plutonic series of Upper Devonian(?) age.

Named for Kinsman Notch in Moosilauke quadrangle.

Kintla Argillite[1] (in Missoula Group)
Kintla Formation (in Missoula Group)

Kintla Member (of Miller Peak Formation)

Precambrian (Belt Series): Northwestern Montana, and southeastern British Columbia, Canada.

Original reference: Bailey Willis, 1902, Geol. Soc. America Bull., v. 13, p. 316, 324.

C. L. Fenton and M. A. Fenton, 1937, Geol Soc. America Bull., v. 48, no. 12, p. 1901–1902. Rank reduced to member status in Miller Peak formation. Consists of argillites and argillaceous sandstones, thinly bedded, dominantly bright red; thin beds of quartzite and pinkish-gray limestone. Contains 30 to 40 feet of purplish amygdaloidal lava. Ripple marks, mud cracks, channels, rain prints, and casts of salt crystals characteristic. Thickness 860 to 900 feet. Type locality and good exposures cited. Underlies Roosville member; overlies Sheppard formation.

S. D. Theodosis, 1955, Billings Geol. Soc. Guidebook 6th Ann. Field Conf., p. 62, chart facing p. 62. In Glacier Park area, only 860 feet of Missoula group is present, represented by Kintla formation, a red argillite which occurs in Kintla Lake area in northwestern part of park.

C. P. Ross, 1959, U.S. Geol. Survey Prof. Paper 296, p. 43–44. Willis (1902) proposed name Kintla argillite for part of Belt series above Shepard formation in northern part of Glacier National Park. He observed thickness of 800 feet and, because he saw no beds above his Kintla, assigned no upper limit. It is now known that Missoula group extends thousands rather than hundreds of feet above Purcell basalt. Because there is no way of separating Kintla argillite of Willis from similar beds at horizons above those he saw, name Kintla not useful at present.

Type locality: Willis gives it as pyramidal peaks on 49th parallel, at head of Kintla drainage [Glacier National Park, Mont.]. Fenton and Fenton give pyramidal peaks of Akamina Ridge, west of Waterton Lakes National Park [British Columbia]. Well exposed on Mount Rowe, Mount Carthew, Mount Custer, and on Boulder Peak.

Kinzers Formation[1]

Lower Cambrian: Southeastern Pennsylvania, Maryland, and Virginia.

Original reference: G. W. Stose and A. I. Jonas, 1922, Washington Acad. Sci. Jour., v. 12, p. 359, 362–363.

A. I. Jonas, 1936, Geol. Soc. America Bull., v. 47, no. 10, p. 1668 (table 1). Correlation chart shows Kinzers (shale) in Appalachian Valley, Hagerstown, Md.

G. W. Stose and A. I. Jonas, 1938, Virginia Geol. Survey Bull. 51–A, p. 21, 22. Proposed to extend names Vintage dolomite, Kinzers formation, and Ledger dolomite to comparable Lower Cambrian formations in Austinville area, Wythe and Carroll Counties, Va. In this area, the Kinzers is about 850 feet thick. Consists of (ascending) massive white crystalline and blue to dove-colored fine-grained fossiliferous limestone, 200 feet thick; argillaceous to sandy ridge-making limestone, buff, and earthy-weathering impure limestone, thin shale, and thin dolomite, 150 feet; thin slabby, fine-grained to compact blue limestone, thick dolomite, and limestone conglomerates, thick-bedded coarse limestone conglomerates at base, 500 feet. Overlies Vintage limestone; underlies Ledger dolomite.

Named for exposures in Pennsylvania Railroad cut at Kinzers, Lancaster County, Pa.

Kinzua Creek Sandstone

†Kinzua Creek Sandstone (in Pottsville Formation)[1]

Pennsylvanian: Northwestern and central northern Pennsylvania.

Original reference: C. A. Ashburner, 1879, Geologic map of McKean County: Pennsylvania 2d Geol. Survey.

Henry Leighton, 1941, Pennsylvania Geol. Survey, 4th ser., Bull. M–23, p. 57, 103. Kinzua Creek sandstone (Pottsville series) is separated from overlying Johnson Run sandstone by Alton coal group and from underlying Olean conglomerate by Marshburg coal and clay. [Also referred to as Kinzua sandstone.]

Named for exposures in Kinzua Creek valley, McKean County. Also noted in Cameron and Clinton Counties.

Kiowa Shale[1]

Kiowa Shale Member (of Purgatoire Formation)

Lower Cretaceous: Central southern Kansas, eastern Colorado, and western Oklahoma.

Original reference: F. W. Cragin, 1894, Colorado Coll. Studies, 5th Ann. Pub., p. 49.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 28. Consists of light-gray, dark-gray, and black fissile shale; contains thin limestone beds throughout, with Champion shell bed at base in type area. Locally, lenticular sandstones occur at any position within shale. Thickens across central and western Kansas toward south and southwest. Thickness 60 to 150 feet. Overlies Cheyenne sandstone; underlies Dakota formation.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Mapped in Cimarron County as member of Purgatoire formation and in northwestern Oklahoma as Kiowa shale.

T. G. McLaughlin, 1955, U.S. Geol. Survey Water-Supply Paper 1256, p. 99–100. Upper member of Purgatoire formation in Baca County, Colo. Commonly overlies Cheyenne sandstone member, although it overlies Morrison formation in Cimarron County, Okla. Underlies Dakota sandstone. Average thickness about 45 feet in southwestern part of Baca County; about 90 feet in places in northeastern part of county.

A. J. Myers, 1959, Oklahoma Geol. Survey Bull. 80, p. 43–46, pl. 1. Name Kiowa shale applied in Harper County to Cretaceous sandstones and shales unconformably overlying Cloud Chief formation. Consists of black to yellow resistant sandstones and thin white, somewhat chalky limestones. Maximum observed thickness 52 feet. Crops out as widely scattered outliers and is overlain by Quaternary sand dunes. Comanche series.

Named for Kiowa County, Kans.

Kipahulu Formation (in Hana Volcanic Series)

Pleistocene(?): Maui Island, Hawaii.

H. T. Stearns *in* H. T. Stearns and G. A. Macdonald, 1942, Hawaii Div. Hydrography Bull. 7, p. 91–92, pl. 18. Chiefly fine-grained aa in dense beds, some of which are columnar jointed. Total thickness may exceed 1,500 feet.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat: Internat., v. 6, Océanie, fasc. 2, p. 104. Pleistocene(?).

Fills deep ancestral Kipahulu Valley cut at end of Kula time. Exposed over an area 6 miles long by ½ to 1 mile wide, East Maui.

†Kirby Clay[1]

Lower Cretaceous (Comanche Series): Central southern Kansas.

Original reference: C. N. Gould, 1898, Am. Jour. Sci., 4th, v. 5, p. 170–174.

Named for Kirby, or C. W., or Fullington Ranch, on upper Medicine River, 10 to 12 miles west of Belvidere, Kiowa County.

Kirby Granite[1]

Age(?): Northeastern Vermont.

Original reference: C. H. Richardson, 1906, Vermont State Geologist 5th Rept.

On Kirby Mountain, eastern part of Kirby Township, Caledonia County.

Kirby Quartz Monzonite (in New Hampshire Plutonic Series)

Devonian: Northeastern Vermont.

J. H. Eric and J. G. Dennis, 1958, Vermont Geol. Survey Bull. 11, p. 28–29, pl. 1. Light-gray to white hypidiomorphic quartz monzonite consisting essentially of gray glassy quartz, biotite, microcline, albite-oligoclase, and, in some specimens, muscovite; in some places where microcline is abundant, rock is true granite. Emplaced after main period of Acadian deformation (Late Devonian).

Exposed in three small bodies, two on north border of Littleton quadrangle in town of Kirby, third near Stiles Pond in town of Waterford.

Kirby Lake Dolomite (in Arroyo Formation or Group)

Kirby Lake Dolomite (in Clear Fork Group)

Permian (Leonard): West-central Texas.

Gayle Scott and others, 1941, West Texas Geol. Soc. [Guidebook] Spring Field Trip, May 10–11, correction sheet. Proposed for preoccupied Cedar Creek. Name credited to [V. C.] Perini.

V. C. Perini, Jr., and J. R. Day, 1946, Abilene Geol. Soc. [Guidebook] November Field Trip, p. 5, 26. Stratigraphic section shows Kirby Lake dolomite in Arroyo formation above Lytle limestone and below Standpipe dolomites and limestone, or 145 feet above Lueders limestone. Page 26 states that Kirby Lake dolomite is member of Arroyo group.

Exposed at spillway at northwest corner of Kirby Lake, southwest of Abilene, Taylor County.

Kirker Tuff[1]

Oligocene: Western California.

Original reference: B. L. Clark, 1918, California Univ. Pub., Dept. Geol. Bull., v. 11, p. 54–111.

C. E. Weaver and others, 1944, Geol. Soc. America Bull., v. 55, no. 5, p. 585, chart 11. Shown on correlation chart as unconformable below Cierbo sandstone and uncomformable above a 50-foot unit termed "Kirker sandstone".

Type locality: On Kirker Creek, north Mount Diablo, San Francisco Bay region.

Kirkers Pass Beds[1]

Miocene: Western California.

Original reference: J. P. Smith, 1910, Jour. Geology, v. 18, table opposite p. 226.

Mount Diablo region.

Kirkfield Limestone or Formation

Kirkfield Limestone Group[1]

Middle Ordovician: Ontario, Canada, and northwestern New York.

Original reference: R. A. A. Johnson, 1911, Canada Geol. Survey Summ. Rept. 1910, p. 190.

G. M. Kay, 1943, Am. Jour. Sci., v. 241, no. 10, p. 598, 599. Along West Canada Creek, N.Y., Kirkfield limestone, 45 feet thick, disconformably overlies Rockland limestone and underlies Shoreham limestone. Name Kirkfield preferred to "Hull" of previous reports. Kirkfield has precedence over Hull. Type Hull at Hull, Quebec, has stratigraphic position of Kirkfield of southern Ontario and northwestern New York, for it lies between "*Triplesia* zone" (Rockland) and "*Cryptolithus* zone" (Shoreham); latter forms basal part of "*Prasopora* beds" (Sherman Fall) of Johnston and Raymond. There are faunal differences between the Hull and Kirkfield but the writer believes them equivalent. There has been assumption by some authors that all echinoderms at Hull, Quebec, are from Hull limestone and are synchronous with those described from type Kirkfield, whereas many are younger.

Marshall Kay, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1411–1412. Summary of Middle Ordovician bordering Allegheny synclinorium. Lower Trentonian formations of northwestern New York and eastern Ontario, the Rockland and Kirkfield or Hull limestones, disconformably overlap Black River rocks, lying locally on Canadian and Cambrian along Mohawk River, and on Precambrian in Ontario; the Rocklandian and Kirkfieldian are considered to be stages.

G. W. Sinclair, 1954, Ohio Jour. Sci., v. 54, no. 1, p. 31–41. Formation studied in Ontario. Concluded that Kirkfield of central Ontario is same age as the Rockland of Ottawa Valley. No beds of Hull age have been recognized in central Ontario.

P. A. Chenoweth, 1952, Geol. Soc. America Bull., v. 63, no. 6, p. 523–525. Formation described in Black River valley, New York, where it is about 100 feet thick. Overlies Rockland formation; underlies Shoreham formation. Trentonian.

Named for occurrence in vicinity of Kirkfield, Victoria County, Ontario.

Kirkfieldian Stage or Substage

Middle Ordovician: Eastern North America.

Marshall Kay, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 8, p. 1413–1414. Stage in lower Trentonian series. [Apparently replaces Hull stage.]

Marshall Kay, 1960, Internat. Geol. Cong., 21st, Copenhagen, pt. 7, p. 30, 33. Rocklandian and Kirkfieldian substages included in Nealmontian stage of Trentonian.

Name derived from Kirkfield, Victoria County, Ontario, Canada, for which Kirkfield limestone was named.

Kirkland Formation[1]

Silurian: Maryland, New York, and Pennsylvania.

Original reference: E. O. Ulrich, 1918, Geol. Soc. America Bull., v. 29, p. 82.

Kirkland Limestone and iron ore[1] (in Clinton Formation or Group)

Silurian: New York.

Original reference: G. H. Chadwick, 1918, Geol. Soc. America Bull., v. 29, p. 327–368.

Tracy Gillette, 1947, New York State Mus. Bull. 341, p. 107–111. The Kirkland at Clinton is fossiliferous hematitic limestone. Thickness 5½ feet on Dawes Quarry Creek; 54 inches at Willowvale. Lower limit of formation sharp. Separated from Dawes sandstone (new) at Clinton and Willowvale shale at Willowvale by unconformity. Underlies Herkimer sandstone.

Well exposed at town of Kirkland, Oneida County.

Kirkman Limestone

Permian: Northeastern Utah.

A. A. Baker and J. S. Williams, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 4, p. 623 (fig. 4), 625–626. Gray to black in part sandy fetid limestone, commonly finely laminated and locally containing some oolitic phosphate. Maximum thickness 1,350 feet; thins southward to 75 feet in Spanish Fork; estimated thickness 500 feet at mouth of Kirkman Hollow. Conformably underlies Diamond Creek sandstone (new); overlies Oquirrh formation.

H. J. Bissell, 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 4, p. 588–589. Described in Strawberry Valley quadrangle. Forms almost continuous outcrop band from Bennie Creek northeast of Mount Nebo in southern Wasatch Mountains northeastward through south-central Wasatch Mountains; disappears beneath Tertiary cover in area between Left Fork of Hobble Creek and Round Valley of Provo Canyon. Thickness 375 feet in North Strawberry Valley. Underlies Diamond Creek sandstone.

Named for exposures in Right Fork of Hobble Creek at mouth of Kirkman Hollow, Utah County.

Kirkwood Formation[1]

Miocene, middle: Eastern New Jersey.

Original reference: G. N. Knapp, 1904, New Jersey Geol. Survey Ann. Rept. State Geologist 1903, p. 81–82.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 23, pl. 1. Shown on plate 1 as Arikareean and Hemingfordian.

Named for exposures at Kirkwood, Camden County.

Kirschberg Evaporite (in Edwards Limestone)

Cretaceous: Central Texas.

V. E. Barnes, 1946, Texas Univ. Bur. Econ. Geology Pub. 4301, p. 40–43 [1944]. Name applied to bed of gypsum, approximately 35 feet thick, in Edwards limestone. Lies about 140 feet above base of Edwards.

Named for occurrence in Cherry Mountain area, Gillespie County. Deposits extend for 10 miles along east-west ridge of Edwards limestone northwest of Fredericksburg. Kirschberg is original German name for Cherry Mountain.

Kirtland Shale[1]

Upper Cretaceous: Northwestern New Mexico and southwestern Colorado.

Original reference: C. M. Bauer, 1916, U.S. Geol. Survey Prof. Paper 98–P.

Harley Barnes, E. H. Baltz, Jr., and P. T. Hayes, 1954, U.S. Geol. Survey Oil and Gas Inv. Map OM–149. Described in Red Mesa area, La Plata and Montezuma Counties, Colo. Consists of three members: unnamed lower shale, Farmington sandstone, and unnamed upper shale. Upper shale member includes 95 feet of pebble-bearing sandstone and sandy shale included in McDermott formation by Reeside (1924). Thickness about 1,125 feet. Overlies Fruitland formation; underlies Animas formation.

E. C. Beaumont and R. B. O'Sullivan, 1955, U.S. Geol. Survey Coal Inv. Map C–32. Mapped in Kirtland quadrangle. Upper and lower members composed principally of greenish-gray shale and separated by predominantly yellowish-green and gray Farmington sandstone member. Overlies Fruitland formation and underlies Ojo Alamo sandstone.

Named for exposures at Kirtland post office, San Juan County, N. Mex.

Kirtley Formation

Miocene: Central eastern Idaho.

A. L. Anderson, 1959, Idaho Bur. Mines and Geology Pamph. 118, p. 15, 21, 27–28, pl. 1. Proposed as substitute for name Carmen formation, which has been used elsewhere as formational name, and use here is discontinued. Although a little conglomerate occurs at or near base, formation characteristically without coarse clastic materials, consisting largely of moderately well-indurated thin-bedded fine-grained rocks, mostly shales with some intercalated sandstone and sandy shale. Good stratification in shales. Some beds highly siliceous; many are sandy. In Salmon quadrangle shale in places darkened by vegetable debris, otherwise, beds are white or light gray. Bentonitic beds not observed in North Fork quadrangle, though conspicuous farther south. Several hundred feet of beds exposed in southern part of North Fork quadrangle, but total thickness probably several times that amount. Text gives age as middle Miocene or younger; mapped as Miocene. Overlies Geertson formation.

Named from Kirtley Creek which flows across it near center of Salmon quadrangle. Extends less than 2 miles into southern part of North Fork quadrangle. Widespread south of lower Carmen Creek in more central part of Salmon Basin.

Kiser Gypsum Member (of Blaine Formation)[1]

Kiser Gypsum Member (of Flowerpot Shale)

Permian: Southwestern Oklahoma and western Texas.

Original reference: C. N. Gould, 1902, Oklahoma Geol. Survey 2d Bienn. Rept., p. 42, 55.

T. S. Jones, 1953, Stratigraphy of the Permian Basin of West Texas: West Texas Geol. Soc., p. 30. Shown on chart as member of Flowerpot shale in western Texas.

G. L. Scott, Jr., and W. E. Ham, 1957, Oklahoma Geol. Survey Circ. 42, p. 16, 17 (fig. 3), 18, pl. 1. Described in Carter area, Oklahoma, as greenish to reddish very shaly well-bedded gypsum, 2 to 5 feet thick. Occurs about 25 feet below top of Flowerpot; stratigraphically above Chaney gypsum member. Blaine formation redefined in this report.

Named for Kiser Salt Plain on Elm Fork of Red River, Greer County, Okla.

Kiskatom Formation[1] (in Hamilton Group)

Kiskatom Redbeds

Middle Devonian: Southeastern New York.

Original reference: G. H. Chadwick, 1932, Eastern States Oil and Gas Weekly, v. 1, no. 17, p. 7.

Winifred Goldring, 1943, New York State Mus. Bull. 332, p. 273–279 [1946]. Kiskatom beds typically consist of an alternation of red and greenish or gray sandstones with interbedded green and red shales, sometimes dark shales. Estimated 2,300 feet of beds in Catskill front where they have maximum thickness. In this area, they include entire Ludlowville and Moscow formations and upper part of Skaneateles formation; west of Kingston, probably no more than the Ludlowville and Moscow, if all of the former; in northern Helderbergs and on Durham quadrangle, the major part of Skaneateles, the Ludlowville, and the Moscow.

G. H. Chadwick, 1944, New York State Mus. Bull. 336, p. 119–122. Redbeds described in Catskill and Kaaterskill quadrangles. Beds here termed Kiskatom reds, with thickness of 2,300 feet, prove to be Middle Devonian, Hamilton age. They are, at least, approximately, the beds formerly taken here to be Oneonta of Naples age (lower "Portage"), though early mapped as "Chemung." Moreover they are the beds to which the name "Catskill" was first applied among these Middle and Upper Devonian red strata. Overlie Ashokan flagstones; underlie Kaaterskill sandstones.

Theodore Arnow, 1949, New York State Water Power and Control Comm. Bull. GW–20, p. 8 (table 1), 15. Formation at top of Hamilton group. Maximum thickness in Albany County about 1,000 feet. Overlies Ashokan formation; underlies Onteora formation. These are continental red beds which were formerly regarded equivalent in age to Oneonta sandstone. Middle Devonian.

Kiskatom is in Greene County.

Kitchen Brook Dolomite (in Stockbridge Group)

Lower Cambrian: Western Massachusetts.

Norman Herz, 1958, U.S. Geol. Survey Geol. Quad. Map GQ–108. Fine-grained white to light bluish-gray, or white-weathering, yellowish-gray massive dolomite; thinner bedded and quartz-feldspar-calcite rich in upper part. Thickness at type locality 450 feet; in Pontoosuc Lake-Town Brook valley thickness may be in excess of 1,800 feet. In vicinity of MacDonald Brook, in Cheshire, the Kitchen Brook is cut out altogether by an unconformity beneath Berkshire schist. Nowhere in quadrangle can complete cross section through dolomite be seen; lower contact, with Cheshire quartzite, and upper contact, with Clarendon Springs dolomite, were not observed in field.

Type section: Along Kitchen Brook, in village of Cheshire, Cheshire quadrangle, Berkshire County.

Kitchener Quartzite[1]

Precambrian (Belt Series): Southeastern British Columbia, Canada, and northern Idaho and northwestern Montana.

Original reference: R. A. Daly, 1905, Canada Geol. Survey Summ. Rept. 1904, p. 96–100.

Named for station on Canadian Pacific Railway (in Kootenay Province of British Columbia).

Kitchi Schist[1]

Precambrian: Northwestern Michigan.

Original reference: C. R. Van Hise and W. S. Bayley, 1895, U.S. Geol. Survey 15th Ann. Rept., p. 490, 492, 496.

W. T. Stuart, E. A. Brown, and E. C. Rhodehamel, 1954, Michigan Geol. Survey Tech. Rept. 3, p. 11 (table 3). Table of geologic formations of Marquette district shows Kitchi schist (Keewatin) below Palmer gneiss and above Mona schist.

Exposed on Kitchi Hills, in vicinity of Deer Lake, Marquette district.

Kite Group

Lower Devonian: South-central Oklahoma.

R. A. Maxwell, 1936, Northwestern Univ. Summ. of Doctoral Dissert., v. 4, p. 132, 134. Name applied to series of argillaceous limestone, cherty limestone, and shale. Thickness about 200 feet. Comprises Haragan formation below and Cravatt formation (new) above. Underlies Bois d'Arc limestone; unconformably overlies Henryhouse formation.

Occurs in Arbuckle Mountain region.

Kitsap Clay Member (of Orting Drift)

Pleistocene: Western Washington.

J. E. Sceva, 1957, U.S. Geol. Survey Water-Supply Paper 1413, p. 17–19, pl. 1. Consists chiefly of clay but contains strata of peat, sand, gravel, and glacial till. Member is well stratified; clay strata are, in most places, finely laminated, and sand and silt are in thin layers. Thickness less than 30 feet to more than 200 feet. Underlies Puyallup sand; overlies unnamed lower member of Orting gravel.

Type section: In sea cliff along Colvos Passage near Maplewood, in Pierce County, south of Kitsap County line, sec. 21, T. 22 N., R. 2 E.

Kittanning coal group (in Allegheny Formation)[1]

Pennsylvanian: Western Pennsylvania and Maryland.

Original reference: J. P. Lesley and I. C. White, 1876, Pennsylvania 2d Geol. Survey map of southern Butler County.

Named for town of Kittanning, Pa.

Kittanning Fire Clay (in Allegheny Formation)[1]

Pennsylvanian: Southwestern Pennsylvania.

Original reference: I. C. White, 1878, Pennsylvania 2d Geol. Survey Rept. Q.

See Lower Kittanning Clay.

Named for occurrence at Kittanning, Armstrong County.

Kittanning Formation[1] (in Allegheny Group)

Pennsylvanian: Western Pennsylvania.

G. H. Ashley, 1923, Eng. Mining Jour.-Press, v. 115, no. 25, p. 1108; 1926, Pennsylvania Geol. Survey, 4th ser., Topog. and Geol. Atlas 65, p. 28, pl. 4. Allegheny group comprises (ascending) Clarion, Kittanning, and Freeport formations. Kittanning formation extends from top of Upper Kittanning coal to base of clay under Lower Kittanning coal.

C. K. Graeber and R. M. Foose, 1942, Pennsylvania Geol. Survey, 4th ser., Topog. and Geol. Atlas 54, p. 37–40. Discussion of Brookville quadrangle. Kittanning formation comprises (ascending) Lower Kittanning clay, Lower Kittanning coal, Middle Kittanning coal, Upper Kittanning sandstone, and Upper Kittanning coal. Overlies Clarion formation (with Lower Kittanning sandstone at top); underlies Freeport formation. Allegheny group.

M. N. Shaffner, 1946, Pennsylvania Geol. Survey, 4th ser., Topog. and Geol. Atlas 55, p. 65, 67. Formation, in Smicksburg quadrangle, comprises (ascending) Lower Kittanning coal, Middle Kittanning coals, Johnstown limestone, and Upper Kittanning coal. Overlies Clarion formation which includes Vanport limestone at top; underlies Freeport formation. Allegheny group; Pittsburgh series.

R. R. Dutcher, 1959, Geol. Soc. America Guidebook Pittsburgh Mtg., p. 70 (fig. 5), 71, 82–114 (includes road log). Middle formation of Allegheny group. In area of present study [Armstrong, Cambria, Clearfield, and Jefferson Counties], formation is about 100 feet thick. Comprises (ascending) Lower Kittanning coal and clay, Middle Kittanning coal, and Upper Kittanning coal. About 50 feet of sedimentary rocks, principally sandstone and shale, lie between each of these beds. Recent studies indicate that at least three more beds are sufficiently distinctive and widespread enough to merit tentative names. Also subdivided into (ascending) unnamed lower part; Lower Kittanning marine shale; Middle Kittanning complex; Nicely Run siltstone and sandstone member (new); Upper Kittanning marine shale; and unnamed upper part. Formation is approximately equivalent to middle Des Moines rocks of Midcontinent region.

E. G. Williams, 1960, Jour. Paleontology, v. 34, no. 5, p. 910 (fig. 2). Includes Lower, Middle, and Upper Kittanning coals. Overlies Clarion formation; underlies Freeport formation.

Carlyle Gray and others, 1960, Geologic map of Pennsylvania (1 :250,000): Pennsylvania Geol. Survey, 4th ser. Mapped as middle formation of Allegheny group.

Named for Kittanning, Armstrong County.

Kittanning Limestone (in Allegheny Formation)[1]

Pennsylvanian: Ohio.

Original reference: E. Orton, Jr., and S. V. Peppel, 1904, Ohio Geol. Survey Bull. 3, p. 92.

Probably named for Kittanning, Armstrong County, Pa.

Kittanning Sandstone Member (of Allegheny Formation)[1]

Pennsylvanian: Western Pennsylvania and eastern Ohio.

Original reference: I. C. White, 1878, Pennsylvania 2d Geol. Survey Rept. Q.

W. O. Hickok 4th and F. T. Moyer, 1940, Pennsylvania Geol. Survey, 4th ser., Bull. C–26, p. 71. Kittanning (Clarion) sandstone discussed in Allegheny group in this report [Fayette County]. In standard section for southwestern Pennsylvania, both Kittanning and Clarion sandstones lie between Lower Kittanning and Clarion coals. Since the sandstones are normally separated by Vanport limestone, which is absent in Fayette County, it is difficult to say definitely whether sandstone lying below Lower Kittanning coal is the Kittanning or Clarion, but, because sandstone commonly occurs in upper part of interval, it is here called Kittanning. Average thickness about 10 feet.

Named for Kittanning, Armstrong County, Pa.

Kittanning Shale (in Allegheny Formation)[1]

Pennsylvanian: Western Pennsylvania.

Original reference: I. C. White, 1878, Pennsylvania 2d Geol. Survey Rept. Q.

See Lower Kittanning shale.

Named derived from Kittanning, Armstrong County.

Kittatinny Limestone[1]

Upper Cambrian and Ordovician: Northern New Jersey and eastern Pennsylvania.

Original reference: H. D. Rogers, 1840, New Jersey Geol. Survey 2d and Final Rept., p. 112.

R. L. Miller, 1937, Geol. Soc. America Bull., v. 48, no. 11, p. 1694 (fig. 1), 1700 (fig. 2), 1704 (fig. 4). Figures 1, 2, and 4 (geol. maps) show Kittatinny limestone in eastern Pennsylvania. New Jersey term, Kittatinny, used here to include dolomitic limestones of Cambrian and Beekmantown age.

B. F. Howell and others, 1944, Geol. Soc. America Bull., v. 55, no. 8, chart 1. Shown on correlation chart as Upper Cambrian.

M. E. Johnson, 1950, geologic map of New Jersey (1:250,000): New Jersey Dept. Conserv. Econ. Devel. As mapped, consists of three units: lower—massive blue, blue-gray limestone with yellowish or silvery shale (Lower Cambrian); middle—light and dark medium-bedded limestones with cryptozoon heads (Upper Cambrian), unconformity; upper—thin and thick, gray or blue cherty magnesian limestone (Beekmantown), unconformity. Underlies Jacksonburg limestone; overlies Hardyston sandstone. Cambro-Ordovician.

F. B. Howell, Henry Roberts, and Bradford Willard, 1950, Geol. Soc. America Bull., v. 61, no. 12, pt. 1, p. 1357, 1366. New Jersey Survey designates its Cambrian and Ordovician limestone collectively as Kittatinny. This collective term not applicable in eastern Pennsylvania, and Cambrian sequence includes Hardyston quartzite (Chickies quartzite in Buckingham Valley), Leithsville limestone, Limeport formation (new), and Allentown formation.

First described in Kittatinny Valley, N.J.

†Kittatinny Sandstone[1]

Silurian: New Jersey.

Original reference: H. D. Rogers, 1840, New Jersey Geol. Survey 2d and Final Rept., p. 112.

Kittery Quartzite[1] (in Merrimack Group)

Kittery Formation

Probably Ordovician and Silurian: Southwestern Maine and southeastern New Hampshire.

Original reference: F J. Katz, 1917, Washington Acad. Sci. Jour., v. 7, p. 198.

M. P. Billings, 1955, Geologic map of New Hampshire (1:250,000): U.S. Geol. Survey. Included in Merrimack group in New Hampshire. Probably Ordovician and Silurian.

M. P. Billings, 1956, Geology of New Hampshire, pt. 2, Bedrock geology: Concord, New Hampshire State Plan. Devel. Comm., p. 39–40. Age tentatively considered Silurian.

H. H. Woodward, 1957, Jour. Geology, v. 65, no. 1, p. 61, 67–69. Termed formation. Not quartzite according to usual definition.

Named for exposures in Kittery, York County, Maine.

†Kittitas System[1]

Eocene: Western central Washington.

Original reference: I C. Russell, 1893, U.S. Geol. Survey Bull. 108.

Well exposed in western part of Kittitas County.

Klamath Gravels[1]

Pleistocene: Northern California.

Original reference: N. E. A. Hinds, 1933, California Jour. Mines and Geology, v. 29, nos. 1, 2, p. 120–121.

Type locality: Near Red Bluff, Tehama County. Named for Klamath Mountains.

†Klamath Schists[1] or Schist Series[1]

Precambrian (?): Northern California.

Original reference: O. H. Hershey, 1901, Am. Geologist, v. 27, p. 225–245. Klamath Mountains.

Kline Member (of Nesson Formation)

Jurassic: Subsurface in North Dakota and Montana, and Manitoba, Canada.

J. W. Nordquist, 1955, Billings Geol. Soc. Guidebook 6th Ann. Field Conf., p. 104, 105–106, fig. 2. Uppermost member of formation; overlies Picard member (new); underlies Piper formation. At type section, consists of (descending) 34 feet of light-gray to white earthy dolomite and fine-grained sandstone; 13 feet of gray-green to purple calcareous shale containing white gypsum; 37 feet of light- to dark-brown finely crystalline limestone, oolitic in part and becoming shaly toward base; 63 feet of light-gray to buff fine- to medium crystalline limestone, earthy, gypsiferous and fossiliferous in part. Pinches out by nondeposition short distance east of Big Snowy uplift and wedges out in like manner on west flank of Bowdoin dome. On west margin of Williston Basin, unconformably overlies either Mississippian, Pennsylvanian, or Triassic beds.

Type section: Interval 4,386 to 4,533 feet in Price Drilling Co. No. 1, Kline well, center SE¼SE¼SE¼ sec. 16, T. 157 N., R. 85 W., Ward County, N. Dak.

Klondike Member (of Columbus Formation)[1]

Middle Devonian: Central Ohio.

Original reference: L. G. Westgate, 1926, Ohio Geol Survey, 4th ser., Bull. 30, p. 17, 22–25.

Wilber Stout and R. A. Schoenlaub, 1945, Ohio Geol. Survey, 4th ser., Bull. 46, p. 21. In southwestern Delaware County overlies Eversole chert member. Thickness about 45½ feet.

J. W. Wells, 1947, Ohio Jour. Sci., v. 47, no. 3, p. 121 (fig. 1). Chart shows Delhi (Klondike) as uppermost member of Columbus. Overlies Eversole member.

Well exposed at quarry of Scioto Lime & Stone Co., popularly known as Klondike quarry, Delaware County.

Klondike Mountain Formation

Oligocene: Northeastern Washington.

Hunting Geophysical Services, Inc., 1960, *in* Washington Div. Mines and Geology Rept. Inv. 20, p. 6. Youngest bedrock formation (aside from certain dikes) in Curlew quadrangle. Unconformably overlies Sanpoil volcanic rocks (new). Consists principally of layers of coarse clastic and pyroclastic rocks with local tuffaceous sandstone, conglomerate, and mudstone in lower part and thick black to gray glassy flows (calcic in composition) in upper part; locally lower part contains black glass, and upper part contains volcanic breccia Includes Tom Thumb member (new) at base. Republic quadrangle and part of Aeneas quadrangle mapped by Muessig and Quinlan (1959, U.S. Geol. Survey Open-file Rept.); Curlew quadrangle mapped by Calkins, Parker and Disbrow (1959, U.S. Geol. Survey Open-file Rept.).

Report discusses parts of Okanogan and Ferry Counties.

Klutina Group[1]

Carboniferous or older: Southeastern Alaska.

Original reference: F. C. Schrader, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 7, p. 410, 413.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000): U.S. Geol. Survey. Appears on map legend under Mississippian rocks undifferentiated.

Forms most of mountains about Lake Klutina, Copper River region.

Knapp Formation[1]

Knapp Formation (in Conewango Group)

Devonian or Carboniferous: Southwestern New York and northern Pennsylvania.

Original reference: L. C. Glenn, 1903, New York State Mus. Bull. 69, p. 967–989.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Knapp sandstone shown on correlation chart as Devonian or Mississippian.

Bradford Willard, 1946, Geol. Soc. America Bull., v. 57, no. 9, p. 781–796. Discussion of continental-marine Mississippian relations in northern Pennsylvania. Marine Mississippian consists of Knapp formation including Kushequa shale and Marvin Creek "limestone." In region of marine-continental transition, Mississippian system represented by approximately 150 feet of beds. Marine fossils disappear eastward as discoidal-pebble conglomerates and sandstones of the Knapp merge with Pocono sandstone and conglomerate. Underlies Pottsville (or Olean); overlies Mount Pleasant shale or Oswayo formation.

I. H. Tesmer, 1954, Hobbies, v. 35, no. 2, p. 30, 33–34. Uppermost formation in Conewango group. Approximate thickness 20 feet in Chautauqua County, N.Y Overlies Oswayo formation. Upper Devonian.

Most eastern exposure is at Knapp's Creek Station, Cattaraugus County, N.Y.

Knapp formational suite[1]

Devonian or Carboniferous: Southwestern New York and northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 111, table opposite p. 60.

Knapp monothem[1]

Devonian or Carboniferous: Southwestern New York and northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls Am. Paleontology, v. 21, no. 71, p. 103–104.

Kneeling Nun Rhyolite Tuff

Miocene(?): Southwestern New Mexico.

F. J. Kuellmer and others, 1953, *in* New Mexico Geol. Soc. Guidebook 4th Field Conf., p. 42 (map), 50 (map). Name appears on map explanations.

H L. Jicha, Jr., 1954, New Mexico Bur. Mines Mineral Resources Bull. 37, p. 39 (table 3), 44–45, pl. 1. Pale lavender-gray and dark-brown welded tuffs with prominent quartz phenocrysts, columnar jointing. Thickness 10 to 200 feet. Disconformable contacts with Sugarlump tuffs below and Mimbres Peak formation above. Derivation of name.

W. E Elston, 1957, New Mexico Bur. Mines Mineral Resources Bull. 38, p. 17 (table 1), 25–27, pl. 1. In Dwyer quadrangle, Kneeling Nun consists of at least two distinct rhyolite beds. Thickness 200 to 400 feet. Conformable with Sugarlump tuffs and could be considered their uppermost member. Underlies Mimbres Peak formation.

Named after prominent rock monument which overlooks town of Santa Rita, Grant County. Kneeling Nun is isolated column of welded rhyolite tuff which stands short distance in front of high escarpment of same rock.

Knickerbocker Andesite

Pliocene or Pleistocene: Western Nevada.

V. P. Gianella, 1936, Nevada Univ. Bull, v. 30, no. 9, p. 33 (table), 73–76, pl. 1. Dark, almost black, massive pyroxene andesite. In vicinity of Knickerbocker shaft, phenocrysts constitute two-fifths of rock; groundmass is light-brown transparent glass. Thickness 200 feet. In general, this andesite overlies Alta andesite breccias (new). Older than American Flat basalt (new). Late Pliocene.

F. C. Calkins and T P. Thayer, 1945, Preliminary geologic map of the Comstock Lode district, Nevada: U.S. Geol. Survey. Upper Pliocene or Pleistocene.

G. A. Thompson, 1956, U.S. Geol. Survey Bull. 1042–C, p. 57, pl. 3. Calkins (oral commun.) states that lava at Knickerbocker shaft is Alta formation and that what Gianella (1936) described as Knickerbocker is best represented by outcrops on Basalt Hill. Knickerbocker andesite unit, as represented by exposures on Basalt Hill, has general resemblance to pyroxene andesite member of Alta, but on fresh surface it is darker and on weathered surface is covered by characteristic buff-colored rind. Dikes of it cut Kate Peak formation. Geographical limits discussed. Age shown on plate as Pliocene or Pleistocene.

Typical occurrence is in vicinity of Knickerbocker shaft and another about 1,500 feet further to west. Distinguished only in Comstock Lode district, Virginia City quadrangle.

†Knife Slates[1]

Precambrian: Northeastern Minnesota.

Original reference: C. R. Van Hise and J. M. Clements, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 3, p. 401–409, map.

Named for Knife Lake, Vermilion district, where they are well developed.

Knife Lake Group

Knife Lake Series[1]

Precambrian: Northeastern Minnesota.

Original reference: F. F. Grout, 1933, Geol. Soc. America Bull., v. 44, no. 5, p. 992–995.

J. T. Stark and V. G. Sleight, 1939, Geol. Soc. America Bull., v. 50, no. 7, p. 1029–1041. Knife Lake series divided into (ascending) Moose Lake conglomerate (or Saddlebag Lake conglomerate), Dike Lake slate, Ogishke group (including Peebles conglomerate, West Gull conglomerate, and Zeta Lake conglomerate), and Knife Lake slate (including tuffaceous slate and graywacke, Agawa iron-formation, argillite, tuff and agglomerate).

J. W. Gruner, 1941, Geol. Soc. America Bull., v. 52, no. 10, p. 1583 (table 1), 1519–1618, pl. 1. Knife Lake series is continental in origin and comprises rocks formerly called Ogishke conglomerate, Agawa iron-formation, and Knife Lake slates. Includes many members (table 1 lists 20); these cannot be separated into three former divisions. No basal conglomerate exists in the sense in which Ogishke conglomerate exists. No distinct Agawa formation present. Conglomerates appear at any horizon in series, and small lenses of iron formation are not restricted to any particular horizon. Named units include (not in sequence): Disappointment Mountain and Moose Lake greenstone conglomerates, Jasper Lake greenstone conglomerates and agglomerates, Ogishke granite pebble conglomerate, Amoeba Lake graywackes, slates, and tuffs, Ensign Lake green slates, tuffs, and graywackes, Kekekabic Lake tuffs, agglomerates, slates, and andesite porphyry, Ensign-Snowbank Lake agglomerates, Ester Lake graywackes, slates and tuffs, Crooked Lake granite pebble conglomerate, and Agamok sediments. Unconformable below Animikie series and above Laurentian series.

F. F. Grout and others, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1031–1036, 1073–1074, 1075. Summary discussion. In Minnesota, Knife Lake group rests unconformably on Keewatin greenstone and an old granite intrusive into the greenstone; it is intruded by Algoman granite; both the Knife Lake and Algoman granite are overlain unconformably by Animikie group. Thickness 11,500 to 21,000 feet. Correlation with Huronian groups is not certain.

Type locality: Knife Lake, on boundary of Minnesota and Ontario. Exposed westward to vicinity of Lake of the Woods.

†Knife Lake Slates[1]

Precambrian : Northeastern Minnesota.

Original reference: C. R. Van Hise and J. M. Clements, 1901, U.S. Geol. Survey 21st Ann. Rept., pt. 3, p. 401–409, map.

J. W. Gruner, 1941, Geol. Soc. America Bull., v. 52, no. 10, p. 1640. Knife Lake slates included in Knife Lake series.

U.S. Geological Survey has abandoned the term Knife Lake Slates. Approved name is Knife Lake Group.

Named for exposures at Knife Lake.

Knifeton Formation or cyclothem (in Cherokee Group)

Pennsylvanian (Des Moines Series) : Southeastern Kansas.

G. E. Abernathy, 1937, Kansas Geol. Soc. Guidebook 11th Ann Field Conf., p. 18, 20, 22; 1938, Kansas Acad Sci. Trans., v. 41, p. 193, 196. Cherokee group divided into 15 cyclic formational units. The Knifeton, fifth in sequence (ascending), occurs above the Bluejacket and below the Weir. Average thickness about 24 feet. Includes 8-inch coal bed here named Knifeton. [For complete sequence see Cherokee group.]

Type locality and derivation of name not given. Cherokee outcrop in Kansas covers area of about 1,000 square miles and includes parts of Labette, Bourbon, Crawford, and Cherokee Counties.

Knight Conglomerate

Knight Formation (in Wasatch Group)[1]

Knight Member (of Wasatch Formation)

Eocene : Southwestern Wyoming and northeastern Utah.

Original reference : A. C. Veatch, 1907, Jour. Geology, v. 15, p. 547–549.

J. H. Donavan, 1950, Wyoming Geol. Assoc. Guidebook 5th Ann. Field Conf., p. 60, 61, 62–63. In south-central Sublette County, considered member of Wasatch formation. Overlies New Fork tongue (new) of Wasatch. Conformably underlies Fontenelle member (new) of Green River formation. Early Eocene.

A. J. Eardley, 1952, Utah Geol. Soc. Guidebook 8, p. 52. In northeastern Utah, where Fowkes formation is absent, Knight conglomerate unconformably overlies Almy conglomerate; underlies Norwood tuff and related Park City volcanics. Middle Eocene.

W. J. Morris, 1955, Dissert. Abs., v. 15, no. 3, p. 394. Name Knight extended from Bridger basin into Washakie basin to include dominantly fluviatile Wasatchian deposits. Includes Hiawatha member and Cathedral Bluffs tongue.

M. C. McKenna, 1955, Wyoming Geol. Assoc. Guidebook 10th Ann. Field Conf., p. 105. Term Knight formation rejected as junior synonym of Wasatch formation.

B. E. Lofgren, 1955, Utah Geol. Soc. Guidebook 10, p. 74 (table 1), 75. Discussion of Tertiary stratigraphy in Ogden Valley. Thickness of Knight conglomerate about 1,200 feet. In Echo Canyon, Eardley (1944) mapped Almy conglomerate and subdivided it into Saw Mill conglomerate and underlying Pulpit conglomerate, these being separated by angular discordance of 5° to 30°. Since Eardley's original mapping, he and thesis students have remapped area and now consider Saw Mill conglomerate as Knight.

N. C. Williams and J. H. Madsen, Jr., 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 123 (fig. 1). In Coalville area, Utah, Knight formation, 2,000 feet thick, unconformably overlies Echo Canyon conglomerate (new).

J. I. Tracey, Jr., and S. S. Oriel, 1959, Intermountain Assoc. Petroleum Geologists Guidebook 10th Ann. Field Conf., p. 128, 129, 130. Discussion of stratigraphy of Fossil basin, Wyoming. Confusion in original definition of Almy, Fowkes, and Knight formations as subdivisions of Wasatch group, and their areal distribution as mapped in much of basin, has led to serious doubt as to the validity of these names, particularly as the names Almy and Knight have been widely used in distant areas. It is hoped that future work will clarify the subdivisions of the Wasatch in the area and perhaps relate them to subdivisions in Bridger basin. At present, use of names Almy and Knight seem inadvisable without explicit statements as to their meaning.

Named for Knight Station, Uinta County, Wyo.

Knight Ranch Conglomerate (in Strawn Group)

Pennsylvanian: Central Texas.

F. B. Plummer, 1950, Texas Univ. Bur. Econ. Geology Pub. 4329, pl. 20. Shown on columnar section as thin conglomerate about 250 feet below Rochelle conglomerate.

Occurs in Brady area, McCulloch County.

Knik Glaciation

Pleistocene: Alaska.

T. N. V. Karlstrom, 1957, Science, v. 125, no. 3237, p. 74 (fig. 1). Named on correlation chart of glacial events. Recognized in Cook Inlet area. Y[illegible]er than Eklutna glaciation and older than Naptowne glaciation.

R. D. Miller and Ernest Dobrovolny, 1959, U.S. Geol. Survey Bull. [illegible] 12–54, pl. 3. Youngest pre-Wisconsin glaciation in Anchorage [illegible] Represented by sorted and unsorted drift that forms deposits of a[illegible] outwash, lateral moraine, ground moraine, pitted outwash, and g[illegible]vial and ice-contact deposits. Includes Bootlegger Cove clay (new), [illegible] locally separates Knik from overlying Naptowne deposits. Till and advance outwash of Knik glacier locally overlie truncated surface of Eklutna till.

Knob Creek facies[1] (of Carwood Formation)

Lower Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv., Div. Geology Pub. 98, p. 77, 163–167.

J. M. Weller and others, 1948, Geol. Soc. America Bull., v. 59, no. 2, p. 127–128, pl. 1. Facies nomenclature discussed. Knob Creek facies listed in Carwood formation.

Name derived from Knob Creek, near Edwardsville, Floyd County.

Knob Hill Andesite

Eocene: North-central Washington.

L. B. Wright, 1947, Am. Inst. Mining Metall. Engineers Tech. Pub. 2197, p. 5. Felspar-rich series of flows about 525 feet thick. Overlain by Miocene shales; underlain by tuffaceous and coarsely fragmental flows resting on folded Paleozoic basement.

Occurs at Knob Hill mine, Republic mining district. Traced along crest of low northward-plunging Republic anticline.

Knob Lick Granite[1]

Precambrian : Southeastern Missouri.

Original reference: C. R. Keyes, 1895, Missouri Geol. Survey Sheet Rept. 4, v. 9, p. 18, 19, 24.

Named for Knob Lick, St. Francois County.

†Knob Noster Group[1]

Pennsylvanian : Central western Missouri.

Original reference: G. C. Broadhead, 1873, Missouri Geol. Survey Prelim. Rept. on Iron Ores, pt. 2, p. 169, 176.

Named for exposures at Knob Noster, Johnson County.

Knobsville (continental) Beds[1]

Middle Devonian : South-central Pennsylvania.

Original reference: Bradford Willard, 1935, Geol. Soc. America Bull., v. 46, Proc. Pal. Soc. Feb. 28, p. 202, 214, 215, 221.

Bradford Willard, 1939, Pennsylvania Geol. Survey, 4th ser., Bull. G–19, p. 199–200. Knobsville continental beds are phase of Mahantango formation and are made up of red and green beds devoid of marine organic remains except for a few poorly preserved specimens of dubious identity which occur at margins of deposit where it passes over into marine strata. This passage is gradual and determines Hamilton age of lower part of the Knobsville. Continental beds thicken eastward until lost through erosion toward Franklin County line.

Well developed between Knobsville and Hustontown, Fulton County, and northward toward Fort Littleton, where they are exposed in highway cuts.

Knobtown Sand[1] or Sandstone (in Pleasanton Group)

Pennsylvanian (Missouri Series) : Western Missouri and eastern Kansas.

Original reference: F. C. Greene, 1933, Missouri Bur. Geology and Mines 57th Bienn. Rept., p. 13, 19, App. 2, pl. 2.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 91. In Linn and Miami Counties, upper part of Pleasanton group partly occupied by massive sandstone (Knobtown) which is locally as much as 25 feet thick.

F. C. Greene and W. B. Howe, 1952, Missouri Geol. Survey and Water Resources Inf. Circ. 8, p. 6, 16. Lies above position of Exline limestone. Thickness about 5 feet in Kansas City area.

Named for outcrop north of Knobtown, Jackson County, Mo., on U.S. Highway 50, sec. 22, T. 48 N., R. 32 W.

Knowlton Amygdaloid[1] (in Central Mine Group)

Precambrian (Keweenawan) : Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S.. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Named for occurrence in Knowlton mine, Ontonagon County.

Knowlton Flow[1]

Precambrian (Keweenawan) : Northern Michigan.

Original reference: B. S. Butler and W. S. Burbank, 1929, U.S. Geol. Survey Prof. Paper 144 (chart compiled by M. G. Wilmarth).

Copper district of Keweenaw Point.

Knox Dolomite[1] **or Group**

Upper Cambrian and Lower Ordovician: Eastern Tennessee, northwestern Georgia, western North Carolina, and southwestern Virginia.

Original reference: J. M. Safford, 1869, Geology of Tennessee, p. 151, 158–159, 203–226.

Charles Butts and Benjamin Gildersleeve, 1948, Georgia Geol. Survey Bull. 54, p. 16–18, geol. map. Knox dolomite used in this report for map unit that corresponds nearly to Knox dolomite of type region. Difference is that Newala limestone, which in Georgia overlies the Knox of the region, is included in the typical Knox. Knox of Georgia includes rocks that in Alabama, Tennessee, and Virginia have been separated into (ascending) Copper Ridge dolomite, Chepultepec dolomite or limestone, and Longview or Nittany dolomite. While these units have been recognized in Georgia, the conditions of exposures and scarcity of fossils make their accurate separation impossible without much more detailed investigation than time permitted for present report. Knox of Georgia includes Longview at top and Chepultepec next below. Whatever Knox there is below the Chepultepec and down to the Conasauga is Copper Ridge. Estimated thickness 3,500 feet. Cambrian and Ordovician (U.S. Geological Survey) or Ozarkian and Canadian (of Ulrich).

John Rodgers and D. F. Kent, 1948, Tennessee Div. Geology Bull. 55, p. 14–32. Referred to as group in Lee Valley, Hawkins County. Comprises (ascending) Copper Ridge dolomite, Chepultepec dolomite, Longview dolomite, Kingsport limestone, and Mascot dolomite.

R. L. Miller and W. P. Brosgé, 1950, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 104, 2 sheets. Group, in Jonesville district, Lee County, Va., comprises Copper Ridge, Chepultepec, Longview, Kingsport, and Mascot dolomites. Overlies Chances Branch dolomite member of Maynardville limestone; underlies Dot limestone (new).

A. C. Munyan, 1951, Georgia Geol. Survey Bull. 57, p. 38–49. Mapped as Knox dolomite in Dalton quadrangle. Undifferentiated. Overlies Conasauga formation; underlies Newala formation.

R. B. Neuman, 1951, Am. Jour. Sci., v. 249, no. 10, p. 744 (table 1). Discussion of Great Smoky fault. Generalized stratigraphic sequence shows Knox group, undivided, 2,000 feet thick. Underlies Mosheim and Lenoir limestones; overlies Rome formation, sequence broken by fault.

John Rodgers, 1953, Tennessee Div. Geology Bull. 58, pt. 2, p. 53–64, pls. For present map, the Knox extends from top of Maynardville limestone to marked disconformity, observable everywhere in east Tennessee between Lower and Middle Ordovician rocks. Where Knox is divided into formations, it is referred to as group; where not subdivided, it is considered a formation, Knox dolomite. Where fully subdivided, consists of (ascending) Copper Ridge dolomite, Chepultepec dolomite, Longview dolomite, Kingsport formation, and Mascot dolomite.

A. T. Allen, 1953, Georgia Geol. Survey Bull. 60, p. 178–179. Report gives measured sections of Knox dolomite near Graysville. Comprises (ascending) Copper Ridge, Chepultepec, Longview, and Newala formations. Approximate total thickness 4,500 feet. Contact between Copper Ridge and underlying Conasauga indefinite at this locality. Top of Knox overlain by Blackford formation.

R. L. Miller and J. O. Fuller, 1954, Virginia Geol. Survey Bull. 71, p. 41–62, table 1, pls. Group described in Rose Hill district, Lee County, where it is about 2,300 feet thick and comprises (ascending) Copper Ridge, Chepultepec, Longview, Kingsport, and Mascot dolomites. Underlies Murfreesboro limestone; overlies Chances Branch member (new) of Maynardville limestone.

J. M. Cattermole, 1955, U.S. Geol. Survey Geol. Quad. Map GQ-76. In Shooks Gap quadrangle, Tennessee, group composed of 2,600 to 3,000 feet of dolomite and limestone. Comprises (ascending) Copper Ridge dolomite, Chepultepec, Longview, and Newala (Kingsport and Mascot undifferentiated).

Josiah Bridge, 1956, U.S. Geol. Survey Prof. Paper 277, p. 7 (fig. 2), 21-24, pl. 1. Knox group as used in this report [Mascot-Jefferson City Zinc district, Tennessee] comprises all strata above Maynardville limestone member of Nolichucky shale and below Lenoir limestone or its Mosheim member. It is virtually the Knox dolomite of Knoxville, Maynardville, and Morristown folios (Keith, 1895, 1901, 1896). Divided into (ascending) Copper Ridge dolomite of Late Cambrian age and Chepultepec, Longview, Kingsport, and Mascot formations of Early Ordovician age. Historical summary of usage of name.

P. B. King and H. W. Ferguson, 1960, U.S. Geol. Survey Prof. Paper 311, p. 28 (table), 55-57, pl. 1. Group, in northeasternmost Tennessee, comprises Conococheague limestone and Jonesboro limestone. Overlies Conasauga group; underlies rocks of Middle Ordovician age (Lenoir limestone at base). Thickness about 3,000 feet in Denton Valley.

Named for development in Knox County, Tenn.

Knox Gneiss[1]

Precambrian: Central southern and eastern Maine.

Original reference: E. H. Perkins and E. S. C. Smith, 1925, Am. Jour. Sci., 5th, v. 9, p. 204-288.

L. A. Wing, 1957, Maine Geol. Survey GP. and G. Survey 1, sheet 1. Mentioned in report on aeromagnetic and geologic reconnaissance survey of parts of Hancock and Penobscot Counties. Appears to be older than surrounding formations but not necessarily equivalent to Ellsworth.

Probably named for occurrence in town of Knox, Waldo County.

†Knox Group[1]

Lower, Middle, and Upper Cambrian and Lower Ordovician: Eastern Tennessee, northern Alabama, northwestern Georgia, and western North Carolina.

Original reference: J. M. Safford, 1869, Geology Tennessee, p. 151, 158-159, 203-226.

Crops out in greater part of surface of East Tennessee Valley. Probably named for Knox County, Tenn.

†Knox Sandstone[1]

Lower Cambrian: Eastern Tennessee, northern Alabama, northwestern Georgia, and western North Carolina.

Original reference: J. M. Safford, 1869, Geology of Tennessee, p. 151, 158-159, 203-226.

Named for Knox County, Tenn.

†Knox Shale[1]

Middle and Upper Cambrian: Eastern Tennessee, northern Alabama, northwestern Georgia, and western North Carolina.

Original reference: J. M. Safford, 1869, Geology of Tennessee, p. 151, 158–159, 204–226.

Named for Knox County, Tenn.

Knox Mountain Granite[1]

Age (?) : Northeastern Vermont.

Original reference: C. H. Richardson, 1906, Vermont State Geologist 5th Rept.

V. R. Murthy, 1957, Vermont Geol. Survey Bull. 10, p. 79–81. Outcrop area extends from East Barre area [this report] northward into Plainfield and St. Johnsbury quadrangles. Although a separate name is given to this granite, Knox Mountain granite and Barre granite may be separate outcrops of single plutonic body. No positive evidence to attest such relationship attainable for this report. Age not stated Rb/Sr age determination on Barre granite gave 330±25 million years. This suggests a Silurian age for the granite, but it is only slightly higher for Middle Devonian.

Named for Knox Mountains in East Barre quadrangle.

Knoxville Formation[1]

Knoxville Series

Upper Jurassic: California and Oregon.

Original reference: C. A. White, 1885, U.S. Geol. Survey Bull. 15, p. 19–32.

F. M. Anderson, 1943, California Div. Mines Bull. 118, pt. 2, p. 184 (fig. 68) [reprint 1941]; 1945, Geol. Soc. America Bull., v. 56, no. 10, p. 909–1014. Knoxville series subdivided into (ascending) Elder Creek, Grindstone, and Newville groups (all new). Maximum thickness more than 16,000 feet. Underlies Paskenta group, Shasta series. Jurassic (early-middle Portlandian to latest Tithonian).

N. L. Taliaferro, 1943, Am. Assoc. Petroleum Geologists Bull., v. 27, no. 2, p. 109–219. Franciscan-Knoxville problem discussed. Term Knoxville used here for sediments and volcanics above what is commonly regarded as Franciscan and below Lower Cretaceous. As commonly described, Knoxville consists of thick series of shales, with minor amounts of sandstone and conglomerate. This is adequate description of bulk of Knoxville in many localities, but it ignores certain important rocks in some localities and entire sections in other regions. Although there is a lithologic difference between Franciscan and Knoxville in many areas, this difference is not universal and types commonly regarded as Franciscan are in many places found in what must be called Knoxville on basis of fauna. The unconformity between Franciscan and Knoxville reported by many writers, is not supported by field evidence. Knoxville is here regarded as upper phase of the Franciscan, and it is suggested that name Franciscan-Knoxville group be used for entire sequence.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 18 (table 3), 31–39, pls. In this report [Coast Ranges immediately north of San Francisco Bay region], Knoxville formation is included in Shasta series. In some areas, Knoxville formation, as used here, may include the Horsetown. Thickness about 11,000 to 13,230 feet. No depositional contact noted with Franciscan formation; most areas contacts are along thrust or normal faults.

M. D. Crittenden, Jr., 1951, California Div. Mines Bull. 157, p. 22 (fig. 4), 26–30, pl. 1. Generalized stratigraphic column (fig. 4) and geologic map of San Jose-Mount Hamilton area shows Knoxville formation above Franciscan formation and below Oakland conglomerate(?). Discussion of unit under heading of Knoxville(?) formation.

J. C. Brice, 1953, California Div. Mines Bull. 166, p. 11, 12 (fig. 2), pl. 1. For purposes of mapping in Lower Lake quadrangle, Franciscan-Knoxville group as defined by Taliaferro has been separated into two units, Franciscan group and Knoxville group. Knoxville, which consists mostly of shale, is about 10,000 feet thick. Underlies undifferentiated Cretaceous which in turn is overlain by Martinez formation. Upper Jurassic.

G. D. Robinson, 1956, U.S. Geol. Survey Geol. Quad. Map GQ–88. Formation, in Hayward quarangle, unconformably overlies Franciscan group and underlies Oakland conglomerate. Late Jurassic.

W. P. Irwin, 1957, Am. Assoc. Petroleum Geologists Bull., v. 41, no. 10, p. 2284–2297. Franciscan group is widely held to be restricted to Late Jurassic age, the Knoxville formation to be an upper shaly phase of the Franciscan group, and the two to be overlain unconformably by detrital strata of Cretaceous age. Paleontologic evidence indicates this view to be incorrect. Rather, Franciscan group seems mainly to have been deposited contemporaneously with the Knoxville, Paskenta, Horsetown, and lower upper Cretaceous strata. Franciscan group of Coast Ranges and strata of Sacramento Valley section may represent two facies of same stratigraphic section.

R. W. Imlay and others, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2776, 2783. Name Riddle formation (new) replaces Jurassic part of Knoxville formation as used by Diller and Kay (1924, U.S. Geol. Survey Geol. Atlas, Folio 218) in southwestern Oregon. Name Days Creek formation (new) replaces Horsetown formation and Cretaceous part of Knoxville formation as used by Diller and Kay.

Named for exposures at Knoxville, Napa County, Calif.

†Knoxville Marble[1]

Lower Ordovician (late Chazy): Eastern Tennessee.

Original reference: J. M. Safford and J. B. Killebrew, 1900, Elements of geology of Tennessee, p. 105, 117, 121.

Named for Knoxville, Knox County, near which it is exposed.

Knoxville Member (of Pascagoula Formation)

Miocene: Southwestern Mississippi.

Mississippi Geol. Soc., 1940, Mississippi Geol. Soc. [Guidebook] Field Trip, Feb. 10–11, p. 4. Referred to as Knoxville zone in Pascagoula formation.

G. F. Brown and W. F. Guyton, 1943, Mississippi Geol. Survey Bull. 56, p. 22. Name Knoxville preoccupied; unit renamed Homochitto member. Underlies Fort Adams members.

Present in Franklin and Wilkinson Counties.

Kodak Sandstone (in Clinton Group)

Kodak White Sandstone[1]

Middle Silurian: Western New York.

Original reference: G. H. Chadwick, 1935, Am. Assoc. Petroleum Geologists Bull., v. 19, no. 5, p. 702.

D. W. Fisher, 1953, Buffalo Soc. Nat. Sci. Bull., v. 21, no. 2, p. 29. Chadwick (1935) was of opinion that Thorold sandstone was absent at Rochester because grayish-white sandstone there did not contain *Arthrophycus*, which he regarded as indicative of the Thorold. To this presumably younger sandstone beneath Maplewood shale he applied name Kodak white sandstone. There is no necessity for name Kodak because *Arthrophycus* has since been found in this sandstone at Rochester.

D. W. Fisher, 1959, New York State Mus. Sci. Service Geol. Survey Map and Chart Ser. 1. Because "Thorold" of Gillette (1947) is not continuous with type Thorold at Thorold, Ontario, name Kodak (Chadwick, 1920 [?]) is revived for basal sandstone of Clinton group in New York, Ontarian stage. Middle Silurian.

Type exposure: Lower Genesee Gorge from lower falls to Kodak Park, Rochester, Monroe County.

Koehler Limestone (in Traverse Group)

Middle Devonian: Northern Michigan.

W. A. Kelly and G. W. Smith, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 3, p. 448 (fig. 1), 450 (fig. 2), 454–455. Defined to include gray bedded dense limestones of sublithographic texture, which are known to overlie Killians black limestone member of Genshaw formation (redefined), and unconformably underlie Gravel Point limestone. Estimated thickness (substantiated by well cuttings) 30 to 40 feet.

Type locality: Abandoned quarry of Campbell Stone Co., 1 mile north of village of Afton, Koehler Township, Cheboygan County.

Kofa Volcanics

Cretaceous: Southwestern Arizona.

E. D. Wilson, 1960, Geologic map of Yuma County, Arizona (1:375,000): Arizona Bur. Mines. Flows, dikes, and plugs of andesitic to rhyolitic composition.

Type locality and derivation of name not given.

Kogosukruk Tongue (of Prince Creek Formation)

Upper Cretaceous: Northern Alaska.

George Gryc, W. W. Patton, Jr., and T. G. Payne, 1951, Washington Acad. Sci. Jour., v. 41, no. 5, p. 166, figs. 2, 3. Nonmarine unit consisting largely of clay, silt, and shale. Bony coal and bentonitic beds common. Sandstone rare and only one conglomerate, 15 feet thick, has been mapped. Uppermost tongue of formation. Total thickness along Colville River is 2,340 feet but this includes marine units of Sentinel Hill member (new) of Schrader Bluff formation (new). In outcrop belt, overlies Tuluga member (new) of Schrader Bluff formation and is covered by thin mantle of Gubik formation.

C. L. Whittington *in* George Gryc and others, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 2, p. 253, fig. 4. Overlies and intertongues with Sentinel Hill member of Schrader Bluff formation.

Named from Kogosukruk River, along which it is well exposed. Equally good if not better exposures readily accessible along Colville River from near its confluence with Anaktuvuk River to Ocean Point just north of 70th parallel.

Koipato Formation[1] or **Group**

Permian and Lower Triassic: Northern Nevada.

Original references: Clarence King, 1876, U.S. Geol. Expl. 40th Par. Atlas, map V; 1878, U.S. Geol. Expl. 40th Par., v. 2, p. 267–278.

H. E. Wheeler 1939, Jour. Paleontology, v. 13, no. 1, p. 105–107. Permian and possibly Triassic at least in part. Thickness 14,000 feet in Humboldt Range.

S. W. Muller and H. G. Ferguson, 1939, Geol. Soc. America Bull., v. 50, no. 10, p. 1590. Disconformably underlies Star Peak formation.

H. G. Ferguson, S. W. Muller, and R. J. Roberts, 1951, Geology of the Winnemucca quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–11]. Rhyolite and trachyte flows, breccias, and tuffs, some andesite, small amounts of conglomerate, sandstone, and tuffaceous slate. In East Range in lower plate, thickness over 4,500 feet; in Sonoma Range, in upper plate, thickness 300 feet or less, in places missing. Permian.

R. E. Wallace and others, 1959, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–220. Rank raised to group. In Buffalo Mountain quadrangle, includes Rochester trachyte below and Weaver rhyolite above. Underlies Star Peak group. Permian, Permian(?), and Triassic.

U. S. Geological Survey currently considers the Koipato to be Permian(?) and Lower Triassic in age.

First described from West Humboldt Range. Koipato is Indian name for West Humboldt Range.

†Koipatoan series[1]

Middle(?) Triassic: Northern Nevada.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 52, 59, 79.

Named for exposures in West Humboldt Range, Humboldt County, the Indian name for which is Koipato.

Kokernot Formation

Recent: Southwestern Texas.

C. C. Albritton, Jr., and Kirk Bryan, 1938, (abs.) Geol. Soc. America Bull., v. 49, no. 12, pt. 2, p. 1863. On basis of disconformities in valley-fill complex the Quaternary (late Pleistocene) has been divided into (ascending) Neville, Calamity, and Kokernot formations.

C. C. Albritton, Jr., and Kirk Bryan, 1939, Geol. Soc. America Bull., v. 50, no. 9, p. 1441–1442, 1445–1446, 1450–1451, 1453–1454. Consists predominantly of uncemented quartz sand and silt with interbedded gravel lentils, Contains cultural material at top and bottom; pottery in upper layers shows that beds were deposited within interval 1100–1400 A. D. Thickness varies from less than 1 foot to 13 feet. At type locality, rests disconformably on both Neville and Calamity formations.

Type locality: West bank of Calamity Creek 1 mile northwest of Neville's ranchhouse, Brewster County. Exposed in section at top of Arroyo banks. Named for Kokernot Ranch.

Koko Volcanics[1] (in Honolulu Volcanic Series)

Pleistocene, upper, or Recent: Oahu Island, Hawaii.

Original reference: H. T. Stearns, 1935, Hawaii Div. Hydrography Bull. 1.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 104–105. Well-bedded gray to brown tuff, partly palagonitized, forming row of cones including Koko Head; and five associated small lava flows of alkali olivine basalt. Includes Koko Crater tuff, Koko Head tuff, Hanauma Bay tuff, and Kaohikaipu lava (Winchell, 1947, Geol. Soc. America Bull., v. 58, no. 1), none of which are regarded as formal names. Overlies Koolau volcanic series with steep erosional unconformity; also soil-covered emerged reef of plus 25-foot (Waimanalo) stand of sea. Extent noted.

Named for Koko Head and Koko Crater, which are cones composed of the tuff. Covers area of about 3 square miles extending northeastward from Koko Head, 2 to 5 miles southwest of Makapuu Head.

Kokomo Limestone[1]

Upper Silurian: Central Indiana.

Original reference: A. F. Foerste, 1904, Indiana Dept. Geology and Nat. History 28th Ann. Rept., p. 33.

J. B. Patton, 1949, Indiana Div. Geology Prog. Rept. 3, p. 13. Gray to brown banded dolomitic limestone, much of which is finely laminated. Although usually described as argillaceous, analyses show little alumina. At Kokomo and near Peru, upper beds are contorted, faulted, and recemented. Unconformably overlies Liston Creek, Mississinewa, and Niagaran reefs; underlies Kenneth limestone or Middle Devonian limestone. Has been considered Cayugan, but upper part may be Devonian.

Named for exposures at Kokomo, Howard County.

Kolekole Volcanics

Pleistocene(?): Oahu Island, Hawaii.

H. T. Stearns, 1946, Hawaii Div. Hydrography Bull. 8, p. 77. Lavas and cinders from secondary eruptions on Waianae Range. Probably correlative with secondary eruptions on Koolau Range. Pleistocene.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc, 2, p. 105. Overlie Waianae volcanic series and decomposed alluvium with erosional disconformity. Thickness about 6 feet. Pleistocene(?).

Crops out near Kolekole Pass in Waianae Range.

†Kolmakof Series[1]

Late Paleozoic to Tertiary(?): Southern Alaska.

Original reference: J. E. Spurr, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 7, p. 161–163, 182.

Crops out along right bank of Kuskokwim River between Kolmakof and beginning of low silt plain just above entrance to Yukon portage route above Kalchagamut.

Koloa Volcanic Series

Koloa Series

Pleistocene and Recent: Kauai Island, Hawaii.

N. E. A. Hinds, 1930, Bernice P. Bishop Mus. Bull. 71, p. 57, 58. Term Koloa series applied to lavas and pyroclastics erupted during Koloa volcanic episode.

H. T. Stearns, 1946, Hawaii Div. Hydrog. Bull. 8, p. 85, 87–89. Volcanic series composed of olivine basalts and ultrabasic rocks carrying nepheline and melilite. Separated from Waimea and Haupu volcanic series (new) by angular erosional unconformity.

G. A. Macdonald, D. A. Davis, and D. C. Cox, 1964, Volcano Letter 526, p. 2 (fig. 1). Overlies Waimea Canyon series [replaces term Waimea series]. Underlies Palikea formation (new).

D. A. Davis and G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 105–106. Pleistocene and Recent. Type locality stated.

G. A. Macdonald, D. A. Davis, and D. C. Cox, 1960, Hawaii Div. Hydrography Bull. 13, p. 52–87, table facing p. 20, pl. 1. Koloa volcanic series, as herein defined, is that series of volcanic rocks and closely associated sedimentary rocks laid down on rocks of Waimea Canyon volcanic series and separated from them by profound erosional unconformity. Series includes lava flows of olivine basalt, nepheline basalt, melilite-nepheline basalt, and basanite, related cinder and tuff cones and ash beds, and closely associated or intercalated sedimentary breccia and conglomerates (Palikeo formation). Maximum exposed thickness 2,100 feet. A large part of the series was during Pleistocene epoch, but it is possible that Koloa eruptions began during the Pliocene.

Type locality: Vicinity of town of Koloa, on south side of island. Widely distributed over eastern two-thirds of island.

Kolosh Member (of Kialagvik Formation)

Lower Jurassic: Southwestern Alaska.

L. B. Kellum, 1945, New York Acad. Sci. Trans., ser. 2, v. 7, no. 8, p. 203 (table 1). Upper part of member of platy to massive medium-grained to conglomeratic greenish-gray sandstone 200 feet thick. Lower part of interbedded sandstone and shale becoming predominantly sandstone at top; 300 feet thick. Overlies Aleuts member (new); underlies Cynthia Falls member (new) of Tuxedni formation.

Kialagvik formation is recognized on Iniskin-Chinitna Peninsula.

Kona Dolomite[1]

Precambrian: Northwestern Michigan.

Original reference: C. R. Van Hise and W. S. Bayley, 1895, U.S. Geol. Survey 15th Ann. Rept., p. 523.

S. A. Tyler and others, 1940, Geol. Soc. America Bull., v. 51, no. 10, p. 1436 (table 1), 1461. Palmer gneiss, previously considered pre-Huronian, consists of metamorphic Mesnard quartzite, Kona dolomite, Wewe slate, and Ajibik quartzite. Table 1 shows lower Huronian sequence in Marquette area (ascending) Mesnard, Kona, Wewe. Palmer gneiss not listed on this table.

Composes Kona Hills, on east shore of Goose Lake, Marquette district.

Kona Tuff Formation

Pleistocene(?) and Recent: Hawaii Island, Hawaii.

C. K. Wentworth, 1938, Hawaiian Volcano Observatory 3d Spec. Rept., p. 90–91. Very fine grained yellow-brown palagonite ash with small amounts of fragments of olivine and feldspar crystals. Thickens gradually upslope from few inches to 5 feet; forms continuous mantle on mountain; grades into cinder cones at summit.

H. T. Stearns and G. A. Macdonald, 1946, Hawaii Div. Hydrography Bull. 9, p. 142; D. A. Davis and G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 106. Included in Hualalai volcanic series (new).

Type locality: Kona district on west side of island. Exposed on southwest slope of Hualalai volcano.

Konawa Formation[1] (in Pontotoc Group)

Permian: East-central Oklahoma.

Original reference: G. D. Morgan, 1924, Bur. Geol. [Oklahoma] Bull. 2, p. 140–141, pls. 3, 27, map.

W. F. Tanner, 1956, Oklahoma Geol. Survey Bull. 74, p. 108–115, pl. 1. Further described in type area. Composed of shales, sandstones, and conglomerates. Shales are thick, varied in color, with red predominating; sandstones are commonly soft, and buff in color; includes two distinctively colored chert assemblages: dark chert conglomerates, here named Maud chert conglomerate member, and multicolored chert conglomerates, here named Jarvis Church conglomerate member. Thickness 600 to 800 feet; formation thickens downdip. Rests with local unconformity on Vanoss (uppermost Pennsylvanian) formation; contact at top of formation (Asher-Konawa following Morgan) appears to be marked by local unconformity.

A. E. West, 1960, Shale Shaker, v. 11, no. 3, p. 4–7. In this report [Lincoln County], formation includes (ascending) Brownville, Americus(?), Long Creek, and Red Eagle limestone members. For purposes of this report, base of formation is defined as top of Grayhorse limestone; top of formation not distinguishable in area. Pennsylvanian and Permian(?).

Type locality: Town of Konawa, Seminole County, located on extreme western edge of outcrop.

Konocti Volcanics (in Clear Lake Volcanic Series)

Quaternary: Northern California.

J. C. Brice, 1953, California Div. Mines Bull. 166, p. 12 (fig. 2), pl. 7. Quartz-, olivine-, and sanidine-bearing dacitic and andesitic lavas 100 to 1,500 feet thick. Shown on columnar section as uppermost unit of series above 50–700 foot unit of obsidian, but age relations of individual units of series are imperfectly known because some units are isolated and contacts of contiguous flows are commonly obscured by sliding.

Covers about 15 square miles south of Clear Lake, Lower Lake quadrangle, in Coast Ranges about 70 miles north of San Francisco. Volcanics also extend beyond quadrangle boundary where they build up Mount Konocti.

Koochiching Granite[1]

Precambrian (Laurentian): Northern Minnesota.

Original reference: A. N. Winchell, 1897, Am. Geologist, v. 20, p. 293–299.

Occurs 2 miles west of Rainy Lake.

Koolau Volcanic Series[1]

Koolau Basalt Series

Pliocene(?): Oahu Island, Hawaii.

Original reference: C. K. Wentworth, 1926, Bernice P. Bishop Mus. Bull. 30.

H. T. Stearns, 1946, Hawaii Div. Hydrog. Bull. 8, p. 75 (table), 77 (chart), 78. Exposed thickness of flows about 3,000 feet. Consists of thin-bedded pahoehoe and aa with small amount of ash. Includes Kailua volcanic series, lavas of which are believed to have accumulated in caldera of Koolau volcano. Separated from Waianae volcanic series by erosional unconformity. Older than Honolulu volcanic series.

C. K. Wentworth and Horace Winchell, 1947, Geol. Soc. America Bull., v. 58, no. 1, p. 49–78. Referred to as Koolau basalt series.

G. A. Macdonald and D. A. Davis, 1956, *in* Jacques Avias and others, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 106–107. Name Koolau volcanic series preferable because consonant with terminology used in describing rocks on other Hawaiian Islands. Includes all lava flows, intrusive rocks, pyroclastics, breccias, and intercalated soil beds making up Koolau Range except those (Honolulu volcanic series) concurrent with erosion of great valleys on its slope. Pliocene(?). Age assignment on basis of degree of weathering and erosion, and unconformable relationships to later Pleistocene rocks and shore lines. Notes on distribution.

No single type locality designated. Well exposed in Nuuanu Pali, the cliff that faces northeastward along northeastern side of range. Crops out over about 500 square miles.

Kootenai Formation[1]

Lower Cretaceous: Southern Alberta and British Columbia, Canada, and Montana.

Original references: Notes and News (J. W. Dawson?), Sci., v. 5, 1885, p. 531–532; G. M. Dawson, 1886, Canada Geol. Survey, new ser., v. 1, p. 126B–134B, 162B–167B.

W. A. Cobban, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 9, p. 1268–1270. Discussion of marine Jurassic formations of Sweetgrass arch, Montana. Overlying Ellis group (herein redefined to include Sawtooth, Rierdon, and Swift formations) are continental beds of Upper Jurassic and Lower Cretaceous age. These beds, 348 to 1,300 feet thick, are divisible into three units. Lower unit, as much as 310 feet thick, rests conformably on Swift formation and consists chiefly of fine-grained rocks, largely clay shale and mudstone, dense gray limestone, and fine to very fine-grained gray and brown sandstone. This unit is considered as Morrison and the other two units, as much as 1,000 feet thick, as Kootenai. West of Kevin-Sunburst dome, the Kootenai rests unconformably on Morrison, Swift, and Rierdon formations. Understanding of this unconformity is important in interpretation of Morrison-Kootenai beds. Cut Bank sandstone is base of Kootenai locally, and younger Sunburst sandstone or bentonitic mudstone is base of formation over rest of Sweetgrass arch area.

R. W. Brown, 1946, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 2, p. 238–248. Fossil plants support hypothesis that an unconformity in basal part of Kootenai formation in Montana, as it has been generally defined in the literature, and at base of Blairmore formation in Canada, marks Jurassic-Cretaceous boundary. Comparison of floras on both sides of unconformity heightens probability that the part of the Kootenai below the unconformity is to be included in the Morrison, which then is likely equivalent in whole or in large part to Kootenay of Canada, and that the part of the Kootenai of the United States corresponds in large part with lower Blairmore of Canada. Flora of upper part of the Kootenai and of lower Blairmore is an accepted Lower Cretaceous flora.

W. R. Lowell and M. R. Klepper, 1953, Geol. Soc. America Bull., v. 64, no. 2, p. 241. Beaverhead formation (new) unconformably overlies Cretaceous Kootenai, Triassic Dinwoody, and Permian Phosphoria. Angular disconcordance of about 25° between Beaverhead and Kootenai exposed in SW¼SE¼ sec. 11, T. 8 S., R. 10 W., near junction of Grasshopper Creek and Beaverhead River, Mont.

W. A. Cobban, 1955, Billings Geol. Soc. Guidebook 6th Ann. Field Conf., p. 107–109. Marine formation, chiefly mudstone, siltstone, and sandstone. Crops out along north flank of Little Belt Mountain uplift, along Disturbed belt, and in part of Sweetgrass Hills. Thickens southwestward from about 350 feet near Sweetgrass Hills to more than 1,300 feet in Disturbed belt. Made up of two major members. Lower member, as much as 250 feet thick, composed of several widespread units, each characterized by some lithologic feature. Upper member, as much as 800 feet thick, not readily subdivided. Lower boundary, on northwest flank of Sweetgrass arch, marked by erosional unconformity. Here, basal bed is Cut Bank sand, which is characterized by black chert grains. Across area from Cut Bank oil and gas field to vicinity of Summit, the Kootenai rests unconformably on beveled edges of marine Rierdon and Swift formations and on siltstone and mudstone that may represent the Morrison. In Disturbed belt between Birch Creek and Missouri River, massive coarse-grained crossbedded sandstone that overlies the Morrison is taken as base of Kootenai. Along north flank of Little Belt Mountain uplift, a salt-and-pepper sandstone resting on the Morrison is considered base of Kootenai. In subsurface over much of Sweetgrass arch, the Sunburst sand, a conspicuous white fine- to coarse-grained sandstone is commonly taken as base of Kootenai. Underlies Colorado shale.

M. R. Klepper, R. A. Weeks, and E. T. Ruppel, 1957, U.S. Geol. Survey Prof. Paper 292, p. 4 (table), 24–26, pl. 1. In southern Elkhorn Mountains, Mont., is 400 to 650 feet thick and comprises basal unit characterized by "pepper and salt" sandstone, a medial unit characterized by red and green shale and siltstone, and an upper unit characterized by gray limestone. Nonmarine origin. Overlies Morrison formation; underlies Colorado formation. Lower Cretaceous.

Name derived from tribe of Indians who hunted over that part of Rocky Mountains.

†Kosciusko Sand or Formation (in Claiborne Group)

†Kosciusko Sandstone Member (of Lisbon Formation)[1]

Eocene: Mississippi.

Original reference: C. W. Cooke, 1925, U.S. Geol. Survey Prof. Paper 140, p. 133–135.

E. P. Thomas, 1942, Mississippi Geol. Survey Bull. 48, p. 40–47. Rank raised to formation. Redefined to include all beds above Zilpha shale and below Wautubbee formation. Formation is heterogeneous highly lenticular nonmarine section in which sand and shale are dominant facies. Basal interval of 50 to 200 feet typically composed of massive to highly crossbedded sands colored red, brown, yellow, purple, pink, violet, gray, and white on outcrop. Shales increase in abundance above basal sand until they usually predominate over sand in upper part of section. Thickness increases along strike from 85 feet at Alabama line to maximum of 400 feet in Attala, Holmes, and Carroll Counties.

H. A. Tourtelot, 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 6. Mapped as Kosciusko sand in Claiborne group.

G. F. Brown, 1947, Mississippi Geol. Survey Bull. 65, p. 45–48. Kosciusko sand crops out in belt 6 to perhaps more than 20 miles wide in northern Mississippi, western or upper boundary flanking alluvial plain in Carroll, Grenada, Tallahatchie, and Panola Counties. Sand extends beneath plain, except for small area adjacent to Bluff Hills where alluvium rests on Zilpha clay. In Carroll County, the massive sand overlaps Zilpha clay and part of Winona sand; farther north, there is evidence that it rests on Basic City shale member of Tallahatta and that near Tennessee line, it may overlap Meridian sand member of Tallahatta. Thickness of exposed section about 100 feet in Carroll County. U.S. Geological Survey currently uses term Sparta sand in preference to term Kosciusko sand.

Named for exposures in vicinity of Kosciusko, Attala County.

Kosk Member (of Modin Formation)

Upper Triassic: Northern California.

A. F. Sanborn, [1953], Stanford Univ. Abs. Dissert., v. 27, p. 436. Upper member of formation. Overlies Devils Canyon member (new); underlies Arvison formation (new).

A. F. Sanborn, 1960, California Div. Mines Spec. Rept. 63, p. 6, 11, pl. 1. Formal proposal of name. Dominantly thin-bedded dark-gray to black argillite. Two beds composed of andesitic flows, coarse tuffs, and agglomerates present; both beds approximately 300 feet thick. Thickness about 3,600 feet at type locality. Overlies Devils Canyon member; underlies Arvison formation.

Type locality: Along Kosk Creek and Devils Canyon from point on Kosk Creek about 1 mile north of Arvison Flat, where upper contact of member is exposed, to its lower contact about one-quarter mile west of junction of Devils Canyon and Alder Creek, Big Bend quadrangle, Shasta County.

Koster (joint) Clays[1]

Upper Cretaceous (Gulf Series): Southwestern Arkansas.

Original reference: R. T. Hill, 1888, Arkansas Geol. Survey Ann. Rept. 1888, v. 2, p. 79, 81.

Named for occurrence at or near Nicholas Koster's house, sec. 13, T. 7 S., R. 21 W., Clark County.

†Kotlo Series[1]

Precambrian and lower Paleozoic: Southeastern Alaska.

Original reference: A. H. Brooks, 1900, U.S. Geol. Survey 21st Ann. Rept., pt. 2, p. 357.

Kotsina Conglomerate[1]

Jurassic or Cretaceous: Central southern Alaska.

Original reference: O. Rohn, 1900, U.S. Geol. Survey 21st Ann. Rept., pt. 2, p. 431, map, pl. 52.

F. H. Moffit, 1938, U.S. Geol. Survey Bull. 894, p. 68, pl. 2. Maximum thickness in mountains north of Ellicott Creek not less than 1,500 feet and in all probability is much more, possibly 2,000 or 2,500 feet. Mapped as Middle or Upper Jurassic.

R. W. Imlay and J. B. Reeside, Jr., 1954, Geol. Soc. America Bull., v. 65, no. 3, chart 10–d facing p. 246, column 17. Upper Cretaceous on correlation chart.

Occurs on Kotsina River.

†Kougarok Group[1]

Ordovician, Silurian, and Devonian(?): Northwestern Alaska.

Original reference: A. J. Collier, 1902, U.S. Geol. Survey Prof. Paper 2, p. 21, map.

Ko Vaya Quartz Monzonite

Age not stated: Central southern Arizona.

Leonid Bryner, 1958, Dissert. Abs., v. 19, no. 6, p. 1341. Intrudes Jaeger diorite complex (new). Older than clastic sediments of continental, fluviatile origin, which are inferred to be Lower Cretaceous.

In South Comobabi Mountains and Ko Vaya Hills, Papago Indian Reservation, Pima County.

Kowak Clay[1]

Pleistocene: Northwestern Alaska.

Original reference: W. H. Dall and G. D. Harris, 1892, U.S. Geol. Survey Bull. 84, p. 265, 327, map.

Occurs in clay bluff, three-quarters mile long and 150 feet high, on left bank of Kowak River, at about long 158°.

Koyukuk Group[1]

Lower Cretaceous: North-central Alaska.

Original reference: F. C. Schrader, 1902, Soc. America Bull., v. 13, p. 246.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000): U.S. Geol. Survey. Appears on map legend.

Occurs along Koyukuk River and may have very wide extent over Koyukuk Basin.

Kramer Lake Beds (in Ricardo Formation)

Miocene, upper: Southern California.

H. S. Gale, 1946, California Jour. Mines and Geology, v. 42, no. 4, p. 326. Series of borate-bearing beds. Members identified (descending) as "green shale," "blue shale," which includes borates and dark-gray shale. These overlies basaltic lava (Saddleback basalt). Maximum thickness of beds about 350 feet.

Present in vicinity of Kramer, southeastern Kern County.

Krebs Formation (in Cherokee Group)

Krebs Group

Pennsylvanian (Des Moines Series): Central and northeastern Oklahoma, southeastern Kansas, and western Missouri.

M. C. Oakes, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 6, p. 1523–1524. Name introduced for lower group of Des Moines series in Oklahoma. Includes all rocks that crop out between top of Atoka formation below and top of Boggy formation above. Comprises (ascending) Hartshorne sandstone, McAlester formation, Savanna formation, and Boggy formation. Extends from northeast flank of Arbuckle Mountains northeastward to Kansas-Oklahoma line and eastward in McAlester basin to Arkansas-Oklahoma line. Thickness about 6,000 feet west of McAlester, along axis of McAlester basin; more than 8,000 feet thick in eastern part of basin; thins southwestward along northeast flank of Arbuckle Mountains; also thinner northeastward, being about 549 feet along Arkansas River and 340 feet along Kansas-Oklahoma line. Conformable on Atoka formation wherever Atoka is present, but unconformable on older rocks both in Arbuckle Mountains, where Boggy formation rests on Ordovician Fernvale limestone, and in northeastern Oklahoma; unconformable below Cabaniss group (new). Krebs and Cabaniss rocks together are nearly but not quite the same, stratigraphically, as Cherokee rocks of southeastern Kansas.

W. V. Searight and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2748 (fig. 1). Group shown on northern Midcontinent composite stratigraphic section as including (ascending) Riverton, Warner, Rowe (new), Dry Wood (new), Bluejacket, and Seville formations.

T. K. Searight, 1954, Missouri Geol. Survey and Water Resources Rept. Inv. 15, p. 23. In southwestern Missouri, group conforms to Midcontinent stratigraphic column. Only Riverton and Warner formations present in Humansville quadrangle.

W. B. Howe, 1956, Kansas Geol. Survey Bull. 123, p. 22 (fig. 5), 27–44. Term Cherokee readopted, and Krebs reduced to rank of subgroup in Cherokee group. Average thickness of outcrop area in Kansas between 200 and 250 feet. Comprises about half of pre-Marmaton Desmoinesian section in Kansas.

J. M. Jewett, 1959, Graphic column and classification of rocks in Kansas: Kansas Geol. Survey. Shown on chart as formation in Cherokee group. Includes Warner sandstone and Bluejacket sandstone together with several coal beds. Underlies Cabaniss formation.

Named for town of Krebs, in T. 5 N., R. 15 E., central Pittsburg County, Okla.

Kreyenhagen Shale[1] or **Formation**

Eocene and Oligocene: Southern California.

Original reference: F. M. Anderson, 1905, California Acad. Sci. Proc., 3d ser., v. 2, p. 163–168.

R. D. Reed and J. S. Hollister, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 12, p. 1566 (fig. 9). In Devils Den area, overlies Point of Rocks sandstone (new).

H. E. Vokes, 1939, New York Acad. Sci. Annals, v. 38, p. 13 (table 1). Formation overlies Domengine formation and underlies Tumey shale.

J. A. Cushman and S. S. Siegfus, 1942, San Diego Soc. Nat. History, v. 9, no. 34, p. 385–426, pls. Shale described at Garza Creek, Kings County. This section compares favorably with type locality at Canoas Creek, originally designated by Anderson (1905). In present work, the two localities together are considered type area of Kreyenhagen. Formation divided lithologically into 10 members (A to J inclusive), lowest (J) is Canoas siltstone member. Thickness about 1,000 feet. Overlies Avenal sandstone; underlies Vaqueros(?) sand. Upper part of Kreyenhagen down to base of sandy "D" member considered equivalent in part at least of Tumey formation of Atwill (1935). Because type Kreyenhagen shale south of Coalinga, referred to as "Kreyenhagen" by Atwill, was not believed to include any correlative of Tumey formation, he believed term "Tumey formation" justified, although term "Wagon Wheel formation" had been proposed some years earlier (Johnson, 1909) for beds occupying a similar position in geologic column. Lower part of formation is Eocene; future work may show that part of Kreyenhagen is Oligocene.

I. F. Wilson, 1943, California Jour, Mines and Geology, v. 39, no. 2, p. 210–213. Kreyenhagen shale is group of foraminiferal calcareous, siliceous clay-shales with some interbedded sandstones and limestone. Occurs on both limbs of Butts Ranch syncline in San Benito quadrangle. Thickness 400 to 1,800 feet on northeast limb; 1,500 to 2,500 feet on southwest limb. On southwest side of syncline, shows following units: lower, 300 to 1,000 feet thick, foraminiferal clay-shales and platy shales with some interbedded sandstone and limestone, and thin glauconitic sandstone at base, equivalent to Canoas siltstone member of Coalinga district; Bear Canyon sandstone member (new), 100 to 300 feet thick; siliceous and calcareous foraminiferal platy shales with some limestone, 500 to 1,500 feet thick. Rests everywhere on Domengine sandstone; underlies Temblor group. Upper Eocene.

B. L. Clark, 1943, California Div. Mines Bull. 118, pt. 2, p. 189 (fig. 73) [preprint 1941]. Correlation chart shows "Kreyenhagen proper" underlying Tumey formation and overlying Canoas silt.

P. P. Goudkoff, 1943, California Div. Mines Bull. 118, pt. 2, p. 248 (fig. 99A), 250 [preprint 1941]. Kreyenhagen shale (formation) shown on correlation chart as underlying Tumey shale and overlying Nortonville claystone in Coalinga area. Forms middle member of Kreyenhagen group and upper part of Clarke and Vokes' (1936) Tejon and Transition stages.

Ralph Stewart, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 34. Formation, in area covered by this report, contains much sand and is divided into (ascending) Nortonville shale, Markley sandstone, and "Sidney" shale members. Overlies Domengine formation. Upper Eocene.

L. I. Briggs, Jr., 1953, California Div. Mines Bull. 167, p. 12 (fig. 2), 41–44, pl. 1. Kreyenhagen formation of this report [Ortigalita Peak quadrangle] includes Kreyenhagen shale as described by Anderson and Pack (1915, U.S. Geol. Survey Bull. 603) and laminated sandstone and shale, radiolarian shale, and pebbly greensand which are termed lower member of formation. Thickness about 700 feet. Overlies Tesla(?) formation; underlies San Pablo formation.

J. E. Schoellhamer and D. M. Kinney, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM–128. In this report [Tumey and Panoche Hills, Fresno County], all strata lying between Domengine sandstone and overlying Temblor formation of Miocene age are included in Kreyenhagen shale. Atwill's sandstone unit of Tumey formation is here called sandstone member of Kreyenhagen. Where sandstone member is absent, the Kreyenhagen consists of about 1,300 feet of thin-bedded chocolate-brown to white soft punky diatomaceous shale and mudstone, with interbedded medium- to coarse-grained sandstone near base and abundant sandstone dikes throughout. Sandstone member is 105 feet thick in Tumey Gulch. Citing of two type areas in original description and assignment of formation to Miocene when later work has shown it to be Oligocene(?) and Eocene in age have led to considerable confusion and extensive bibliography. Woodring and others (1940, U.S. Geol. Survey Prof. Paper 195) described differences in interpretation of Kreyenhagen in general areas and problems that have arisen from them.

H. P. Smith, 1956, California Univ. Pubs. Geol. Sci., v. 32, no. 2, p. 67, 68 (fig. 2), geol. map. Formation, in Devils Den area, consists of tan, buff, and chocolate-brown argillaceous silts about 1,000 feet thick. Van Couvering and Allen's (1943) Welcome formation designated as member of

Kreyenhagen. Conformable on Point of Rocks sandstone; underlies Wagonwheel formation. Eocene or Oligocene.

V. S. Mallory, 1959, Lower Tertiary biostratigraphy of the California Coast Ranges: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 55–73, fig. 7. Included in Narizian stage (redefined).

Type locality: At Kreyenhagen wells, on Canoas Creek in central part of Reef Ridge area, about 12 miles south of town of Coalinga, Fresno County.

Krider Limestone Member (of Nolans Limestone)

Krider Limestone (in Sumner Group)[1]

Permian: Southeastern Nebraska and eastern Kansas.

Original reference: G. E. Condra and J. E. Upp, 1931, Nebraska Geol. Survey Bull. 6, 2d ser., p. 60.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 163; R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 41. Member of Nolans limestone. Commonly two beds of limestone separated by bed of shale, each about 1 foot thick; in southern Kansas, the separating shale is somewhat thicker. Underlies Paddock shale member; overlies Odell shale. Wolfcamp series.

Type locality: Roadcut one-fourth mile south of Krider, Gage County, Nebr.

Kriley Formation

Eocene(?): Central eastern Idaho.

A. L. Anderson, 1959, Idaho Bur. Mines and Geology Pamph. 118, p. 15, 21–22. Chiefly thick conglomerate, basal part of which occurs in clifflike exposures more than 100 feet high near Kriley Creek. Coarsely textured conglomerate composed of boulders up to 1 foot in diameter firmly cemented in silty and sandy matrix. The generally well water-worn boulders largely derived from Lemhi quartzite with some admixture of granitic rocks. Near Kriley Creek, thick massive bed of conglomerate overlain by light-colored well-stratified beds of sandy shale and sandstone. South of Boyle Creek, conglomerate thicker than usual, showing better developed bedding along lower few tens of feet and made up mostly of boulders ranging up to 6 inches. Thickness of formation over 600 feet. Unconformably overlies Lemhi quartzite near Kriley Creek and unconformably underlies Challis volcanics. Directly underlies Geertson formation south of Boyle Creek. No fossils to date formation. Either deposited in response to Laramide uplifts in Paleocene time, or deposited with post-Laramide Eocene conglomerates. Age given as Paleocene(?) on geologic map and Eocene(?) on composite stratigraphic table.

Named from its position near Kriley Creek, in North Fork quadrangle, Lemhi County. Best and perhaps only exposures are along east side of Salmon River, both north and south of Boyle Creek. Exposures north of Boyle Creek extends nearly to Kriley Creek.

Kriz Lens (in Hueco Formation)

C. O. Dunbar, 1953, Am. Jour. Sci., v. 251, no. 11, p. 799 (fig. 1), 801 (fig. 2), 802–803, pl. 1. Limestone lens about 600 feet across and 150 feet thick at top of Hueco formation. Lower part of Hueco grades upward into light-gray limestone mostly in thin even beds, but with a few thick layers, upper one of which locally thickens to form the Kriz lens.

Occurs in east slope of Victorio Peak in Sierra Diablo, Trans-Pecos Texas. Kriz lens forms convenient landmark near Ellis Porter ranchhouse.

Kruger alkaline body[1]

Kruger Alkaline Syenites

Tertiary: Central northern Washington, and southern British Columbia, Canada.

Original reference: R. A. Daly, 1906, Geol. Soc. America Bull., v. 17, p. 349.

C. D. Campbell, 1939, Am. Jour. Sci., v. 237, no. 9, p. 531–549. Further described as Kruger alkaline syenites. Intrudes Anarchist series; intruded by Similkameen granite.

Occurs on Washington-British Columbia boundary. Probably named from Kruger Mountain, British Columbia.

Kruger Schist[1]

Carboniferous(?): Southern British Columbia, Canada, and central northern Washington.

Original reference: R. A. Daly, 1906, Geol. Soc. America Bull., v. 17, p. 329–376.

Probably named for occurrences on roughly tabular Kruger Mountain, British Columbia.

Kruger Mountain Malignite

Mesozoic: Northeastern Washington.

A. C. Waters and Konrad Krauskopf, 1941, Geol. Soc. America Bull., v. 52, no. 9, p. 1368–1369, pl. 1. Dark coarse-grained rock, consisting dominantly of augite, hastingsite, and microcline. Listed as intrusive rock older than Colville batholith.

Exposures limited to two small hills on either side of Okanogan Valley about 4 miles south of international boundary, Okanogan County.

†Kugruk Group[1]

Ordovician, Silurian, and Devonian(?): Northwestern Alaska.

Original reference: A. J. Collier, 1902, U.S. Geol. Survey Prof. Paper 2, p. 21, map.

Probably named for Kugruk Mountain and Kugruk [Kougarok] River, Seward Peninsula.

Kuhiwa Basaltic Andesite (in Hana Volcanic Series)

Pleistocene(?): Maui Island, Hawaii.

G. A. Macdonald *in* H. T. Stearns and G. A. Macdonald, 1942, Hawaii Div. Hydrography Bull. 7, p. 230 (table), 249–251, pl. 1. Single aa flow; locally two or more flow-units separated by clinker are present. Basal clinker generally thin and absent. Sparingly vesicular, locally nonporphyritic, but usually with a few phenocrysts of brownish-green olivine. Maximum thickness in drill holes east of Makapipi Stream 75 feet. Overlies Mossman basalt (new), generally with several inches of soil at contact. Each member of series underlain by local erosional unconformity.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 107. Pleistocene(?).

Named for exposures along Kuhiwa Gulch near highway, Haleakala (East Maui) volcano. Occupies most of area east of Makapipi Stream; tongue between east and west forks of Makaino Stream is similar in composition and stratigraphic relations and is probably branch of same lava flow.

Kukpowruk Formation (in Nanushuk Group)

Lower Cretaceous: Northwestern Alaska.

E. G. Sable, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 11, p. 2637–2640, figs. 2, 3. Largely marine inshore deposit of interbedded shale, siltstone, and sandstone with minor amounts of claystone, conglomerate, and carbonaceous shale. Rock types vary in abundance both laterally and vertically; thick resistant sandstone units most abundant in southern part of outcrop area, south of type locality. Thins eastward and northward from about 5,000 feet on upper Kukpowruk River to about 2,000 feet along lower Utukok River. Base of formation rises in stratigraphic section by intertonguing with Torok formation, as traced northeastward. Basal contact placed at lowest persistent sandstone beds which form break in slope above lowlands underlain by Torok formation. Underlies nonmarine Corwin formation with gradational contact.

R. M. Chapman and E. G. Sable, 1960, U.S. Geol. Survey Prof. Paper 303–C, p. 64–101, pl. 8. Described and mapped in Utukok-Corwin region. Chiefly marine rocks (inshore facies) with some nonmarine rocks (coastal facies) in upper part and in southernmost exposures. Dominant rock types are shale, siltstone, sandstone, and claystone. Northeastward facies changes from sandstone to shale in basal part of formation, which overlies and intertongues with Torok formation. Thins northeastward from more than 5,000 feet to about 2,000 feet. Similar to Grandstand formation of Nanushuk group mapped in areas further east.

Type locality: Along Kukpowruk River between long 162° 42′ and 162° 44′ W., about 34 miles above river mouth. Lower part better exposed in foothills south of type locality. Named from river.

Kula Volcanic Series

Tertiary, upper (?) : Maui Island, Hawaii.

H. T. Stearns *in* H. T. Stearns and G. A. Macdonald, 1942, Hawaii Div. Hydrography Bull. 7, p. 65 (table), 67 (table), 69, 74–90, pls. 1, 15, 16. Chiefly aphanitic dense gray to steel-blue andesitic type aa flows with thick clinker beds. Lenticular bedding common. Thin-bedded aa and pahoehoe present near summit, but pahoehoe scarce farther seaward, except in transition zone at bottom of series. Flows average about 20 feet in thickness near summit and 50 feet near periphery; some flows 200 feet thick. Numerous erosional unconformities and interstratified soil beds indicate that upper Kula lavas accumulated in waning phase of a volcano when time interval between flows became progressively longer; as the lavas changed to more siliceous composition, they became progressively more viscous and their flows shorter; thus they accumulated chiefly about summit where they attained thickness of 2,000 feet or more. Underlie Hana lavas (new) at shallow depths; in deep valleys, were probably removed by erosion before Hana time because here Hana lavas lie on alluvium or on Honomanu basalts (new). Overlie and generally transitional into Honomanu volcanic series.

G. A. Macdonald *in* H. T. Stearns and G. A. Macdonald, 1942, Hawaii Div. Hydrography Bull. 7, p. 285–291. Discussion of petrography.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 107–108. Late Tertiary (?).

Named for settlement along upper and lower road leading to Kula Sanatorium on west slope.

Kulthieth Formation

Eocene and Oligocene(?): Southeastern Alaska.

D. J. Miller, 1957, U.S. Geol. Survey Oil and Gas Inv. Map OM–187, sheets 1 and 2. Nonmarine and marine sandstone and siltstone with many intercalated thin beds of high-rank coal. Includes three predominantly sandy units at type locality—upper 1,400 feet and the intervals, 1,900 to 3,200 feet and 3,600 to 5,400 feet below top. These alternate with three predominantly or conspicuously silty units. About 65 percent of section at type locality of sandstone, most abundant type being massive to crossbedded and arkosic that is gray to olive gray on fresh surfaces and weathers yellowish gray to brown. Total thickness at least 9,300 feet. Underlies Poul Creek formation with apparent conformity.

Type locality: In vicinity of small lake at head of northeasternmost branch of Kulthieth River where what is believed to be the most complete and least disturbed section occurs.

Kummer Series[1]

Kummer Formation (in Puget Group)

Eocene: Western Washington.

Original reference: G. W. Evans, 1912, Washington Geol. Survey Bull. 3, p. 42–49.

C. E. Weaver, 1937, Washington [State] Univ. Pubs. in Geology, v. 4, p. 55, 56–57. Uppermost formation of group in Green River area. Consists of alternating layers of well-stratified sandy, carbonaceous shales, and medium- to coarse-grained massive brownish-gray sandstone; intercalated with these strata are thin seams of coal, bone, and impure carbonaceous material; includes 475-foot sandstone at base. [Referred to as Kummer sandstone by Evans.] Maximum thickness 1,800 feet. Overlies Franklin formation. Formations in Green River Canyon are involved in anticlinal and synclinal folds whose axes trend northeast.

Name derived from Kummer, King County.

Kupikipikio Basalt[1]

See **Black Point Basalt.**

Kupikipikio Black Ash[1]

See Diamond Head Black Ash.

Kure Sandstone

Pleistocene, upper: Eastern North Carolina.

W. B. Wells, 1944, Elisha Mitchell Sci. Soc. Jour., v. 60, no. 2, p. 129–130, pls, 63, 64. Vertical cliff exposes four layers (or horizons) which show progressively decreasing consolidation upward; each lies unconformably on the preceding. Maximum exposed thickness of exposure slightly more than 9 feet. Kure sandstone constitutes a hard base layer with its surface averaging about 1 foot above high-tide level. It is of medium texture, infiltrated, in upper few feet, with organic matter and iron and sufficiently consolidated above to be classified as rock. It is so resistant to sandfilled wave and current erosion as to form a shelf extending out into the strand. Locally as much as 14 to 18 feet exposed without base being exposed. Underlies Castalia sand (new); unconformably overlies a coquina rock here designated Cape Fear coquina.

Exposed between Kure's Beach fishing pier and Ethyl Dow Bromine Plant on lower Cape Fear Peninsula.

Kushequa Shale Member[1] (of Knapp Formation or monothem)

Devonian or Carboniferous: Northwestern Pennsylvania.

Original reference: K. E. Caster, 1934, Bulls. Am. Paleontology, v. 21, no. 71, p. 47, 103, table opposite p. 61.

C. R. Fettke, 1938, Pennsylvania Geol. Survey, 4th ser., Bull. M–21, p. 26. Caster considered the Kushequa the basal member of the Knapp and placed base of Mississippian at bottom instead of top of Knapp. In this report, Knapp beds tentatively listed under Mississippian.

Probably named for Kushèqua, McKean County.

Kushtaka Formation[1]

Eocene: South-central and southeastern Alaska.

Original reference: G. C. Martin, 1905, U.S. Geol. Survey Bull. 250, p. 14.

J. T. Dutro, Jr., and T. G. Payne, 1957, Geologic map of Alaska (1:2,500,000): U.S. Geol. Survey. Eocene.

Exposed in valley of Bering River and its tributaries and on shores of Lake Kushtaka, Controller Bay region.

†Kuskokwim Gravels and Silts[1]

Pleistocene: Central southern Alaska.

Original reference: J. E. Spurr, 1900, U.S. Geol. Survey 20th Ann. Rept., pt. 7, p. 175–176.

Fills bottom of Ptarmigan Valley on west side of divide between the Skwentna and the Kuskokwim.

Kuskokwim Group

Lower and Upper Cretaceous: Southwestern Alaska.

W. M. Cady and others, 1955, U.S. Geol. Survey Prof. Paper 268, p. 21 (table), 35–47, pl. 1. Graywacke and closely related rocks make up practically all of group. Rocks called graywacke are variety of sandstone. Shales, which are about half as abundant, are a siltstone facies of the graywacke which is intimately interbedded with the sandstone. Breccias and conglomerates, also facies of the graywacke, present in a few localities. All rocks are dark. Rocks altered to hornfels in contact-metamorphic zones adjacent to stocks. In general, angularity of grain and poor sorting of grains characterize the group. Estimated thickness between 40,000 and 65,000 feet. Thickest continuous, most readily observed, and essentially unrepeated sections of group exposed in transecting gorge of lower course of Holokuk River downstream from mouth of Chineekluk Creek. Group thins appreciably to the southwest of central Kuskokwim region and also thins northeastward in Kuskokwim Mountain belt. Basal zones of group, comprising 5,000 to 10,000 feet of massive graywacke and shale, overlie and flank rocks of Gemuk group (new) along axis of Gemuk anticlinorium. Overlies Holitna group (new) in some areas, with fault contact. Unconformably underlies Iditarod basalt (new), Holokuk and Waterboot basalts (new). Lower (?) and Upper Cretaceous.

J. M. Hoare and W. L. Coonrad, 1959, U.S. Geol. Survey Misc. Geol. Inv. Map I–285. In Bethel quadrangle, Kuskokwim group restricted to sedimentary rocks. Fossils of Middle Jurassic age found in volcanic rocks formerly included in the Kuskokwim. Group is Lower and Upper Cretaceous.

Named for Kuskokwim River.

Kuskulana Formation[1]

Upper Triassic: Alaska.

Original reference: O. Rohn, 1900, U.S. Geol. Survey 21st Ann. Rept., pt. 2, p. 423, 424, 433.

Occurs along valley of Kuskulana River and its tributaries in Kotsina-Kuskulana district.

Kuzitrin Formation[1]

Devonian (?): Northwestern Alaska.

Original reference: A. H. Brooks, G. B. Richardson, and A. J. Collier, 1901, Reconnaissance in Cape Nome and Norton Bay regions, Alaska, in 1900: U.S. Geol. Survey Spec. Pub. 28, map.

Typically exposed in Kigluaik Mountains, Seward Peninsula. Named for Kuzitrin River.

Kwaguntan series

Precambrian: Northern Arizona.

Charles Keyes, 1938, Pan-Am. Geologist, v. 70, no. 2, p. 107 (chart), 109. Comprises (ascending) Oveja, Solitude, Carbon Butte, Echo, Walhalla, and Nunkoweap formations. Consists of sandstones, shales, and limestones. Thickness 1,750 feet. Younger than Chuaran series.

Grand Canyon region.

Kyle sandstone[1]

Tertiary: Southeastern Nevada.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 52, 79.

Occupies abandoned canyon of Old Virgen [Virgin] River. Named for exposures at Kyle Station, in Meadow Valley, below Caliente, Lincoln County.

Kyrock Conglomerate

Pennsylvanian: Central Kentucky.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 89; A. C. McFarlan, 1943, Geology of Kentucky: Lexington, Ky., Kentucky Univ., p. 109. Massive conglomeratic sandstone impregnated with asphalt. Equivalent to lower conglomerate of Caseyville and part of channel which connected Eastern Interior and Appalachian coal fields.

Exposed on Nolin River at Kyrock, Edmonson County. Traced eastward into Hart, Green, Taylor, and Larue Counties.

Labadie Limestone Member (of Vamoosa Formation)

Labadie Limestone Member (of Nelagoney Formation)[1]

Pennsylvanian (Virgil Series): Northeastern Oklahoma.

Original reference: C. F. Bowen, 1918, U.S. Geol. Survey Bull. 686–F, p. 45.

W. F. Tanner, 1956, Oklahoma Geol. Survey Circ. 40, p. 41, 45–47, pl. 1. Reallocated to Vamoosa formation. Described as gray to white limestone characterized by wavy bedding. Commonly 6 to 8 feet thick; in sec. 17, T. 27 N., R. 10 E., total thickness (measured and estimated) about 35 feet; here the Labadie is approximately 170 feet below Middle Oread limestone. Top of Labadie is 60 to 80 feet above Cheshewalla sandstone member at base of formation.

Named for exposures at and near Labadie Point, sec. 9, T. 26 N., R. 10 E., Osage County.

Labahia Member (of Goliad Formation)[1]

Pliocene: Central Texas.

Original reference: F. B. Plummer, 1933, Texas Univ. Bull. 3232, p. 530, 752, 754.

J. H. Quinn, 1955, Texas Univ. Bur. Econ. Geology Pub. 5516, p. 69–71. Top member of Goliad. Overlies Lagarto member. Contains middle Pliocene fauna.

Typically exposed along San Antonio River near La Bahia Mission, south of Goliad, Goliad County.

Laberdie Limestone Member (of Pawnee Formation)

Pennsylvanian (Des Moines Series): Eastern Kansas.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 38, pt. 11, p. 315, 320–321, pl. 1. Light-gray crystalline limestone; thin wavy irregular beds in upper part; more massive in lower. Thickness 8 to 30 feet, thickens southward. Overlies Mine Creek shale where that member is present; underlies Bandera shale.

J. M. Jewett, 1946, Kansas Geol. Survey Bull. 58, p. 65. Discussed as cyclothem in Pawnee megacyclothem.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 7; L. M. Cline and F. C. Greene, 1950, Missouri Geol. Survey and Water Resources Rept. Inv. 12, p. 30. Laberdie member is lateral equivalent of Coal City limestone of Iowa. Name Laberdie suppressed in favor of Coal City which has priority.

Type exposure: In quarry in SW cor. sec. 6, T. 23 S., R. 25 E., 1 mile west of Prescott, Linn County. Name derived from Laberdie Creek, which is about 100 feet west of quarry.

†Labette Beds[1]

Pennsylvanian: Eastern Kansas.

Original reference: L. C. Wooster, 1905, The Carboniferous rock system of eastern Kansas.

Labette Shale[1] (in Marmaton Group)

Labette Shale (in Henrietta Group)

Labette Shale Member (of Henrietta Formation)[1]

Pennsylvanian (Des Moines Series): Eastern Kansas, southwestern Iowa, western Missouri, and northeastern Oklahoma.

Original reference: E. Haworth, 1898, Kansas Univ. Geol. Survey, v. 3, p. 36–37, 92, 94, 100.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 38, pt. 11, p. 309–312. Comprises beds between Fort Scott and Pawnee limestones. Thickness 40 to 80 feet in Kansas. Includes Englevale sandstone member. Included in Marmaton group. Pro tempore type exposure designated.

L. M. Cline, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 26–27 (fig. 2). Columnar section shows Labette shale in Henrietta group.

M. C. Oakes, 1952, Oklahoma Geol. Survey Bull. 69, p. 26–28, measured sections. South of T. 23 N., Oklahoma, Pawnee and Altamont limestones merge to form Oologah limestone, whose base marks top of Labette from that point southward to vicinity of Broken Arrow, Tulsa County, where Oologah grades abruptly into calcareous shale. In Tulsa County, consists of clay shale, silty to sandy shale, and lenticular sandstone. Thickness

180 to 250 feet. Conformably overlies Fort Scott limestone. In Marmaton group.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 32–33, fig. 5. Comprises rocks between Pawnee and Fort Scott formations. Not subdivided, but Mystic and Marshall coals recognized. Thickness 6 feet in Appanoose County; 15 feet in Madison County. Marmaton group.

Type exposure (pro tempore): Exposure beginning near middle of north line and extending to point near NE cor. sec. 22, T. 33 S., R. 20 E., near town of Labette. Named for exposures at Labette, Labette County, Kans.

La Boca Formation

La Boca Marine Member (of Panamá Formation)

Miocene, lower: Panamá.

[T. F. Thompson], 1943, Panamá Canal, Spec. Eng. Div., 3d Locks Proj., pt. 2, chap. 3, p. 16–17. Name La Boca formation applied to group of marine-deposited sediments stratigraphically overlying Culebra formation, as originally defined. Composed largely of medium-hard silty or sandy dark-gray tuffaceous shales, with occasional massive crossbedded sandstone members present in lower parts.

W. P. Woodring and T. F. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 2, p. 231–242, 246 (fig. 2). Strata assigned to La Boca were formerly referred to Culebra formation, Emperador limestone member of Culebra formation, and Caimito formation. Maximum thickness 600 feet.

W. P. Woodring, 1955, U.S. Geol. Survey Misc. Geol. Inv. Map I–1; 1957, U.S. Geol. Survey Prof. Paper 306–A, p. 40–41. Rank reduced to member status in Panamá formation. Consists principally of silty or sandy tuffaceous mudstone, flaggy tuffaceous sandstone, calcareous tuffaceous sandstone, conglomerate, and coralliferous limestone. Agglomerate and tuff, presumed to represent tongues from Pedro Miguel agglomerate member and main part of formation, respectively, are other constituents. Overlies Cucaracha formation or interfingers with upper part of formation. Nevertheless if La Boca is correctly identified, it also overlaps Cucaracha and Culebra formations and rests directly on Bas Obispo formation.

Type region: Miraflores Locks area, Canal Zone. Name derived from La Boca, near entrance of Balboa Harbor.

Laborcita Formation (in Magdalena Group)

Pennsylvanian and Permian: South-central New Mexico.

Carel Otte, Jr., 1959, New Mexico Bur. Mines Mineral Resources Bull. 50, p. 16–17, 28–58, 68–69, 95–96, 98–105, pls. 1–9, 12–14; 1959, Soc. Econ. Paleontologists and Mineralogists and Roswell Geol. Soc. Guidebook Joint Field Conf., p. 196–207. Thompson (1942) described strata overlying upper Virgilian beds in La Luz Canyon. These beds, composed of red and gray shale, sandstone, conglomerate, and a few limestones, contain fusulinids of early Wolfcampian age in upper part. Beds of similar age occurring in central New Mexico directly below Abo formation received three different names in 1946. Kelley and Wood introduced name Red Tanks member of Madera limestone in Lucero uplift; Stark and Dapples assigned name Aqua Torres formation in Los Pinos Mountains; Wilpolt and others designated same sequence Bursum formation which term has been widely adopted. Lloyd (1949) and Pray (1952, unpub. thesis [1954, New Mexico Geol. Soc. Guidebook 5th Field Conf.]) applied name Bursum to Thompson's sequence of "transition beds" that overlie the strata of Fresnal group in La Luz Canyon. In Sacramento Mountains, "transition beds" consist largely of marine sequence of fossiliferous gray shale, limestone, and sandstone, whereas in central New Mexico Bursum formation is predominantly red beds that occur interbedded with a few thin fusulinid-bearing limestones. In addition, upper part of "transition beds" occurring north of Tularosa are younger than "Bursum" age. Term Laborcita proposed for strata consisting largely of gray and red mudstones, gray limestones, sandstones, and conglomerates between top of Holder formation and top of highest marine limestone underlying main mass of Abo red beds. Thickness approximately 480 feet at type section; 536 feet in central area, base and top exposed; about 1,000 feet in northern area.

Type section: Near mouth of Laborcita Canyon, Otero County. Base of section is 700 feet southeast center sec. 13, T. 15 S., R. 10 E., at north side of canyon; top is about 1 mile northeast of base.

Lacey Member (of Mount Simon Formation)

Upper Cambrian: Northern Illinois (subsurface).

J. S. Templeton, Jr., 1950, Illinois Acad. Sci. Trans., v. 43, p. 153 (fig. 2), 154 (fig. 3), 155. Name applied to conglomeratic sandstone overlying Mayfield member (new). Type section extends from depths of 1,880 to 2,070 feet. Thickness 176 to 230 feet. Underlies Gunn member (new).

Type well: McQueen No. 1 (well 6), in SW¼NE¼NE¼ sec. 27, T. 42 N., R. 3 E., DeKalb County. Name derived from Lacey School, 2½ miles east of type well.

Lackawanna Sandstone (in Pocono Formation)[1]

Mississippian: Northeastern Pennsylvania.

Original reference: I. C. White, 1881, Pennsylvania 2d Geol. Survey Rept. G_5, p. 56–57, 235.

Along Roaring Branch, Lycoming County.

Lackawaxen Conglomerate[1]

Upper Devonian: Pennsylvania, western Maryland, and eastern West Virginia.

Original reference: I. C. White, 1882, ser. 2, Pennsylvania Geol. Survey Rept. G_6. p. 73.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Listed as unit in upper part of Chemung sandstone of western Maryland, eastern West Virginia, and south-central Pennsylvania. Underlies Upper shale and sandstone of Chemung; overlies Middle Chemung (Wellsburg sandstone).

Exposed a short distance below Lackawaxen village and at other places in Lackawaxen Township, Pike County, Pa.

Lackey Creek Stage

Pleistocene (Wisconsin): Central Colorado.

G. M. Richmond, 1953, Friends of the Pleistocene Rocky Mountain Sec. [Guidebook] 2d Ann. Field Trip, Oct. 4–5, Correlation chart. In proposed time-stratigraphic standard for Rocky Mountains, Lackey Creek stage occurs in Tazewell-Cary interval between Bull Lake stage and Pinedale stage.

Twin Lake area.

Lac La Belle Conglomerate (in Portage Lake Lava Series)

Lac La Belle Conglomerate[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: L. L. Hubbard, 1898, Michigan Geol. Survey, v. 6, p. 67–72, pl. 4.

H. R. Cornwall, 1954. U.S. Geol. Survey Geol. Quad. Map GQ–51. Included in Portage Lake lava series. One of several sedimentary rock units which constitute excellent reference planes for stratigraphic subdivision of formation.

Occurs just north of Lac la Belle, Keweenaw County.

Laclede Sandstone[1]

Upper Cambrian: Central Missouri.

Original reference: G. H. Scherer, 1905, Bradley Geol. Field Sta. Drury Coll. Bull., v. 1, pt. 2, p. 59, 61, 62.

Probably named for Laclede County.

Lacomb Gravels

Pleistocene, lower: Northwestern Oregon.

I. S. Allison, 1953, Oregon Dept. Geology and Mineral Industries Bull. 37, p. 9, geol. map. Name applied to high-level gravel remnants on hills between Albany and Jefferson. Thickness about 100 feet. Older than Leffler gravels. Name credited to [W. M.] Felts (unpub. thesis).

Type locality: Lacomb, Linn County, about 15 miles southeast of Albany quadrangle.

Lacorocah meta-andesite tuff member (of greenstone complex)

Precambrian: North-central New Mexico.

Parry Reiche, 1949, Geol. Soc. America Bull., v. 60, no. 7, p. 1186, 1188. Light gray, crudely bedded, and weakly schistose, with clastic texture and rare or no quartz. Some beds crowded with light-gray slaty flattened pebbles. Member shows great diversity; ranges from altered acidic lava, now quartz-albite rock, to talc-tremolite aggregate presumably of very basic igneous origin. Such extreme types not common. Thickness unknown, but certainly more than 2,000 feet.

Extends northeasterly across NW¼ sec. 22, T. 8 N., R. 5 E., Bernalillo County.

La Cruz Peak Formation (in Mesaverde Group)

Upper Cretaceous: West-central New Mexico.

W. H. Tonking. [1954], Geologic map and sections of the Puertecito quadrangle, New Mexico (1:48,000): New Mexico Bur. Mines Mineral Resources [preprint?] Bull. 41, pl. 1; 1958, New Mexico Bur. Mines Mineral Resources Bull. 41, p. 19–20, 21 (fig. 6), pl. 1. Sequence of olive- to bluish-gray marine shales, sandy shales, and gray to yellow crossbedded quartzose sandstones and subgraywackes. In western half of region, includes three persistent massive grayish-yellow sandstone beds which contain abundant *Halymenites*. Thickness over 600 feet. Top is placed at top of Gallego sandstone of Winchester (1920) which ranges from 0 to 80 feet in thickness; because this sandstone is not present in eastern half of area, upper contact of the La Cruz Peak is drawn at top of marine beds which are generally 75 to 125 feet below coal beds of overlying Crevasse

Canyon formation. Unconformably overlies Tres Hermanos(?) sandstone member in west and Mancos shale in east.

D. B. Givens 1957, New Mexico Bur. Mines Mineral Resources Bull. 58, p. 10. As mapped in Dog Springs quadrangle, differs from formation as defined by Tonking, in that shale, which he included at base of formation, is here included in Mancos shale.

Named for La Cruz Peak in secs. 13 and 24, T. 2 N., R. 6 W. Socorro County.

La Cygne Shale Member[1] (of Marmaton Formation)

Pennsylvanian: Eastern Kansas.

Original reference: R. C. Moore, 1920, Kansas Geol. Survey Bull. 6, pt. 2, p. 18, 21, 28.

Named for town of La Cygne, Linn County.

Ladd Formation

Upper Cretaceous: Southern California.

W. P. Popenoe, 1937, Jour. Paleontology, v. 11, no. 5, p. 380. Named on generalized section of formations in Santa Ana Mountains. Thickness about 1,700 feet. Comprises two members, Baker (at base) and Holz. Unconformably underlies Williams formation (new); overlies Trabuco formation.

W. P. Popenoe, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 2, p. 166, 168 (fig. 2), 170–171. In this report, name Baker member altered to Baker Canyon member. (Baker Canyon member has also been referred to as Baker conglomerate). Type locality designated.

W. P. Woodring and W. P. Popenoe, 1945, U.S. Geol. Survey Oil and Gas Inv. Prelim. Chart 12. Stratigraphic section shows the Ladd underlying Silverado formation (new).

Type locality: Region immediately west of mouth of Ladd Canyon, tributary of Silverado Canyon, Santa Ana Mountains, Orange County.

Ladentown Diabase[1]

Upper Triassic: Southeastern New York.

Original reference: C. A. Hartnagel, 1912, New York State Handb. 19, p. 92.

Near Ladentown, Rockland County.

Ladiga Sandstone[1]

Lower Cambrian: Eastern Alabama.

Original reference: E. A. Smith, 1888, Alabama Geol. Survey Rept. Prog. 1884–1888, geographic map of Alabama.

C. E. Resser, 1938, Geol. Soc. America Spec. Paper, 15, p. 4. Shown as abandoned in list of stratigraphic terms of southern Appalachians.

Named for Ladiga, Calhoun County.

Ladore Shale (in Kansas City Group)[1]

Ladore Shale (in Bronson Group)

Ladore Shale Member (of Kansas City Formation)[1]

Pennsylvanian (Missouri Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: G. I. Adams, 1904, U.S. Geol. Survey Bull. 238, pls. 1, 2.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, pt. 4, p. 193. Ladore shale included in Bronson group. Thickness 2 to 50 feet. Overlies Hertha limestone; underlies Swope limestone

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4); F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 11. Ladore formation underlies Swope formation and overlies Hertha formation. Kansas City group. Bronson reduced to subgroup of Kansas City group. This is classification agreed upon by Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 41. Thickness of formation 14 feet in south-central Iowa; about 5 feet in Sarpy County, Nebr.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 28, fig. 5. Ladore, in Madison County, near Winterset, is a 14½-foot complex of shale separated by siltstones containing limestone nodules. Upper shales are greenish; basal unit red and silty. Cores from Pottawattamie County show this shale to have same lithology as in Madison County but only 8 feet thick. Underlies Swope formation; overlies Hertha limestone.

Named for exposures at Ladore, Neosho County, Kans.

Ladronesian series[1]

Carboniferous: New Mexico.

Original references: C. R. Keyes, 1906, Science, new ser., v. 23, p. 921; 1906, Am. Jour. Sci., 4th, v. 21, p. 298–300.

Probably named for Sierra Ladrones, 30 miles north of Socorro, Socorro County.

Ladson Formation

Pleistocene: Southeastern South Carolina.

H. E. Malde, 1959, U.S. Geol. Survey Bull. 1079, p. 36–54, pls. 1, 5. Consists of sand and clay, coarse grained or conglomeratic at base. Divided into four members (ascending) characterized, respectively, by phosphate, fine sand, medium-grained sand, and coarse sand. Thickness in type section 33½ feet. Rests on eroded Tertiary deposits (Cooper marl). Pleistocene sequence in area is (ascending) Ladson sand on Tenmile Hill, Pamlico formation, and terrace deposits along Goose Creek. Outcrops in lower part of formation identified by Cooke (1936) as Talbot formation. Sloan (1908) had variously identified beds of Ladson with Lafayette phase, Hampton clays, Tenmile sands, and Accabee gravels—names no longer used. Type section measured from drill hole.

Type section: Auger hole 242, 1 mile N. 58° W. of Ladson, Charleston County. Weathered parts of all units crop out in west bank of Poppenheim swamp west of Ladson.

†Lady Washington Sandstone[1]

Pennsylvanian: Southwestern Indiana.

Original reference: E. T. Cox, 1871, Indiana Geol. Survey 2d Ann. Rept., p. 145, 146, 160, 298.

Forms high bluff on Ohio River at Rockpoint [Rockport], Spencer County, known familiarly as "The Lady Washington."

†Lafayette Formation[1]

Lafayette Gravel

Late Cenozoic: Central Lowland, Interior Low Plateau, Ozark Plateau province, Mississippi embayment part of Coastal Plain province.

Original reference: E. W. Hilgard, 1891, Am. Geologist, v. 8, p. 130.

P. E. Potter, 1955, Jour. Geology, v. 63, no. 1, p. 1–35; v. 63, no. 2, p. 115–132. Discussion of petrology and origin of Lafayette gravel and history and present status of term Lafayette. Lafayette gravel, as used in this study, refers to distinctive deposit found in Central Lowland, Interior Low Plateau, Ozark Plateau province, and Mississippi embayment part of Coastal Plain province. Consists primarily of insoluble components: chert, sandstone, quartz and quartzite pebbles, cobbles, and boulders associated with noncalcareous sands, silts, and clays, which in the aggregate are either stained or, less commonly, cemented by oxides of iron and manganese. Occurs as local blanket deposits in western Kentucky in area of 1,300 square miles as lenticular terrace and channel deposits, generally poorly exposed beneath glacial drift, and in glaciated regions. Thickness rarely exceeds 50 feet except in axial parts of lower Mississippi delta. In regions underlain by pre-Mesozoic rocks, Lafayette gravel commonly restricted either to higher terraces of more prominent streams, to abandoned channels of previous stream cycles, or to isolated exposures, which in Central Lowland province occupy positions on some of highest and oldest erosion surfaces. By contrast, in Coastal Plain province the gravel is considerably more extensive.

Named for Lafayette County, Miss., where first recognized.

Lafayette Granite Porphyry[1]

Late Carboniferous (?): Northwestern New Hampshire.

Original reference: C. R. Williams, 1934, Appalachia, v. 20, no. 4, p. 69–78.

Extends length of Franconia Ridge trail from Mount Lafayette, in Franconia quadrangle, to Little Haystack.

Lafayette Serpentine[1]

Precambrian: Southeastern Pennsylvania.

Original reference: T. D. Rand, 1900, Philadelphia Acad. Nat. Sci. Proc. 1900, pt. I.

Named for occurrence at Lafayette, Montgomery County.

Lafferty Limestone[1]

Silurian: Central northern Arkansas.

Original reference: H. D. Miser, 1920, U.S. Geol. Survey Bull. 715–G.

C. K. Swartz and others, 1942, Geol. Soc. America Bull., v. 53, no. 4, chart 3. Shown on correlation chart as Middle Silurian (Niagaran).

Well exposed at Tate Spring, 1¼ miles north of Penters Bluff Station, Izard County. Named for West Lafferty Creek which is half a mile east of exposure.

Lagarto Clay[1]

Lagarto Member (of Goliad Formation)

Miocene (?): Southern and eastern Texas.

Original reference: E. T. Dumble, 1894, Jour. Geology, v. 2, p. 560.

H. B. Stenzel, F. E. Turner, and C. J. Hesse, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 7, p. 977–1011. Geographically restricted to exclude outcrops around Burkeville. On basis of new age determinations, it is believed that term Fleming formation is applicable to these beds.

A. W. Weeks, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 12, p. 1724–1725, 1727. Lagarto of Dumble considered member of Goliad formation. Lagarto (emended) by Plummer (1933, Texas Univ. Bull. 3232) is discarded. Part of section assigned to Lagarto (emended) is here included in Cuero formation (new). Unit termed Lower Lagarto by Weeks (1933, Am. Assoc. Petroleum Geologists Bull., v. 17, no. 5) herein assigned to Cuero formation (new). Goliad is considered Pliocene.

Named from Lagarto Creek, Live Oak County, where typically exposed.

Lagarto Creek Beds (in Goliad Sand)[1]

Pliocene: Southern Texas.

Original reference: F. B. Plummer, 1933, Texas Univ. Bull. 3232, p. 530, 753, 754.

Crop out on Lagarto Creek, which flows through parts of Live Oak and Jim Wells Counties.

Lagonda Sandstone Member (of Cherokee Shale)[1]

Lagonda Formation (in Cabaniss Group or Cherokee Group)

Lagonda Member (of Senora Formation)

Pennsylvanian (Des Moines Series): Western Missouri, southeastern Kansas, and northern Oklahoma.

Original reference: C. H. Gordon, 1893, Missouri Geol. Survey Sheet Rept. 2, (v. 9), p. 19 [1896].

H. S. McQueen, 1943, Missouri Geol. Survey and Water Resources, 2d ser., v. 28, p. 90–93, pl. 5. Rank raised to formation in Cherokee group. Restricted at top by transfer of Squirrel sandstone to Henrietta group. Thickens in northwesterly direction and in northwestern Missouri may attain thickness of nearly 50 feet. Unconformably overlies Bevier formation; unconformably underlies section of shale the base of which is usually marked by Squirrel sandstone.

A. G. Unklesbay, 1952, Missouri Geol. Survey and Water Resources, 2d ser., v. 33, p. 86–90. Formation described in Boone County. In this report, term Lagonda not used in original sense but includes beds between Bevier coal (except fossiliferous shales on the coal) and top of the Cherokee (to base of Fort Scott). It here includes "Squirrel" sandstone, Mulky coal, and Breezy Hill limestone. Thickness as much as 30 feet. Overlies "Bevier formation"; in some places unconformably underlies Blackjack Creek limestone member of Fort Scott.

W. B. Howe and W. V. Searight, 1953, Missouri Geol. Survey and Water Resources Rept. Inv. 14, pl. 1. In Livingston and Carroll Counties, formation overlies Bevier formation and underlies Excello formation. Cabaniss group.

W. V. Searight and others, 1953, Am. Assoc. Petroleum Geologists Bull., v. 37, no. 12, p. 2748 (fig. 1). Overlies Bevier formation; underlies Mulky formation. Cabaniss group.

C. C. Branson, 1954, Oklahoma Geol. Survey Guidebook 2, p. 5. Listed as Lagonda coal cycle in Senora formation in Oklahoma. Includes Lagonda sandstone, Lagonda shale, upper Lagonda sandstone, and Iron Post coal. Overlies Bevier coal cycle; underlies Mulky coal cycle. Cabaniss group.

R. D. Alexander, 1954, Oklahoma Geol. Survey Circ. 31, p. 13, 16 (fig. 2). Geographically extended into northeastern Oklahoma where it is allocated to member status in Senora formation. Occurs above Verdigris member and below Breezy Hill member.

W. V. Searight, 1955, Missouri Geol. Survey and Water Resources Rept. Inv. 20, p. 29 (fig. 19), 37. Base of formation is at top of Bevier coal bed, and in Missouri top is beneath base of Breezy Hill limestone. As presently regarded, formational definition is identical with Gordon's (1893) definition of Lagonda sandstones and shales. The "Squirrel" sandstone is widely recognized zone in this formation. McQueen's (1943) redefinition of Lagonda is not followed. Thickness 29 feet in Vernon County, Mo. Cabaniss group.

W. B. Howe, 1956, Kansas Geol. Survey Bull. 123, p. 22 (fig. 5), 80–84 strat. sections. Formation includes beds above Bevier coal and extending to top of Iron Post coal. In Oklahoma-Kansas-Missouri area, formation includes a lower limestone and shale member, shale, sandstone, and underclay, and Iron Post coal bed. Only two of these divisions are persistent throughout area; they are the thick shale and overlying sandstone units. Lower limestone and shale member is well developed only in southeastern Kansas and is not known in Oklahoma. Iron Post coal is present only in Oklahoma. In Kansas and Missouri, underlies Breezy Hill limestone member of Mulky formation, Cabaniss subgroup of Cherokee group.

Named for exposures at Lagonda, Chariton County, Mo.

†Lagrange Formation[1]

Eocene: Western Tennessee, southern Alabama, southern Illinois, Mississippi, and southeastern Missouri.

Original reference: J. M. Safford, 1864, Am. Jour. Sci., 2d, v. 37, p. 361, 369–370.

Named for exposures at Lagrange, Fayette County, Tenn.

†La Grange Sandstone (in Chester Group)[1]

Mississippian: Northwestern Alabama.

Original reference: E. A. Smith, 1879, Alabama Geol. Survey Prog. Rept. 1877 and 1878, p. 17, 34, 36.

Named for La Grange, Colbert County.

Lagro Formation

Pleistocene: Indiana.

H. H. Gray, R. D. Jenkins, and R. M. Weidman, 1960, Indiana Geol. Survey Bull. 20, p. 19 (fig. 3). Named on diagram showing formations of Pleistocene age in Indiana. Name appears above Trafalgar formation (new). Name credited to W. J. Wayne (in preparation).

Type locality and derivation of name not given.

Laguna Basalt Flow[1]

Pleistocene: New Mexico.

Original reference: R. L. Nichols, June 1934, Geol. Soc. America Proc. 1933, p. 453.

Occurs in San Jose Valley, Valencia County.

Laguna Formation[1]

Pliocene(?): Northern California.

Original reference: A. M. Piper and others, 1939, U.S. Geol. Survey Water-Supply Paper 780, p. 33 (table), 57–61, pl. 1.

G. H. Davis and others, 1959, U.S. Geol. Survey Water-Supply Paper 1469, p. 46–47, pls. Complex assemblage of silt, clay, sand, and minor lenticular gravel. Maximum thickness 400 feet. Overlies Mehrten formation. Apparently at least in part coeval with Tulare formation on west of San Joaquin Valley and with Kern River formation near southern end of valley. General stratigraphic relations and paleontologic data suggest Pliocene(?) and possibly early Pleistocene age.

Type locality: North bank of Hadselville Creek, short distance from its junction with Laguna Creek, San Joaquin County.

Laguna Latite Series

Eocene, middle or younger, or Pliocene(?): Northern Utah.

D. R. Cook, 1957, Utah Geol. Soc. Guidebook 12, p. 65 (fig. 6). As shown on chart, middle Eocene Laguna latite series (new) overlies Packard rhyolite series and is overlain by Swansea quartz monzonite.

J. M. Foster, 1959, Brigham Young Univ. Research Studies, Geol. Ser., v. 6, no. 4, p. 35, 36, 39, pl. 4. Principal types of extrusive rocks in area consist of (ascending) Packard rhyolite series, Laguna latite sequence, and sequence of basalt flows. Age of material just preceding basalt flows probably middle Eocene or younger, possibly as young as Pliocene.

Present in Bismark Peak area, north Tintic district, Utah County.

Laguna Seca Formation

Paleocene and Eocene: West-central California.

M. B. Payne, 1951, California Div. Mines Spec. Rept. 9, p. 11–13, 16 (fig. 9), 23, pl. 4. Fine-grained gray massive abundantly micaceous concretionary homogeneous sand section, semiplaty in part. Thickness 1,120 feet. Underlies Domengine sandstone; lower contact progressively transgresses northward upon lower members of Moreno formation; in some areas unconformably overlies Cima sandstone lentil of Dos Palos shale of Moreno formation. Is not exact correlative of Martinez and cannot be traced into type locality of Martinez which is about 100 miles north of Laguna Seca Canyon. Cannot be mapped south into type Lodo in Panoche Creek. Cima sandstone and Laguna Seca sandstone of this report were included in "Tejon" (Domingene) by Anderson and Pack (1915, U.S. Geol. Survey Bull. 603).

L. I. Briggs, Jr., 1953, California Div. Mines Bull. 167, p. 37–39, pls. 1, 3. Described in Ortigalita Peak quadrangle as underlying Tesla(?) formation.

Type locality: North branch of Laguna Seca Creek, near NE cor. sec. 18, T. 12 S., R. 11 E., in southeast Panoche Hills, Fresno County.

Lagunita Formation (in San Andres Group)

Permian: North-central New Mexico.

W. F. Tanner, 1956, Jour. Sed. Petrology, v. 26, no. 4, p. 307–308. Contorted brecciated vuggy limestone. Has overall appearance similar to travertine. Fragments in formation are pink, red, gray, dark blue, green, and yellow. Commonly occur in pebble and cobble size ranges. Thickness ranges from a few inches to about 90 feet, but generally does not exceed 20 feet. Represents middle unit of group; underlies Bernal formation; overlies Glorieta formation. Typical beachrock, altered slightly by later solution and recrystallization.

Named from village of Lagunita, near Santa Fe Railroad between Las Vegas and Santa Fe (approximately 35°23′, 105°14′). Better and more accessible exposure at northwest corner of base of Chapelle Hill, on Santa Fe Railroad, between villages of Chapelle and Bernal (approximately sec. 36, T. 14 N., R. 15 E.).

Lagunitas Clastic Member (of Treasure Mountain Rhyolite)

Miocene, upper: Northwestern New Mexico.

W. R. Muehlberger, 1960, New Mexico Geol. Soc. Guidebook 11th Field Conf., p. 100–101. Interbedded and parallel-bedded volcanic sandstone, volcanic conglomerate, tuffaceous mudstone, and tuffaceous breccia. Thickness 232 feet. Overlies Toltec andesite member (new); underlies Osier Mountain member (new). Name credited to E. L. Trice (unpub. thesis).

Crops out in Chama area, northern Rio Arriba County.

La Habra Formation

La Habra Conglomerate[1]

Pleistocene, upper: Southern California.

Original reference: R. Eckis, 1934, California Dept. Pub. Works, Div. Water Resources Bull. 45, p. 38, 49.

D. L. Durham and R. F. Yerkes, 1959, U.S. Geol. Survey Oil and Gas Inv. Map OM–195. Lower part of formation consists of poorly bedded to massive sandy pebble to cobble conglomerate. Overlying the conglomerate are friable massive reddish-colored silty sandstone and siltstone beds. Maximum exposed thickness in eastern Puente Hills [this report] about 600 feet. Nonmarine. Rests with widespread unconformity upon fossiliferous marine strata ranging in age from Pliocene to early Pleistocene. Formation assigned late Pleistocene age.

Type area: Foothills south of Whittier fault between Brea and Carbon Canyons, Los Angeles County. Name derived from town of La Habra.

Lahabia Member (of Goliad Formation)[1]

Pliocene: Central Texas.

Original reference: F. B. Plummer, 1933, Texas Univ. Bull. 3232, p. 530, 752, 754.

J. H. Quinn, 1955, Texas Univ. Bur. Econ. Geology Pub. 5516, p. 69–71. Top member of Goliad. Overlies Lagarto member. Contains middle Pliocene fauna.

Typically exposed along San Antonio River near La Bahia Mission, south of Goliad, Goliad County.

Lahaina Volcanic Series

Pleistocene or Recent(?): Maui Island, Hawaii.

H. T. Stearns *in* H. T. Stearns and G. A. Macdonald, 1942, Hawaii Div. Hydrography Bull. 7, p. 65 (table), 180–181, pl. 1. Comprises firefountain deposits and lava flows emitted after erosion approached present stage. Chiefly picritic basalts and nepheline basanite. Commonly lie on gravel deposits and appear to be late Pleistocene or Recent. Comprise Kekaa cinder cone, Laina volcanics, Kilea volcanics, and Hele cinder cone.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 108–109. Pleistocene or Recent(?).

Named from town of Lahaina. Lie on leeward side of West Maui.

LaHood Formation

Precambrian (Belt Series) : Southwestern Montana.

R. G. Alexander, Jr., 1955, Yellowstone-Bighorn Research Proj. Contr. 195, p. 14, 17–36, pl. 3. At type section, consists of arkosic sandstone and conglomerate with very minor amounts of silt shale distributed irregularly throughout unit. Upper 820 feet of section composed of sandstone with only occasional erratic boulders. Next lower 775 feet varies from upper part mainly in being slightly harder so that its exposures are more pronounced. Below this unit is 930 feet of arkosic sandstone containing irregular conglomeratic lenses, of which the largest observed was 240 feet long and 30 feet thick. Combined thickness over 2,700 feet. Underlies Flathead sandstone in type section. In some localities interfingers with, and underlies Greyson shale with transitional contact. Base obscured.

Type section: Along creek which crosses U.S. Highway 10S from the northeast approximately three-fifths mile southeast of LaHood Park, in Jefferson Canyon, sec. 12, T. 1 N., R. 3 W., and sec. 7, T. 1 N., R. 2 W., Jefferson County.

La Huerta Siltstone Member (of Salado Formation)

Permian: Southeastern New Mexico (subsurface).

W. B. Lang, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 1, p. 63, 68, 72–74. Halite and silt. Massive, variably textured. Dull reddish-brown shale makes 35 percent of core in places. Fine stringers and needle crystals of white anhydrite. Shale makes irregular local bands. Thickness 5 feet.

Described from Fletcher No. 1 well in lot 4, sec. 1, T. 21 S., R. 28 E., Eddy County. Name taken from La Huerta townsite north of Carlsbad, where member would crop out if it were present at surface.

Laina Volcanics (in Lahaina Volcanic Series)

Pleistocene or Recent(?) : Maui Island, Hawaii.

H. T. Stearns *in* H. T. Stearns and G. A. Macdonald, 1942, Hawaii Div. Hydrography Bull. 7, p. 158 (table), 180–181. In exposure on north bank of Kahoma stream, consists of 10 feet of vesicular thin-bedded pahoehoe resting on 8 inches of firefountain debris and 3 feet of alluvial soil. Soil overlies 30 feet of bouldery conglomerate, which in turn rests on Wailuku basalts (new). A few thin flows are intercalated with cinders in cone, and on north side 2 feet of pahoehoe overlies 8 feet of fine cinders, which in turn rests on 4 feet of soil and partly decomposed feldspar olivine Wailuku basalt. Laina lavas are covered with 1 to 1½ feet of soil underlain with a few inches of partly decomposed rock.

G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 109. Pleistocene or Recent(?).

Lavas form valley-fill 60 feet thick on inland side of Puu Laina cone where they pooled in pre-eruption valley of Kahoma stream. Cone is 1 mile northeast of Mala at altitude of 650 feet. Fan on which cone rests is middle or late Pleistocene.

Laird Sandstone

Miocene(?) : Northwestern California.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 17 (table 3), 65–67, pl. 9. Proposed for light-brownish-gray massive sandstone locally containing shale layers in upper part and subordinate conglomerate at base. Underlies Monterey shale; rests on quartz diorite. Thickness ranges from 10 to over 100 feet.

Name derived from Lairds Landing on Tomales Bay, Marin County. Exposed on Point Reyes Peninsula.

La Jara shale[1]

Upper Cretaceous: New Mexico.

Original reference: C. R. Keyes, 1915, Conspectus of geologic formations of New Mexico: Des Moines, Robert Henderson, State Printer, p. 2, 8.

Around southern end of Rocky Mountains. Derivation of name not given.

La Jara Peak Member (of Datil Formation)

Miocene, upper(?): Southwestern New Mexico.

W. H. Tonking, 1954, Dissert. Abs., v. 14, no. 2, p. 340. Composed of flows and flow breccias of basalt in lower parts and basaltic andesite in upper part. Overlies Hells Mesa member (new); underlies Santa Fe formation.

W. H. Tonking, 1957, New Mexico Bur. Mines Mineral Resources Bull. 41, p. 26, 30–32, fig. 2, pl. 1 [preprint? 1954?]. Flows are dark- to medium-gray aphanophyres, which are in part red, oxidized, and scoriaceous. Lower part of member has distinctive red speckled appearance. Horizontal sheeting common, giving rock stratified appearance. Crude columnar jointing developed in more massive outcrops. Flow breccias, as well as block flows (aa type), abundant throughout section. Three volcanic sandstone and conglomerate beds intercalated in uppermost part of member. Consists of a number of flows; exact number not determined. Maximum thickness about 2,500 feet. Type section contains 1,175 feet of lava and 25 feet of intercalated volcanic conglomerate and sandstone. Type section designated.

Type section: Measured in northern Bear Mountain, in secs. 27 and 34, T. 2 N., R. 5 W., 3 to 3.5 miles south-southwest of La Jara Peak, Puertecito quadrangle, Socorro County. Named for La Jara Peak in secs. 11 and 14, T. 2 N., R. 5 W.

La Jolla Formation[1]

Eocene, middle: Southern California.

Original reference: B. L. Clark, 1926, California Univ. Pub., Dept. Geol. Sci. Bull., v. 16, no. 5, p. 103, 111, 117.

L. G. Hertlein and U. S. Grant 4th, 1939, California Jour. Mines and Geology, v. 35, no. 1, p. 65–67. Comprises Delmar sand, Torrey sand, and Rose Canyon shale members. Delmar and Torrey members not positively identified in San Diego quadrangle. Rose Canyon shale attains thickness of at least 300 feet. Underlies Poway conglomerate and in some areas San Diego formation. Middle Eocene.

Named for exposures in La Jolla quadrangle, San Diego County.

Lak Member (of Sundance Formation)

Lak Member (of Rierdon Formation)

Upper Jurassic: Northwestern Wyoming and South Dakota.

R. W. Imlay, 1947, Am. Assoc. Petroleum Geologists Bull., v. 31, no. 2, p. 257–259. Defined as 25 to 100 feet, or more, of dominantly red fine-grained sandstone and siltstone gradationally overlying Hulett sandstone member and underlying Redwater shale member (both new). At type section, consists of at least 80 feet of soft maroon sandstone and siltstone including 2-foot bed of greenish-gray siltstone 15 feet below top.

J. A. Peterson, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 4, p. 466 (table 2), 475, 482. Reallocated to member status in Rierdon formation herein assigned to Sundance group.

Type section: On west side Stockade Beaver Creek about 5 miles northeast of New Castle, Wyo., in sec. 18, T. 45 N., R. 60 W. Named after Lak Reservoir on L. A. K. Ranch. Reservoir is about 3 miles south of type section.

Lake Amygdaloid[1] (in Central Mine Group)

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler, 1929, U.S. Geol. Survey Prof. Paper 144.

Named for occurrence in Lake mine, Ontonagon County.

Lake Basalt

Pliocene(?) and Pleistocene: Northern California.

H. A. Powers, 1932, Am. Mineralogist, v. 17, no. 7, p. 262–266. Basalt porphyry. Older than Warner basalt.

C. A. Anderson, 1941, California Univ. Dept. Geol. Sci. Bull., v. 25, no. 7, p. 364–365, geol. map. Map legend shows Lake basalt younger than Warner basalt.

Type locality: Eastern floor of Medicine Lake basin where it crops out in low glaciated mounds which protrude through mantle of pumice and lake gravel, Modoc Lava-Bed quadrangle.

Lake Flow[1]

Precambrian (Keweenawan): Northern Michigan.

Original reference: B. S. Butler, 1929, U.S. Geol. Survey Prof. Paper 144.

Named for occurrence in Lake mine, Ontonagon County.

†Lake Gneiss[1]

Precambrian(?) to Carboniferous: Eastern New Hampshire.

Original reference: C. H. Hitchcock, 1874, Geology New Hampshire, pt. 1, p. 508–545.

Lake Winnipesaukee region.

†Lake Quartzite Schist[1]

Lower Paleozoic or older: Northern Alaska.

Original reference: F. C. Schrader, 1900, U.S. Geol. Survey 21st Ann. Rept., pt. 2, p. 474.

Named for great prominence at Chandalar Lake, Chandalar Lake region.

Lake Quartz Syenite[1]

Devonian or Carboniferous: East-central New Hampshire.

David Modell, 1936, Geol. Soc. America Bull., v. 47, no. 12, p. 1895. 1905–1906, pl. 1. Medium-grained subporphyritic to seriate-textured quartz syenite. Subporphyritic aspect most characteristic. Coarser and more equigranular in Diamond Island exposures. Contains inclusions of fine-grained diorite locally. Older than Albany quartz syenite; younger than Sawyer quartz syenite. Assigned to White Mountain magma series.

Excellent exposures on Rattlesnake and Diamond Islands in Lake Winnipesaukee. Also found at Gerrish Point and to the north.

Lake Agassiz Clays[1]

Pleistocene: Mississippi Valley.

Original reference: W. J. McGee, 1888, Am. Jour. Sci., 3d, v. 35, p. 462.

Lake Agnes Quartz Monzonite

Tertiary: Northeastern Colorado.

K. A. Gorton, 1953, Wyoming Geol. Assoc. Guidebook 8th Ann. Field Conf., p. 89–90. Light-gray coarsely crystalline equigranular rock with speckled appearance due to sharp contrast between dark hornblende and biotite and light-colored orthoclase and plagioclase. In contact with Precambrian gneiss and with Pierre shale. Later than Laramide thrust faulting.

Well exposed near Lake Agnes in sec. 15, T. 6 N., R. 76 W., Cameron Pass area.

Lake Albany Clays[1]

Pleistocene: Eastern New York and western Vermont.

Original reference: G. H. Chadwick, 1910, New York State Mus. Bull. 140, p. 157–160.

Lake Ardmore Formation (in Springer Group)

Lake Ardmore Sandstone Member (of Springer Formation)[1]

Lower Pennsylvanian: Central southern Oklahoma (subsurface and surface).

Original reference (subsurface): R. Roth, 1928, Econ. Geology, v. 23, p. 45.

C. W. Tomlinson, 1929, Oklahoma Geol. Survey Bull. 46, p. 17–19. Surface outcrop noted; derivation of name given.

R. C. Moore and others, 1944, Geol. Soc. America Bull., v. 55, no. 6, chart 6 (column 37). Shown on correlation chart as Lake Ardmore sandstone; here the Springer is considered a group. Lower Pennsylvanian.

C. W. Tomlinson and William McBee, Jr., 1959, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 2: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 6 (fig. 2), 11–13. About 500 to 700 feet above Overbrook sandstone is Tomlinson's (1929) Lake Ardmore sandstone member, a persistent unit which is only 15 to 20 feet thick at locality where it was named (NE¼NW¼SE¼ sec. 2, T. 4 S., R. 2 E.). Northeast of town of Springer (NW¼SW¼ sec. 4, T. 3 S., R. 2 E.), three separate sandstone members crop out in uppermost 500 feet of Springeran series as here defined—the 500 feet of section next below Primrose sandstone. One of these, possibly the second from top, may be identical with original Lake Ardmore member. But it is possible that this member has split into several sandstones with intervening shales. Interval between base of Primrose sandstone above and top of Overbrook sandstone some distance below, has increased here to about 1,000 feet, as compared to 800 feet at Lake Ardmore. Name Lake Ardmore formation suggested for these three sandstones in top 500 feet of Springer series near Springer. Formation regarded as extending from base of the Primrose down to base of lowest of the three sandstones of Lake Ardmore formation there. Includes Target limestone of Bennison (1954) as member. Springer group.

Type locality (formation) NW¼SW¼ sec. 4. T. 3 S., R. 2 E., Carter County. Named for a sportsman's lake in sec. 2, T. 4 S., R. 1 E., where it forms narrow peninsulas and islets.

Lake Bonneville Beds[1]

Lake Bonneville Group

Pleistocene: Northern Utah and southeastern Idaho.

Original reference: G. K. Gilbert, 1875, U.S. Geol. and Geog. Survey Terr. W. 100th M., v. 30, p. 89.

K. C. Bullock, 1951, Utah Geol. and Mineralog. Survey Bull. 41, p. 21–22. Deposits laid down by Lake Bonneville are divided into three formations each of which represents a different stage in the level of the lake. These are (ascending) Alpine, Bonneville, and Provo, Gilbert (1890, U.S. Geol. Survey Mon. 1) referred to these as Intermediate, Bonneville, and Provo stages of Lake Bonneville.

C. B. Hunt, H. D. Varnes, and H. E. Thomas, 1953, U.S. Geol. Survey Prof. Paper 257–A, p. 1, 17–29, pl. 1. Pleistocene Lake Bonneville group, which includes Alpine, Bonneville, and Provo formations, is unconformable above unnamed pre-Lake Bonneville deposits and below unnamed post-Provo deposits. Lake Bonneville was product of last glacial period and is believed to be of Wisconsin age.

Northern Utah Valley.

Lake Bridgeport Shale[1] (in Graford Formation)

Pennsylvanian: North-central Texas.

Original reference: G. Scott and J. M. Armstrong, 1932, Texas Univ. Bull. 3224, p. 29.

H. L. Strimple, 1951, Jour. Paleontology, v. 20, no. 2, p. 200–207. Crinoid fauna described.

Probably named for occurrence near Bridgeport, Wise County.

Lake Charles Formation

Recent: Southern Texas.

W. A. Price, 1939, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 23, no. 12, p. 1875. Lake Charles formation and Ingleside formation (new) replace Beaumont formation.

Report discusses Rio Grande delta; states that Lake Charles formation is not present on delta.

Lake Church Formation[1]

Middle Devonian: Southeastern Wisconsin.

Original reference: E. R. Pohl, 1929, Pub. Mus. City Milwaukee Bull., v. 11, p. 7–8.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, p. 1770, chart 4. Age given on correlation chart as Middle Devonian.

Well exposed in and about Lake Shore stone quarry near Lake Church, Ozaukee County.

Lake City Limestone

Lake City Limestone (in Claiborne Group)

Eocene, middle: Subsurface in northern and central Florida and southern Georgia.

P. L. Applin and E. R. Applin, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 12, p. 1681–1682, 1693–1698, 1704 (fig. 25). Name applied to limestone facies of early middle Eocene in northern Florida and the peninsula. Made up of alternating layers of dark-brown and chalky limestone with gypsum or chert present in some wells and in Cosden's Lawson well No. 1, Marion County, a 25-foot bed of lignite. Lateral gradational lithologic change from limestone facies of the peninsula into clastic facies which contains a fauna related to that of Cook Mountain formation of Claiborne age is noted in wells from Wakulla County west to Walton County. Starting as highly glauconitic chalky limestone, the rock becomes increasingly sandy until it develops into chalky glauconitic sand. Normally 400 to 500 feet thick in Tallahassee area; in Pierce County, Ga., and southern part of peninsula 200 to 250 feet. In north Florida and north half of peninsula, underlies Tallahassee limestone (new) and equivalent nonfossiliferous limestone; along northeast coast and in south half of peninsula, underlies Avon Park limestone (new); in west Florida, where late middle Eocene beds are not definitely known to be present, early middle Eocene clastic facies of Cook Mountain age underlies Ocala limestone; overlies lower Eocene unit. Oldsmar limestone (new), Avon Park limestone, Tallahassee limestone (with its equivalent nonfossiliferous facies), and Lake City limestone represent Claiborne group in peninsular Florida, and where all three units are present they appear to make in most places, a conformable sequence.

R. O. Vernon, 1951, Florida Geol. Survey Bull. 33, p. 88–89, 90–94. In Claiborne group. As used by Applin and Applin (1944), Lake City limestone is predominantly chalky to granular limestone, containing chert and gypsum in some areas. The limestone grades laterally into clastic facies in series of wells extending from Wakulla County westward to Walton County. In practice, the Lake City is commonly identified from its fauna, the top being marked by first appearance of *Dictyoconus americanus* (Cushman) and as thus used it was faunal zone. Recently, present writer [Vernon] has found, particularly in Citrus and Levy Counties, that formation was lithologic unit having diagnostic lithologic characteristics as well as distinct fauna. Formation characterized by several lithologies which probably occur as thin beds in thick carbonate section. These beds include a pseudo-oolite, a brown to coffee-colored chert, a bentonitic(?) clay, and a brownish-gray laminated finely crystalline dolomite containing seams of black carbon and flattened decalcified specimens of *Fabularia vaughani, Coskinolina* sp., *Archaias columbiaensis,* and larger *Valvulinidae* giving it a mottled and laminated appearance. Occasionally last mentioned rock is seamed with peat and not fossiliferous. Applin and Applin (p. 1739) assigned 411 feet of dolomite in Florida Oil Discovery-Sholtz well, Levy County, to the nonfossiliferous limestone [lying between the Lake City and Avon Park], but it is herein considered dolomitized Lake City limestone and included in that formation. Thickness in wells in Levy and Citrus Counties 575 to 923 feet.

Characteristically shown in samples from Lake City well, Columbia County, Fla., No. W–299, of Florida Geological Survey.

Lake Coahuila deposits

Pleistocene, upper: Southern California.

L. A. Tarbet and W. H. Holman, 1944, (abs.) Am. Assoc. Petroleum Geologists Bull., v. 28, no. 12, p. 1782. A thin veneer of lake marls covering most of surface below ancient beach line. Thickness as much as 100 feet.

T. W. Dibblee, Jr., 1954, California Div. Mines Bull. 170, chap. 2, p. 23 (fig. 2), 25 (fig. 2). Shown on columnar sections as unconformably overlying

Brawley formation (new) or as unconformably overlying Ocotillo conglomerate (new).

This may or may not be the same deposit referred to as Coahuila silt (Hanna, 1926).

Occurs on west side of Imperial Valley.

Lake Creek Coal Member (of Modesto Formation)

Pennsylvanian: Southeastern Illinois (subsurface).

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 37, 49 (table 1), pl. 1. Name applied to coal encountered at depth of 86½ feet in drill hole. Occurs above Pond Creek coal member (new) and below West Franklin limestone member. Coal has been referred to informally as 3rd Cutler Rider coal. Name credited to Cady (unpub. ms.). Piasa limestone and DeGraff, Pond Creek, and Lake Creek coals may be included in complex West Franklin limestone in eastern part of area. Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification.

Type locality: Consolidated Coal Co. drill hole 91 in SW¼NE¼NE¼ sec. 21, T. 8 S., R. 3 E., Williamson County. Name derived from Lake Creek Township in which drill hole is located.

Lake Creek Formation

Pleistocene (Cary-Mankato): Central Colorado.

G. M. Richmond, 1953, Friends of the Pleistocene, Rocky Mountain sec. 2d Ann. Field Trip, Oct. 4–5, correlation chart, geol. map. Consists of lower and upper member. Overlies Twin Mountain formation (new); underlies Mount Champion formation (new).

Twin Lakes region, Lake County.

Lake Creek Member (of Wood River Formation)

Pennsylvanian (Virgilian): Central and eastern Idaho.

M. R. Thomasson, 1959, Dissert. Abs., v. 20, no. 3, p. 999. Older than Wilson Creek member (new); younger than Slate Creek member (new).

Deposited in Muldoon trough, aligned N. 30° W.

Lake Creek Shale Member (of Pierre Shale)[1]

Upper Cretaceous: Northwestern Kansas.

Original reference: M. K. Elias, 1931, Kansas Univ. Bull., v. 32, no. 7.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 22, 23 (fig. 11). Thin-bedded flaky dark-gray and black shale with limestone concretions, zones of concretionary limonite, and locally gypsum. Thickness 200 feet. Overlies Weskan shale member; underlies Salt Grass shale member.

Named for Lake Creek, in northwestern part of Wallace County, along which most extensive outcrops occur.

Lake Crockett Formation

Cretaceous (Eagle Ford): North-central Texas.

C. L. McNulty, 1954, Am. Assoc. Petroleum Geologists Bull., v. 38, no. 2, p. 335–337. Suggested that name Fish Bed conglomerate (Taff, 1893, Texas Geol. Survey 4th Ann. Rept), which is misleading nongeographic and limited in definition, be abandoned and replaced by Lake Crockett formation. Proposed that formation consist of an upper Lake Crockett member, which shall be the silty shale lying between basal Austin chalk and former Fish Bed conglomerate, and of a lower Lake Crockett sand member, which shall be the Fish Bed stratum and the underlying gray sand, and which is equivalent to the former sub-Clarksville of east Texas basin. At Lake Crockett, underlies Ector formation and is about 26½ feet thick.

Named for exposures in ravine below spillway of Lake Crockett, Fannin County.

Lake Enchantment sediments

Precambrian : Northern Michigan.

Justin Zinn and others, 1955, Studies of stratified rocks occurring below the Huronian succession in the Marquette district, Michigan: Minnesota Univ. Center for Continuation Study, Inst. of Lake Superior Geology [no pagination]. Remnant of metamorphosed stratified rock. Older than Mesnard quartzite; unconformably overlies Keewatin greenstones.

Along margin of Marquette syncline or adjacent to nearby Huronian synclines in Marquette district.

Lake Flirt Marl[1]

Pleistocene and Recent: Southern Florida.

Original reference: E. H. Sellards, 1919, Florida Geol. Survey 12th Ann. Rept., p. 73–74.

C. W. Cooke, Julia Gardner, and W. P. Woodring, 1943, Geol. Soc. America Bull., v. 54, no. 11, chart 12. Lake Flirt [spelled Flint], Pleistocene, overlies Pamlico formation.

G. G. Parker and C. W. Cooke, 1944, Florida Geol. Survey Bull. 27, p. 70. In some places, Miami oolite is overlain by thin fresh-water marl and limestone here classified as Lake Flirt marl. Very late Pleistocene or Recent in age.

M. C. Schroeder, 1954, Southeastern Geol. Soc. 8th Field Trip, p. 18, 20–22. Maximum thickness about 8 feet along Caloosahatchee River in old Lake Flirt bottom. It is doubtful whether use of name is justified outside of Caloosahatchee River area. In many places in upper Everglades, the fresh-water marl lies between the rock floor and overlying organic soils. Although marl is not the same everywhere, some being indurated, it has all been included in the Lake Flirt by Parker and Cooke.

J. R. DuBar, 1958, Gulf Coast Assoc. Geol. Soc. Trans., v. 8, p. 133 (table 1), 135, 136, 147. Typically overlies Pamlico formation unconformably, but reworking of sediments at many localities makes separation of the two formations difficult. In this report, beds containing abundant fresh-water mollusks definitely assigned to the Lake Flirt. Pleistocene (Wisconsin).

Named for occurrences at Lake Flirt, De Soto County.

Lake Fork Quartz Latite

Lake Fork Andesite[1]

Miocene (?) : Southwestern Colorado.

Original references: W. Cross and E. S. Larsen, 1923, U.S. Geol. Survey Prof. Paper 131, table opposite p. 184; 1923, U.S. Geol. Survey Bull. 718, table opposite p. 12.

E. S. Larsen, Jr., and Whitman Cross, 1956, U.S. Geol. Survey Prof. Paper 258, p. 14, 64–68, pls. 1, 2. Defined as a group of dark quartz latites, in part flows, in part clastic beds, that immediately preceded deposition of San Juan tuff. Thickest part—about 4,000 feet—is east of Lake Fork of Gunnison River near heads of Indian and Trout Creeks; from this area, it thins out rapidly in all directions, and 5 or 6 miles from central area is only a few hundred feet thick. Central part not overlain by younger rocks; flanks overlain by San Juan or Potosi rocks. Directly overlies Precambrian and Paleozoic rocks.

Named for exposures in Lake Fork of Gunnison River in Uncompahgre quadrangle. Exposures are confined to area in central part of quadrangle about 20 miles across.

Lake Hanbury Slate Group[1]

Huronian: Northern Michigan.

Original reference: C. Rominger, 1881, Mich. Geol. Survey, v. 4, pt. 2, p. 182.

Crops out north of Norway, Quinnesec, and Chapin mines, Menominee iron region.

Lake Kemp Formation (in Lueders Group)

Lake Kemp Limestone (in Lueders Formation)[1]

Permian (Leonard Series): Central northern Texas.

Original reference: M. M. Garrett, A. M. Lloyd, and G. E. Laskey, Geologic map of Baylor County: Texas Bur. Econ. Geology.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Given formational status in the Lueders herein designated as group. Overlies Maybelle limestone; underlies Arroyo formation of Clear Fork group.

R. C. Moore, 1949, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 80, sheet 2. Examination of type outcrops of Maybelle and Lake Kemp beds affords no satisfactory ground for classing the limestones as parts of the Lueders. No basis found for recognizing any limestone beds of the Lueders in Colorado River area [mapped in this report] as corresponding to Maybelle and Lake Kemp beds, respectively.

Occurs at east end of Lake Kemp, Baylor County.

†Lake Lahontan Beds[1]

Pleistocene: Northwestern Nevada.

Original reference: I. C. Russell, 1885, U.S. Geol. Survey Mon. 11, p. 143.

U.S. Geological Survey has abandoned the term Lake Lahontan beds.

Sediments deposited in Lake Lahontan.

Lake Lytle Limestone[1]

Permian: Texas.

Original reference: J. Hornberger, Jr., 1932, Texas Bur. Econ. Geology, geol. map of Throckmorton County.

Lake Missoula Beds[1]

Pleistocene: Southwestern Montana.

Original reference: C. M. Langton, 1935, Jour. Geology, v. 43, p. 34–35.

Missoula, Ravalli, and Granite Counties.

Lake Monongahela deposits[1]

Pleistocene: Southwestern Pennsylvania.

Original reference: R. R. Hice, 1905. Am. Ceramic Soc. Trans., v. 7, pt. 1.

Near mouth of Beaver River.

Lakemont Formation[1]

Middle Silurian: Pennsylvania.

Original reference: E. O. Ulrich, 1923, Maryland Geol. Survey, Silurian Volume, index.

Named from section near Lakemont Park, between Hollidaysburg and Altoona, Blair County.

Lake Murray Formation (in Dornick Hills Group)

Pennsylvanian (Atoka Series) : Southern Oklahoma.

B. H. Harlton, 1956, *in* Ardmore Geol. Soc., Petroleum geology of southern Oklahoma—a symposium, v. 1: Tulsa, Okla., Am. Assoc. Petroleum Geologists, p. 137 (fig. 2), 139–140. Proposed for strata from top of Otterville to top of Frensley limestone. Attains maximum development in Harrisburg trough where it is over 3,300 feet thick. Not a single sequence and may be divided into three units which are uniform throughout the trough; they are (ascending) Bostwick, Griffin sandstone (new), and Frensley members. Unconformably underlies Big Branch formation (redefined) ; unconformably overlies Golf Course formation (new).

Named for exposures south of south shore of Lake Murray, Murray County.

Lake Neosho Shale Member (of Altamont Limestone)

Pennsylvanian (Des Moines Series) : Eastern Kansas, southwestern Iowa, and northwestern Missouri.

J. M. Jewett, 1941, Kansas Geol. Survey Bull. 38, pt. 11, p. 329, 331–332, pl. 1. Defined as shale between Tina limestone member below and Worland limestone member above. Contains oblong, irregularly shaped phosphatic concretions. Thickness in Kansas 2½ to 6 feet.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. v (fig. 1), 8. Overlies Amoret limestone member (Amoret replaces name Tina).

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 31, fig. 5. Geographically extended into southwestern Iowa, upper part of shale is dark gray and fossiliferous; beneath shale is persistent coal streak underlain by clay that is gray above and red below. Thickness about 6 feet. Overlies Amoret limestone member; underlies Worland limestone member.

Type section: Southeast of Lake Neosho in Neosho County State Park, SW sec. 23, T. 30 S., R. 20 E., Neosho County, Kans.

Lake Newark Formation

Miocene, upper, and (or) Pliocene: Northeastern Nevada.

T. E. Eakin, 1960, Nevada Dept. Conserv. Nat. Resources Rept. 1, p. 26. Bedded rhyolite tuff and coarser pyroclastics; in part lacustrine. Thickness 430 feet. Unconformably underlies Belmont fanglomerate (new) ; unconformably overlies Illipah formation (new). Name credited to F. L. Humphrey (in press).

F. L. Humphrey, 1960, Nevada Bur. Mines Bull. 57, p. 43–45, pl. 1. Formal proposal of name. Succession of bedded rhyolite tuffs and pyroclastics Includes both bedded tuffs which were deposited on lake floor and subaerial pyroclastics which were deposited above level of lake. Materials in both types of deposits are of same age and source, but the two members are differentiated because of different depositional conditions which accompanied their formation. Member 1 includes bedded tuffs which are present up to an altitude of about 7,400 feet. Unbedded pyroclastics are found above this elevation. Member 1 has maximum thickness of about 350 feet. Member 2 is as much as 80 feet thick in places. Unconformably overlies Illipah formation (new); older than Lampson formation (new); underlies Belmont fanglomerate (new). On basis of fossils, tentatively considered upper Miocene or Pliocene. As mapped, includes Lampson formation.

In Newark Valley, White Pine County.

Lake Pinto Sandstone Member (of Mineral Wells Formation)[1]

Lake Pinto Sandstone Member (of Salesville Formation)

Middle Pennsylvanian: Central northern Texas.

Original references: F. B. Plummer and R. C. Moore, 1922, Jour. Geology, v. 30, p. 25, 31; Texas Univ. Bull. 2132, p. 77, charts.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 88. Salesville raised to formational status and expanded below to base of Lake Pinto sandstone, Lake Pinto underlies Dog Bend limestone member of Salesville and overlies Village Bend limestone member of East Mountain shale. Name Mineral Wells dropped in this report.

Leo Hendricks, 1957, Texas Univ Bur. Econ. Geology Pub. 5724, p. 23–24, fig. 3, pl. 1. In this report [Parker County], Lake Pinto considered basal member of Salesville, although author does not wholly agree with Cheney's reclassification. Sandstone and associated beds show facies changes across county. Thickness as much as 50 feet. Underlies unnamed shale member, that includes Dog Bend limestone bed in lower part; overlies shale in East Mountain formation.

J. W. Shelton, 1958, (abs.) Geol. Soc. America Bull., v. 69, no. 12, pt. 2, p. 1515–1524, pl. 1. In eastern Palo Pinto County, Strawn-Canyon boundary placed at base of Lake Pinto sandstone which overlies Village Bend limestone.

Named for Lake Pinto, one-half mile west of Mineral Wells, Palo Pinto County.

Lakeport Limestone[1]

Silurian: Central New York.

Original reference: G. H. Chadwick, 1918, Geol. Soc. America Bull., v. 29, p. 327–368.

Lakeport hole, Madison County.

†Lake Shore trap[1]

Precambrian (Keweenawan): Northern Michigan and Wisconsin.

Original reference: R. D. Irving, 1883, U.S. Geol. Survey Mon. 5, p. 186, pls. 17, 18.

Named for exposures on shore of Lake Superior at Keweenaw Point, Mich.

Lakeside Clay (in Golden Valley Formation)

Eocene: Eastern Montana.

Great Northern Railway Co. Mineral Research and Development Department, 1958, Great Northern Railway Co. Mineral Research and Devel. Dept. Rept. 5, p. 7, map. Gray clay about 6 feet thick. White Earth clay, South Ross clay, and East Tioga clay occurs in same general area.

Occurs one-half mile north of Lakeside Station, in SW¼SW¼ sec. 18, T. 27, N., R. 59 E., on Great Northern mainline, Roosevelt County.

†Lake Superior Group[1]

[Upper Cambrian] : Northern Michigan.

Original reference: A. Winchell, 1871, Michigan Geol. Survey Rept. Prog., p. 26–27.

Upper Peninsula.

Lake Superior Sandstone[1]

Lake Superior Sandstone Member (of St. Croixan Formation)

Upper Cambrian : Northern Michigan and eastern Minnesota.

Original reference: D. Houghton, 1840, Michigan Geol. Survey 3d Rept. for 1839, H. Doc. 8, p. 13.

A. C. Lane and A. E. Seaman, 1907, Jour. Geology, v. 15, p. 691–692, table facing p. 681. In view of uncertainty of relation of the three parts of Lake Superior sandstone, as used by Houghton, separate names seem useful. Term Freda is proposed for that west of Cooper Range; term Jacobsville for that east of Cooper Range and term may apply to all the Lake Superior sandstone skirting the coast at intervals to Grand Island; term Munising sandstone is to apply to upper 250 feet of Lake Superior sandstone which crosses bluffs back of Munising.

S. G. Bergquist, 1937, Michigan Acad. Sci., Arts and Letters Papers, v. 22, p. 421 (footnote). Ulrich seems to have good evidence to support view that St. Croixan formation of Wisconsin area extends into Superior region of Alger County, Mich. So-called Lake Superior sandstone would thus be included as a member of the formation.

See Lake Superior Series.

Named for occurrence on south shore of Lake Superior, northern Michigan.

Lake Superior Series

Precambrian (Keweenawan) : Northeastern Minnesota.

C. R. Stauffer and G. A. Thiel, 1941, Minnesota Geol. Survey Bull. 29, p. 10, 11–13. In addition to lava flows and other igneous rocks included in the Keweenawan, the thick sediments along south shore of Lake Superior should be included in the series. They are mainly sandstones and shales with occasional important conglomerates, the whole of which may be several thousand feet in thickness. These are the beds which Houghton (1840) called Lake Superior sandstone, part of which was designated by Irving (1883, U.S. Geol. Survey Mon. 5) as the Western sandstone. Since this deposit of arenaceous sediments has been divided into several formations, the earlier term is used as a series name. Although these sandstones and shales have occasionally been considered Cambrian in age, their lack of fossils makes classification more or less indeterminate. They definitely underlie St. Croixian series and may be interbedded with Keweenawan lava flows. Made up of Fond du Lac beds below and Hinckley sandstone above. Precambrian.

Named for occurrence in Lake Superior district.

Laketown Dolomite[1]

Middle and Upper Silurian: Northeastern and western Utah, southern Idaho, and southwestern Wyoming.

Original reference: G. B. Richardson, 1913, Am. Jour. Sci., 4th, v. 36, p. 407, 410.

C. P. Ross, 1937, U.S. Geol. Survey Bull. 877, p. 11 (table), 19, 23–25. In Bayhorse region, Idaho, overlies Saturday Mountain formation and underlies Jefferson dolomite. Thickness about 2,500 feet.

J. S. Williams, 1948, Geol. Soc. America Bull., v. 59, no. 11, p. 1137–1138, pl. 1. Described in Logan quadrangle, Utah, where it is 1,150 feet thick, disconformably underlies Water Canyon formation (new) and disconformably overlies Fish Haven dolomite. Middle Silurian.

J. D. Love, J. L. Weitz, and R. K. Hose, 1955, Geologic map of Wyoming (1:500,000); U.S. Geol. Survey. Mapped in southwestern Wyoming.

J. K. Rigby, 1958, Utah Geol. Soc. Guidebook 13, p. 28 (fig. 4), 33–34. Described in Stansbury Mountains where it is 614 to 664 feet thick; underlies Sevy dolomite and overlies Fish Haven dolomite. In some areas, as in vicinity of Dolomite, lower part of formation is exposed below Stansbury formation (new).

U.S. Geol. Survey currently considers the Laketown dolomite Middle and Upper Silurian on the basis of studies now in progress.

Named for exposures in Laketown Canyon, Rich County, Utah.

Lake Trammel Sandstone[1]

Permian: Central northern Texas.

Original reference: W. E. Wrather, 1917, Southwestern Assoc. Petroleum Geologists Bull., v. 1, p. 95–96, pl.

Occurs west of Aspermont, Stonewall County, and west of Sweetwater, Nolan County.

Lake Valley Limestone[1]

Lower Mississippian: Southern New Mexico.

Original reference: E. D. Cope, 1882, Eng. and Min. Jour., v. 34, p. 214.

L. R. Laudon and A. L. Bowsher, 1941, (abs.) Tulsa Geol. Soc. Digest, v. 9, p. 73–75; 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 12, p. 2114, 2125–2158. Restricted at base to exclude unit herein named Caballero formation. Subdivided into (ascending) Alamogordo, Arcente, and Dona Ana members. Underlies Magdalena formation. Thickness 29 to 420 feet. Osage.

L. P. Entwistle, 1944, New Mexico Bur. Mines Mineral Resources Bull. 19, p. 13, 22, pl. 2. In Boston Hill mining district, disconformably underlies Magdalena formation disconformably overlies Percha shale. Thicknesses: 657 feet; 325 feet. Not subdivided in this area.

P. F. Kerr and others, 1950, Geol. Soc. America Bull., v. 61, no. 4, p. 283 (fig. 5), 284. In Santa Rita district, underlies Oswaldo limestone (lower Magadalena) and overlies Percha shale.

V. C. Kelley and Caswell Silver, 1952, New Mexico Univ. Pubs. in Geology 4, p. 31 (table), 83–85. In some parts of Caballo Mountains, underlies Red House formation (new) of Magdalena group; overlies Percha formation. Alamogordo and Nunn members recognized. Thickness 49 feet.

Well exposed in Lake Valley mining district, Sierra County.

Lake Vantage Lavas

Miocene, upper: Central Washington.

G. F. Beck, 1936, Northwest Sci., v. 10, no. 3, p. 22. Name applied to pillow lavas, in which petrified logs from Vantage forest have been buried, together with underlying sediments. Horizon occurs about 800 feet down in Yakima basalt and extends over an area of 6 miles in diameter.

Occurs near Vantage, on Columbia River.

Lakeview Limestone[1]

Middle Cambrian: Northern Idaho.

Original reference: E. Sampson, 1928, Idaho Bur. Mines and Geology Pamph. 31, p. 9.

C. E. Resser, 1938, Smithsonian Misc. Colln., v. 97, no. 3, p. 3, 4. Overlies Rennie shale. Not overlain by other beds. Consists of two rock types: cliff-forming massive beds which vary from nearly pure limestone to nearly pure dolomite; and shaly beds containing thin-bedded fossiliferous limestone. Fossils described.

Named for exposures at town of Lakeview, near southeast end of Pend Oreille Lake.

Lakeview Quartz-Hornblende Diorite[1]

Lakeview Tonalite

Triassic(?) or Upper Jurassic(?): Southern California.

Original reference: P. H. Dudley, 1935, California Jour. Mines and Geology, v. 31, no. 4, p. 491, 502, map.

R. H. Merriam, 1941, Am. Jour. Sci., v. 239, no. 5, p. 366–371. Termed Lakeview tonalite in Ramona quadrangle.

E. S. Larsen, Jr., 1948, Geol. Soc. America Mem. 29, p. 57. Replaced by Lakeview Mountain tonalite (new).

Occurs throughout greater part of Lakeview Mountains, Riverside County.

Lakeview Mountain Tonalite

Cretaceous: Southern California.

E. S. Larsen, Jr., 1948, Geol. Soc. America Mem. 29, p. 57–58, pl. 1. Replaces name Lakeview quartz-hornblende diorite as proposed by Dudley (1935) and term Lakeview tonalite as used by Merriam (1941). Uniform rather coarse-grained nearly white rock with scattered black plates of biotite and stout prisms of hornblende. In contact with Bonsall tonalite; character of contact indicates Bonsall tonalite intrudes Lakeview Mountain tonalite, but the two probably not very different in age.

Richard Merriam, 1958, California Div. Mines Bull. 177, p. 13–14, 16 (fig. 2), pl. 1. Described and mapped in Santa Ysabel quadrangle. Younger than Green Valley tonalite. Contacts with rocks other than Green Valley tonalite poorly exposed; hence, no definite age determination could be made.

Occurs in Elsinore, San Jacinto, Ramona, and Santa Ysabel quadrangles. Underlies most of Lakeview Mountains in Elsinore quadrangle.

Lake Waco Formation

Cretaceous (Gulf Series): Central Texas.

W. S. Adkins and F. E. Lozo *in* F. E. Lozo, 1951, Fondren Sci. Series, no. 4, p. 119, 120, 133 (fig. 14), 137 (fig. 16), 139 (fig. 17). Proposed for section [of Eagle Ford] underlain by Woodbine sand or Pepper shale and overlain by emended South Bosque formation. Consists of grayish-white to brownish wavy-bedded limestones and dark silty shales with bentonite layers. Thickness 60 to 80 feet. Includes (ascending) newly defined members Bluebonnet, Cloice, and Bouldin.

Type area and section: West-facing Bosque Escarpment from Lake Waco Dam spillway south to the Moody Hills between McGregor and Moody, McLennan County; type section in Cloice Branch, from cement plant to old South Bosque brickyard pit.

†Lake Winnipesaukee Gneiss[1]

Precambrian(?) to Carboniferous: Eastern New Hampshire.

Original reference: C. H. Hitchcock, 1874, Geology New Hampshire, pt. 1, p. 508–545.

Lake Winnipesaukee region.

Lake Wolford Leucogranodiorite

Cretaceous: Southern California.

E. S. Larsen and N. B. Keevil, 1947, Geol. Soc. America Bull., v. 58, no. 6, p. 490. Named in report on study of batholith of southern California.

E. S. Larsen, Jr., 1948, Geol. Soc. America Mem. 29, p. 82–85, pl. 1. Described as fine-grained light-colored rock with average composition of leucogranodiorite. Makes up several widely separated bodies that differ considerably from place to place in each of main masses. Older than Woodson Mountain granodiorite and believed younger than San Marcos gabbro. Derivation of name given.

Named from its characteristic outcrops about Lake Wolford in western part of Ramona quadrangle. Occurs in San Luis Rey quadrangle, where it underlies an area of about 45 square miles.

Lakota Formation (in Inyan Kara Group)

Lakota Formation (in Dakota Group)

Lakota Sandstone (in Inyan Kara Group)[1]

Lower Cretaceous: Western South Dakota, northeastern Nebraska, and eastern Wyoming.

Original reference: N. H. Darton, 1899, Geol. Soc. America Bull., v. 10, p. 387.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 15 (fig. 7). Shown on columnar section as basal formation in Dakota group. Underlies Fuson shale.

K. M. Waagé, 1959, U.S. Geol. Survey Bull. 1081–B, p. 18–25, 32–33, 34–50, 84–86, strat. sections. Subdivision and nomenclature of Inyan Kara group adjusted to conform with its twofold lithogenetic division; Fall River formation redefined to correspond to upper part, and term Lakota extended to include entire lower part. Regional transgressive disconformity [see Dakota group] is contact between Lakota and Fall River formations. Lakota comprises Minnewaste limestone member and Fuson shale member. Name Lakota should not be used outside Black Hills region. Type section at Lakota Peak not considered adequate for reference or comparison; standard reference section herein designated. At standard reference section, where only Minnewaste member is present, formation is 460 feet thick; overlies Unkpapa sandstone and disconformably underlies Fall River formation. Sequence of Lakota rocks in southern part of Black Hills is markedly different from that in northwestern part. Additional beds are added progressively at base of formation as it thickens eastward and southeastward. Relationship of these beds to underlying Morrison not completely understood, but they do interfinger.

Base of Lakota is an arbitrary, indefinite, and inconstant boundary generally drawn at base of first appreciable sandstone bed above Sundance formation, the local distinctive Unkpapa sandstone excepted.

W. J. Mapel and G. B. Gott, 1959, U.S. Geol. Survey Mineral Inv. Field Studies Map MF-218. Referred to as formation—heterogeneous sequence of light-gray to light- to dark-gray siltstone, variegated sandy mudstone and claystone, and some limestone. Thickness as much as 550 feet in Cascade Springs and Angostura Reservoir quadrangles at southern end of Black Hills; thins irregularly westward to less than 100 feet along parts of Inyan Kara Creek and Government Canyon. In some areas, overlies Morrison formation, and in others, Unkpapa sandstone; underlies Fall River formation.

W.A. Pettyjohn, 1960, (abs.) South Dakota Acad. Sci. Proc., v. 38, p. 34–38. Dakota controversy discussed. Suggested that term Dakota group be used to include Lakota, Fuson, Fall River, Skull Creek, and Newcastle formations.

Type locality: Lakota Peak, a summit hogback range, 4 miles northwest of Hermosa, Custer County, S. Dak. Composite reference section. Exposures in valley of Fall River in center W½NW¼ sec. 33, NE½NE¼ sec. 32, and adjacent parts sec. 29, T. 7 S., R. 6 E., Fall River County, Hot Springs quadrangle, South Dakota. Exposures are between 4 and 5 miles south of Hot Springs.

Lalor Sands[1]

Quaternary (probably Recent): Southern New Jersey.

Original reference: J. B. Woodworth, 1911, Harvard Univ. Peabody Mus. American Arch. and Eth. Papers, app., p. 238–241.

Named for Lalor farm, near Riverview Cemetery, Trenton, Mercer County.

Lamar Limestone Member (of Bell Canyon Formation)

Lamar Limestone Member (of Delaware Mountain Formation)[1]

Upper Permian (Guadalupe Series): Western Texas and southeastern New Mexico.

Original reference: W. B. Lang, 1937, Am. Assoc. Petroleum Geologists Bull., v. 21, no. 7.

P. B. King, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 4, p. 583–586, pl. 2; 1948, U.S. Geol. Survey Prof. Paper 215, p. 57–58, pl. 3. Reallocated to member status in Bell Canyon formation (new). Separated from underlying Rader limestone member (new) by several thousand feet of sandstone beds; separated from overlying Castile formation by about 20 feet of fine-grained slabby sandstone. Thickness at type locality about 15 feet; about 150 feet at mouth of McKittrick Canyon.

G. E. Hendrickson and R. S. Jones, 1952, New Mexico Bur. Mines Mineral Resources Ground-Water Rept. 3, p. 18. Crops out at base of reef escarpment just north of south county line of Eddy County, N. Mex.

N. D. Newell and others, 1953, The Permian reef complex of the Guadalupe Mountains region Texas and New Mexico; San Francisco, W. H. Freeman and Co., p. 15, 53. Separated from underlying Rader member by McCombs limestone member (new).

Type locality: Escarpment north of Lamar Canyon, where canyon is crossed by Western Gas pipeline, about 15 miles due east of Guadalupe Point, Delaware Basin, Tex.

Lamb Dolomite[1]

Middle(?) and Upper Cambrian: Western Utah.

Original reference: T. B. Nolan, 1930, Washington Acad. Sci. Jour., v. 20, no. 17, p. 421–432.

U.S. Geological Survey currently designates the age of the Lamb Dolomite as Middle(?) and Upper Cambrian on the basis of a study now in progress.

Named for exposures in Lamb Gulch, on north side of Dry Canyon, Gold Hill district.

Lamb Point Tongue (of Navajo Sandstone)

Jurassic and Triassic(?): Southwestern Utah.

Paul Averitt and others, 1955, Am. Assoc. Petroleum Geologists Bull., v. 39, no 12, p. 2521. Applied by R. F. Wilson (in press) to rocks in Kanab area, formerly classified as Wingate by Gregory (1950). Consists of grayish-white to grayish-orange fine-to very fine-grained crossbedded sandstone. Base of tongue approximately 300 feet above top of Springdale sandstone member of Moenave throughout Kanab area; east of Sevier fault in vicinity of Moccasin, Ariz., eolian structures are absent in tongue; it is pale reddish-brown sandstone and is assigned to Kayenta formation. Approximately 400 feet thick in Kanab Canyon; 520 feet to east in Johnson Canyon; still farther east, thickens and coalesces with basal part of main body of Navajo; southwest of Kanab, thins from 400 to 142 feet in 5 miles; 93 feet at Moki Mountain southwest of Kanab. Since Lamb Point tongue thins westward from Kanab and since Shurtz tongue (new) thins southward from Cedar City, it is possible that they join somewhere between the two localities. Overlain by Tenney Canyon tongue (new) of Kayenta formation.

Type locality and derivation of name not stated.

Lamoille Glacial Stage[1]

Pleistocene: Northeastern Nevada.

Original reference: E. Blackwelder, 1931, Geol. Soc. America Bull., v. 42, p. 911, 918.

Ernst Antevs, 1945, Am. Jour. Sci., v. 243A, table 2. Listed on correlation chart of mountain glaciations in western United States.

Largest glacier of this stage issued from Lamoille Canyon, Ruby Mountains, northeastern Nevada.

Lamotte Sandstone[1]

Upper Cambrian: Eastern and central Missouri.

Original reference: A. Winslow, 1894, Missouri Geological Survey, v. 6, p. 331, 347–358.

G. F. Brightman, 1938, Jour. Geology, v. 46, no. 3, p. 250 (table 1), 254. Underlies Tom Sauk member (new) of Bonneterre formation.

E. B. Branson, 1944, Missouri Univ. Studies, v. 19, p. 16–18. Largely quartz grains varying in color through light gray, reddish brown, red, green, and shades of yellow. Shale layers a few inches thick common throughout formation. Underlies Bonneterre formation. Oldest Cambrian formation that appears at surface in Missouri. No complete section exposed.

Named for Mine La Motte Station, Madison County.

Lamoureux[1] or Lamoureaux shale[1]

Devonian: Nevada.

Original reference: C. R. Keyes, 1923, Pan-Am. Geologist, v. 40, p. 52, 79.

Named for exposures in Lamoureux Canyon, Eureka district.

Lampasas Series

Pennsylvanian: Texas.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1), 81–82. Proposed for beds younger than Morrow but older than type Strawn. Series forms extensive wedge between eastward-dipping type Marble Falls and westward-dipping Strawn beds. Type Marble Falls belongs to Morrow series, but Marble Falls beds in McCulloch and Kimble Counties are for most part believed to be post-Morrow. In southeastern Oklahoma, regional unconformities at top of Morrow and at base of Savanna are considered as marking lower and upper boundaries of Lampasas. Upper Pottsville and lower Allegany beds of older classifications included in Lampasas. Includes Big Saline (new) and Smithwick groups. Epoch marks first appearance of family Fusulinidae, possibly excepting genus *Stafella*. Development of *Fusiella* and *Fusinella* occurred during Big Saline time and early types of *Wedekindellina* and *Fusulina* species during Smithwick epoch. Genus *Mesolobus*, characteristic of Strawn (Des Moines) series, is thought to be absent in Lampasas.

M. G. Cheney and others, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 2, p. 156–164. Type section and correlatives discussed. Proposed that Lampasas-Strawn boundary in Brazos River outcrop section be placed at base of conglomerate which rests on Dennis Bridge limestone at Dennis highway bridge in southwestern Parker County. Placement of Connoquenessing, Mercer, and Clarion groups of Pennsylvanian in Kanawha series (upper Pottsville) favors inclusion of approximately equivalent Big Saline, Smithwick, and Parks groups in correlative series of Mid-Continent region.

F. B. Plummer, 1945, Texas Univ. Bur. Econ. Geology Pub. 4401, p. 76. Name Lampasas has been applied by Cheney in place of restricted Bend. Type outcrops designated by Cheney are same as those near Bend, type locality for the Bend. Seems confusing to substitute a new name for Bend, a term long in good usage by State and Government surveys.

R. C. Spivey and T. G. Roberts, 1946, Am. Assoc. Petroleum Geologists Bull., v. 30, no. 2, p. 181–186. Lampasas not appropriate as series name because in type area it is only partly exposed and because, as defined it includes beds of Des Moines age and excludes part of Marble Falls which is post-Morrow in age.

Type section: Around Llano uplift of central Texas and in area to north. Best outcrops of beds are in western Lampasas and eastern San Saba Counties near village of Bend. McAnnelly's Bend in vicinity of village of Bend has been used as type area of Bend division.

Lampkins Sandstone Member[1] (of Carwood Formation)

Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1931, Indiana Dept. Conserv. Div. Geology Pub. 98, p. 77, 118, 178, 183, 291.

J. M. Weller and others 1948, Geol. Soc. America Bull., v. 59, no. 2, pl. 2 facing p. 126. Member of Carwood formation. Part of Gent facies of formation.

Named for Lampkins Bridge across Salt Creek, south-center sec. 15, T. 8 N., R. 1 E., 3 miles southwest of Belmont, Monroe County.

Lampson Formation

Pliocene and (or) Pleistocene: Northeastern Nevada.

F. L. Humphrey, 1960, Nevada Bur. Mines Bull. 57, p. 45–46. Consists of bedded tuffs and gravels containing basalt pebbles. Thickness in some areas as much as 300 feet. Younger than Lake Newark formation (new). Underlies Belmont fanglomerate (new). Mapped with Lake Newark formation.

Named for exposures in Lampson Canyon, White Pine mining district, White Pine County.

La Muda Limestone Member (of Frailes Formation)

La Muda Limestone[1]

Upper Cretaceous: Puerto Rico.

Original reference: C. P. Berkey, 1915, New York Acad. Sci. Annals, v. 26, p. 22.

C. A. Kaye, 1959, U.S. Geol. Survey Prof. Paper 317–A, p. 7 (table), 10 (fig. 4), 18–19, pl. 2. Rank reduced to member status in Frailes formation (new). La Muda as used in this report follows usage of Berkey and not Meyerhoff and Smith (1931, New York Acad. Sci. Scientific Survey of Porto Rico and the Virgin Islands, v. 2, p. 3); their La Muda is referred to Trujillo Alto limestone. Texture varies; fine-grained pure limestone; solution openings and veins of coarsely crystalline calcite common; thin sections show Foraminifera, Radiolaria, and small broken grains of calcareous algae. Thickness 35 to 60 feet. Forms lenticular limestone in lower part of Frailes and is not a single bed or stratigraphic horizon. In type area, directly overlies Tortugas andesite (new) in vicinity of El Laberinto; to the northwest, rests on what seems to be the Guaynabo (without the intervening andesite); in type section of Frailes, the La Muda is separated from Tortugas andesite by about 200 feet of noncarbonate rock of Frailes.

Type locality: Vicinity of La Muda, a roadside settlement that fringes highway for a mile or more southeast of intersection of Highways 1 and 20, San Juan area.

Lana Conglomerate[1]

Precambrian: Northwestern Vermont.

Original reference: W. G. Foye, 1919, Vermont State Geologist 11th Rept., p. 85.

Occurs just above Falls of the Lana, north of Silver Lake, southern part of Addison County.

Lana Shale[1]

Precambrian: Northwestern Vermont.

Original reference: E. J. Foyles, 1929, Vermont State Geologist 16th Rept., p. 284.

Probably named for Falls of the Lana, Addison County.

Lanai Volcanic Series

Lanai Basalt[1]

Pliocene and Pleistocene(?) : Lanai Island, Hawaii.

Original reference: C. K. Wentworth, 1925, Bernice P. Bishop Mus. Bull. 24, p. 34.

H. T. Stearns, 1946, Hawaii Div. Hydrography Bull. 9, p. 67; G. A. Macdonald and D. A. Davis *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 110. Thin-bedded and pahoehoe basaltic flows, a few mixed cinder and spatter cones; about 375 feeding dikes. Composes cone of Lanai volcano. Thickness above sea level 3,370 feet; base not exposed. Includes Lanai basalt and Manele basalt. Overlain by marine limestone of probable Pleistocene age.

Well exposed in Kaholo Pali (cliff) on southwest side of island, and in deep canyons on northeastern slope. Covers area of about 135 square miles and comprises entire island except for small areas of alluvium.

†Lancaster Limestone[1]

Cambrian and Ordovician: Eastern Pennsylvania.

Original reference: J. P. Lesley and P. Frazer, Jr., 1880, Pennsylvania 2d Geol. Survey Rept. C_3, map of Lancaster County.

Lance Formation[1]

Upper Cretaceous: Colorado, Montana, North Dakota, South Dakota, and Wyoming.

Original reference: J. B. Hatcher, 1903, Am. Geologist, v. 31, p. 369–375.

W. R. Calvert, 1912, U.S. Geol. Survey Bull. 471, p. 189–198. In eastern Montana and southwestern North Dakota, includes Colgate sandstone member (new).

E. R. Lloyd, 1914, U.S. Geol. Survey Bull. 541, p. 249–250. In Cannonball River lignite field, North Dakota, includes Cannonball marine member (new), 250 to 300 feet thick, in upper part. Eocene(?).

E. R. Lloyd and C. J. Hares, 1915, Jour. Geology, v. 23, no. 6, p. 527–547. In western part of North Dakota and South Dakota, comprises (ascending) unnamed lower part, Ludlow lignitic member (new), and Cannonball marine member.

G. S. Rogers and Wallace Lee, 1923, U.S. Geol. Survey Bull. 749, p. 19–34. In Tullock Creek coal field, Montana, includes Tullock member (new), about 300 feet thick, in upper part.

W. T. Thom, Jr., and C. E. Dobbin, 1924, Geol. Soc. America Bull., v. 35, p. 490, 491–493. Restricted to exclude Colgate sandstone which is allocated to member status in underlying Fox Hills sandstone. Comprises Hell Creek, Tullock, Ludlow lignitic, and Cannonball members.

C. E. Dobbin and J. B. Reeside, Jr., 1929, U.S. Geol. Survey Prof. Paper 158–B, p. 9–25. Discussion of contact of Fox Hills and Lance formations. Writers [Dobbin and Reeside] advocate view that Laramie, Arapahoe, and Denver formations of Denver Basin are represented in Lance formation. Contact between Lance and Fox Hills is conformable except where local unconformities are present along minor erosion planes at many horizons within both formations. Measured sections show Lance present in Montana, Wyoming, North Dakota, and South Dakota.

E. M. Schlaikjer, 1935, Harvard Coll. Mus. Comp. Zoology Bull., v. 76, no. 2, p. 31–54, 65. In Goshen County, Wyo., includes Torrington member (new), 60 to 100 feet thick, as top member.

W. G. Pierce, 1936, U.S. Geol. Survey Bull. 847–B, p. 53–57, pl. 11. In Rosebud coal field, Montana, comprises (ascending) Hell Creek and Tullock members. Underlies Fort Union formation. Age has long been in controversy. Since decision in 1914 by U.S. Geological Survey to refer the Lance tentatively to the Tertiary, there has been much paleontologic and structural evidence which seems to warrant placing at least part of the Lance in the Cretaceous. Tertiary age used in this report inasmuch as studies of age of Lance still in progress. Mapped as Eocene(?).

E. P. Rothrock, 1937, South Dakota Geol. Survey Rept. Inv. 28, p. 4, 6–13. Described in Harding County where it includes Hell Creek and Ludlow members. Thickness 800 feet. Overlies Fox Hills formation; underlies Fort Union.

C. W. Wilson, Jr., 1938, Am. Assoc. Petroleum Geologists Bull., v. 22, no. 1, p. 106–108. In Carbon County, Mont., comprises (ascending) Hell Creek and Tullock members. Thickness 690 feet. Overlies Colgate sandstone; underlies Fort Union formation.

M. H. Stow, 1938, Geol. Soc. America Bull., v. 49, no. 5, p. 735–736, 744–745, pls. 1, 2. Upper Cretaceous Lance formation comprises Hell Creek and Tullock members. Underlies Lebo member of Fort Union; overlies Lennep sandstone. Area of report Big Horn Basin.

A. J. Collier and M. M. Knechtel, 1939, U.S. Geol. Survey Bull. 905, p. 10–11, pl. 3. In McCone County, Mont., where Lance is about 300 feet thick, it is underlain by Fox Hills sandstone of Upper Cretaceous age and underlies Fort Union formation of Eocene age. Footnote (page 10) states that since present report was written the Hell Creek and Tullock members have been raised to rank of formation in official classification of the Geological Survey, the Hell Creek being assigned to the Cretaceous and the Tullock to the Cretaceous or Eocene. Lance is Eocene(?).

Erling Dorf, 1940, Geol. Soc. America Bull., v. 51, no. 2, p. 213–236. Discussion of relationship between floras of type Lance and Fort Union formations. Paleobotanical evidence supports known vertebrate evidence in placing boundary between true Lance and "Fort Union" at base of nondinosaur-bearing Tullock, Ludlow, or Bear formations or their equivalents; that is, at top of *Triceratops*-bearing Hell Creek or Lance formations as originally defined. Such a view is not contradicted by marine invertebrates of Cannonball beds, which interfinger with the Ludlow and the lower "Fort Union." In proposed revision, Lance formation (equivalent to Hell Creek formation) is restricted to Upper Cretaceous; Tullock formation (equivalent to Ludlow formation and Cannonball marine member) is basal formation of Paleocene Fort Union group. Lance overlies Fox Hills sandstone.

V. H. Kline, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 3, p. 338. Generalized columnar section for North Dakota shows that Lance, 0 to 800 feet thick, comprises (ascending) Hell Creek, Cannonball, and Ludlow members. Overlies Fox Hills sandstone; underlies Fort Union formation. Tertiary.

O. A. Seager and others, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 8, p. 1415, 1416. There has been little agreement and no accepted solution of "Lance-Laramie" problem. In North Dakota, lithology and paleontology of strata formerly classified as "Lance" permit subdivision into formations whose stratigraphic positions are quite definite. Classification shows Cannonball and Ludlow as members of Paleocene Fort Union formation and the Hell Creek a formation in Upper Cretaceous.

Erling Dorf, 1942, Carnegie Inst. Washington Pub. 508, pt. 2, p. 83–159, pls. At type locality, consists of about 2,600 feet of dull-gray sandy shales alternating irregularly with lenticular light-colored sandstones and thin lignite beds. Along Lance and Lightning Creeks are numerous exposures which show that individual units are very irregular, sandstones passing laterally into shales and vice versa. Overlies Fox Hills sandstone; underlies Fort Union group, lower limit of which, in Lance Creek area, is equivalent to Tullock formation. Upper limit drawn at top of dinosaur-bearing beds. This horizon coincides with marked change, without a recognized erosional or structural unconformity, from the characteristic dull-gray shales and shaly sandstones of typical Lance formation to sequence of more persistent ridge-forming yellowish sandstones, yellowish sandy shales, and coal beds. Formation at Lance Creek has yielded abundant fossil remains of vertebrates, invertebrates, and plants. Flora described. Upper Cretaceous.

R. W. Brown, 1943, Geol. Soc. America Bull., v. 54, no. 1, p. 79–80. Lance of Wyoming equivalent to Laramie formation (redefined) of Denver Basin.

J. B. Reeside, Jr., 1944, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 10. Discussion of thickness and general character of Cretaceous deposits in Western Interior of United States. Correlation chart shows Lance in northern Great Plains, overlies Fox Hills sandstone and underlies Ludlow formation and Cannonball formation. Upper Cretaceous. [Ludlow and Cannonball previously considered members of Lance.]

H. E. Summerford and others, 1947, *in* Wyoming Geol. Assoc. Guidebook 2d Ann. Field Conf., p. 19. Road log of Bighorn Basin mentions Ilo Ridge member of Lance formation on east flank of Grass Creek anticline. Basal unit of formation; overlies Meeteetse formation.

G. B. Downs, 1947, Wyoming Geol. Assoc. Guidebook 2d Ann. Field Conf., p. 140. In Bighorn Basin area, name Lance applied only to Cretaceous or Hell Creek part of "Lance" of early writers. Youngest Mesozoic sequence of Bighorn Basin. Underlies Fort Union formation with angular disconformity; distinguished from underlying Meeteetse formation by general absence of coal beds, absence of coarse sediments, and presence of dark-brown concretions which weather from the sandstone of the Lance. The Lance is predominantly sand or poorly consolidated sandstone with lesser amounts of sandy clay and shale which range in color from gray and drab to light brown. Maximum thickness 1,400 feet.

L. A. Hale, 1950, Wyoming Geol. Assoc. Guidebook 5th Ann. Field Conf., p. 55. Area of report, Rock Springs uplift, Sweetwater County, Wyo. Along east side of uplift continental sediments lie conformably on marine Lewis shale and unconformably beneath Wasatch formation. This sequence of beds was named Black Butte coal group by Schultz and later Laramie formation. A thickness of 1,500 feet was given but nowhere is entire formation exposed. Proposed here that term Lance formation be applied in favor of Laramie formation in order to conform with currently accepted terminology of post-Montana pre-Tertiary formation in Wyoming.

Lance consists of basal member of light to yellowish-gray sandstone locally 80 feet thick. This member rests upon Lewis shale and forms prominent hills and precipitous cliffs along contact. Overlying beds consist of sandstone, clay shale, and thin coal beds that are less resistant to weathering than basal sandstone. Formation exposed only on east side of uplift between North Table Mountain and Black Butte Creek. Elsewhere the Wasatch lies unconformably in turn upon the Lewis, Almond, Ericson, and in one locality (T. 15 N., R. 104 W.) upon Rock Springs formation.

R. K. Hose, 1955, U.S. Geol. Survey Bull. 1027–B, p. 65, pls. 6, 8. Described in Crazy Woman Creek area, Johnson County, Wyo., where it overlies Bearpaw shale and underlies Fort Union formation. Thickness 1,950 to 2,200 feet. Contact with Bearpaw arbitrarily placed at top of 6-inch bentonite bed in Bearpaw. Lower 600 feet, which contains dinosaur bones, is of Late Cretaceous age. No fossils found in upper part within mapped area and assignment of entire Lance to Upper Cretaceous is one of convenience. Lower 100 feet may, in part, be equivalent to Fox Hills sandstone which is recognized about 20 miles south of mapped area.

W. J. Mapel, 1959, U.S. Geol. Survey Bull. 1078, p. 59–60, pls. 1, 3. At type locality, Lance beds conformably overlie Fox Hills sandstone and underlie Fort Union formation. Fox Hills sandstone not distinguished in Buffalo-Lake De Smet area, Wyoming [this report], and beds here classified as Lance rest directly on Bearpaw shale. Contact between Bearpaw and Lance placed arbitrarily at top of bed of grayish-yellow bentonite 1 foot thick underlain by 2 to 3 feet of fine-grained light-gray sandstone; this sandstone carries marine fauna. Underlies Fort Union formation. Thickness 1,970 feet 5 miles south of mapped area. Upturned edges of steeply dipping beds in Lance are exposed in southwestern, west-central, and northwestern parts of area in an outcrop band a quarter to a half mile wide trending northwestward parallel to Bighorn Mountain front.

Type locality: Lance Creek area, north-central part Niobrara County (formerly a part of Converse County), Wyo. Mouth of Lance Creek is in sec. 11, T. 39 N., R. 62 W.

†Lance Creek Beds[1]

Upper Cretaceous: Wyoming, northwestern Colorado, Montana, western North Dakota, and South Dakota.

Original reference: J. B. Hatcher, 1903, Am. Geologist, v. 31, p. 369–375.

Named for exposures on Lance Creek, Niobrara County (formerly part of Converse County), Wyo.

Lancha Limestone (in Pacheta Member of Lowell Formation)

Lower Cretaceous: Southeastern Arizona.

A. A. Stoyanow, 1949, Geol. Soc. America Mem. 38, p. 12. Grayish, bluish-gray, and pinkish limestone in places arenaceous or partly silicified. Thickness 11 feet. Underlies unnamed yellow dolomite. Overlies Morita formation.

In standard section of Lowell formation in Ninety One Hills. Type locality of formation also designated as Ninety One Hills area, immediately north of international border in vicinity of international monument No. 91, southeast of Bisbee Junction on Southern Pacific Railway, Cochise County.

Landaff Granite[1]

Upper Devonian or Upper Carboniferous: West-central New Hampshire.

Original reference: M. P. Billings, 1935, Geology of Littleton and Moosilauke quadrangles, New Hampshire, p. 28, Moosilauke map.

M. P. Billings, 1937, Geol. Soc. America Bull., v. 48, no. 4, p. 511, pl. 12. Fine-grained pink to gray hastingsite granite. May be part of White Mountain magma series.

Mapped largely in Landaff Township, Moosilauke quadrangle, Grafton County.

Lander Sandstone Member (of Bighorn Dolomite)[1]

Lander Sandstone

Upper Ordovician: Western Wyoming.

Original reference: A. K. Miller, 1930, Am. Jour. Sci., 5th, v. 20, p. 196–213.

J. D. Love, 1939, Geol. Soc. America Spec. Paper 20, p. 18, 19. Well exposed in several localities on southern margin of Absaroka Range. Thickness commonly about 7 feet. Underlies middle massive dolomite member. In some areas, rests with slight erosional unconformity on Gallatin limestone.

E. B. Branson and C. C. Branson, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 1, p. 124 (table 1), 126 (fig. 2), 129. Referred to as Lander sandstone. Overlies Gallatin formation; underlies Bighorn dolomite. Thickness as much as 20 feet.

A. B. Shaw and C. R. DeLand, 1955, Wyoming Geol. Assoc. Guidebook 10th Ann. Field Conf., p. 41. Overlies Open Door limestone (new) of Gallatin group.

Named from exposures about 10 miles southwest of Lander.

Landes Limestone[1]

Middle Devonian: Northeastern West Virginia.

Original reference: D. B. Reger, 1924, West Virginia Geol. Survey Rept. on Mineral and Grant Counties, p. 313, 745.

G. A. Cooper and others, 1952, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart below Genesee shale and above Hamilton shale.

Named for occurrence in public road along North Mill Creek, 0.2 mile north of Landes, Grant County.

Landgraff Sandstone (in Pocahontas Formation)[1]

Pennsylvanian: Southern West Virginia.

Original reference: R. V. Hennen and R. M. Gawthrop, 1915, West Virginia Geol. Survey Rept. Wyoming and McDowell Counties, p. 235.

Once quarried at Landgraff, McDowell County.

Landisburg Sandstone[1]

Silurian: Central Pennsylvania.

Original reference; J. P. Lesley, 1892, Pennsylvania 2d Geol. Survey Summ. Final Rept., v. 2, p. 761–777.

Landisburg, Perry County.

Landrum Member (of Cook Mountain Formation)

Landrum Shale Member (of Crockett Formation)

Eocene, middle (Claiborne) : Eastern Texas.

H. B. Stenzel, 1938, Texas Univ. Bur. Econ. Geology Pub. 3818, p. 20 (table), 125, 134–148. Series of brown lignitic shales and marls about 100 feet thick, overlying Wheelock marl member (new) and underlying Spiller sand member (new) of Crockett formation. Lower and upper boundaries transitional and interfingering.

H. B. Stenzel, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 9, p. 1665–1671. Reallocated to member status in Cook Mountain formation. Includes bentonite-bearing Hurricane marine lentil (new).

Type locality: On north-flowing tributary of Two-Mile Creek which enters Two-Mile Creek on William Johnson Survey; Two-Mile Creek flows through the J. L. Landrum survey near Two-Mile Church, Leon County.

Landston formation[1]

Middle Cambrian: Utah.

Original reference: C. R. Keyes, 1924, Pan-Am. Geologist, v. 41, p. 38.

Derivation of name not stated.

Lane Shale (in Kansas City Group)

Lane Shale (in Lansing Group)[1]

Lane Shale Member (of Lansing Formation)[1]

Pennsylvanian (Missouri Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original references: E. Haworth, 1895, Kansas Univ. Quart., v. 3, p. 277, pl. facing p. 290; 1895, Am. Jour. Sci., 3d, v. 50, p. 460, pl. facing p. 466.

J. R. Clair, 1943, Missouri Geol. Survey and Water Resources, 2d ser., v. 27, pl. 1. Columnar section, Jackson and Cass Counties, Mo., shows Lane shale in Lansing group. Includes (ascending) Island Creek shale, Farley limestone, and Bonner Springs shale members. Underlies Plattsburg limestone; overlies Iola limestone which includes (ascending) Frisbie limestone, Quindaro shale, and Argentine limestone members.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4), 2032–2033; F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 13–14. Settlement of "Iola problem" has led to several changes in Missouri Survey's classification of middle and upper Kansas City beds so as to bring interstate agreement in nomenclature. Liberty Memorial shale (Clair, 1943), overlying Raytown limestone, is no longer considered uppermost member of Chanute shale but is suppressed as junior synonym of Lane shale. Frisbie limestone, Quindaro shale, and Argentine limestone, which were indicated as members of Iola limestone are classified with overlying Island Creek shale and Farley limestone as members of Wyandotte formation. Island Creek shale and Farley limestone, which were associated with overlying Bonner Springs shale as members of Lane shale, are included in Wyandotte formation. Bonner Springs shale is recognized as formational unit between Wyandotte and Plattsburg formations. Hence, Lane shale in Missouri is removed from Lansing group and placed in Kansas City group where it occupies interval between Iola limestone and Wyandotte limestone.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 35. Thickness of formation 14 feet in Sarpy County, Nebr. Overlies Iola formation; underlies Frisbie limestone member of Wyandotte formation. Kansas City group.

T. L. Welp, L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 64, p. 418 (fig. 1), 420. Thickness of Lane formation about 10½ feet in Madison and Adair Counties, Iowa. Overlies Iola formation; underlies Frisbie limestone member of Wyandotte formation. Kansas City group.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 25, fig. 5. Recognized in Madison County as an olive to dark-gray fossiliferous shale containing limestone lenses; at some localities, has thin bed of maroon and green shale at base. In Union County, consists of greenish-gray to yellow calcareous shale with lenses of gray fossiliferous shale. Thickness 7 feet, Madison County; about 10 feet, Union County. Underlies Wyandotte limestone; overlies Iola limestone. Kansas City group.

Named for exposures at Lane, Franklin County, Kans.

Lanes Tongue (of Ankareh Formation)

Triassic: Eastern Idaho and western Wyoming.

Bernhard Kummel, 1954, U.S. Geol. Survey Prof. Paper 254–H, p. 173, 175 (fig. 18), pl. 38. Prominent tongue of Ankareh in upper part of Thaynes formation pinches out westward toward Fort Hall.

Present in Sheep Creek section, Grays Range, Idaho.

Lanesboro formational suite (of Wellsburg monothem)

Lanesboro Member (of New Milford Formation)[1]

Upper Devonian: Northeastern Pennsylvania.

Original reference: Bradford Willard, 1936, Geol. Soc. America Bull., v. 47, no. 4, p. 571–589.

K. E. Caster, 1938, Jour. Paleontology, v. 12, no. 1, p. 45 (fig. 7), 46. Termed formational suite; upper unit in monothem. Further described as typically containing massive sandstone or flaggy zone at top, a predominantly shaly zone in middle, and a prominent sandstone zone at base. Newly named Drinker Creek sandstone occurs at base.

Named for exposures near Lanesboro, Susquehanna County.

†Laneville Shale[1]

Pennsylvanian: Eastern Kansas and northwestern Missouri.

Original reference: E. Haworth and M. Z. Kirk, 1894, Kansas Univ. Quart., v. 2, p. 108.

Named for exposures at Laneville, Labette County, Kans.

Laney Shale Member (of Green River Formation)[1]

Eocene, middle: Southwestern Wyoming.

Original reference: A. R. Schultz, 1920, U.S. Geol. Survey Bull. 702.

J. J. Donavan, 1950, Wyoming Geol. Assoc. Guidebook 5th Ann. Field Conf., p. 63–64. Overlies Fontenelle member (new) of Green River.

W. H. Bradley, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 5, p. 1072–1074. At type locality and around Washakie basin and southward into Colorado, Laney shale member is characterized by buff laminated, or massive marlstone, buff tuffaceous sandstone, and soft marly shale, in which ostracods are fairly common. Interbedded with these rocks are moderate number of oil shale and organic marlstone, algal, and oolitic layers; fish bones, plant fragments, and snail or fresh-water clam shells are characteristic. In Bridger basin, beds that have been called Laney are predominantly white dolomitic marlstone, oil shale, or greenish-gray dolomite; though regularly bedded or laminated, they characteristically lack fossils, algal deposits, and oolites. This unit differs from type Laney in having thick and extensive saline facies; no saline facies of any kind are known in the Laney beyond limits of Bridger basin. Concluded from this study that what has been called Laney shale member in Bridger basin is older than type Laney and is time equivalent of Cathedral Bluffs and New Fork tongues of Wasatch formation. Beds in Bridger basin formerly thought to be Laney shale member of Green River herein renamed Wilkins Peak member. Recognition of Wilkins Peak member and its equivalence to Cathedral Bluffs tongue of Wasatch forces recognition of equivalence of Morrow Creek member with Schultz' type Laney shale member; hence, Morrow Creek member is abandoned, and name Laney shale member substituted. Laney shale member rests on Wilkins Peak member or one or another of tongues of Wasatch formation that are approximate time equivalents of Wilkins Peak member. Laney is overlain by Bridger formation. Tower sandstone lentil of Green River formation is redefined as lentil in Laney shale member.

Named for Laney Rim. Sweetwater County.

†Lang division[1]

Tertiary: Southern California.

Original reference: O. H. Hershey, 1902, Am. Geologist, v. 29, p. 349–372.

Named for exposures at Lang, Los Angeles County.

Langdon Shale (in Wabaunsee Group)

Pennsylvanian (Virgil Series): Northwestern Missouri, southwestern Iowa, south-central Kansas, and southeastern Nebraska.

G. E. Condra and E. C. Reed, 1943, Nebraska Geol. Survey Bull. 14, p. 42. Proposed for shale between base of Dover limestone above and top of Maple Hill limestone below. Thickness at type locality about 19 feet; 50 feet or more in north-central Kansas; thinner in southeastern Nebraska; replaces name Table Creek shale.

G. E. Condra, 1949, Nebraska Geol. Survey Bull., v. 14, p. 15. Occurrence, from southwestern Iowa, southeastern Nebraska, and northwestern Missouri to south-central Kansas.

R. C. Moore and M. R. Mudge, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2275–2276. Pillsbury shale (new) replaces Langdon shale (Condra and Reed, 1943); investigations have established Langdon shale, at its type section, as correlative with Wamego shale member of Zeandale limestone (new); accordingly name Langdon shale is abandoned.

Type locality: In Missouri River valley bluffs southeast of Langdon, Atchison County, Mo., or northwest of Craig, Holt County, Mo.

Langston Limestone[1]

Middle Cambrian: Southeastern Idaho and northeastern Utah.

Original reference: C. D. Walcott, 1908, Smithsonian Misc. Colln., v. 53, no. 1804, p. 6, 7.

Charles Deiss, 1938, Geol. Soc. America Bull., v. 49, no. 7, p. 1114–1115, 1117 (fig. 4), 1119–1120. Walcott's Blacksmith Fork section emended.

Langston consists of series of interbedded dull-tan, blue- and white-gray limestones, and dolomites which weather to red brown, and a basal 75- to 80-foot zone of white-gray calcareous quartzitic thin-bedded sandstone, 75-foot zone of buff-weathering thick-bedded dolomite occurs 68 feet below top of formation. Thickness 575 feet in type section which was measured on spurs that form sides of lower one-half mile of North Cottonwood Canyon on north side of Blacksmith Fork. Overlies Brigham quartzite; underlies Ute limestone (emended).

J. S. Williams and G. B. Maxey, 1941, Am. Jour. Sci., v. 239, no. 4, p. 279–281; J. S. Williams, 1948, Geol. Soc. America Bull., v. 59, no. 11, p. 1132–1133, pl. 1. In Logan quadrangle, Utah, includes Spence shale (formerly considered member of Ute formation) near base. At type locality, essentially two tan-weathering dolomites with an intermediate limestone member. Thicknesses 340 to 380 feet. Northward formation as a whole thickens slightly, but basal dolomite thins and disappears as *Ptarmigania* limestone and Spence shale appear and thicken at base of formation. Overlies Brigham quartzite; underlies Ute formation.

G. B. Maxey, 1958, Geol. Soc. America Bull., v. 69, no. 6, p. 649–650, 654–655, 656, 657–658, 662, 663, 664, 665, 669–671, 673 (fig. 3). Subdivided to include Naomi Peak limestone member (new). Several measured sections given. Section on north side of High Creek Canyon, sec. 11, T. 14 N., R. 2 E., near Richmond, Utah, considered most typical. Here both Naomi Peak and Spence members are present. Thickness 484 feet. Overlies Pioche formation. Some beds formerly assigned to Ophir and Maxfield formations are here assigned to Langston. Lower and Middle Cambrian.

Most accessible locality is Blacksmith Fork Canyon, Cache County, Utah, but strike of beds carries formation into valley of Langston Creek, Bear County, Idaho.

†Lang Syne Beds[1]

Eocene, lower: Central South Carolina.

Original reference: E. Sloan, 1908, South Carolina Geol. Survey, ser. 4, Bull. 2, p. 449, 451–452.

Named for exposures at Lang Syne plantation, Calhoun County.

Lanoria Quartzite[1]

Precambrian: Western Texas.

Original reference: G. B. Richardson, 1909, U.S. Geol. Survey Geol. Atlas, Folio 166.

T. S. Jones, 1953, Stratigraphy of the Permian basin of West Texas: West Texas Geol. Soc., p. 1. Overlies Red Bluff granite and unconformably underlies about 1,500 feet of red rhyolite porphyry.

R. L. Harbour, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 11, p. 1786 (fig. 1), 1790. Overlies Mundy breccia (new). Consists of 2,600 feet of quartzite, siltstone, and shale. Underlies unnamed rhyolite.

Named for exposures just west of old settlement near base of Franklin Mountains, 8 miles northeast of El Paso, El Paso County.

†Lanphier Beds (in Cheyenne Sandstone)[1]

Lower Cretaceous (Comanche Series): Central southern Kansas.

Original reference: F. W. Cragin, Am. Geologist, v. 16, p. 361, 367.

Named for draw running through Lanphier claim (which may be called Lanphier Draw), in southeast corner of Kiowa County.

Lansdale Shale (in Newark Group)[1]

Upper Triassic: Southeastern Pennsylvania.

Original references: B. S. Lyman, 1893, Pennsylvania Geol. Survey geol. and topog. map of Bucks and Montgomery Counties; 1895, Pennsylvania 2d Geol. Survey Summ. Final Rept., v. 3, pt. 2, p. 2589–2638.

Underlies Lansdale, Montgomery County.

L'Anse Series[1]

Age (?) : Northeastern Michigan.

Original reference: T. B. Brooks, 1873, Michigan Geol. Survey, v. 1, pt. 1, p. 151–155.

L'Anse iron district, Baraga County.

Lansing Group[1]

Lansing Formation[1]

Pennsylvanian (Missouri Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: H. Hinds, 1912, Missouri Bur. Geology and Mines, v. 11, 2d ser., p. 7.

R. C. Moore, 1936, Kansas Geol. Survey Bull. 22, p. 45 (fig. 8), 123–137. Group includes strata from base of Plattsburg to top of Stanton limestone. Average thickness about 75 feet; more than 150 feet in parts of southern Kansas. Overlies Bonner Springs shale of Kansas City group; underlies Weston shale of Pedee group.

H. S. McQueen and F. C. Greene, 1938, Missouri Geol. Survey and Water Resources, 2d ser., v. 25, p. 27, pl. 5. Group in Missouri includes (ascending) Lane shale which comprises Island Creek shale, Farley limestone, and Bonner Springs shale members, Plattsburg limestone, Vilas shale, and Stanton limestone. Underlies Weston shale of Pedee group; overlies Iola limestone of Kansas City group.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2031 (fig. 4), 2033–2034. Interstate agreement recognized Lansing group as defined by Moore, that is, comprising Plattsburg limestone, Vilas shale, and Stanton limestone.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. vi (fig. 2), 14. Lansing group revised for Missouri to accord with interstate agreement. Island Creek shale, Farley limestone, and Bonner Springs shale, formerly included in Lansing group, now included in upper part of Kansas City group.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 31–34. Exposed thickness of group about 52 feet in Nebraska; average thickness 70 feet in northwestern Missouri.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 24, fig. 5. Group in southwestern Iowa comprises Plattsburg limestone, Vilas shale, and Stanton limestone. Thickness about 29 feet. Underlies Kansas City group. Pedee-Douglas groups not differentiated.

Type locality: Lansing, Leavenworth County, Kans.

774–954—vol. 2—66——42

Lansingan series

Paleozoic (Cambric): Arkansas, Iowa, Minnesota, and Missouri.

C. R. Keyes, 1941, Pan-Am. Geologist, v. 75, no. 1, p. 74–76. Oneota limestone and Richmond sandstone beneath constitute valid, though imperfect taxonomic series for which term Lansingan is proposed. In eastern Missouri, Delassus sandstone, Potosi dolomite, and Eminence cherty dolomite are assigned to the series.

Lantern Hill Silexite

Lantern Hill quartz rock[1]

Age not stated: Southeastern Connecticut.

Original reference: H. E. Gregory, 1906, Connecticut Geol. Nat. History Survey Bull. 6, p. 136.

W. G. Foye, 1949, Connecticut Geol. Nat. History Survey Bull. 74, p. 64–65. Referred to as silexite. Resistant mass of almost pure silica located in Lantern Hill; smaller mass occurs to north. Derivation of name.

Named for Lantern Hill located on boundary between towns of North Stonington and Ledyard, New London County.

Lantz Mills facies (of Edinburg Formation)

Middle Ordovician: Western Virginia.

B. N. Cooper and G. A. Cooper, 1946, Geol. Soc. America Bull., v. 57, no. 1, p. 78, 79, 82. Edinburg formation (new) embraces two equivalent facies: one of cobbly to nodular buff-weathering limestone, the Lantz Mills facies, which is mainly developed in northern and western parts of Shenandoah Valley; and relatively thicker body of black limestone and shale, Liberty Hall facies (new), typically developed in Harrisonburg-Staunton area. Thickness, where typically exposed, 188 feet.

Typically exposed along Swover Creek near Lantz Mills, 4.6 miles N. 69° W. of Edinburg, Shenandoah County.

Laona Sandstone[1]

Laona Siltstone Member (of Canadaway Formation)

Upper Devonian: Western New York.

Original reference: J. Hall, 1841, New York Geol. Survey 5th Ann. Rept., p. 177.

Wallace de Witt, Jr., and G. W. Colton, 1950, U.S. Geol. Survey Geol. Quad. Map GQ–30. In Silver Creek quadrangle, Laona sandstone overlies Gowanda member of Perrysburg formation.

J. F. Pepper and Wallace de Witt, Jr., 1951, U.S. Geol. Survey Oil and Gas Inv. Chart OC–45. Laona sandstone of Hall overlies Perrysburg formation (new).

I. H. Tesmer, 1955, New York State Mus. Sci. Service Circ. 42, p. 10 (fig. 2), 17. Referred to as siltstone member of Canadaway formation. Overlies Gowanda member; underlies Westfield member. Name credited to L. C. Beck (1840, Fourth annual report on the mineralogical and chemical department of the Survey of New York, p. 57–58).

Named for exposures at Laona, Chautauqua County.

Lapa Lava Member (of Robles Formation)

Upper Cretaceous: Puerto Rico.

H. L. Berryhill, Jr., R. P. Briggs, and Lynn Glover 3d, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 2, p. 144, 145. Present in siltstone-sandstone facies of formation. Rests on rocks of volcanic complex in its southernmost outcrops; toward the north, overlies a lower tongue of siltstone of the Robles. Its stratigraphic position within formation becomes increasingly higher as this siltstone thickens. Thickness of lava ranges from a few inches to more than 1,000 feet; thickest in central and southern parts of island; pinches out toward the east, north, and northwest. Diagnostic features are pillowed structure and prominent phenocrysts. Appears to represent two lava effusions which in southern part of island are separated by thin layers of siltstone. Name credited to Berryhill and Glover (in press).

H. L. Berryhill, Jr., and Lynn Glover 3d, 1960, U.S. Geol. Survey Misc. Geol. Inv. Map I–319. Intertongues with Cayey siltstone member (new) in Cayey quadrangle. Thickness about 350 meters at type locality.

Type section: U.S. Military Reservation; begins at base of hill at point 1.2 kilometers N.40°W. of road intersection at Rabo del Buey and extends up ridge southwestward in Coamo quadrangle. Named for exposures in hills west of Río Lapa in Barrio Lapa between Rabo del Buey and Capilla de Santa Marta.

Lapara Sand Member (of Goliad Sand)[1]

Pliocene: Southern Texas.

Original reference: E. T. Dumble, 1893, Brown coal and lignite of Texas, p. 154.

A. W. Weeks, 1945, Am. Assoc. Petroleum Geologists Bull., v, 29, no. 12, p. 1727. In southwestern Texas, from central Duval County to the Rio Grande, divisions of the Goliad have been mapped. Section of sand and gravel at the base of the Goliad, ordinarily unconsolidated but in some places cemented to a firm siliceous conglomerate where it overlaps older beds sufficiently to rest on the Catahoula, is considered Lapara; upper section considered Lagarto. More work needed to determine full relations of these units to the Lapara and Lagarto divisions of Dumble in Live Oak County.

Type locality: Exposures along Lapara Creek in Live Oak County.

La Perla Shale Member (of Yegua Formation)

Eocene (Claiborne): Southern Texas.

J. M. Patterson, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 2, p. 259 (fig. 2), 264, Green and gray sandy bentonitic shale characterized by abundance of oyster beds. Thickness ranges from 50 to 150 feet. Basal member of formation. Overlies Falcon sandstone member (new) of Cook Mountain formation; underlies Mier sandstone tongue (new) of Yegua formation.

Named for La Perla ranchhouse, located on bank of Rio Grande, north part of San Ygnacio quadrangle.

†La Plata Sandstone[1]

Upper Jurassic: Southwestern Colorado and southeastern Utah.

Original reference: W. S. Cross *in* C. W. Purington, 1898, U.S. Geol. Survey 18th Ann. Rept., pt. 3, p. 759.

M. I. Goldman and A. C. Spencer, 1941, Am. Assoc. Petroleum Geologists Bull., v. 25, no. 9, p. 1746–1751. Five members differentiated in section covered by name La Plata sandstone. Unit 1 is correlated with Entrada sandstone; other units are considered members of Morrison and named (ascending) Pony Express limestone, Bilk Creek sandstone (new), Wanakah marl (restricted usage of Burbank's original Wanakah), and Junction Creek sandstone (new).

E. B. Eckel, 1949, U.S. Geol. Survey Prof. Paper 219, p. 28. Term Wanakah as used in this report [La Plata district, Colorado] is equivalent to La Plata limestone and middle La Plata shale as these terms are applied by local miners, and to middle part of La Plata sandstone as defined in La Plata folio (no. 60) and other reports on parts of southwestern Colorado. In La Plata district and elsewhere, rocks here placed in Wanakah were formerly regarded as part of Morrison formation.

Named for extensive development in La Plata Mountains, Colo.

Lapoint horizon (in Duchesne River Formation)[1]

Eocene (Duchesnean) : Eastern Utah.

Original reference: J. L. Kay, 1934, Carnegie Mus. Annals, v. 23, p. 357–359.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, p. 23, pl. 1. Overlies Halfway horizon. Eocene (Duchesnean).

Typically exposed along head of Halfway Hollow, east and north of Lapoint, Uintah County.

La Posta Quartz Diorite[1]

Late Mesozoic : Southern California.

Original reference: W. J. Miller, 1935, California Jour. Mines and Geology, v. 31, no. 2, p. 115–141.

W. J. Miller, 1946, Geol. Soc. America Bull., v. 57, no. 5, p. 485, table 4. Described under Late Mesozoic plutonics. In sequence in San Diego County, La Posta quartz diorite is younger than Descanso granodiorite or Stonewall diorite and older than Rattlesnake granite.

Typical exposures occur in general vicinity of La Posta Valley, southern Peninsular Range, San Diego and Imperial Counties.

Lar Quartz Diorite

Pre-Cretaceous (?) : Southern California.

G. J. Neuerburg, 1953, California Div. Mines Spec. Rept. 33, p. 3, 7 (table 1), 11–12, pl. 1. Fine- to medium-grained quartz diorite in Lar pluton. Separated into three parts: foliated biotite quartz diorite, massive biotite quartz diorite, and sheared biotite quartz diorite. Present also as large blocky inclusions in Feliz pluton and as microbreccia in Cahuenga Peak fault block; makes up entire exposure in Riverside fault block. Suggested sequence of intrusion in area is Vermont quartz diorite (new), Lar quartz diorite, and Feliz granodiorite (new).

Occurs in Griffith Park area, city of Los Angeles.

Laramie Formation[1]

Upper Cretaceous: Eastern Colorado.

Original reference: C. King, 1876, U.S. Geol. Expl. 40th Par. Atlas, maps 1, 2,.

C. H. Dane and W. G. Pierce, 1936, Am. Assoc. Petroleum Geologists Bull., v. 20, no. 10, p. 1310 (fig. 2), 1313–1320. In southeastern part of Denver basin, underlies Dawson arkose; in vicinity of Denver, underlies Arapahoe formation; overlies Fox Hills sandstone.

R. L. Nace, 1936, Wyoming Geol. Survey Bull. 26, p. 9–16. Note on type locality.

R. W. Brown, 1943, Geol. Soc. America Bull., v. 54, no. 1, p. 65–86. Discussion of Cretaceous-Tertiary boundary in Denver basin, Colorado. Stratigraphic and paleontologic evidence show that Laramie formation, Arapahoe formation, and the Cretaceous parts of Denver formation and Dawson arkose comprise a unit correlative with Lance formation and its equivalents. Proposed herein that the Laramie be redefined to include all the Upper Cretaceous sequence between top of Fox Hills and base of the Paleocene in Denver basin; that term Arapahoe as Arapahoe conglomerate member be retained for the conglomerate immediately overlying present Laramie formation; that terms Denver formation and Dawson arkose be restricted to the Tertiary strata. The Laramie as expanded is equivalent to typical Lance formation and Hell Creek formation; to Medicine Bow formation plus basal part. of Raton formation with the exception that both the Medicine Bow and Vermejo as now defined may include in their basal parts some strata that should be referred to Fox Hills sandstone.

J. T. Stark and others, 1949, Geol. Soc. America Mem. 33, p. 56–57, pl. 1. Described in South Park, Colo., where it consists of sandstone, shale, volcanic tuff, and coal. Maximum thickness 375 feet. Overlies Fox Hills formation; unconformably underlies Denver formation.

L. A. Hale, 1950, Wyoming Geol. Assoc. Guidebook 5th Ann. Field Conf., p. 55. Along east side of Rock Springs uplift, continental sediments lie conformably on marine Lewis shale and unconformably beneath Wasatch formation . This sequence of beds was named Black Butte coal group by Schultz and later Laramie formation. Proposed here to use term Lance formation in preference to Laramie to conform with currently accepted terminology of post-Montana pre-Tertiary formations in Wyoming.

S. O. Reichert, 1956, Geol. Soc. America Bull., v. 67, no. 1, p. 107–112, pl. 1,. Discussion of post-Laramie correlations in Denver basin, Colorado. In view of limits set for Arapahoe, Denver, and Dawson formations, the Laramie should be restricted to definition used by Emmons, Cross, and Eldridge (1896, U.S. Geol Survey Mon. 27) rather than extended as proposed by Brown (1943).

Type locality not designated in original description. Since name Laramie is now restricted to strata in Denver Basin of Colorado, it may be considered that type locality is in Denver Basin region east of Front Range of Colorado.

Laredo Formation (in Claiborne Group)

Eocene, middle: Southern Texas and northern Mexico.

Julia Gardner, 1938, Washington Acad. Sci. Jour., v. 28, no. 7, p. 297–298. Proposed for part of measured section of Claiborne group, that in the report on "Geology and ground-water resures of Webb County, Tex.," by Lonsdale and Day (1937), is included under name Cook Mountain formation, and for all beds of equivalent age in Rio Grande embayment. Overlies Mount Selman formation; underlies Yegua formation. Beds include both soft and indurated, glauconitic sandstone, glauconitic marl and clay, and thin limestones, commonly concretionary. In Laredo district, sands and sandstones make up more than 50 percent of formation; farther north, upper third of formation includes more clay than sandstone. Thickness near Laredo about 630 feet.

Area in which name is to apply extends from Frio, McMullen, and Live Oak Counties, Tex., into Mexico.

Lares Limestone [1] (in Río Guatemala Group)

Oligocene: Puerto Rico.

Original references: B. Hubbard, 1920, Science, new ser. v. 51, no. 1320, p. 396; 1923, New York Acad. Sci. Scientific Survey of Porto Rico and the Virgin Islands, v. 2, pt. 1, p. 42–44. [States name first used by author in paper presented before New York Academy of Sciences in 1917. Maury (1919, Am. Jour. Sci., 4th, v. 48) used term Lares limestone for beds overlying Sebastian shale; no distribution or stratigraphic limits given.]

A. D. Zapp, H. R. Bergquist, and C. R. Thomas, 1948, U.S. Geol. Survey Oil and Gas Inv. Prelim. Map 85. Included in Río Guatemala group. Limestone occurs in two bioherms. The western, which is more extensive, averages about 400 meters in thickness between the Rio Manati on the east and the Río Guajataca on the west, a distance of about 50 kilometers; westward, thinning is accomplished by lateral intertonguing of lower beds with San Sebastián formation and of upper beds with Cibao marl. Eastern bioherm has maximum thickness of about 250 meters between longitude lines through towns of Morovis and Corozal, a distance of about 10 kilometers; here, too, wedging out is by lateral intertonguing with the San Sebastian and Cibao. Locally underlies Aguda limesonte (new).

Type locality: North of Lares, where it forms the Cuesta and an extensive area of haystack or *pepino* hills.

Lares Shales[1]

Tertiary: Puerto Rico.

Original reference: C. P. Berkey, 1915, New York Acad. Sci. Annals, v. 26, p. 61.

†Largo Beds[1]

Eocene, lower: Northwestern New Mexico.

Original reference: Walter Granger, 1914, Am. Mus. Nat. History Bull., v. 33, p. 205–207.

G. G. Simpson, 1948, Am. Jour. Sci., v. 246, no. 6, p. 368, 369, 370–374. In type region of San Jose formation (new) are two distinguishable clay facies, corresponding to Granger's (1914) Almagre and Largo beds. "Largo" facies forms upper part of formation throughout type region except where it has been removed by erosion. Intergrades with "Almagre" facies below and no sharp distinction can be made.

Exposed principally in area drained by head of Largo Arroyo, in high bluff west of Ojo San Jose. Simpson measured section near where continental divide crosses pass between head of the Largo and southwest branch of "Almagre" Arroyo, mostly in NE¼ sec. 8, T. 23 N., R. 1 W., Rio Arriba County.

Larimer Sandstone Member (of Pierre Shale)[1]

Upper Cretaceous: Central northern Colorado.

Original reference: M. W. Ball, 1924, Am. Assoc. Petroleum Gologists Bull., v. 8, no. 1, p. 81–87.

G. R. Scott and W. A. Cobban, 1959, Rocky Mountain Assoc. Geologists 11th Field Conf. Symposium, p. 128, 129 (fig. 3). Olive-gray fine-grained massive sandstone with brown calcareous sandy concretions. Commonly consists of two to four thin ledge-forming brown sandstone beds separated by thicker units of softer and lighter colored sandstone. Thickness 141 feet near Douglas Lake; 78 feet at Fossil Creek, Separated from younger Richard sandstone member by 171 feet of sandy shale near Douglas Lake; 115-foot concealed interval between members at Fossil Creek; separated from older Rocky Ridge sandstone member by 164 to 187 feet of soft yellowish-gray sandstone and sandy shale with gray sandstone concretions. Large and varied invertebrate fauna.

Named for exposures in Larimer County Canal 4 miles north of Fort Collins, Larimer County. Well developed from Round Butte southward nearly to Boulder.

Larke Dolomite[1] (in Beekmantown Group)

Lower Ordovician: Central Pennsylvania

Original reference: Charles Butts, 1918, Am. Jour. Sci., 4th v. 46, p. 527, 534, 537.

Charles Butts, 1945, U.S. Geol. Survey Geol. Atlas Folio 227. Described in Hollidaysburg-Huntingdon area where it overlies Mines dolomite and underlies Nittany dolomite. Total thickness 200 feet.

Well exposed at Larke, 3 miles south of Williamsburg, Blair County.

Larrabee Member (of Glens Falls Formation)

Middle Ordovician (Mohawkian): Eastern New York and western Vermont.

G. M. Kay, 1947, Geol. Soc. America Bull., v. 48, no. 3, p. 262–263. Constitutes lower part of Glens Falls formation that is of Hull age, the upper Glens Falls being lowest Sherman Fall. At type section, member is composed of about 20 feet of bedded relatively pure limesones above Isle la Motte limestone; underlies *Cryptolithus*-bearing upper Glens Falls, the Shoreham member (new) of lowest Sherman Fall age. Larrabee varies in lithology and thickness; in lower Mohawk Valley, composed of thin-bedded limestones with coarse-textured ledges in upper part; thickness 15 to 25 feet between Patterson and Fultonville; lies on Lowville to west and on Amsterdam toward east.

R. B. Erwin, 1957, Vermont Geol. Survey Bull. 9, p. 30–31, 61–62, 69–71, 73–74, pls. 1, 2. Described on Isle La Motte and South Hero Islands, Vt., where it is about 70 to 75 feet thick.

Type section: Quarry one-fourth mile south of Larrabee Point, Addison County, Vt.

Larsh Shale Member (of Deer Creek Limestone)

Larsh Shale (in Deer Creek Limestone[1] Member of Shawnee Formation)

Pennsylvanian (Virgil Series): Southeastern Nebraska, southwestern Iowa, northeastern Kansas, and northwestern Missouri.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 40, 43, 49, 50.

G. E. Condra and E. C. Reed, 1937, Nebraska Geol. Survey, 2d ser., Bull. 11, p. 8, 12, 16, 20, 54, fig. 2. Member of Deer Creek limestone in Shawnee group. Overlies Rock Bluff limestone member; underlies Haynies limestone member.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, p. 179. Referred to as Larsh-Burroak shale member of Deer Creek limestone. Average thickness 3½ feet. Underlies Ervine Creek limestone member; overlies Rock Bluff limestone member.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2035 (fig. 5). Interstate agreement recognizes Larsh shale member of Deer Creek formation. Overlies Rock Bluff limestone member; underlies Haynies limestone member.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. vii (fig. 3), 17–18. In Missouri, interval between Rock Bluff limestone member and uppermost limestone of Deer Creek is occupied by shale. This shale has been referred to as Rock Bluff-Ervine Creek shale with implication that intervening Haynies limestone is absent in Missouri. Shale is here called Larsh-Burroak. Missouri Survey recognizes the possibility that Burroak shale may be absent in Missouri and that uppermost limestone of Deer Creek may include both Haynies and Ervine Creek members.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 18, fig. 5. Larsh shale, in southwestern Iowa, is gray to olive green argillaceous and blocky to thin bedded in upper part; lower part black and fissile. Thickness about 2 feet throughout entire area where Burroak and Larsh slates are differentiated. Overlies Rock Bluff limestone member; underlies Haynies limestone member. In some areas referred to as Burroak-Larsh shale.

Type locality: Ervine Creek valley, 2½ miles east and 1¼ miles north of Union, Cass County, Nebr.

LaSalle cyclothem (in Bond-Mattoon Formation)

LaSalle cyclothem (in McLeansboro Group)

Pennsylvanian: Northern Illinois.

J. M. Weller and A. H. Bell, 1936, Illinois Geol. Survey Rept. Inv. 40, p. 26 (fig. 5). LaSalle cyclothem in McLeansboro formation shown on columnar section. Occurs above Macoupin cyclothem.

J. M. Weller and W. A. Newton, 1938, (abs.) Geol. Soc. America Proc. 1937, p. 329. Upper part of McLeansboro, from Shoal Creek limestone up to highest Pennsylvanian strata is divided into following cyclothems (descending): Merom, Shumay, Woodbury, Gila, Greenup, Newton, Upper Bogota, Lower Bogota, Cohn, LaSalle, Macoupin, Flannigan, and Shoal Creek.

J. M. Weller and A. H. Bell, 1941, Illinois Geol. Survey Rept. Inv. 76, p. 7. In Effingham, Fayette, and Shelby Counties, includes LaSalle limestone.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 52 (table 2), 55 (table 3). In Bond-Mattoon formations (both new).

Type locality not given, but type locality of LaSalle limestone is in sec. 14, T. 33 N., R. 1 E., LaSalle County.

†La Salle Formation[1]

Pennsylvanian: Northeastern Illinois.

Original reference: F. W. De Wolf, 1910, Illinois Geol. Survey Bull. 16, p. 180.

Named for La Salle County.

LaSalle Limestone (in McLeansboro Group)

LaSalle Limestone Member (of Bond Formation)

LaSalle Limestone Member (of McLeansboro Formation)[1]

Middle and Upper Pennsylvanian: Northeastern Illinois.

Original reference: G. H. Cady, 1908, Illinois Geol. Survey Bull. 8, p. 128–134.

H. R. Wanless and Raymond Siever, 1956, Illinois Geol. Survey Circ. 217, p. 12, pl. 1. Included in LaSalle cyclothem, McLeansboro group. Type locality stated.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 39, 50 (table 1), pl. 1. Reallocated to member status in Bond formation (new). LaSalle and Hall limestone members are only named units in formation in northern Illinois. Presentation of new rock-stratigraphic classification of Pennsylvanian strata in Illinois.

Type locality: Sec. 14, T. 33 N., R. 1 E., La Salle County.

Lasca Formation

Cretaceous: Western Texas.

R. M. Huffington, 1947, Harvard Univ. Summ. of Theses, 1943–45, p. 196. Lasca formation, 600 feet thick, most likely late Washita in age. Overlies Tarantula formation (new); underlies Etholen formation.

Area of report is northern Quitman Mountains, southern Hudspeth County.

Las Cascades Agglomerate

Las Cascades (Cascadas) Formation[1]

Oligocene(?): Panamá.

Original references: D. F. MacDonald, 1913, Isthmian geology, ann. Rept. Isthmian Canal Comm., app. S, p. 568; 1913, Geol. Soc. America Bull., v. 24, p. 708.

W. P. Woodring and T. F. Thompson, 1949, Am. Assoc. Petroleum Geologists Bull., v. 33, no. 2, p. 228–229, 236, 246 (fig. 2). Las Cascadas agglomerate, Bas Obispo formation, and Bohío formation, all tentatively considered early Oligocene in age, are oldest formations along the Canal. Las Cascadas agglomerate and pyroclastic Bas Obispo formation are interpreted to represent accumulation of volcanic products at periphery of a volcanic pile. Unconformably underlies Culebra formation.

W. P. Woodring, 1957, U.S. Geol. Survey Prof. Paper 306–A, p. 28, 31–32, pl. 1. Overlies Bas Obispo formation Las Cascadas agglomerate and the Bas Obispo probably would ordinarily be combined as one formation; however, they differ in induration. Matrix of Las Cascadas consists of soft fine-grained altered tuff and bentonitic clay. Thickness not determined. According to plate 1, near Gamboa agglomerate rests on Bohío formation, Gatuncillo formation, or basement complex; confirmation of this overlap is needed; in eastern part of Gatun Lake area, appears to grade into Caimito formation. No fossils present; doubtfully referred to Oligocene because of inferred relations to Bohío and Caimito formations.

Type region: Northern part of Gaillard Cut, C. Z.

Las Cruces Formation

Mississippian (Meramec); Western Texas and central southern New Mexico.

L. R. Laudon and A. L. Bowsher, 1949, Geol. Soc. America Bull., v. 60, no. 1, p. 11, 12, 17, 37–38. Hard, dense, black, sublithographic, even-bedded, gray-weathering, sparsely fossiliferous limestone. Distinguished by relatively thin, remarkably even beds from 4 to 16 inches thick, averaging about 10 inches. Free of chert in type section. Maximum thickness approximately 60 feet in type area; 59 feet in type section. Unconformably overlies "Percha" shale (Canutillo formation of Nelson, 1940) and unconformably underlies Rancheria formation (new) in Franklin Mountains. Also overlies Lake Valley formation in some sections in southern part of area.

Type section: On southwest side of small fork of shallow canyon that leaves west slope of Franklin Mountains almost directly east of Vinton, Tex. (SW¼ sec. 67, S. Blk. 82, El Paso County, Tex.). Named from town of Las Cruces, N. Mex. Exposed mainly in Franklin Mountains; also in San Andres Mountains in Bear Canyon.

Las Feveras Formation

Tertiary or Quaternary: Northeastern New Mexico.

G. O. Bachman, 1953, U.S. Geol. Survey Oil and Gas Inv. Map OM–137. Sequence of brownish-red alluvium and gravel. Rests on Sangre de Cristo formation; overlain by basalt flow emitted in part from Ocate volcanic cone. Thickness more than 150 feet about 1 mile northwest of Ocate, but this is not complete representation of formation.

Named for Las Feveras Canyon which drains into northwestern part of Ocate Valley, Mora County. Well exposed in sides of three small basalt-capped buttes west of road about 2 miles north of Ocate.

La Sierra Tonalite

Cretaceous: Southern California.

E. S. Larsen, Jr., and N. B. Keevil 1947, Geol. Soc. America Bull., v. 58, no. 6, p. 488. Named in report on study of the batholith of southern California.

E. S. Larsen, Jr., 1948, Geol. Soc. America Mem. 29, p. 71–72, pl. 1. Described as light-gray tonalite. Intruded by Woodson Mountain granodiorite. Derivation of name given.

Named for its occurrence in hills of La Sierra, north and east of Corona, Riverside County.

Las Juntas Shale

Eocene, lower: Northwestern California.

C. E. Weaver, 1953, Washington [State] Univ. Pubs. in Geology, v. 7, p. 19 (chart), 30–31, pls. 4A, 4B, 4C. Name introduced for clay shales, silty shales, and interbedded sandstones between Vine Hill sandstone (new) below and Muir sandstone (new) above. Thickness at type section 1,017 feet. Las Juntas shale underlying Vine Hill sandstone of this report were classified and mapped jointly as Martinez group in San Francisco folio (Lawson, 1914) and the former as Capay shale in Carquinez quadrangle in 1949 (Weaver, Geol. Soc. America Mem. 35).

B. Y. Smith, 1957, California Univ. Pub., Geol. Sci., v. 32, no. 3, p. 144–146, 147. Since Pacheco syncline generally accepted as type area for the Martinez, it is particularly difficult to follow Weaver's (1953) omission of that term as an appropriate designation for lower part of sequence, and it seems desirable that Weaver's new units, Vine Hill, Las Juntas, and

Muir, be included either as members within Martinez formation or as formations within Martinez group. Systematic description of Foraminifera.

Type section: In east limb of Pacheco syncline in highway cuts and hillside outcrops east and southeast of Martinez, Contra Costa County. Only part of beds are exposed in west limb of fold where they lie adjacent to and along east side of Southampton fault.

Las Marías Limestone

Las Marías Limestone Member (of Río Blanco Formation)

Upper Cretaceous: Puerto Rico.

R. C. Mitchell, 1954, Puerto Rico Univ. Agr. Expt. Sta. Tech, Paper 13, p. 47, 48 (table 4), 94 (cross section). Distinctive grayish-blue limestone. [May be synonymous with Atalaya limestone.]

P. H. Mattson, 1960, Geol. Soc. America Bull., v. 71, no. 3, p. 344, pl. 1. Referred to as member of Río Blanco in Mayagüez area. Occurs as lenses of massive hematite-stained fragmental limestone in southern part of Río Blanco outcrop.

First mentioned in Lares district.

Las Posas Formation[1]

Pleistocene: Southern California.

Original reference: E. D. Pressler, 1929, California Univ. Pub., Dept. Geol. Sci. Bull., v. 18, no. 13, p. 325–345.

T. L. Bailey, 1943, Geol. Soc. America Bull., v. 54, no. 10, p. 1557. Name abandoned. San Pedro as defined in this paper synonymous with Pressler's (1929) Las Posas except that his so-called Kalorama member is retained in Santa Barbara formation.

Manley Natland, 1953, Pacific Petroleum Geologist, v. 7, no. 2, p. 2. Included in upper part of newly defined Hallian stage in Ventura Basin.

Probably named from Las Posas Hills, Ventura County.

Lassen Dacites[1]

Cenozoic: Northern California.

Original reference: Howel Williams, 1932, California Univ. Pub., Bull. Dept. Geol. Sci., v. 21, no. 5, p. 71 (map).

O. P. Jenkins, 1943, California Div. Mines Bull. 118, p. 679. Cenozoic.

Occur in Mount Lassen region.

Lassen sequence, suite, volcanic rocks

Age not stated: Northern California

J. A. S. Adams, 1955, Geochim. et Cosmochim. Acta., v. 8, p. 74–85. Collective term used for volcanic rocks in Lassen Volcanic National Park. Includes a number of named units.

Howel Williams (1932, California Univ. Pub., Bull. Dept. Geol. Sci., v. 21, no. 8) used term lava sequence of Lassen region.

Lasso Limestone

Aquitanian: Mariana Islands (Tinian).

Risaburo Tayama, 1939, Correlation of the strata of the South Sea Islands: Geol. Soc. Japan Jour., v. 46, no. 549, p. 346 (correlation chart) [English translation in library of U.S. Geol. Survey]. Raso limestone named on correlation chart. Correlated with Tapotchau [Tappotcho] limestone on Saipan, and Hirippo limestone on Rota. Miocene.

Risaburo Tayama, 1952, Coral reefs in the South Seas: Japan Hydrog. Office Bull., v. 11, p. 54, table 4 [English translation in library of U.S. Geol. Survey, p. 65]. Lasso limestone. Oligocene.

S. Hanzawa *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 42. Name Lasso limestone credited to M. Kodaira (unpub. ms.) who applied name to pink-colored limestone and underlying limestone conglomerate which unconformably overlies andesitic agglomerate and unconformably underlies Mariana limestone. Aquitanian.

Exposed along base of cliff bounding western margin of Carolinas Plateau in Kanat Tadung.

Last Chance Andesite[1]

Tertiary: New Mexico.

Original reference: H. G. Ferguson, 1927, U.S. Geol. Survey Bull. 787.

Named for exposures at Last Chance mine, south of Silver Creek, Mogollon district.

Last Chance Quartz Monzonite

Post-Pennsylvanian; Northern Utah.

Bronson Stringham, 1953, Geol. Soc. America Bull., v. 64, no. 8, p. 965. Medium fine-grained granitoid rock. Texture and mineral composition much more uniform than Bingham granite with which it is associated.

Occurs in Last Chance intrusive stock. Crops out in area west, southwest, and south of Bingham copper mine, Salt Lake County.

Las Tetas Lava Member (of Robles Formation)

Upper Cretaceous: Puerto Rico.

H. L. Berryhill, Jr., R. P. Briggs, and Lynn Glover 3d, 1960, Am. Assoc. Petroleum Geologists Bull., v. 44, no. 2, p. 144, 145–146. Varies from pillow lava to very massive igneous rock that could be in part intrusive. Thickness about 1,000 feet in vicinity of Cayey; southward, thins and pinches out. Represents several effusions; in southernmost outcrops, layers are separated by lenses or tongues of volcanic siltstone, volcanic sandstone, and volcanic conglomerate. Lies about 900 feet above Lapa lava member (new) and separated from it by thick middle tongue of siltstone within the formation. Name credited to Berryhill and Glover (in press).

H. L. Berryhill, Jr., and Lynn Glover 3d, 1960, U.S. Geol. Survey Misc. Geol. Inv. Map I–319. Overlies Cayey siltstone member (new); underlies Colloa member (new).

Named for exposures at and near prominent topographic features, Las Tetas, which lie west of Highway 1 at point 650 meters southwest of intersection of Highway 1 and Highway 162, Cayey quadrangle.

Las Vigas Formation[1]

Lower Cretaceous: Northern Mexico and southwestern Texas.

Original references: R. H. Burrows, 1909, Min. and Sci. Press, v. 99, p. 293; 1910, Soc. Geol. Mexicana, Bol. t. 7, p. 93.

Gayle Scott, 1939, Texas Univ. Bur. Econ. Geology Pub. 3945, p. 973 (chart), 977, 978. Discussion of correlation of Trinity strata on basis of cephalopod fauna. Las Vigas formation, which underlies the Cuchillo, is older than any Trinity sediments cropping out anywhere else in Texas except in Torcer formation of Malone Mountain area.

Named for exposures in Conchos River valley, northern Chihuahua, Mex., west of Presidio, Tex.

Las Virgenes Sandstone[1]

Eocene, lower: Southern California.

Original reference: R. N. Nelson, 1925, California Univ. Pub., Dept. Geol. Sci. Bull., v. 15, no. 11, p. 400–401, map.

Named for typical development at head of Las Virgenes Canyon, on south side of Simi Hills, Ventura County.

Latah Formation[1]

Miocene, middle or upper: Eastern Washington and western Idaho.

Original reference: J. T. Pardee and Kirk Bryan, 1926, U.S. Geol. Survey Prof. Paper 140, p. 4–12.

J. W. Hosterman, 1960, U.S. Geol. Survey Bull. 1091, p. 7–8, pls. 2, 3, 4. In general vicinity of clay deposits in Washington and Idaho, the Latah is interbedded with Columbia River basalt and is divided into an upper an lower part by the unit of basalt on which residual clay is developed.

Typical exposure on slope west of Latah Creek, a short distance south of Spokane, Spokane County, Wash.

Latham Shale

Lower Cambrian: Southern California.

J. C. Hazzard, 1954, California Div. Mines Bull. 170, chap. 4, p. 30 (table 1), pl. 2. Greenish-gray platy shale with thin buff-weathering sandy limestone layers. Thickness 55 to 75 feet. Underlies Chambless limestone; overlies Prospect Mountain quartzite. Replaces preoccupied name Kelso.

Type locality: About a mile southwest of Latham's cabin in northern Providence Mountains, San Bernardino.

Latir Peak Latite

Tertiary: Central northern New Mexico.

P. F. McKinlay, [1955?], New Mexico Bur. Mines Mineral Resources Bull. 42, p. 14, pl. 1. Occurs as thick flows, sills, and dikes. Is porphyritic with an aphanitic to glassy groundmass. Color in most outcrops is light gray, but near Latir Peak much of rock is reddish. Intrusive into rocks of pre-Tertiary age and closely associated with the andesite series of mid-Tertiary(?) age.

Named after Latir Peak, where the rock is well exposed. Makes up most of Latir Peak and high ridges that lie to south of peak. One of the largest exposures is near headwaters of Cabresto and Bitter Creeks, along southern edge of Latir Peak quadrangle, Taos County.

Latonia Shale (in Eden Group)[1]

Upper Ordovician: Northern Kentucky and southwestern Ohio.

Original reference: N. M. Fenneman, 1916, Ohio Geol. Survey, 4th ser., Bull. 19, p. 63.

Wilber Stout, Karl Ver Steeg, and G. F. Lamb, 1943, Ohio Geol. Survey, 4th ser., Bull. 44, chart facing p. 108. Shown on chart as formation including (ascending) Economy, Southgate, and McMicken members. Underlies Fairview formation; overlies Fulton formation.

Named for Latonia, Kenton County, Ky.

Latour Formation[1]

Miocene, middle or upper: Northern Idaho.

Original reference: O. H. Hershey, 1912, Geol. Soc. America Bull., v. 23, p. 529–536.

Deposited in [ancient] Lake Latour, Coeur d'Alene region.

Latrania Sand Member (of Imperial Formation)

†Latrania Sands[1]

Miocene, middle, to Pliocene, lower: Southern California.

Original reference: G. D. Hanna, 1926, California Acad. Sci. Proc., 4th ser., v. 14, no. 18, p. 435.

A. M. Keen and Herdis Bentson, 1944, Geol. Soc. America Spec. Paper 56, p. 21 (fig. 4). Listed as sand member of Imperial formation.

Exposed on Coyote Mountain, Imperial County.

La Tuna Member (of Magdalena Formation)

Pennsylvanian: Western Texas.

L. A. Nelson, 1937, Colorado Univ. Studies, v. 25, no. 1, pl. 89. In Franklin Mountains, Tex., Magdalena formation divided into (ascending) La Tuna, Berino, and Bishops Cap member (all new).

L. A. Nelson, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 167, 170. Thickness about 361 feet. Basal part is massive light- to dark-gray limestone, 340 feet thick. Underlies Berino member; overlies Helms shale. Derivation of name given.

M. L. Thompson, 1942, New Mexico Bur. Mines Mineral Resources Bull. 17, p. 23. On basis of fusulinid studies, it seems inadvisable to apply Nelson's terms to Pennsylvanian rocks of central New Mexico.

Named for town of La Tuna, Tex., on Santa Fe Railroad at Texas-New Mexico line.

†Lauderdale Chert[1]

Mississippian: Northern Alabama.

Original reference: E. A. Smith, 1892, Sketch of geology of Alabama: Birmingham, Ala., Roberts & Son, pamph., 36 p.

Named for development in Lauderdale County.

Laughery Formation (in Richmond Group)[1]

Upper Ordovician: Southeastern Indiana.

Original reference: A. F. Foerste, 1912, Denison Univ. Sci. Lab. Bull., v. 17, p. 22.

Exposed along Laughery Creek in Ripley County.

†Laulau Limestone

Miocene (Aquitanian): Mariana Islands (Saipan).

Risaburo Tayama, 1938, Geomorphology, geology, and coral reefs of Saipan Island: Tropical Industry Inst., Palau, South Sea Islands, Bull. 1 [English translation in library of U.S. Geol. Survey, p. 56–60.] Variegated, white, black, red, brown, and yellow, tuffaceous, marly, arenaceous, limestones. As exposed at Laulau railway cut, limestone is conglomeratic in lower part; arenaceous, white, and stratified in middle; upper part, hard pink unstratified limestone. Has been called *Eulepidina* limestone. Unconformably overlies Densinyama beds.

Josiah Bridge *in* W. S. Cole and Josiah Bridge, 1953, U.S. Geol. Survey Prof. Paper 253, p. 9–10. Grades laterally into water-laid Donni tuff. Miocene (Aquitanian).

P. E. Cloud, Jr., R. G. Schmidt, and H. W. Burke, 1956, U.S. Geol. Survey Prof. Paper 280–A, p. 63. Included in Tagpochau limestone of this report.

Named for exposures in railway cuts on south side of Laulau Mountains northwest of village of Laulau on north side of Laulau (Magicienne) Bay.

Laupahoehoe Volcanic Series

Pleistocene and Recent(?) : Hawaii Island, Hawaii.

G. A. Macdonald, 1945, Am. Jour. Sci., v. 243, no. 4, p. 212 (fig. 1), 213, 214. Largely andesites with lesser amounts of olivine basalts. Separated from older Hamakua volcanic series (new) by erosional unconformity.

H. T. Stearns and G. A. Macdonald, 1946, Hawaii Div. Hydrog. Bull. 9, p. 153 (table), 159–166. Comprises two members: lower, largely lava flows, predominantly andesitic with lesser amounts of olivine basalts, Pleistocene; and upper, a few andesite flows, Recent.

D. A. Davis and G. A. Macdonald *in* Jacques Avias and others, 1956, Lexique Strat. Internat., v. 6, Océanie, fasc. 2, p. 110. Maximum exposed thickness about 200 feet; total thickness probably more than 1,000 feet. Pleistocene and Recent(?) ; age assignment depends on relation to Pahala ash and to glaciation.

Named for exposures at Laupahoehoe Peninsula where typical andesite flow has built lava delta. Comprises entire upper part of Mauna Kea with some flows extending onto lower slopes.

Laurel Dolomite[1] or Limestone[1]

Laurel Limestone Member (of Wayne Formation)

Laurel Limestone Member (of Bainbridge Formation)

Laurel Member (of Alger Formation)

Middle Silurian; Southern Indiana, west-central Kentucky, southeastern Missouri, Ohio, and west-central Tennessee.

Original reference: A. F. Foerste, 1896, Cincinnati Soc. Nat. History Jour., v. 18, p. 190–192.

Wilber Stout, 1941, Ohio Geol. Survey, 4th ser., Bull. 42, p. 35, table facing p. 46. In Ohio considered member of Alger formation. Underlies Massie member and overlies Osgood. Thickness 5 to 9 feet; average 6 feet.

J. R. Ball, 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 1, p. 10–11. Laurel limestone geographically extended into southeastern Missouri where it is considered member of Bainbridge formation; overlies Osgood member. Characteristically massive, light-gray, with pinkish calcite crystals.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 248–249. Laurel limestone included in Wayne group. In central Tennessee, uniformly bedded limestone with beds that range from a few inches to a foot or more in thickness. Fine-grained and light gray with varying amounts of red and pink grains; locally entirely dolomitic; in some areas, contains silt, also may be oolitic at top. Average thickness 30 feet. Conformably overlies Osgood formation; conformably underlies Waldron shale or unconformably underlies Chattanooga shale.

J. B. Patton, T. G. Perry, and W. J. Wayne, 1953, Indiana Geol. Survey Field Conf. Guidebook 6, pl. 1. In Indiana, Laurel formation underlies Waldron and overlies Osgood. Consists of limestone, pale-tan to gray, dense to finely crystalline, thin-bedded, cherty, moderately dolomitic. Thickness 27 to 40 feet. In Clinton group.

Named for Laurel, Franklin County, Ind.

Laurel Gneiss or Pseudomigmatite

Laurel Migmatite

Age unknown (post-Glenarm Series): Maryland.

Ernst Cloos and C. H. Broedel, 1940, Geologic map of Howard County and adjacent parts of Montgomery and Baltimore Counties (1:62,500): Maryland Geol. Survey. Migmatite—granitized schist mixed with impure granite; muscovite and biotite granite.

R. W. Chapman, 1942, Geol. Soc. America Bull., v. 53, no. 9, p. 1300–1328. Although Laurel gneiss resembles a true migmatite, term pseudomigmatite is more appropriate. Gneiss is bounded on north by Guilford granite and Wissahickon formation, on northeast by gabbro, on east by Cretaceous gravels, on south by gneiss, and on west by the Wissahickon.

Ernst Cloos *in* Ernst Cloos and C. W. Cooke, 1953, Geologic map of Montgomery County and District of Columbia (1:62,500): Maryland Dept. Geology, Mines and Water Resources. Mapped in Montgomery County as Laurel gneiss. Very similar to Sykesville formation and possibly its equivalent southwest of Woodstock anticlinorium.

Occurs in vicinity of Laurel, about 17 miles southwest of Baltimore.

Laurel Canyon Formation

Paleozoic: California.

E. B. Mayo, 1934, California Jour. Mines & Geology, v. 30, no. 1, pl. 2. Crystalline limestone (marble). Devonian in part.

O. P. Jenkins, 1938, Geologic map of California (1:500,000): California Div. Mines, sheet 4. Shown on map legend.

Mapped in Laurel and Convict basins, Mono County.

Laurens Member (of Trimmers Rock Sandstone)

Laurens Member[1] (of Tully Limestone)

Upper Devonian: Eastern New York and eastern Pennsylvania.

Original references: G. A. Cooper, 1933, Am. Jour. Sci., 5th, v. 26, p. 544; 1934, Am. Jour. Sci., 5th, v. 27, p. 10.

G. A. Cooper and others, 1942, Geol. Soc. America Bull., v. 53, no. 12, pt. 1, chart 4. Shown on correlation chart as Middle Devonian.

M. E. Johnson and Bradford Willard, 1957, Geol. Soc. America Guidebook for Atlantic City Mtg., Trip 4, fig. 1. Shown on columnar section as member at base of Trimmers Rock sandstone.

Well exposed in Houghtaling's Glen, 1½ miles northeast of Laurens, Otsego County, N.Y.

Laurentian Series[1]

Precambrian: Lake Superior region.

Original reference: W. E. Logan, 1854, Canada Geol. Survey Rept. Prog. 1852–1853, p. 7, 8.

F. F. Grout and others, 1951, Geol. Soc. America Bull., v. 62, no. 9, p. 1029. Term Laurentian widely used but variously defined. Originally used by Logan (1854) to refer to exposures of gneiss, granite, and other old rocks north of St. Lawrence River. Special committee (Hays and others, 1905, Jour. Geology, v. 13, no. 2) approved term for "granites and gneissoid granites which antedate or protrude through the Keewatin, and which are pre-Huronian;" also for granites of unknown age. Cooke (1920, Jour. Geology, v. 28, no. 4) urged that term Laurentian be reserved for those granites that cut all rocks below base of Huronian and that other terms be found for those that cut only Keewatin. Tendency since that time, even among Canadian writers, is to use term Laurentian for oldest granites. Radioactivity determinations may show seven or more Precambrian granites. In Minnesota [Minnesota Geological Survey], three groups are recognized: the first post-Keewatin and pre-Knife Lake; second (Algoman) post-Knife Lake and pre-Animikie; and third Keweenawan. Term Laurentian is commonly used for oldest group (our [Minnesota Geological Survey] pre-Knife Lake granites), but some of them may be older than others.

Named for occurrence north of St. Lawrence River. Area has been named Laurentides in early history of Canada.

La Vaca Formation

Miocene, middle: Panamá.

Incidental mention: R. A. Terry, 1956, California Acad. Sci. Occasional Paper 23, p. 59.

W. P. Woodring *in* R. Hoffstetter and others, 1960, Lexique Strat. Internat., v. 5, Amérique Latine, fasc. 2a, p. 337. An undefined name. Miocene(?).

On Burica Peninsula, Chiriquí Province.

Lava Falls Tongue (of Muav Formation)

Lower and (or) Middle Cambrian: Northwestern Arizona.

E. D. McKee, 1945, Carnegie Inst. Washington Pub. 563, p. 14 (fig. 1), 29, 95. Consists partly of aphanitic limestone and partly of fine-grained dolomite, but nearly everywhere weathers into a resistant cliff with red-brown surface. At type section, divisible into three units; basal ledge-forming dolomitic limestone; middle slope-forming unit of green shale and brown siltstone; and upper cliff-forming carbonate unit. Eastward extension of carbonate deposits from Spencer Canyon member (new) of Muav formation. Thickness at Granite Park 20 feet; farther east at Toroweap 17½ feet, and at Gateway Canyon 16½ feet. Older than Parashant tongue (new); younger than Garnet Canyon tongue (new).

Type locality: About 1 mile east of Lava Falls at foot of Toroweap Valley, Grand Canyon.

Lavender Member (of Fort Payne Chert)

Lavender Shale Member (of Fort Payne Chert)

Mississippian: Northwestern Georgia.

Charles Butts *in* Charles Butts and Benjamin Gildersleeve, 1948, Georgia Geol. Survey Bull. 54, p. 42–45. Dark compact massively bedded calcareous shale or argillaceous limestone with small amount of limy material interbedded in Fort Payne chert. Thickness about 50 feet. Overlain by chert locally as much as 50 feet thick; in some areas, rests directly on Chattanooga shale.

V. J. Hurst, 1953, Georgia Geol. Survey Bull. 60, p. 218. Lavender shale not readily separable from dark-colored siliceous argillaceous limestone which occurs with and above it. Much of what Butts called shale is actually limestone; hence, the dark-colored siliceous, argillaceous limestone in lower two-thirds of the Fort Payne together with the associated calcareous shale is referred to in this report as Lavender member. Thickness of Lavender member appears to be reciprocally related to thickness of bedded chert, as 1 mile south of West Rome, 30 to 50 feet of bedded chert is overlain by 80 to 100 feet of Lavender member, whereas 15 miles north, near Gore, about 150 feet of chert is exposed and Lavender member is missing.

Type locality: On railroad one-third mile west of Lavender Station, and in quarry in shale at underpass of U.S. Highway 27, beneath Southern Railway, about 1 mile north of Rome.

La Ventana Tongue (of Cliff House Sandstone)

La Ventana Sandstone Member (of Mesaverde Formation)[1]

Upper Cretaceous: Northwestern New Mexico.

Original reference: C. H. Dane, 1937, U.S. Geol. Survey Bull. 860–C.

E. C. Beaumont, C. H. Dane,and J. D. Sears, 1956, Am. Assoc. Petroleum Geologists Bull., v. 40, no. 9, p. 2159–2160. Classified as tongue of Cliff House formation. On outcrop, does not connect with Cliff House but does connect in northern part of San Juan Basin with Mesaverde group undivided. Seems possible that somewhere in subsurface it will be found to connect essentially with main body of Cliff House to which, genetically, it is clearly related as part of upper transgressive marine-sandstone sequence of Mesaverde group.

Named from town of La Ventana, Sandoval County, on the Rio Puerco near which unit crops out, and from La Ventana Mesa east of Rio Puerco, on which top of basal unit is exposed.

Laverne Formation[1]

Pliocene, lower: Northwestern Oklahoma and southwestern Kansas.

Original reference: C. N. Gould, 1927, Oklahoma Univ. Bull., Proc. Oklahoma Acad. Sci., v. 6, pt. 2, p. 235–238.

J. C. Frye and C. W. Hibbard, 1941, Kansas Geol. Survey Bull. 38, p. 398–403. Geographically extended into southwestern Kansas where it is well exposed along both sides of Cimarron Valley in southeastern Seward County and in southwestern Meade County. Consists of shale, sandstone, and limestone; locally contains a hard conglomerate; buff, blue gray, and gray. Thickness about 60 feet. Laverne beds dip at angles as much as 15° and are overlain by horizontal beds of the Ogallala. Miocene and lower Pliocene.

C. W. Hibbard, 1949, Michigan Univ. Mus. Paleontology Contr., v. 9, no. 5, p. 91–105. Unconformably underlies Rexroad formation in Seward and Meade Counties, Kans.

A. J. Myers, 1959, Oklahoma Geol. Survey Bull. 80, p. 47–50, pl. 2. In Harper County, consists of interbedded gray to blue-gray sandy chalk, blue-gray to tan shales, gray fine-grained thin-bedded sandstone, and massive tan to pink coarse-grained sandstone; basal part is coarse conglomerate containing abundance of black iron-stained pebbles; conglomerate not continuous. Thickness as much as 35 feet. At no place is Ogallala in contact with Laverne. Lower Pliocene (p. 48). Type locality stated.

Type locality: In vicinity of Laverne, Harper County, Okla.

Lavery Till

Pleistocene (Wisconsin): Northwestern Pennsylvania.

V. C. Shepps and others, 1959, Pennsylvania Geol. Survey Bull., 4th ser., G–32, p. 10 (fig. 3), 13 (fig. 4), 38–41, pl. 1. Light-gray moderately pebbly calcareous silt till deposited during Lavery advance in approximately middle Cary time. Lavery advance followed Kent advance and preceded Hiram advance.

G. W. White, 1960, U.S. Geol. Survey Bull. 1121–A, p. 2 (table 1), 3 (fig. 1), 6–7. In northeastern Ohio Lavery till is underlain unconformably by Kent till and overlain unconformably by Hiram till except in small area where it constitutes surface material.

Type area: At and north of hamlet of Lavery, Erie County, 4½ miles west of Edinboro on U.S. Route 6N.

La Vida Member (of Puente Formation)

Miocene, upper: Southern California.

J. E. Schoellhamer and others, 1954, U.S. Geol. Survey Oil and Gas Inv. Map OM–154. Defined as basal member of formation. Consists mainly of gray to black laminated siltstone with thin interbedded feldspathic sandstone beds. Maximum exposed thickness about 3,000 feet. Underlies Soquel member (new). In some areas, base is not exposed; in other areas, La Vida rests unconformably on El Modeno volcanics (new) or on Topanga formation or on Sespe and Vaqueros formations, undivided.

Named for La Vida Mineral Springs, located in Carbon Canyon about 3 miles north of Yorba Linda, in eastern part of Puente Hills, Orange County.

Lawler Peak Granite

Precambrian: West-central Arizona.

C. A. Anderson, E. A. Scholz, and J. D. Strobell, Jr., 1955, U.S. Geol. Survey Prof. Paper 278, p. 1, 18–19, pl. 3. Typical Lawler Peak granite is essentially porphyritic biotite-muscovite granite. Orthoclase phenocrysts as much as 3 inches long embedded in medium- to coarse-grained groundmass. In northern exposures, white muscovite granite forms masses more than a mile in length; biotite is absent and muscovite is more abundant than in normal Lawler Peak granite; known as muscovite facies. Also includes a gneissic facies and an altered facies. Intruded by Cheney Gulch granite (new). Intrudes all formations of Yavapai series, and gabbro, alaskite porphyry, and granodiorite gneiss.

Exposed for about 9 square miles in hilly country in northeast corner of Bagdad area, Yavapai County, where outcrops on Lawler Peak suggested name for the granite.

Lawlor Tuff

Pliocene: Northern California.

B. L. Clark, 1943, California Div. Mines Bull. 118, pt. 2, p. 189. Shown on correlation chart as "Lawler tuff;" underlies Los Medanos formation.

C. E. Weaver, 1949, Geol. Soc. America Mem. 35, p. 110 (table 24), 121–122, pls. 12, 13. Described as pumiceous andesitic tuff. Thickness 50 to 100 feet. Tuffs dip from 15° to 30° NE. In Los Medanos Hills, underlies Wolfskill formation (new) and overlies Neroly formation. Derivation of name given.

Named for exposures in Lawler [Lawlor] ravine, in southwestern Antioch quadrangle, where it forms a bond generally less than 300 feet wide.

Lawrence Clay (in Allegheny Formation)[1]

Lawrence underclay member

Pennsylvanian: Southeastern Ohio and West Virginia.

[Original reference]: Wilber Stout and others, 1923, Ohio Geol. Survey Bull. 26, p. 269.

A. T. Cross and M. P. Schemel, 1956, West Virginia Geol. Survey, v. 22, pt. 2, p. 46. Noted in West Virginia.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 61. Lawrence underclay member of Lawrence-Lower Kittanning cyclothem in report on Athens County. At most places, combined with Lower Kittanning underclay. Allegheny series.

Lawrence coal and clay named from Lawrence Furnace, Elizabeth Township, Lawrence County, Ohio.

Lawrence cyclothem

Pennsylvanian (Allegheny Series): Ohio.

N. K. Flint, 1951, Ohio Geol. Survey, 4th ser., Bull. 48, p. 40, 46. Includes (ascending) Kittanning shale and (or) sandstone, Lawrence clay, Lawrence coal. Occurs above Scrubgrass cyclothem and below Lower Kittanning cyclothem.

Present in Ohio column but not easily recognized in Perry County; in this report, treated as part of Lower Kittanning cyclothem.

Lawrence Shale (in Douglas Group)[1]

Lawrence Shale Member (of Douglas Formation)[1]

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: E. Haworth, 1894, Kansas Univ. Quart., v. 2, p. 122.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. vii (fig. 3), 15, 16. Formation in Missouri consists of two unnamed shale members separated by Amazonia limestone member. Ireland limestone member, present in Kansas, not identified in Missouri. Because of absence of this sandstone. Robbins shale at top of Stranger formation cannot be differentiated, if present in Missouri, from shale of Lawrence formation below Amazonia member. Base of Lawrence is drawn in Missouri at top of Haskell limestone.

G. E. Condra, 1949, Nebraska Geol. Survey Bull. 16, p. 26–27. Thickness 23 feet in Platte Valley; about 42 feet in Weeping Water Valley.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 69–72. Extends from base of Toronto limestone member of Oread limestone to disconformity below Ireland sandstone or, in places where disconformity is undeterminable, to top of Haskell limestone member of Stranger formation. Includes Ireland sandstone member below and Amazonia limestone member above. Thickness 40 to 175 feet.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 23–24, fig. 5. In Iowa it is not possible to locate accurately unconformity separating Pedee group of Missouri series from Douglas group of Virgil series. Individual units of interval poorly defined, and for this reason entire interval considered as unit and referred to as Douglas-Pedee group. Locally in subsurface it has been possible to recognize Iatan limestone, uppermost formation of Pedee group, and Stranger shale, lowermost formation of Douglas group. Because it is rarely possible to differentiate these formations in Iowa, entire interval is called Lawrence-Weston shale.

Named for exposures at Lawrence, Douglas County, Kans.

Lawrence shale and (or) sandstone member

Pennsylvanian: Eastern Ohio.

M. T. Sturgeon and others, 1958, Ohio Geol. Survey Bull. 57, p. 61. Lawrence shale and (or) sandstone member included in Lawrence cyclothem in report on Athens County. Shale and sandstone below so-called Lower Kittanning underclay is actually member of Lawrence cyclothem but is usually called (Lower) Kittanning shale and sandstone. Thickness of member about 5 feet. Allegheny series.

Lawrenceville Shale (in McLeansboro Formation)

Pennsylvanian: Southeastern Illinois and southwestern Indiana.

J. A. Culbertson, 1932, The paleontology and stratigraphy of the Pennsylvanian strata between Caseyville, Kentucky, and Vincennes, Indiana: Urbana, Ill., Univ. Illinois, Abs. Thesis, p. 3, 7–8. Calcareous shale containing a gastropod fauna. Underlies New Harmony sandstone (new); overlies Grayville limestone (new).

Named from exposures in and near Lawrenceville, Ill.

Lawson Limestone

Upper Cretaceous: Northeastern Florida (subsurface).

P. L. Applin and E. R. Applin, 1944, Am. Assoc. Petroleum Geologists Bull., v. 28, no. 12, p. 1681, 1708–1711, 1746 (fig. 31). Name applied to limestone facies of late Upper Cretaceous occurring in northeastern Florida and the peninsula. Occurs below Cedar Keys limestone and above beds of Taylor age. Divided into two members: upper, a white and cream-colored calcitic porous limestone containing gypsum in most wells—thickness ranges from 40 feet in Sholtz well No. 2, Levy County, to 300 feet in Cory well No. 1, Monroe County; lower, a hard white and cream-colored microfossiliferous chalky limestone—commonly 300 to 400 feet thick in Sholtz well No. 2, 75 feet.

R. O. Vernon, 1951, Florida Geol. Survey Bull. 33, p. 82–84. In recent oil tests, particularly, Humble-Hodges well No. 1, in Taylor County, fauna characterizing upper member occurs very high in section in interval normally considered Cedar Keys formation of Paleocene age. This indicates that upper Lawson is transitional bed including fossils characterizing both Paleocene and Cretaceous; since characteristic Cretaceous fossils are present, it is considered to represent top of Cretaceous in peninsular Florida by most workers.

Name derived from J. S. Cosden's Lawson well No. 1, sec. 25, T. 13 S., R. 20 E., Marion County.

Lawson Shale Member (of Carbondale Formation)

Pennsylvanian: Western and northern Illinois.

R. M. Kosanke and others, 1960, Illinois Geol. Survey Rept. Inv. 214, p. 35, 48 (table 1), 65, pl. 1. Proposed for shale above Brereton limestone member in western Illinois, formerly called Sheffield shale; name Sheffield preempted. Thickness about 7½ feet. Stratigraphically below Copperas Creek sandstone member. Presentation of new rock-stratigraphic classification of Pennsylvanian of Illinois. Cyclical classification is retained but is entirely independent of rock-stratigraphic classification.

Type locality: Center sec. 24, T. 16 N., R 6 E., Bureau County. Name derived from Lawson Creek, about 1 mile west of type exposure.

Laytonville Limestone

Upper Cretaceous: Northern California.

H. E. Thalmann, 1943, (abs.) Geol. Soc. America Bull., v. 54, no. 12, pt. 2, p. 1827. Reddish slightly siliceous limestone; contains foraminiferal assemblage that indicates at least a Turonian age. Laytonville limestone regarded as synchronous deposit of Calera limestones of quarries of Permanente Cement Company, Santa Clara County, and of Calera limestone at its type locality in Calera Valley, San Mateo County.

Crops out about 200 yards east of Redwood Highway, 2 miles north of Laytonville, Mendocino County.

Lazeart Sandstone Member (of Adaville Formation)[1]

Upper Cretaceous: Southwestern Wyoming.

Original reference: A. C. Veatch, 1907, U.S. Geol. Survey Prof. Paper 56.

R. H. Peterson, D. J. Gauger, and R. R. Lankford, 1953, Utah Geol. and Mineralog. Survey Bull. 47, p. 16 (fig. 4), 17–18. Basal member of Adaville formation. Consists of white sandstone 100 to 200 feet thick. Underlies Adaville-Lazeart coal.

Well exposed at Adaville mine, 2 miles south of Hodges Pass Tunnel, near Kemmerer, on Oregon Short Line.

Lazy Bend Formation (in Millsap Lake Group)

Lazy Bend Member (of Millsap Lake Formation)[1]

Pennsylvanian: North-central Texas.

Original reference: E. H. Sellards, 1933, Texas Univ. Bull. 3232, p. 106, 107, from manuscript of report by G. Scott and J. M. Armstrong, on geology of Parker County.

M. G. Cheney, 1940, Am. Assoc. Petroleum Geologists Bull., v. 24, no. 1, p. 66 (fig. 1). Rank raised to formation in Millsap Lake group. Underlies Grindstone Creek group; overlies Dickerson group. Includes (ascending) Kickapoo Falls limestone, Dennis Bridge limestone, and Brannon Bridge limestone members.

M. G. Cheney and others, 1945, Am. Assoc. Petroleum Geologists Bull., v. 29, no. 2, p. 163. Lampasas-Strawn boundary in Brazos River outcrop section placed at base of conglomerate which rests on Dennis Bridge limestone at Dennis highway bridge in Parker County. Hence, Lazy Bend formation, Millsap Lake group, and Strawn series of Brazos River outcrop section are restricted to beds above Dennis Bridge limestone at Dennis.

Leo Hendricks, 1957, Texas Univ. Bur. Econ. Geology Pub. 5724, p. 13–18, fig. 3, pl. 1. In this report [Parker County], beds cropping out along Brazos River upstream from Dennis Bridge to beyond Lazy Bend are placed in Lazy Bend formation. Includes (ascending) Hill Creek member (with Dennis Bridge limestone bed at base), Steussy member, and Brannon Bridge member. There is no continuous type section of formation; knowledge of succession is gained by mapping key beds between separated outcrops, and type sections are established member by member. Underlies Grindstone Creek formation. Classification in this paper does not go above formation rank.

Named for Lazy Bend on Brazos River, Parker County.

Leach Formation

Mississippian or older: North-central Nevada.

S. W. Muller, H. G. Ferguson, and R. J. Roberts, 1951, Geology of the Mount Tobin quadrangle, Nevada: U.S. Geol. Survey Geol. Quad. Map [GQ–7]. Altered basic volcanics (greenstone) and pyroclastics, with much dark chert and siliceous argillite, probably largely tuffaceous. Beds of dark vitreous quartzite at top. Interbedded slate, limestone, and conglomerate near forks of Leach Canyon. May be identical with Pumpernickel formation. Thickness may exceed 6,000 feet; base not exposed. Underlies Inskip formation with gradational contact. Pennsylvanian(?).

R. J. Roberts and others, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 12, p. 2847. Throughout most of outcrop area Leach and Inskip formations are in fault contact and their stratigraphic relations are not definitely known, but Leach appears to underlie Inskip. Considered to be Mississippian or older.

Named for Leach Canyon on west flank of East Range, Mount Tobin quadrangle.

Leach Canyon Tuff Member (of Quichapa Formation)

Oligocene: Southwestern Utah and eastern Nevada.

J. H. Mackin, 1960, Am. Jour. Sci., v. 258, no. 2, p. 90–91, 92 (fig. 2), 98. Single depositional unit, uniform in lithology through thickness of 450 to 500 feet. Except at base and near top, rock consists of matrix with texture of unglazed porcelain, gray to flesh in color, enclosing fragments of dark-red felsite, light-gray pumice, and other rocks, and crystals of quartz, feldspar, biotite, and other pyrogenic minerals, mostly broken. Basal member of formation; at type locality, underlies Swett tuff member (new); overlies Hole-in-the-Wall member of Isom formation (both new); elsewhere, lava flows or other volcanic rocks, local in origin and extent, present at contacts. Has zircon age of 28 million years; this suggests that Quichapa formation is Oligocene. Discussion of ignimbrites of area.

E. F. Cook, 1960, Intermountain Assoc. Petroleum Geologists Guidebook 11th Ann. Field Conf., p. 138 (fig. 3). Geographically extended into eastern Nevada.

Type locality: South side Leach Canyon, Desert Mound quadrangle, Utah.

Lead System[1]

Precambrian: Southwestern South Dakota.

Original reference: J. J. Runner, 1934, Am. Jour. Sci., 5th, v. 28, p. 354–372.

J. R. Berg, 1946, South Dakota Geol. Survey Rept. Inv. 52, p. 4, 6–7, map (on page following title page). Shown on map legend as composed of (ascending) Poorman formation, amphibolite formation, Homestake formation, Ellison formation, Northwestern formation, Garfield formation, and Roubaix group (new). Text states that youngest rocks of Roubaix group in Galena-Roubaix district are younger than and overlie rocks of Lead system.

In the Black Hills.

Lead Creek Limestone[1] (in Tradewater Formation)

Pennsylvanian: Western Kentucky.

Original reference: A. F. Crider, 1913, Kentucky Geol. Survey, 4th ser., v. 1, pt. 1, p. 279.

H. R. Wanless, 1939, Geol. Soc. America Spec. Paper 17, p. 89, Marine limestone above Lead Creek coal, Tradewater formation. Equivalent to Minshall limestone (Indiana), Seville limestone (Illinois), and Curlew limestone (western Kentucky).

Named for Lead Creek, Hancock County.

Lead Point Argillite[1]

Paleozoic(?): Northeastern Washington.

Original reference: C. E. Weaver, 1920, Washington Geol. Survey Bull. 20, p. 79, map.

Derivation of name not stated but probably named for Lead Point, Stevens County.

Leadville Limestone[1] or Dolomite

Lower and Upper Mississippian: Colorado.

Original reference: G. H. Eldridge, 1894, U.S. Geol. Survey Geol. Atlas, Folio 9.

W. S. Burbank, 1941, U.S. Geol. Survey Bull. 906–E, p. 194, 196 (chart). Name Leadville limestone introduced into Uncompahgre district for beds containing Mississippian fossils that lie just above Ouray limestone which is restricted to dolomitic limestone beds of Upper Devonian age. Lower part of unit consists of predominantly dark blue-gray or brownish-gray limestone with sandy layers near base; upper part mostly coarser textured clastic limestone with interbeds of reddish shale; locally, thin-bedded cherty and ferruginous limestone at top. Thickness 180 to 230 feet.

K. G. Brill, Jr., 1942, Am. Assoc. Petroleum Geologists Bull., v. 26, no. 8, p. 1386. In Gore area, unconformably underlies Belden shale member (new) of Battle Mountain formation.

Ogden Tweto and T. S. Lovering, 1947, Colorado Mining Resources Board [Bull.], p. 380 (chart). In Gilman district, subdivided to include Gilman sandstone member (new) at base. Overlies Dyer dolomite member of Chaffee formation; underlies Maroon formation.

H. F. Donner, 1949, Geol. Soc. America Bull., v. 60, no. 8, p. 1220 (fig. 2), 1221–1222. Described in McCoy area where it is about 150 feet thick and consists of massive- to thin-bedded fine-grained bluish-gray limestone that is locally lithographic. Disconformable contact with overlying McCoy formation and underlying Sawatch formation. Early Mississippian.

Ogden Tweto, 1949, Colorado Sci. Soc. Proc., v. 15, no. 4, p. 152 (table 1), 177–186. In Pando area, Mississippian Leadville dolomite comprises basal sandy member, Gilman sandstone, about 20 feet thick, unconformably overlain by dolomite member with average thickness of about 80 feet. Unconformably overlies Dyer dolomite member of Chaffee formation; unconformably underlies Belden shale.

I. H. Mackay, 1953, Colorado School Mines Quart., v. 48, no. 4, p. 29–33. In Thomasville-Woods Lake area, Leadville limestone is 68 to 180 feet thick and consists of arenaceous, gray dolomitic limestone at base rapidly becoming nearly pure, bluish-gray limestones. Unconformably overlies Chaffee limestone; unconformably underlies Weber(?) formation.

J. C. Cooper, 1955, Four Corners Geol. Soc. Guidebook [1st] Field Conf., p. 63, 65. Many names have been used for rocks of Mississippian age in Four Corners area. Proposed here that Mississippian rocks in area be called Leadville limestone for upper limestone unit and Madison formation for underlying dolomite. Leadville is unconformably overlain by Molas shale and underlain by transitional conformable contact with Madison formation.

W. M. Merrill and R. M. Winar, 1958, Am. Assoc. Petroleum Geologists Bull., v. 42, no. 9, p. 2109 (table 1), 2111 (fig. 2), 2115 (fig. 4). In San Juan-Needles Mountain area, disconformably underlies Coalbank Hill member (new) of Molas formation

Named for occurrence in Leadville district.

†Leadville Porphyry[1]

Eocene: Colorado.

Original references: S. F. Emmons, 1882, U.S. Geol. Survey 2d Ann. Rept., p. 215–230; U.S. Geol. Survey Leadville Atlas; 1886, U.S. Geol. Survey Mon. 12, p. 76; 1927, U.S. Geol. Survey Prof. Paper 148.

In Leadville district.

†Leander Beds[1]

Lower Cretaceous: Texas.

Original reference: R. T. Hill, 1890, Texas Geol. Survey 1st Ann. Rept., p. 105, 126.

Exposed between Florence and Leander, Williamson County.

Leaning Tower Quartz Monzonite[1]

Cretaceous: California.

Original reference: F. C. Calkins, 1930, U.S. Geol. Survey Prof. Paper 160, p. 123, map.

U.S. Geological Survey currently designates the age of the Leaning Tower Quartz Monzonite as Cretaceous on basis of a study now in progress.

Named for fact that it forms considerable part of slopes of Leaning Tower, Yosemite National Park.

Leatham Formation

Lower Mississippian: Northeastern Utah and southeastern Idaho.

F. D. Holland, Jr., 1952, Am. Assoc. Petroleum Geologists Bull., v. 36, no. 9, p. 1719–1720, figs. 1, 17. Name proposed for shales, sandy shales, and nodular limestones which unconformably overlie Devonian Jefferson formation and conformably underlie basal brownish-black shale of Mississippian Madison. Base of formation marked by 3-inch medium-dark-gray arenaceous limonitic conglomeratic limestone. Uppermost 2 feet composed of dark-gray to brownish-gray hard dense thinly bedded silty limestone. Thickness 76 feet at type locality where beds dip 18° N. 77° W.

Type locality: North wall of Leatham Hollow, three-fourths mile west of Left Fork of Blacksmith Fork at NW cor. sec. 34, T. 11 N., R. 2 E., Salt Lake base and meridian, Utah.

Leatherwood Granite[1]

Precambrian: Central southern Virginia.

Original reference: A. I. Jonas, 1928, Geol. map of Virginia, prelim. ed.: Virginia Geol. Survey.

W. R. Griffitts, R. H. Jahns, and R. W. Lemke, 1953, U.S. Geol. Survey Prof. Paper 248–C, p. 144.

Mapped at and around Leatherwood, Henry County.

Leatherwood Quartz Diorite

Post-Cretaceous: Southeastern Arizona.

F. L. Peirce, 1958, Dissert. Abs., v. 19, no. 2, p. 300. Orogeny which apparently took place during Laramide time was accompanied by emplacement of Leatherwood quartz diorite which was followed by emplacement of Catalina granite (new).

R. L. DuBois, 1959, Arizona Geol. Soc. Guidebook 2, p. 113–114. Ranges from massive to gneissic in texture and generally composed of biotite, quartz, oligoclase, and epidote. Comprises stock that intrudes Cretaceous rocks.

On northeastern slope of Santa Catalina Mountains.

L'Eau Frais Shale[1]

Eocene: Southwestern Arkansas.

Original reference: R. T. Hill, 1888, Arkansas Geol. Survey Ann. Rept. 1888, v. 2, p. 52, 188.

At mouth of L'Eau Frais, Clark County.

Leavenworth Glacial Stage

Pleistocene: Central Washington.

B. M. Page, 1939, Jour. Geology, v. 47, no. 8, p. 785, 795–805. Named as second of three successive stages of valley glaciation in Leavenworth area. Characterized by deposition of Leavenworth till and outwash. Preceded by Peshastin stage (new) and followed by Stuart stage (new).

Leavenworth Limestone Member (of Oread Limestone)[1]

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, and southeastern Nebraska.

Original reference: G. E. Condra, 1927, Nebraska Geol. Survey Bull. 1, 2d ser., p. 32, 33, 38.

R. C. Moore, 1948, Am. Assoc. Petroleum Geologists Bull., v. 32, no. 11, p. 2035 (fig. 5); 1949, Kansas Geol. Survey Bull. 83, p. 148. Leavenworth limestone member of Oread formation; underlies Heebner shale member; overlies Snyderville shale member. This is classification agreed upon by State Geological Surveys of Iowa, Kansas, Missouri, Nebraska, and Oklahoma, May 1947.

T. L. Welp, L. A. Thomas, and H. R. Dixon, 1957, Iowa Acad. Sci. Proc., v. 64, p. 418 (fig. 1), 419. In section measured near Winterset, is blue-gray massive limestone about 1 foot thick.

H. G. O'Connor, 1960, Kansas Geol. Survey Bull. 148, p. 40, pl. 1. Thickness 0.8 to 2 feet thick in Douglas County, except south of Worden fault where it is 3.4 feet. Composed of single massive bed of hard gray-blue fine-grained limestone.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 22–23, fig. 5. Single massive limestone bed. Thickness 1.1 to 1.3 feet. Overlies Snyderville shale member; underlies Heebner shale member.

Type locality: Highway cut in divide northwest of Federal Penitentiary, Leavenworth, Kans.

†Lebanon Beds[1]

Upper Ordovician: Southwestern Ohio and northern Kentucky.

Original reference: J. S. Newberry, 1873, Ohio Geol. Survey, v. 1, p. 103, 119, table opposite p. 89.

Named for Lebanon, Warren County, Ohio.

Lebanon Gabbro

Pre-Triassic: Eastern Connecticut.

J. M. Aitken, 1951, Connecticut Geol. Nat. History Survey Bull. 78, p. 10 (table 1). Incidental mention in chart. Name credited to W. G. Foye (unpub. ms.).

John Rodgers and others, 1956, Preliminary geological map of Connecticut (1:253,440): Connecticut Geol. Nat. History Survey. Dark speckled medium- to coarse-grained gabbro. Many shear zones and local areas of schistose and pencilled gabbro; otherwise fairly massive.

Named for town of Lebanon, New London County.

Lebanon Granite[1] (in Oliverian Plutonic Series)

Lebanon Group

Middle or Upper Devonian (?): West-central New Hampshire.

Original reference: C. H. Hitchcock, 1908, Vermont State Geologist 6th Rept., p. 155–156.

C. A. Chapman, 1939, Geol. Soc. America Bull., v. 50, no. 1, p. 145–146, pl. 6. Group includes Lebanon granite and border gneiss. Term granite is restricted to granitic core-rock. Two types are somewhat gradational near their contacts. Upper Devonian (?).

M. P. Billings, 1955, Geologic map of New Hampshire (1:250,000): U.S. Geol. Survey. Lebanon granite of Oliverian plutonic series consists of two mappable units: the granite proper, a subporphyritic granulated biotite granite, and the border gneiss, granulated gneiss varying in composition from amphibolite to quartz monzonite. Middle or Upper Devonian (?).

Named for village of Lebanon in southwestern Grafton County.

†Lebanon Group[1]

Lower Ordovician (Chazy): Tennessee.

Original reference: J. M. Safford, 1869, Geology Tennessee, p. 151, 159, 258–268.

Named for Lebanon, Wilson County.

Lebanon Limestone (in Stones River Group)[1]

Middle Ordovician: Central and western Tennessee and northwestern Georgia.

Original reference: J. M. Safford, 1851, Am. Jour. Sci., 2d, v. 12, p. 353, 354–356.

Charles Butts and Benjamin Gildersleeve, 1948, Georgia Geol. Survey Bull. 54, p. 22, 26–27, geol. map. Geographically extended into northwestern Georgia where it crops out along both sides of McLemore Cove along outside margin of Stones River belt north to Tennessee. Composed largely of very thin bedded limestone intercalated in gray shelly limestone all more or less argillaceous. Thickness about 200 feet.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 39–44, fig. 11. Consists of dense fine-grained blue to gray and dove-colored limestone with many interbedded layers of medium-grained and coarsely crystalline texture. Limestone beds commonly range from 1 to 6 inches, average 2 to 3 inches in thickness, and are separated by thin partings of gray and grayish-blue calcareous shale. At average interval of 57 feet from base and 33 feet from top of formation is a massive-bedded member that averages 5 feet in thickness. Thickness 74 to 118 feet; average 92 feet. Conformably overlies Ridley limestone; unconformably underlies Carters limestone. Safford did not designate type section; his measured section near Readyville, Rutherford County, is here considered type section. Alternate type section given.

Type section: In Cannon County, Tenn., on western slope of prominent hill behind mill at Readyville, a short distance northeast of where Murfreesboro-Woodbury Highway crosses East Fork of Stones River. Alternate type section: On eastern outskirts of Lebanon, Wilson County; section begins 1 block south of highway to Carthage on eastern city limits of Lebanon and continues northeastward to a massively bedded member near top of hill north of highway.

Lebanon Junction Siltstone Member (of Brodhead Formation)

Lower Mississippian: Central Kentucky.

P. B. Stockdale, 1939, Geol. Soc. America Spec. Paper 22, p. 76, 147. A 40-foot gritty siltstone unit in lower part of Pilot Knob facies (new), Brodhead formation (new). Overlies Culver Springs shale member (new).

Measured section on south slope of knob, 1 mile northwest of Lebanon Junction, southern Bullitt County.

Lebeau Member (of Le Moyen Formation)

Recent: Southwestern Louisiana (subsurface and surface)

P. H. Jones *in* P. H. Jones, A. N. Turcan, Jr., and H. E. Skibitzke, 1954, Louisiana Dept. Conserv. Geol. Bull. 30, p. 89–90, 91. Basal part is coarse-grained channel-fill deposit of fluviatile origin, upper part is fine-grained silts and clays derived from floodwaters; deposition of member continues to present time. Lies in a pre-Recent channel cut into Pleistocene terrane to depths as great as 300 feet and commonly greater than 200 feet. Essentially contemporaneous with and merges into marine, beach, and marsh deposits of Mermentau member.

Typically represented beneath town of Lebeau in T. 4 S., R. 5 E., in St. Landry Parish, on U.S. Highway 71 about 6 miles southeast of Le Moyen. Underlies all modern floodplain of Mississippi River.

Lebec Quartz Monzonite

Jurassic(?): Southern California.

J. C. Crowell, 1952, California Div. Mines Special Rept. 24, p. 8–9, pls. 1, 2. Typical quartz monzonite; contains two facies, one, gray and medium grained making up about 80 percent of rock, and the other, buff and more coarse grained. Since Tejon Lookout granite (new) intrudes similar rocks the Lebec and Tejon Lookout are probably related although now separated by Garlock fault.

Exposed over about 14 square miles of Lebec quadrangle northwest of Garlock fault near Lebec, Kern County. Confined to hanging wall block of Pastoria thrust zone and not recognized north of Pastoria thrust or south of Garlock and San Andreas faults.

Lebo Andesitic or **Shale Member** (of Fort Union Formation)[1]

Lebo Formation (in Fort Union Group)

Paleocene: Central northern, southern, and eastern Montana.

Original reference: R. W. Stone and W. R. Calvert, 1910, Econ. Geology, v. 5, p. 746.

G. G. Simpson, 1937, U.S. Natl. Mus. Bull. 169, p. 15 (table), 21–29. Basal formation in Fort Union group as used in this report [Crazy Mountain field]. Thickness 1,350 feet. Underlies Melville formation (new); overlies Bear formation (new). Paleocene.

A. J. Collier and M. M. Knechtel, 1939, U.S. Geol. Survey Bull. 905, p. 11–13, pl. 3. In McCone County, Mont., Lebo shale member is about 400 feet thick and consists of thick beds of dark shale alternating with thick beds of white sandy clay and sandstone and coal beds. Underlies Tongue River member; overlies Tullock member of Lance formation. Eocene.

H. E. Wood 2d and others, 1941, Geol. Soc. America Bull., v. 52, no. 1, pl. 1. Paleocene (Dragonian-Torrejonian).

W. J. McMannis, 1955, Geol. Soc. America Bull., v. 66, no. 11, pl. 7. Plate 7 shows Livingston formation intertongues with Claggett, Judith River, Bearpaw, Lennep, Hell Creek, Tullock, and Lebo formations.

W. J. Mapel, 1958, Wyoming Geol. Assoc. Guidebook 13th Ann. Field Conf., p. 218 (fig. 1), 220–221. As used in this report Fort Union formation comprises three members (ascending): Tullock, Lebo shale, and Tongue River.

Named for exposures on Lebo Creek, northeast of Crazy Mountains.

Le Boeuf Conglomerate[1] Member (of Cattaraugus Formation)

Upper Devonian or Mississippian: Northwestern Pennsylvania.

Original reference: I. C. White, 1881, Pennsylvania 2d Geol. Survey Rept. Q_4, p. 101, 103, 104, 112, 239.

I. H. Tesmer, 1958, (abs.) Geol. Soc. America Bull., v. 69, no. 12, pt. 2, p. 1651. Listed as member of Cattaraugus formation in proposed sequence of Upper Devonian or Mississippian conglomerates in southwestern New York and northwestern Pennsylvania.

Exposed in Le Boeuf Township, Erie County, along French Creek.

Leclaire Dolomite[1]

Silurian (Niagaran): Central eastern Iowa.

Original reference: J. Hall, 1858, Iowa Geol. Survey, v. 1, pt. 1, p. 46, 73–75.

Type locality: Leclaire, Scott County.

†Lecompton Beds[1]

Pennsylvanian: Eastern Kansas.

Original reference: L. C. Wooster, 1905, The Carboniferous rocks system of Kansas.

Named for Lecompton, Douglas County.

Lecompton Limestone (in Shawnee Group)[1]

Lecompton Limestone Member (of Pawhuska Formation)

Lecompton Limestone Member (of Shawnee Formation)[1]

Pennsylvanian (Virgil Series): Eastern Kansas, southwestern Iowa, northwestern Missouri, southeastern Nebraska, and central northern Oklahoma.

Original references: E. Haworth, 1895, Kansas Univ. Quart., v. 3, p. 278, pl. opp. p. 290; Am. Jour. Sci., 3d, v. 50, pl. opp. p. 466.

R. C. Moore, J. C. Frye, and J. M. Jewett, 1944, Kansas Geol. Survey Bull. 52, p. 179–180. Includes (ascending) Spring Branch limestone, Doniphan shale, Big Springs limestone, Queen Hill shale, Beil limestone, King Hill shale, and Avoca limestone members. Thickness 30 to 50 feet. Underlies Tecumseh shale; overlies Kanwaka shale. Shawnee group.

F. C. Greene and W. V. Searight, 1949, Missouri Geol. Survey and Water Resources Rept. Inv. 11, p. 16, 17. Included in Shawnee group in Missouri.

H. D. Miser and others, 1954, Geologic map of Oklahoma (1:500,000): U.S. Geol. Survey. Lecompton limestone mapped in northern Oklahoma.

M. C. Oakes, 1959, Oklahoma Geol. Survey Bull. 81, p. 49, 50, 51, measured sections. Basal member of Pawhuska formation in Oklahoma; underlies Plummer member. In Creek County, consists of gray fossiliferous sandy limestone, generally thin bedded to platy, and 10 to 30 feet thick.

P. B. Greig, 1959, Oklahoma Geol. Survey Bull. 83, p. 25–26, 38–41, pls. Described in Pawnee County where it is classified as member of Pawhuska formation. Consists of several thin beds of fossiliferous limestone, flaggy in upper part, and interbedded shale. Commonly 10 feet thick. Separated from overlying Turkey Run limestone member by unnamed shale interval as much as 77 feet thick.

H. G. Hershey and others, 1960, Iowa Highway Research Board Bull. 15, p. 19–20, fig. 5. Formation comprises (ascending) Spring Branch limestone, Doniphan shale, Big Springs limestone, Queen Hill shale, Beil limestone, King Hill shale, and Avoca limestone members. Thickness 34 feet north of Thurman; 30 feet at Stennett; 11 feet north and east of Greenfield. Underlies Tecumseh shale; overlies Kanwaka shale. Shawnee group.

Named for exposures at Lecompton, Douglas County, Kans.

†Lecompton Shale[1]

Pennsylvanian: Eastern Kansas and northwestern Missouri.

Original reference: E. Haworth, 1898, Kansas Univ. Geol. Survey, v. 3, p. 64, 94.

Named for exposures at Lecompton, Douglas County, Kans.

Le Conte Flows

Recent: Southwestern Oregon.

Howel Williams, 1944, California Univ. Pub., Dept. Geol. Sci. Bull. 27, no. 3, p. 53, 62. Discussion of volcanoes of Three Sisters region. Name applied to flows from Le Conte Crater.

Le Conte Crater is south and west of South Sister Mountain.

Ledbetter Slate

Ordovician: Northeastern Washington.

C. F. Park, Jr., 1938, Econ. Geology, v. 33, p. 713 (chart), 714 (fig. 2). Named on map and stratigraphic chart. Thickness 2,500 feet. Underlies Devonian(?) limestone; overlies Metaline limestone (new).

C. F. Park, Jr., and R. S. Cannon, Jr., 1943, U.S. Geol. Survey Prof. Paper 202, p. 6 (table), 19–22, pl. 1. Black fine-grained carbonaceous slate with black limestone near top. Overlies Metaline limestone, base sharply defined; upper contacts poorly exposed. Derivation of name given.

R. G. Yates and J. F. Robertson, 1958, U.S. Geol. Survey Mineral Inv. Field Studies Map MF–137. Described in Leadpoint quadrangle where it is about 1,000 feet thick; complete section not exposed. Overlies Metaline limestone. Poorly preserved graptolites indicate Ordovician age.

Named for Ledbetter Lake, Pend Oreille County.

Ledger Dolomite[1]

Lower Cambrian: Southeastern Pennsylvania, and northern Virginia.

Original reference: G. W. Stose and A. I. Jonas, 1922, Washington Acad. Sci. Jour., v. 12, p. 359, 363.

G. W. Stose and A. I. Jonas, 1938, Virginia Geol. Survey Bull. 51–A, p. 21. Proposed to extend names Vintage dolomite, Kinzers formation, and Ledger dolomite to comparable Lower Cambrian formations in area southeast of Austinville, Va.

Named for Ledger, Lancaster County, Pa.

Ledyard Formation

Ledyard Member (of Ludlowville Shale)[1]

Middle Devonian: Central and western New York.

Original reference: G. A. Cooper, 1930, Am. Jour. Sci., 5th, v. 19, p. 218, 224.

R. G. Sutton, 1951, Rochester Acad. Sci. Proc., v. 9, nos. 5–6, p. 364–369, pl. 1. In Batavia quadrangle, about 75 miles west of type locality of Lenyard, Wanakah and Ledyard shale members of the Ludlowville were not separated as defined by Cooper (1930); Ledyard-Wanakah member overlies Centerfield limestone member and underlies Tichenor limestone member.

T. B. Coley, 1954, Jour. Paleontology, v. 28, no. 4, p. 453, 454, 455 (fig. 2). Referred to as formation. Thickness 26 feet at Jacox Run near Geneseo. Overlies Centerfield formation; underlies Wanakah formation. Ostracodes discussed.

R. S. Boardman, 1960, U.S. Geol. Survey Prof. Paper 340, p. 4–5. Term Ledyard in this report [trepostomatous Bryozoa] follows usage of Cooper (1930). Thickness 60 to 100 feet at type locality; 30 feet at Lake Erie.

Type locality: On Paines Creek, Ledyard Twp., Cayuga Lake area.

Lee Formation[1] or Group

Lower Pennsylvanian: Southwestern Virginia, eastern Kentucky, and Tennessee.

Original reference: M. R. Campbell, 1893, U.S. Geol. Survey Bull. 111, p. 28, 36.

W. A. Nelson, 1925, Tennessee Div. Geology Bull. 33–A, p. 38–53. Rank raised to group and subdivided into (ascending) Gizzard formation (including Warren Point sandstone), Sewanee conglomerate, Whitwell shale, Herbert conglomerate, Eastland shale lentil, Newton sandstone, Vandever shale, Rockcastle conglomerate, and Duskin formation. Thickness 200 to 1,400 feet. Deposited on top of irregular eroded Pennington formation. Lower Pottsville.

L. C. Glenn, 1925, Tennessee Div. Geology Bull. 33–B, p. 276. Formation, in Fentress County, comprises Rockcastle sandstone above and shale interval below, either simple or complex, for which name Fentress is suggested.

Charles Butts and W. A. Nelson, 1925, Tennessee Div. Geology Bull. 33–D, p. 5–17. In Crossville quadrangle, Lee group comprises (ascending) Gizzard formation, Sewanee conglomerate, Whitwell shale, Bonair sandstone with Eastland shale lentil, Vandever shale, and Rockcastle sandstone. Underlies Briceville shale; overlies Pennington shale.

H. R. Wanless, 1946, Geol. Soc. America Mem. 13, p. 9–54. Discussion of strata of Lee age in Tennessee and lists following subdivisions (ascending): Gizzard formation, Sewanee conglomerate, Whitwell formation, Herbert sandstone, Eastland shale, Newton sandstone, Vandever shale, Rockcastle sandstone, Duskin Creek formation, Corbin conglomerate or sandstone, and Naese sandstone.

Andrew Brown and others, 1952, U.S. Geol. Survey Circ. 171, p. 9. Formation described in côal field of southwest Virginia where outcrops are confined to northwest and southeast sides of field. Thickness about 900 feet in northwestern exposures; 1,530 to 1,800 feet in southeastern area. Underlies Norton formation; overlies Bluestone formation. Pottsville group.

C. W. Wilson, Jr., J. W. Jewell, and E. T. Luther, 1956, Pennsylvanian geology of the Cumberland Plateau: Tennessee Div. Geology [Folio]. Lee group as used by Wanless (1946) discontinued, and units included in newly defined Gizzard, Crab Orchard Mountains, and Crooked Fork groups.

K. J. Englund, 1957, U.S. Geol. Survey Coal Inv. Map C–39. In Scott and Campbell Counties, Tenn., formation is about 850 feet thick and consists of massive beds of crossbedded partly conglomeratic medium- to coarse-grained sandstone and thin beds of shale, siltstone, and coal. Overlies Pennington formation; underlies Briceville shale.

K. J. Englund, 1957, U.S. Geol. Survey Coal Inv. Map C–40. Term Lee formation extended into Tennessee by Keith (1896, U.S. Geol. Survey Geol. Atlas, Folio 25). In area of present report [Ivydell quadrangle, Tennessee], formation composed of massive conglomeratic sandstone, interbedded with siltstone, shale, and a few thin beds of coal and underclay. Various sandstone beds have been designated as top of Lee, but, because these beds are gradational and lenticular in this area, upper contact of Lee is drawn at base of persistent Red coal of Ashley and Glenn (1906, U.S. Geol. Survey Prof. Paper 49). Thickness 900 to 1,400 feet. Overlies Pennington formation; underlies Briceville shale.

R. P. Briggs, 1957, U.S. Geol. Survey Coal Inv. Map C–42. Eyl (1927, Structural geologic map of Lee County, Kentucky: Kentucky Geol. Survey, ser. 6) defined Lee formation as all of lower Pennsylvanian rocks from Mississippian-Pennsylvanian contact to top of Zachariah coal bed. In present report, top of Lee formation is lowered to base of Zachariah coal bed. Locally the Zachariah has a rider coal bed; hence, base of coal bed is more persistent horizon than top. Placing of top of formation at base of Zachariah coal follows Campbell (1898, U.S. Geol. Survey Geol. Atlas, Folio 47) who placed contact between Lee formation and Breathitt formation at base of Pittsburg (Kentucky) coal bed, which is probably equivalent of the Zachariah. Exposed thickness about 275 feet in Campton quadrangle, Kentucky. Underlies Breathitt formation.

K. J. Englund and H. L. Smith, 1960, (abs.) Geol. Soc. America Bull., v. 71, no. 12, pt. 2, p. 2015. Upper part of Pennington formation and lower part of Lee formation intertongue in their type area of outcrop, Lee County, Va., and in adjacent parts of Kentucky and Tennessee. Contact between these formations, which has been interpreted as an unconformity between Mississippian and Pennsylvanian systems, is transitional as result of intertonguing and lateral gradation between marine and nonmarine facies. Lateral gradation is most evident in sandstone beds, which in Lee formation are characteristically thickly crossbedded fine- to coarse-grained quartzose, conglomeratic sandstones as much as 300 feet thick. These sandstone tongues of the Lee grade laterally to thin wavy-bedded, very fine- to fine-grained sandstones, 20 to 30 feet thick that are typical of, and are included in, the Pennington. Conversely, tongues of light-olive-gray slightly calcareous shale in upper part of Pennington wedgeout between sandstone tongues of Lee formation. Pennington-Lee contact rises stratigraphically northward in this intertonguing sequence. Marine invertebrate fossils indicate Late Mississippian age of Pennington. Plant fossils have been reported to show that Lee formation is of Early Pennsylvanian age. Intertonguing of Lee and Pennington suggests that they are partly contemporaneous.

Type locality: Lee County, Va.

Lee Quartz Diorite[1]

Precambrian: Western Massachusetts and Connecticut.

Original reference: B. K. Emerson, 1898, U.S. Geol. Survey Mon. 29, p. 18.

Named for exposure in East Lee, Berkshire County, Mass.

Leecher Metamorphics

Age uncertain (pre-Chelan batholith): Northwestern Washington.

J. D. Barksdale, 1948, Northwest Sci., v. 22, no. 4, p. 165, 166. Series consisting of distinctly banded hornblende schist, quartz-oligoclase-hornblende gneiss, biotite-quartz-oligoclase gneiss, and calc-silicate rocks. Pronounced banding and rapid alternation of rocks of diverse mineral and chemical compositions. Predominant easterly dip that varies from 25° to vertical. In fault contact on the west with Newby formation (new). Invaded from the east by granitic rocks of Okanogan complex, and in contact on the south with Methow gneiss (new).

774–954—vol. 2—66——44

Type locality: Curving belt from 1 to 3 miles wide east of Methow River in Leecher Creek drainage and in vicinity of town of Carlton, Methow quadrangle.

Leech River Group[1] or Formation

Pennsylvanian-Cretaceous: British Columbia, Canada, and northwestern Washington.

Original reference: C. H. Capp, 1910, Canada Geol. Survey Summ. Rept. 1909, p. 87.

R. A. Anderson, 1941, Washington State Coll. Research Studies, v. 8, no. 3, p. 201. Suggested that Leech River series may be correlated with Granite Falls limestone on basis of fusilinids.

J. A. Jeletzky, 1954, (abs.) Geol. Soc. America Bull., v. 65, no. 12, pt. 2, p. 1270. Suggested that age of Leech River series is more probably Triassic or lower Jurassic than Paleozoic.

W. R. Danner, 1960, (abs.) Geol. Soc. America Bull., v. 71, no. 12, pt. 2, p. 2056. Recent studies of geology of San Juan Islands have necessitated revision of at least four major units established by McLellan (1927, Washington [State] Univ. Pubs. in Geology, v. 2). Leech River group, originally designated as Pennsylvanian-Permian was found to include rocks of Early and Middle Pennsylvanian and Cretaceous age.

Occurs on San Juan Islands and Vancouver Island.

Leeds facies (of Schoharie Formation)

Middle Devonian: Eastern New York.

Winifred Goldring and R. H. Flower, 1942, Am. Jour. Sci., v. 240, no. 10, p. 683, 686, 691–693. As traced southward, Schoharie grit changes rapidly to a shaly and cherty facies, here termed Leeds facies. Name Saugerties formation—suggested by Chadwick (1940) as possible name for new formation, if such it proved to be —is considered inadvisable.

J. H. Johnson, 1957, Dissert. Abs., v. 17, no. 10, p. 2247. Rickard facies (new) passes eastward into sparingly fossiliferous Leeds facies in Albany County. Within New York, the Leeds is divisible into Aquetuck lithofacies below and Saugerties lithofacies above.

Named for exposures in falls of the Catskill in Leeds Gorge, Greene County.

Leeds Sandstone (in Silver Reef Sandstone Member of Chinle Formation)

Upper Triassic: Southwestern Utah.

P. D. Proctor, 1953, Utah Geol. and Mineralog. Survey Bull. 44, p. 25, 28, pl. 2. Mainly white to buff fine- to medium-grained sandstone. Sandstone weathers mainly white and buff to brown and stands out as prominent ledge maker. Stream crossbedding prominent in many places. Ripple marks rare; current type noted. Sandstone beds range from massive 15-foot beds to thin platy sandstones. Lenticular interbedded dark-gray to green or locally maroon shales may be present. Sandstones contain clay galls and balls which may be sufficiently abundant locally to form clay ball conglomerates. Clay balls range from ¼ inch to more than 4 feet in diameter. Total thickness as much as 60 feet. Underlies Tecumseh sandstone (new); overlies Trail Hill sandstone (new) with local unconformity.

Named for exposures near Leeds mine, Silver Reef (Harrisburg) Mining District, Washington County.

Lee Flat Limestone

Upper Mississippian and Pennsylvanian (?) : Southern California.

W. E. Hall, E. M. MacKevett, 1958, California Div. Mines Special Rept. 51, p. 7 (table 1), 8–9, pl. 2. Predominantly thin-bedded medium- to dark-gray limestone. Locally limestone is broken by thin sandy iron-stained partings or by thin beds and lenses of chert. Estimated to be more than covered by basalt and alluvium, and faulting in exposed section vitiates estimate. At least 520 feet thick at type locality where it conformably overlies Perdido formation. Underlies Keeler Canyon formation of Pennsylvanian and Permian age. Nonfossiliferous; age derived from stratigraphic position; occupies same stratigraphic position that upper part of Perdido formation and Rest Spring shale occupy in Quartz Spring area and Ubehebe Peak quadrangle; the Lee Flat, then, represents facies change from clastic section of siltstone, shale, and minor limestone in the latter areas to fine-grained limestone in Darwin quadrangle.

Type section: Trends south from top of prominent hill nine-tenths mile S. 36° E. of main shaft of Lee mine, Darwin quadrangle, central Inyo County. Named for exposures near Lee Flat, alluviated area east of Santa Rosa Hills.

Leeic period

Paleozoic: Iowa and upper Mississippi Valley.

C. R. Keyes, 1941, Pan-Am. Geologist, v. 75, no. 2, p. 98 (chart), 149–150. Term proposed for time span of so-called Early Carbonic limestone section. Lies between the Carbonic above and the Yorkic below. Includes Mississippian, Chartresan, and Oshawanan.

Name derived from Lee County, Iowa, where rocks are fully exposed.

Lee Ranch Tongue (of Abo Sandstone)

Lower Permian (Leonard Series) : Central southern New Mexico.

G. O. Bachman and P. T. Hayes, 1958, Geol. Soc. America Bull., v. 69, no. 6, p. 690 (fig. 1), 694, 695–697, 698 (fig. 5). At type locality, 106 feet thick and consists predominantly of salmon-red shale and siltstone, but some thin-bedded fine-grained soft-weathering sandstone beds are present. In northern part of area, consists predominantly of reddish-brown very thin bedded cross-laminated very fine-grained sandstone and siltstone. Conformably overlies Hueco limestone and intertongues with it near south end of mapped area. Conformably underlies siltstone and sandstone beds, and locally, white gypsum beds of Yeso formation; contact is gradational and therefore arbitrary, though transition zone does not exceed a few feet.

Type locality: SE¼ sec. 11, T. 20 S., R. 11 E., about 7 miles southwest of O. M. Lee Ranch headquarters, Otero County. Generally poorly exposed in narrow slope-forming outcrop on backslope of topographic shelf formed by Hueco limestone.

Leesport Limestone[1]

Middle Ordovician: Southeastern Pennsylvania.

Original reference: G. W. Stose and A. I. Jonas, 1927, Geol. Soc. America Bull., v. 38, p. 505–536.

R. L. Miller, 1937, Geol. Soc. America Bull., v. 48, no. 11, p. 1687–1718. Discussion of relations of Jacksonburg and Leesport formations. Leesport formation was designated by Stose and Jonas (1927) to include argillaceous limestones ("cement rock") which underlie Martinsburg shales and overlie Beekmantown or Stones River limestones in area between Lehigh and Susquehanna Rivers. Relations of these beds to Chambersburg limestone of south-central Pennsylvania and to Jacksonburg limestone of eastern Pennsylvania are confused, and paleontological evidence is lacking. Hence, Stose and Jonas deemed it inadvisable to imply any correlation by applying either of these names and designated these beds as new formation. They chose exposure in cut of Reading Railroad at West Leesport on Schuylkill River as type section. Results of present study have led to conclusion that argillaceous limestones east of Schuylkill should all be referred to Jacksonburg rather than Leesport. Reasons for this decision are discussed under following headings: (1) Leesport type section; (2) lithology of Leesport "cement rock"; (3) continuity of "cement rock"; (4) structure of Egypt region; and (5) relation to overlying and underlying beds. Choice of type section was unfortunate in that the section is one of complex structure and lithology is quite unlike typical "cement rock" elsewhere in Leesport belt. Figure 5 [of present report] is structure section traced from panoramic photograph; blank areas in illustration represent covered areas in railroad cut. One hundred and thirty-four feet of beds is exposed, but interrelationship of different parts of exposure is obscure. Contact of limestones with Martinsburg shale is a fault. Lithologically, rocks in this section are strikingly different from "cement rock" which has been called Leesport in areas to east. Platy limestones at north end of section closely resemble limestones interbedded with Martinsburg. Massive calcareous sandstones have their counterpart in limestones which have been provisionally interpreted as within Martinsburg formation. The 70 feet of thin-bedded limestones at south end of railroad cut are only rocks exposed which are lithologically similar to "cement rock". Stratigraphic position of units in this section is uncertain. If name Leesport is used for these enigmatic rocks, the "cement rock" to east should be given another designation. "Leesport cement rock" in areas between Lehigh and Schuylkill Rivers is identical with cement rock facies of the Jacksonburg. One of the reasons why it has not seemed feasible in past to apply name Jacksonburg to western "cement rock" areas is because of discontinuity of belt of outcrop west of Lehigh River. This discontinuity is much more striking on earlier geologic maps than is shown on Figure 4 of present report. According to present interpretation, the Jacksonburg belt is interrupted in Egypt region because of faulting and continues half a mile farther west in its normal position at base of Martinsburg shale hills. Evidence indicates that the "cement rock" disconformably overlies Beekmantown in this area.

Carlyle Gray, 1951, Pennsylvania Geol. Survey, 4th ser., Prog. Rept. 136, p. 15. Name Jacksonburg applied in this report to all impure limestones in part formerly called Leesport lying between Annville limestone or Beekmantown formation and Martinsburg formation in Berks County. Name Leesport, defined by Stose and Jonas (1927), not used because much of the lithology at type section not similar to that of beds under discussion. Name Jacksonburg used until Leesport is redefined.

C. E. Prouty, 1959, Pennsylvania Geol. Survey, 4th ser., Bull. G–31, p. 5, table 1. Stose and Jonas (1927) mapped argillaceous limestones in Pennsylvania between Susquehanna and Lehigh Rivers that have same stratigraphic position as Jacksonburg below the Martinsburg and above the Beekmantown. Because of uncertain relationship of these limestones to the stratigraphically similar Jacksonburg to northeast and Chambersburg to southwest of Susquehanna River, they assigned name Leesport formation to these rocks. "Leesport" has not been mapped consistently and has been variously assigned to different units. Type section is highly complex and so problematical that comparative studies cannot be made. It appears that Leesport as defined and mapped should not be considered a valid formation and should either be redefined or renamed. Interval between Beekmantown group and Martinsburg formation, embodying essentially the Leesport in east-central Pennsylvania and in restricted sense the Jacksonburg of eastern Pennsylvania and western New Jersey, is divided into (ascending) Annville, Myerstown, and Hershey limestones.

Type section (Miller, 1937): Cut of Reading Railroad at West Leesport, Berks County.

Leesville Limestone Member (of Harrodsburg Limestone)[1]

Mississippian: Southern Indiana.

Original reference: P. B. Stockdale, 1929, Indiana Acad. Sci. Proc., v. 38, p. 233–242.

J. M. Weller and A. H. Sutton, 1940, Am. Assoc. Petroleum Geologists Bull. 24, no. 5, p. 805. In Indiana, the Warsaw limestone is divisible into two parts. Lower part has been divided into three members (ascending): Ramp Creek, Leesville, and Guthrie Creek. The Leesville is a massive crinoidal limestone layer 1½ to 8 feet thick.

Named for exposures at Leesville, eastern Lawrence County.

Leesville Member (of Little Valley Formation)

Upper Jurassic[?] or Cretaceous[?]: Northern California.

J. E. Lawton, 1956, Dissert. Abs., v. 16, no. 10, p. 1885. Lower member of formation. Underlies Round Mountain member (new); overlies Grizzly Creek member of Crack Canyon formation (both new). Upper Jurassic and Cretaceous section, about 40,000 feet thick, consists of sequence of shale and silty shale which alternate with sequences of sandstone.

Occurs in Morgan-Wilbur area in Lake, Yolo, and Colusa Counties.

Le Fever Limestone

Upper Silurian: Southeastern New York.

G. H. Chadwick, 1944, New York State Mus. Bull. 336, p. 47, 51, 52 [1946]. Name applied to massive "coralline" limestone that underlies Rondout waterlime and overlies Rosendale waterlime as defined by Hartnagel (1905). Previously termed Cobleskill but is later than Cobleskill. Name credited to R. M. Logie (unpub. ms.).

Occurs in area from Kingston, Ulster County, southward.

Leffler Gravels

Pleistocene: Northwestern Oregon.

I. S. Allison, 1953, Oregon Dept. Geology and Mineral Industries Bull. 37, p. 9–10. Proposed for alluvial deposit composing terrace on south rim of North Santiam River valley in Stayton quadrangle; also proposed to apply name to similar deposits of equivalent age elsewhere in Willamette Valley and to refer all such deposits to Leffler stage of alluviation. Older than Linn gravels (new).

Type locality: Gravel terrace on south rim of North Santiam River valley, near Leffler, Stayton quadrangle. Name derived from Southern Pacific Railway Station near foot of terrace.

Lefulufulua Trachyte

Pliocene and lower Pleistocene (?) : Samoa Islands (Tutuila)

H. T. Stearns, 1944, Geol. Soc. America Bull., v. 55, no. 11, p. 1285 (table 1). Named in list of eight trachytes that are described as dense jointed cream-colored trachytic dikes, plugs, and crater fills later than most of Pliocene volcanics. Thickness of series 2,141 feet or more. Lefulufulua plug associated with Olomoana volcanics.

Legion Shale Member[1] (of Grenola Limestone)

Permian : Eastern Kansas, southeastern Nebraska, and northern Oklahoma.

Original reference: G. E. Condra and C. E. Busby, 1933, Nebraska Geol. Survey Paper 1.

R. C. Moore and others, 1951, Kansas Geol. Survey Bull. 89, p. 48. Consists of shale, mostly gray but locally zones of black; in central Kansas upper part commonly fossiliferous. Thickness 4 to 12 feet. Underlies Burr limestone member; overlies Sallyards limestone member. Permian. Wolfcamp series.

Type locality: Cuts on U.S. Highway 40, just southwest of American Legion Golf Club grounds, about 1¾ miles southwest of Manhattan. Riley County, Kans.

Legion Creek Granite

Precambrian : Central Texas.

V. E. Barnes, 1940, *in* Geol. Soc. America [Guidebook] 53d Ann. Mtg., p. 51, 53 (geol. map). Coarse-grained granite.

Map is of Cut Off Gap area, Gillespie County.

Lego Limestone Member (of Wayne Formation)[1]

Lego Limestone (in Wayne Group)

Middle Silurian : West-central Tennessee.

Original reference: A. F. Foerste, 1903, Jour. Geology, v. 11, p. 565, 578–582, 694.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 244, 251–252, figs. 2, 75, 80, 81, 82. Rank raised to formation in Wayne group. Conformably overlies Waldron shale; conformably underlies Dixon formation; locally unconformably underlies Chattanooga shale or Pegram formation. Thickness 25 to 35 feet; average between 27 and 30 feet.

Named for Lego, Decatur County.

†Le Gore Limestone[1]

Lower Ordovician (Beekmantown) : Western Maryland.

Original reference: G. W. Stose and A. I. Jonas, 1935, Washington Acad. Sci. Jour., v. 25, no. 12, p. 564–565.

East of Le Gore quarry, at northern edge of Frederick limestone valley, Frederick County.

Le Grand beds[1]

Mississippian : Central northern Iowa.

Original reference: C. R. Keyes, 1893, Iowa Geol. Survey, v. 1, p. 57.

Named for Le Grand, Marshall County.

Lehigh Limestone[1]

Middle Ordovician : Northeastern Pennsylvania.

Original reference: E. C. Eckel, 1904, U.S. Geol. Survey Bull. 225, p. 449, 450.

Lehigh and Northampton Counties.

Lehighton Member (of Tully Formation)

Upper Devonian : East-central Pennsylvania.

R. E. Stevenson and W. S. Skinner, 1949, Pennsylvania Acad. Sci. Proc., v. 23, p. 31, 32. Upper member of formation. Consists of abundantly fossiliferous thin-bedded sandy shale. Thickness about 20 feet. Overlies Brodhead Creek member; underlies Brallier [shale]. Lenses out east of Weissport.

Type section: On Pennsylvania Highway 412, one-half mile south of Lehighton, along Mahoning Creek, Carbon County.

Lehigh Valley cement rock[1]

Middle Ordovician : Northeastern Pennsylvania.

Original reference: E. O. Ulrich, 1911, Geol. Soc. America Bull., v. 22, p. 563.

Lehigh and Northampton Counties.

Lehman Formation (in Pogonip Group)

Lower Ordovician (Chazyan) : Eastern Nevada and western Utah.

L. F. Hintze, 1951, Utah Geol. and Mineralog. Survey Bull. 39, p. 2, 19–20, 63, 67, 75. Thin- to thick-bedded fossiliferous blue-gray calcilutite with a few beds of sandstone and quartzite. Thickness at type locality about 200 feet; eastward from Ibex, Utah, thins to disappearance; westward, more than doubles in thickness by overlying Swan Peak(?) quartzite grading into Lehman lithology. Overlies Kanosh shale (new); in Ibex area, base is lowest interbedded sandstone ledge; upper limit is top of highest calcilutite beneath Swan Peak(?) quartzite.

Type locality: Bluff on north side of Smooth Canyon and in SE¼ sec. 24, T. 22 S., R. 15 W., near Ibex, Millard County, Utah. Named for exposures in Snake Range near Lehman Caves, Nev.

Lehmer Limestone Member (of Admire Shale)[1]

Pennsylvanian : Southeastern Nebraska.

Original reference: G. E. Condra, 1935, Nebraska Geol. Survey Paper 8, p. 5, 9.

At old Lehmer quarry, 4 miles southwest of Falls City, Richardson County.

Leicester Marcasite Member (of Moscow Formation)

Middle Devonian : Western New York.

R. G. Sutton, 1951, Rochester Acad. Sci. Proc., v. 9, nos. 5–6, p. 356, 379–380. Name proposed for top member of formation. Consists of lenses of yellowish-brown very fossiliferous sometimes nodular pyrite and marcasite; weathers to reddish-brown limonitic powder. Maximum thickness 6 inches. Overlies Windom member; underlies Genesee group, possibly unconformably. Previously termed Tully pyrite; not equivalent in age to Tully limestone.

Wallace de Witt, Jr., and G. W. Colton, 1959, Am. Assoc. Petroleum Geologists Bull., v. 43, no. 12, p. 2816–2817, 2827. Sutton's Leicester marcasite is lenticular layer of pyrite and marcasite in base of Geneseo shale member of Genesee formation.

Type locality: Along banks of Beards Creek one-fourth mile northwest of Leicester, Livingston County. Extends from west shore of Canandaigua Lake to Lake Erie.

Leigh Dolomite Member (of Bighorn Dolomite)[1]

Leigh Formation

Upper Ordovician: Western Wyoming.

Original reference: C. W. Tomlinson, 1917, Jour. Geology, v. 25, p. 118, 225–257.

H. R. Wanless, R. L. Belknap, and Helen Foster, 1955, Geol. Soc. America Mem. 63, p. 15–16. Rank raised to formation. Underlies Darby formation.

R. B. Boeckerman and A. J. Eardley, 1956, Wyoming Geol. Assoc. Guidebook 11th Ann. Field Conf., p. 181. In Jackson quadrangle, Lincoln County, formation consists of slabby gray dolomite with smooth white to yellowish weathered zones. Thickness 30 feet. Unconformably underlies Darby formation; unconformably overlies Bighorn dolomite. Silurian or Devonian.

Named for typical development on Leigh Creek, Teton Range.

Leighton Gray Shale Member (of Pembroke Formation)[1]

Silurian: Southeastern Maine.

Original reference: E. S. Bastin and H. S. Williams, 1914, U.S. Geol. Survey Geol. Atlas, Folio 192, p. 6–7.

Named for exposures on Leighton Neck, Penbroke Township, Washington County.

†Leightons Cove Series[1]

Silurian: Southeastern Maine.

Original reference: N. S. Shaler, 1886, Am. Jour. Sci., 3d, v. 32, p. 53, 56.

Named for exposures at Leighton's Cove, Cobscook Bay district, eastern coast of Washington County.

Leila Trachyte

Pliocene and lower Pleistocene(?): Samoa Islands (Tutuila).

H. T. Stearns, 1944, Geol. Soc. America Bull., v. 55, no. 11, p. 1285 (table 1). Named in list of eight trachytes that are described as dense jointed cream-colored trachytic dikes, plugs, and crater fills later than most of Pliocene volcanics. Thickness of sequence 2,141 feet or more. Leila plug associated with Alofau volcanics (new).

Leipers Limestone[1]

Leipers Formation (in Maysville Group)

Upper Ordovician: Western Tennessee and northwestern Alabama.

Original reference: C. W. Hayes and E. O. Ulrich. 1903, U.S. Geol. Survey Geol. Atlas, Folio 95.

C. W. Wilson, Jr., 1949, Tennessee Div. Geology Bull. 56, p. 179–193. Leipers formation as now defined includes all strata of Maysville group in central basin because it is only formation that has been proposed. Widely diverse facies are included but all carry Maysville fossils. Separated from underlying Catheys formation of Nashville group and overlying beds, regardless of age, by unconformities; locally underlain with apparent unconformity by Inman formation (new) of Eden group: unconformably underlies Arnheim formation. Thickness throughout most of out-crop belt less than 75 feet; thickens northward in Summer, Macon, Jackson, and Clay Counties to maximum of 175 feet. Hayes and Ulrich proposed no type section other than along Leipers Creek. Section suggested by Bassler (1932, Tennessee Div. Geology Bull. 38) as representing type area is here accepted as type section. It contains only two facies, but no section, anywhere, would contain adequate representations of all facies of Leipers.
