LEXICON OF GEOLOGIC NAMES OF THE UNITED STATES

PART 1, A–L

GEOLOGICAL SURVEY BULLETIN 896

UNITED STATES DEPARTMENT OF THE INTERIOR
Harold L. Ickes, Secretary

GEOLOGICAL SURVEY
W. C. Mendenhall, Director

Bulletin 896

LEXICON OF GEOLOGIC NAMES OF THE UNITED STATES
(INCLUDING ALASKA)

(Also includes the names and ages, but not the definitions, of the named geologic units of Canada, Mexico, the West Indies, Central America, and Hawaii)

Compiled by
M. GRACE WILMARTH
Secretary of the Committee on Geologic Names
of the United States Geological Survey
April 1, 1905, to April 30, 1937

LEXICON OF GEOLOGIC NAMES OF THE UNITED STATES

Compiled by M. Grace Wilmarth

INTRODUCTION

The compilation of a lexicon of geologic names was suggested to the compiler more than 25 years ago, by Dr. T. W. Stanton, who served as chairman of the Committee on Geologic Names from 1912 to January 1931, when he became Acting Chief Geologist of the United States Geological Survey, and later served as Chief Geologist until his retirement September 30, 1935. Dr. Stanton suggested that the definitions should state, briefly, the lithology, thickness, age, underlying and overlying formations, and type locality; and the formal definitions herein given have been compiled in accordance with that suggestion.

The compilation of the lexicon was undertaken as a piece of "knitting work," or a byproduct, but during the years that have elapsed between the initiation and the completion of the task, the volume of routine work that has flowed across the compiler's desk has been so steady and so heavy that work on the lexicon has been very desultory, being stopped for intervals of weeks, months, and even a year at a time. During all of these pauses in the work the coining of new names went on apace, until the lexicon as it stands today probably includes three times as many names as were in the literature when the work was started. During the periods when no work was being done on the lexicon itself, however, data were constantly being compiled that were needed in its preparation and in the routine work of the committee.

After the lexicon was started it was found that many names had been redefined (some of them more than once), and that the original definitions are not those in current use. This made necessary the compilation of the different definitions, thus adding greatly to the labor and to the contemplated size of the book. Work on the lexicon also made evident the need for stratigraphic charts, against which the definitions, redefinitions, and geographic distribution of the units could be checked. For the last few years work on the lexicon has kept pace with the preparation of these State charts.

In order to avoid undesirable duplication of names, and to supply information frequently sought, the names, geographic areas, and ages of the principal underground geologic units have been listed; also the names and geographic regions of Pleistocene moraines, with a reference to the publication in which an outline or a description of each will be found. The names of coal beds and ore beds have not been listed.

The time terms have also been listed, but the full definitions of the era, system, and series terms having been given in United States Geological Survey Bulletin 769, 1925, only very brief definitions of them are given here, with a reference to Bulletin 769.

In order to reduce the size of the book certain words, frequently used, have in most places been abbreviated in the text. These abbreviations are listed beyond. The points of the compass have also been abbreviated, and in general the names of the States, except in the top captions. The word "the" has been eliminated wherever practicable. Certain signs have also been employed, as follows:

= indicates equivalent to or equivalent of.
+ means plus.
± means plus or minus, or more or less.
*** indicate intervening beds.

Some entries have been inserted for the benefit of the layman, or to direct attention to Survey usage—for example:

Palaeozoic. An early spelling of Paleozoic.
Cainozoic. An early spelling of Cenozoic.
Waverlian. A variant of Waverlyan.

The endeavor has been made to make the digests of the definitions as brief as possible. The material has usually been gleaned from many pages of the reports cited, but in order to economize time and space, all pages from which the digested material was obtained are usually not listed, but only the page containing the essential part of the definition or the inclusive pages of the paper cited.

It may be noticed that unequal treatment has been accorded to the names—that is, most names have only one entry (a digest of the original definition), many names have several entries, and some names have many entries. In explanation it may be said that the original definitions of most geologic names are the definitions still in current use; that other names have been redefined (some of them several times), necessitating a digest of the redefinitions; that still other names have had a long and interesting history leading up to their present commonly accepted definitions and location in the geologic column, necessitating brief mention of the views of the geologists who have contributed most to their elucidation; and that some other names are still "bones of contention," necessitating brief mention of divergent views regarding them. But to cite the reports of those who have simply described a geologic unit, already named, in some particular field in which they have worked, or to explain the misidentifications of the units in different areas, is quite outside the scope of this book. Where there is disagreement regarding the age of a unit, the views of several authorities usually are given.

Definitions and redefinitions are given of only the units found in the United States and Alaska, but the names and current age designations of the geologic units of Canada, Mexico, Hawaii, the West Indies, and Central America are also listed, together with citations to the publications in which they were first defined, as recorded in United States Geological Survey Bulletin 191, by F. B. Weeks, and subsequent accessions to that list by J. M. Nickles and Miss E. M. Thom; the compiler has examined very few of the books cited for the foreign names. Where it was possible to do so without the expenditure of much time, the original definitions of a few Canadian units are given. A few widely used paleontologic names by which some geologic units have been designated have also been listed, together with the geographic names by which they are now known.

The capitalization of time terms in digested matter is that of the author cited.

The stratigraphic papers summarized and used in the preparation of this lexicon are largely those listed in Bulletin 191 and the subsequent accessions to that list up to January 1, 1936. The lexicon contains some names of 1936 coinage, but part of the 1936 literature the compiler has, necessarily, left to her successor to digest and record.

Names printed in black-face type are in current use by the United States Geological Survey; names preceded by a dagger (†) have been either abandoned by their authors or rejected for use in the classification of the United States Geological Survey; names in roman type without a dagger have not been considered by the Committee on Geologic Names of the United States Geological Survey for use in Survey reports.

The age assignments of the units whose names are printed in black-face type are those at present in use by the United States Geological Survey. That some of these age assignments will be changed, as evidence accumulates, is to be expected. The age assignments of units not printed in black-face type are those given by their authors or in subsequent reports cited. The use of a well-known group name in parentheses following the age designation of a unit does not mean that the United States Geological Survey classifies the unit as belonging to the group mentioned, but that its fossils indicate correlation with that group.

The counties mentioned in the top captions are not intended to indicate exact geographic distribution of the unit described, but are given as clues to the part of the State in which it occurs.

Survey geologists have been generous of time and knowledge in the endeavor to connect geologic units of early reports with those in current use.

The compiler hopes that the lexicon will prove a time saver for the busy geologist, who, like all other "humans," needs frequently to refresh his memory quickly.

The State charts compiled in connection with this lexicon (photolithographs of which have been distributed by the United States Geological Survey) bear dates as follows:

Ala., March 1935.
Ariz., March 1932.
Ark., August 1934.
Calif., January 1927.
Colo., June 1931.
Conn., April 1929.
Del., November 1936.
Fla., March 1935.
Ga., March 1935.
Idaho, September 1932.
Ill., August 1936.
Ind., February 1930.
Iowa, April 1930.
Kans., October 1936.
Ky., February 1930.
La., March 1931.
Maine, September 1935.
Md., April 1929.
Mass., April 1929.
Mich., June 1929.
Minn., August 1929.
Miss., March 1935.
Mo., March 1930.
Mont., July 1932.
Nebr., October 1936.
Nev., February 1933.
N. H., September 1935.
N. J., April 1929.
N. Mex., February 1932.
N. Y., January 1928.
N. C., March 1935.
N. Dak., September 1931.
Ohio, February 1930.
Okla., January and February 1931.
Oreg., August 1934.
Pa., April 1928.
R. I., April 1929.
S. C., March 1935.
S. Dak., September 1931.
Tenn., August 1929.
Tex., September 1930.
Utah, December 1932.
Vt., September 1935.
Va., April 1929.
Wash., July 1934.
W. Va., April 1929.
Wis., August 1929.
Wyo., April 1925.

LEXICON—Part 1, A-L

Aarde shale.

Pennsylvanian: Northeastern Kansas.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 94, 96). [See under *Bachelor Creek ls.* On p. 21 *Aarde sh.* is described as consisting of 3 ft. of yellowish gray clayey sh. with Nodaway coal near base. On p. 20 it is given a thickness of 4½ ft.]

R. C. Moore, 1934 (personal communication April 20), stated that lower part of Howard ls. intertongues with upper part of Severy sh., which accounts for Aarde sh. containing Nodaway coal. The underlying Bachelor Creek ls. also interfingers in Severy sh., he stated.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 39, 205–207). Bachelor Creek ls. is basal memb. of Howard ls. in southern Kans., from Greenwood Co. southward. Where it is absent, as in N. Kans., the Nodaway coal and other beds that are strat. = Aarde sh. memb. of Howard ls. are classed as belonging to top of Severy sh., because bdy btw. the 2 shales can not be drawn. In northern area Severy sh. extends up to base of Church ls. Named for Aarde farm, sec. 4, T. 26 S., R. 11 E., Greenwood Co.

Aaron slate.

Pre-Cambrian: Central southern Virginia and central northern North Carolina (Virgilina district).

F. B. Laney, 1917 (Va. Geol. Surv. Bull. 14, pp. 15, 19–27, and map). *Aaron sl.*—A slate-like rock formed by mixtures of varying amounts of andesitic volcanic ash and ordinary land waste, which through pressure and other agents of metamorphism have been changed or altered into a kind of hybrid sl., in some places into a schist. Varies from nearly pure greenstone to fairly pure argill. ss. and sl., and in certain places is decidedly conglomeratic. The rock is by no means normal sl., and term "sl." was applied to it only after much hesitation and many vain attempts to find a better name. In field work it was called "sandy tuff." It immediately overlies Hyco quartz porphyry. Is well exposed at many places along Aaron's Creek [Person and Granville Counties, N. C.]. Assigned to Ord. (?).

A. I. Jonas, 1928 (Va. Geol. Surv. prel. ed. geol. map of Va.). [The block of pre-Camb. extrusive rocks younger than Glenarm series and designated "greenstone volcanics" is stated to include a porphyritic amygdaloidal and tuffaceous facies called *Aaron slate.*]

Abbeville-York zone.

Pre-Cambrian: Northwestern South Carolina.

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published 1908, in S. C. Geol. Surv., ser. 4, Bull. 2) and 1907 (Summary of mineral resources of S. C., pp. 6, 9, 12). *Abbeville-York zone (Archean)*.—This area is very wide along its northerly bdy, which is constituted by State line, but narrows along its SW. bdy, formed by Savannah River. Is bounded on NW. by Cherokee and Anderson-Spartanburg zones; on SE. by a line which proceeds southwesterly from a point on State line 1.5 mi. NW. of Hornsboro, thence crossing Lynches River 1.8 mi. above mouth of Rocky Creek, thence to Heath Springs, thence below Peays Ferry (Wateree River) by Longtown, thence to head of Sawneys Creek, thence across Broad River (above its confluence with Little River), thence S. of Little Mtn, thence N. of Culbreath Mine, thence N. of Meeting St. (2 mi.), and thence direct to a point near McCormick, whence it continues to Savannah River, S. of mouth of Little River. Marble, of seeming upper Cherokee equivalence, appears along upper limit of Abbeville-York zone interruptedly from E. side of Enoree River to E. side of Saluda River. Rocks consist of gneissoids, granite, syenite, quartz, mica and hornblende schists and slates, qtzite, gabbro, trachyte, porphyries, sericite schists, quartz monzonite schists, diorite slates, diorite, trachyte, pyroxenite, amphibolite, felsite, soapstone.

Named for exposures in Abbeville and York Counties.

Abbyville gabbro.

Pre-Cambrian: Central southern Virginia (Mecklenburg County).

F. B. Laney, 1917 (Va. Geol. Surv. Bull. 14, pp. 37–38, map). *Abbyville gabbro.*—Much altered intrusive hornblende gabbro of dirty greenish gray color; coarse grained. Occurs in vicinity of Abbyville, Mecklenburg Co., Va.

A. I. Jonas, 1928 (Va. Geol. Surv. prel. ed. geol. map of Va.), mapped the hornblende gabbro around Abbyville, Va., as of pre-Camb. age and as intrusive into Glenarm series (Algonkian?).

Abercrombie formation.

Middle Cambrian: Western Utah (Gold Hill district).

T. B. Nolan, 1930 (Wash. Acad. Sci. Jour., vol. 20, No. 17, Oct. 19, pp. 421–432). *Abercrombie fm.*—Most characteristic type is a blue-gray dense ls. whose thin bedding is caused by thin bands or partings of yellow, buff, pink, or light-gray fossiliferous sh. The ls. bands are ¼ to ½ inch thick. The shaly material is present only locally along many bedding planes and similar splotches of sh. occur less commonly within the ls. and not parallel to the bedding. With increase or decrease in amount of sh. the rock grades into lenticular sh. beds or into relatively massively bedded lss. Thickness 2,700± ft. Middle Camb. fossils. Grades into underlying Busby qtzite and into overlying Young Peak dol. Abercrombie Peak, on ridge S. of Dry Canyon, in Gold Hill dist., is underlain by this fm., hence the name.

See also U. S. G. S. P. P. 177, 1934.

Aberdeen formation.

Triassic: British Columbia.

C. Camsell, 1910 (Canada Geol. Surv. Mem. 2, pp. 45, 66). [Assigned to Carbf.]

H. S. Bostock, 1930 (Canada Geol. Surv. Summ. Rept. 1929, pt. A, p. 203). [Assigned to Triassic.]

Aberdeen sandstone. (In Pottsville formation.)

Pennsylvanian: Western Kentucky.

A. F. Crider, 1915 (Ky. Geol. Surv., 4th ser., vol. 3, pt. 1, pp. 173–175). *Aberdeen ss.*—Coarse, massive, cliff-making ss., 40 ft. thick, forming steep cliffs in region of Aberdeen, Butler Co. Forms bluff on which Morgantown is situated. Base of ss. is 75 ft. above low water at Morgantown. Either rests on Aberdeen coal or is separated from it by 4 to 6 ft. of sh. Well-marked erosional uncon. at base.

Named for Aberdeen, Butler Co., where it stands out in prominent cliffs along Green River. Typically exposed at Aberdeen Ferry.

Aberdeen sandstone member (of Blackhawk formation).

Upper Cretaceous: Central eastern Utah (Book Cliffs).

F. R. Clark, 1928 (U. S. G. S. Bull. 793). *Aberdeen ss. memb. of Blackhawk fm.*—Massive, medium-grained buff ss., 60 to 200 ft. thick, lying 160± ft. above Star Point ss. Underlies Castlegate "A" coal and overlies lower part of Spring Canyon coal group, but in places grades laterally into part of that coal group. Exposed near Aberdeen mine, NE. of Kenilworth, Castlegate quad., Carbon Co.

Abilene conglomerate.

Tertiary: Central Kansas.

C. S. Prosser, 1895 (Jour. Geol., vol. 3, pp. 786, 789, 797). *Abilene cgl.*—Cgl., 15 to 20 ft. thick, lying about 150 ft. above base of Marion fm. Underlain by shaly buff lss. and overlain by buff lss. and marls of Marion fm.

L. C. Wooster, 1905 (The Carboniferous rock system of eastern Kans.). *Abilene cgl.* consists of ls. and quartz pebbles and is top memb. of Marion beds as here defined.

J. W. Beede, 1909 (Kans. Acad. Sci. Trans., vol. 22, pp. 248–256). *Abilene cgl.* is top memb. of Marion fm. [See under †*Marion fm.*]

R. C. Moore and W. P. Haynes, 1917 (Kans. Geol. Surv. Bull. 3). *Abilene cgl. memb.*—Top memb. of Marion fm. Is a peculiar, somewhat variable, conglomerated ls. At type loc., in vicinity of Abilene, it is a calc. cgl. containing some sand and ss. pebbles. In vicinity of Herington and Marion it is represented, according to Beede, by "heavy, hard, perhaps dolomitic stone, composed of fragments of yellow, orange, and gray masses firmly united in a light-gray cementing material." Overlies Pearl sh. memb.

R. C. Moore, 1920 (Kans. Geol. Surv. Bull. 6, pt. 2, p. 63, footnote). So-called *Abilene cgl.* is Tert. [See fuller statement under †*Marion fm.* Other geologists continued to classify these beds as Perm.]

E. C. Parker, 1925 (A. A. P. G. Bull., vol. 9, No. 6, p. 982, in reply to question of C. N. Gould: "Is it not true that at the location the Abilene fm. is a mud or clay cgl.?"). This bed in type section at Abilene, Kans., at the few exposures where it is unaltered, is a soft gray ls. about 2 ft. thick. The interval down to top of Herington ls. varies from 40 ft. at Abilene, Kans., to about 50 ft. at Ponca City, Okla. In majority of exposures this calc. material has been partly or wholly dissolved and redeposited in same horizon, often with gyp. derived by solution from strata higher in the section. Due to this mode of origin, pieces of the green sh. above *Abilene ls.*, as it might better be named, have been included in some places in this massive bed of secondary ls. It can no more be called a cgl. than the top memb. of the Herington, which is often similarly altered at type vicinity.

W. A. Ver Wiebe, 1937 (letter dated April 15). Geologists of Wichita and other parts of Kans. are agreed as to Tert. age of Abilene cgl.

Named for Abilene, Dickinson Co.

Abilene formation.

Permian: Central and central northern Texas.

W. E. Wrather, 1917 (SW. Ass. Pet. Geol. Bull., vol. 1, pp. 95–96). *Abilene fm.*—Thin fossiliferous lss. separated by red and blue clays. Thickness 170 ft. Top memb. of Wichita beds. Occurs around Abilene and perhaps southward beneath Callahan Divide. Thins out and disappears to N., but underlying Lueders ls. persists to within a few mi. of Red River.

J. W. Beede and V. V. Waite, 1918 (Univ. Tex. Bull. 1816, pp. 45–46). The term *Arroyo fm.* is given to series of soft lss., marls, shales, and gyp., 260 ft. thick in Runnels Co., which occur on and near Los Arroyo, 2¼ mi. W. of Ballinger. There is one persistent bed of gyp. in lower part of fm., and some shales are red. It is apparently the same set of rocks to which Wrather applied *Abilene fm.* in Taylor Co., but that name had already been used for other fms. and *Arroyo* is substituted for it. The correlation of upper part of fm. with the ls. at the standpipe at Abilene was substantiated by W. A. Riney. This fm. is tentatively placed as top memb. of Wichita stage. Differs considerably from underlying Lueders fm.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 169, 175). The preoccupied name *Abilene fm.* is discarded, and is replaced with *Arroyo fm.*

Abilene limestone.

See 1925 entry under *Abilene cgl.*

Abitibi group.

Pre-Cambrian: Quebec.

M. E. Wilson, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 276). *Abitibi group*, pre-Camb. (Keewatin?).

Abitibi River formation.

Devonian: Ontario.

T. E. Savage and F. M. Van Tuyl, 1919 (Geol. Soc. Am. Bull., vol. 30, pp. 341, 373, 375). *Abitibi River ls.*, Dev., Canada.

R. H. Hawkins, 1933 (Am. Inst. Min. Met. Engrs., Contr. No. 40, p. 1), assigned *Abitibi River fm.* to Middle Dev.

Abo sandstone (also **Abo redbeds**). (Of Manzano group.)

Permian (lower): New Mexico (widespread).

W. T. Lee, 1909 (U. S. G. S. Bull. 389). *Abo ss.*—Coarse-grained ss., dark red to purple, usually conglomeratic at base; with subordinate amount of sh., which attains prominence in some places. Thickness 300 to 800 ft. Upper limit is drawn below the gyp., for obvious reason that in many places the overlying or Yeso fm. contains beds of gyp. and gypsiferous sh. at several horizons, through a thickness in some places of 1,000 ft. or more. Is basal memb. of Manzano group and rests uncon. upon Magdalena group. Named for Abo Canyon, at S. end of Manzano Range.

Abram conglomerate.

Pre-Cambrian: Western Ontario (near Sioux Lookout).

F. J. Pettijohn, 1930 (Jour. Geol., vol. 38, No. 6, pp. 568–573). Imbricated arrangement of pebbles in several bands of a pre-Camb. cgl. (which writer has chosen to call *Abram cgl.*), near Sioux Lookout, western Ont., is described. The Abram cgl. in all belts contains varied assemblage of pebbles; granites, greenstones, and green schists, felsites, metadiorites, metadiabases, and quartz are most common. One belt of the cgl. occurs on shores of Abram Lake.

Abram series.

Pre-Cambrian: Ontario (Abram Lake region).

F. J. Pettijohn, 1934 (Cgl. of Abram Lake, Ont., and its extensions: Geol. Soc. Am. Bull., vol. 45, pp. 480, 481, 484, 486–505). In 1930 (Jour. Geol., vol. 38, pp. 568–573) writer described and named *Abram series.* [His 1930 paper introduced *Abram cgl.*, which appears to apply to only basal part of this *Abram series.*] *Abram series* consists of (descending): (1) Mica schists(?); (2) sl. and sl. cgl. alternating, 1,000+ ft.; (3) graywackes, siltstones, slates, tuff slates, cherty slates, and iron fm., 1,250 ft.; (4) qtzite, some green schists, and rhyolite porphyry, 50 to 700 ft.: (5) massive to laminated arkosite with sporadic granite pebbles, underlain by massive arkosite with pebbles and boulder beds, 5,300 ft.; (6) boulder cgl., 0 to 1,000 ft.; (7) basal brown grit, 30 to 100 ft. Rests, with great uncon., on post-Keewatin intrusives, and underlies post-Abram intrusives ("Algoman").

Abrams mica schist.

Pre-Cambrian (?): Northern California (Trinity and Shasta Counties).

O. H. Hershey, 1901 (Am. Geol., vol. 27, pp. 225–245). *Abrams mica schist.*—Composed of thin folia of muscovite of dull colors (gray, light-brown, yellow and dull red) separated by irregular layers of white quartz, representing the original laminae. Very highly siliceous throughout. Is of sed. origin, being originally a series of argill. ss. beds in part finely laminated. Thickness about 1,000 ft. in upper Coffee Creek section, but may be much thicker at Bully Choop, to S. Named for Abrams P. O., in upper Coffee Creek region.

According to J. S. Diller (unpublished ms. on Weaverville quad.) the Abrams mica schist is 5,000 ft. thick.

N. E. A. Hinds, 1932 (Univ. Calif. Pub., Dept. Geol. Sci. Bull., vol. 20, No. 11, pp. 375–410), introduced *Siskiyou terrane* to include Abrams and Salmon fms.

Abrigo limestone.

Upper Cambrian: Southeastern Arizona.

F. L. Ransome, 1904 (U. S. G. S. P. P. 21). *Abrigo ls.*—Distinguished from other calc. fms. of Paleozoic by prevailing thin bedding, and particularly by conspicuous laminated structure produced by alternation of thin irregular sheets of chert with layers of gray ls.; the ls. layers are 2 to 3 inches thick, the chert layers usually thinner. Dominant color dark greenish yellow. Very fissile greenish yellow calc. shales are generally characteristic feature of lower half of Abrigo. Thickness 770 ft. Rests conformably on Bolsa qtzite and is apparently conformably overlain by Martin ls. (Dev.). Named for exposures in Abrigo Canyon, 3 mi. SW. of Bisbee. In Mount Martin section upper limit of Abrigo fm. is defined by a bed of pure white qtzite 8±ft. thick. This qtzite is persistent and is always found immediately underlying the Martin ls., which carries Dev. fossils. It apparently records the consummation of an increasing supply of sandy sediments during later phases of deposition of Abrigo ls. and contrasts with the more purely calc. beds of overlying Dev. fm.

N. H. Darton, 1925 (Univ. Ariz., geol. ser. No. 3, Bull. 119, pp. 48–51). Fossils collected from Abrigo ls. are now classified as Upper Camb. by E. Kirk and C. E. Resser; but it is possible that the higher beds may prove to be Ord.

A. A. Stoyanow, April 30, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 461–540), divided Abrigo ls. of Bisbee dist. (type area) into (descending): Copper Queen ls. (Upper Camb.), new name, 81 ft.; *Abrigo fm.* [restricted] (Upper Camb.), 420 ft.; and Cochise fm. (Middle Camb.), new name, 200 ft. The U. S. Geol. Survey has not yet had occasion to consider these innovations.

Acadia series.

A variant of *Acadian series.* Proposed by G. H. Ashley, 1923 (Eng. and Min. Jour.-Press, vol. 115, pp. 1106–1108).

Acadian series (or epoch).

Geographic name for Middle Cambrian deposits and the time covered by their deposition. For definition see U. S. G. S. Bull. 769, pp. 98–100.

Acadian disturbance.

A term applied by C. Schuchert and C. O. Dunbar (Textbook Geol., pt. 2, p. 65, 1933) to diastrophic movements in late Dev. and earliest Miss. time.

Acauminac formation.

Devonian: Canada.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 208). *Acauminac fm.*, Dev., Canada.

Only record of name.

†Accabee gravels.

†Accabee phos-gravels.

Pleistocene: Southern South Carolina (Charleston County).

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published 1908, in S. C. Geol. Surv., ser. 4, Bull. 2) and 1907 (Summary of mineral resources of S. C., pp. 12, 20, 21). Resting on Bohicket marl sands a bed of coarse gravel (⅛ inch diam.) occurs, and embraces rounded lumps of phosphate rock and numerous quartz pebbles (2''); its littoral line overlaps and extends more northerly than Bohicket marl-sand. Along northerly exposures it attains elev. of 16 ft. (M. L. T.). This bed, which is generally missing, attains in places thickness of 4 ft.; it affords the irregular seam of phosphate rock known to miners as "flying rock." Is a marine deposit.

C. W. Cooke (personal communication, 1935). The beds described are a facies of Pamlico fm.

Named for exposures in pit at Corn Hill, near Accabee Flats, W. of Charleston.

†Acila shales.

A paleontologic name applied in early repts to Olig. beds in NW. Oreg. that were later named *Nye fm.* by H. G. Schenck. Contain sp. of *Acila.*

Ackerman formation. (In Wilcox group.)

Eocene (lower): Mississippi and southwestern Alabama.

E. N. Lowe, 1913 (Miss. Geol. Surv. Bull. 10, pp. 23–35). Lowest div. of Wilcox fm. might well be called *Ackerman beds*, because typically exhibited in great cut 1 mi. E. of town of Ackerman [Choctaw Co., NE. Miss.]. Consists of dark gray clays and sandy clays, lignite clays and lignite with occasional beds and concretionary masses of carbonate ore. Thickness 400 ft. Underlies Holly Springs sand and conformably overlies Midway group.

In present usage of names the Wilcox is treated as a group and the Ackerman as basal fm. of that group. The Ackerman represents lower part of Nanafalia fm. of Ala. as originally defined, but Nanafalia fm. has been restricted by C. W. Cooke to beds overlying Ackerman fm. (†Coal Bluff beds of early Ala. repts), which extends a short distance into Ala. (See under *Nanafalia fm.*, also under *†Coal Bluff beds.*)

Acme dolomite. (In Blaine formation.)

Permian: Central northern Texas and Texas Panhandle (Hardeman to Stonewall Counties).

A. M. Lloyd and W. C. Thompson, 1929 (A. A. P. G. Bull., vol. 13, p. 951 and pl. 9). *Acme dol.*—Above Mangum dol. the first prominent dol. is a series of several beds, 1 to 6 ft. thick, which has been called the Acme, from type exposure in Hardeman Co., where thick beds of gyp. below the dol. are mined. The Acme is traced southward to Stonewall Co. and may be correlated with reasonable certainty with McCaulley beds of Fisher Co. It lies 64 ft. above Mangum dol. and 90 ft. below Guthrie dol.

See also 1933 entry under *McCaulley dol.*

Acworth gneiss.

Pre-Cambrian: Northwestern Georgia (Cartersville district).

C. W. Hayes, 1901 (Am. Inst. Min. Engrs. Trans., vol. 30, p. 408). The extreme SE. corner of mapped area is occupied by *Acworth gneiss*, which, like Corbin granite, is probably Archean in age, and formed the foundation on which oldest sediments of region were deposited.

Appears to be same as Carolina gneiss. Named for development around Acworth, Cobb Co.

Ada formation.

Pennsylvanian: Central southern Oklahoma (Pontotoc and Seminole Counties).

G. D. Morgan, 1924 (Bur. Geol. [Okla.] Bull. 2, pp. 128–132, pls. 3, 27, and map. Name was also used by Morgan, but not defined. in Okla. Geol. Surv. Circ. No. 12, pl. and p. 15, 1923). *Ada fm.*—Ls. cgls. and coarse sss. are very prominent along greater portion of outcrop. The shales are mostly light colored. Near base is a thin black ls. that is very persistent in vicinity of Ada. Clastic material becomes less toward N. and in vicinity of Vamoosa is very scarce. With decrease in amount of clastic material the fm. becomes thinner. Average thickness is 100± ft. At N. edge of quad. it is only 60± ft. thick. Contains asphalt. Fossils scarce. North of Canadian River it appears to rest conformably on Vamoosa fm., but to S. it overlaps Vamoosa and several older fms. Underlies Vanoss fm.

Named for development within and to W. of town of Ada, Pontotoc Co.

Ada shale. (In Bluefield formation.)

Mississippian: Southeastern West Virginia, southwestern Virginia (Tazewell County), and eastern Tennessee (?).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe and Summers Counties, pp. 300, 421). *Ada shale.*—Olive green, fissile, calc. toward base, 30 to 60 ft. thick. Marine fossils. Underlies Talcott sh. and overlies Reynolds ls., all members of Bluefield group [fm.]. Type loc. on N. side of East River, in public road btw. Ada and Stony Gap, and less than ¼ mi. W. of Ada, Mercer Co. Also observed in Monroe and Summers Counties, W. Va.; in Tazewell Co., Va.; and far down in Tenn., being quite typical at Daisy, Hamilton Co. Can be traced NE. in W. Va. nearly to head of Greenbrier Valley and possibly to southern Pa.

Adair moraine.

Pleistocene (Wisconsin stage): Southeastern Michigan. Shown on moraine map (pl. 32) in U.S.G.S. Mon. 53. Named for Adair, St. Clair Co.

Adamana shales.

Lower Triassic: Northeastern Arizona.

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, pp. 250, 335). *Adamana shales* proposed for Ward's 4th sh. bed above Aubreyan lss. [Kaibab ls.] in Moenkopian section of Navajo country. Exposed in full thickness (200 ft.) near R. R. station of Adamana, Apache Co.

Adams Branch limestone memb. (of Graford formation).

Pennsylvanian: Central Texas (Colorado River region).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 387, 391). *Adams Branch ls.*—Hard, fossiliferous, unevenly textured, bluish ls., base somewhat aren. in places. Thickness 25 to 30 ft. Memb. of Canyon div. Underlies Cedarton bed and overlies Brownwood bed. [Type loc. is Adams Branch, Brown Co., close to town of Brownwood.]

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31, 34; Univ. Tex. Bull. 2132, pp. 59, 84, 96, 101, 102, 114). *Adams Branch ls.* is top memb. of

Graford fm. in both Brazos River and Colorado River valleys. Is 10 to 30 ft. thick in S. part of area and 100 locally to N. Is massive escarpment-forming ls. Forms escarpment 100 to 150 ft. high. Underlies Cedarton sh. and ss. and overlies Brownwood memb. of Graford fm. In Brazos River valley underlies Seaman Ranch sh.

E. H. Sellards, 1931 (News Letter from Bur. Econ. Geol. Univ. Tex., dated Sept. 1931), stated that *Adams Branch ls.* is approx. same as Palo Pinto ls., and treated it as a memb. of Palo Pinto fm.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 111), extended top of Graford fm. up to top of Merriman ls. (Clear Creek ls. of Drake), which had been mistaken for Adams Branch ls. in some previous repts, but which is a much younger ls. (See 1933 entry under *Graford fm.*) This definition of Graford fm. was adopted by U. S. Geol. Survey in 1935.

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501), drew top of Graford fm. of Colorado River region at top of Adams Branch ls. memb.

In 1935 the U. S. Geol. Survey adopted (for rept by Wallace Lee and C. O. Nickell, soon to be published by Tex. Geol. Survey) a definition of Graford fm. that included in it a great thickness of rocks younger than true Adams Branch ls. of Colorado River region. (See under *Graford fm.*)

Adamsian.

A time term employed by C. [R.] Keyes to cover rocks of Cordilleran region interpreted as having been formed during middle part of Huronian epoch. (See Iowa Acad. Sci. Proc., vol. 24, p. 56, 1917.)

Adams Lake series.

Adams Lake group.

Names applied by Canadian geologists to rocks of pre-Camb. age in Adams Lake region of southern British Columbia. (See G. M. Dawson, 1890, Canada Geol. Surv., n. s., vol. 4, pp. 29B, 31B.)

Adaville formation.

Upper Cretaceous: Southwestern Wyoming.

A. C. Veatch, 1907 (U.S.G.S.P.P. 56). *Adaville fm.*—Yellow, gray, and black carbonaceous clays, with irregularly bedded brown and yellow sss. and numerous coal beds. South of Hodges Pass tunnel there is at base a prominent white ss. (*Lazeart ss. memb.*), 100 to 200 ft. thick, immediately above which is Adaville-Lazeart coal, 20 to 84 ft. thick, and associated with it beds containing plants and invertebrate remains older than Laramie; the overlying strata contain lower Laramie leaves. Thickness of fm. 4,000+ft. Uncon. underlies Evanston fm. and overlies Hilliard fm. At Adaville mine, 2 mi. S. of Hodges Pass tunnel, on Oregon Short Line, a bed of coal 84 ft. thick has been cut, and as whole fm. shows a like phenomenal amount of coal, and is, moreover, well exposed at this point, it has been named *Adaville fm.*

Addington sandstone member (of Wise formation).

Pennsylvanian: Southwestern Virginia (Wise and Scott Counties).

J. B. Eby, 1923 (Va. Geol. Surv. Bull. 24). *Addington ss. memb.*—Hard white ss., 20 to 40 ft. thick, underlying Addington coal and resting on Clintwood coal or separated from it by few ft. [0 to 20, according to A. W. Giles, Va. Geol. Surv. Bull. 26, 1925] of sh. Named for Addington Station, 1½ mi. S. of Glamorgan, Wise Co.

Addington formation.

Permian: Central southern Oklahoma (Jefferson County).

J. R. Bunn, 1930 (Okla. Geol. Surv. Bull. 40PP, pp. 8–9, etc.). *Addington fm.*—Uppermost memb. of red beds exposed in Jefferson Co. Few ft. to several hundred ft. thick; max. thickness on high bluffs just E. of Addington (Jefferson Co.). Is characterized by the brilliant red and vermilion hues of its sh. members, which are often broken by white and light-gray sh. and sandy sh. streaks. The sss. are characterized by black red color and slabby appearance on weathering. The weathered slabs are extremely hard and resistant. When freshly broken they resemble fine-grained reddish qtzite. In general the sss. show varying amount of pink or red color unless subjected to constant water saturation, in which case they are sometimes soft and light colored. Base is generally characterized by thin to massive, resistant, reddish ss. There is some evidence these beds are not entirely conformable with underlying Claypool fm. (Penn.). The Addington contains the only beds in county that are typical of lower Perm. red beds of Okla Assigned to Perm.

Addison formation.

Middle Ordovician (Trenton): Northwestern Vermont (Addison County).

E. J. Foyles, 1929 (16th Rept. Vt. State Geol., pp. 275–279). *Addison fm.* [heading].—In central part of Ferrisburg Twp [NW. part of Addison Co.] there is a broad flat valley covered with Champlain clays through which protrude occasional knots of sh. and calcilutyte. The transition from the ls. to the shaly ls. and sh. is imperceptible. No contacts seen, but the change in kind of sediment is evident. The sh. is sometimes crossed by cleavage lines of sl. No fossils known. Since this broad band of sediment appears to be so distinct through 5 Twps it is proposed to distinguish it by the name *Addison shaly ls.* It is considered to be a local facies equiv. in age to the Canajoharie. [In tables on pp. 279 and 288 this fm. is called *Addison sh.*]

Addy quartzite.

Paleozoic: Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 61, map). *Addy qtzite.*—Chiefly massive, hard, crystalline, light-colored qtzite. Associated with it in subordinate amounts are belts of quartz mica schist highly metamorphosed banded slates, and well banded qtzites with much white mica developed. In vicinity of Addy the hard massive phase grades over into alternating interbedded qtzites and argillites in bands from a few inches to several ft. thick. Thickness 8,000± ft. Overlies Deer Trail argillite and underlies Chewelah argillite and Old Dominion ls.; apparently conformable both above and below.

Adelphian.

Name proposed by C. [R.] Keyes (Pan-Am. Geol., vol. 45, pp. 150–151, 1926) to replace *Nebraskan*, as applied to Pleist. pre-Kansan till, "because of use of Nebraskan for other deposits." Derived from hamlet of Adelphi "8 mi. or so SE. of Des Moines, Iowa."

Adirondack gneiss.

Pre-Cambrian: Northeastern New York (Adirondack region).

C. H. Hitchcock, 1879 (Macfarlane's Geol. Ry Guide, p. 56). *Adirondack gneiss* included in Laurentian.

F. J. H. Merrill, 1901 (geol. map of N. Y.). *Adirondack gneiss (gneisses including granites).* [Mapped over large part of Adirondack region. The block is placed beneath the Grenville blocks, and according to later mapping the rocks are chiefly of igneous origin.]

G. H. Chadwick, 1930 (Geol. Soc. Am. Bull., vol. 41, p. 82). [See 1930 entry under *Adirondack anorthosyte.*]

Adirondack anorthosyte.

Pre-Cambrian: Eastern New York (Adirondack Mountains).

G. H. Chadwick, 1930 (Geol. Soc. Am. Bull., vol. 41, p. 82). It is pretty generally agreed that at about middle of Precambrian 3 igneous masses invaded Adirondack area. These were (1) the anorthosyte, (2) the "syenyte" and allied "granits," and (3) the "basic gabbros." Local expressions of these have cognomens, but there is need for a general term for each. It is here proposed to call them respectively by names long unofficially in use by some of us, respectively: (1) The *Adirondack anorthosyte;* (2) the *Ausable "syenyte" or nordmarkyte series* (named for development along Ausable River and in quarries around Ausable Forks, N. Y.; and (3) the *Elizabethtown gabbros* (named for development around Elizabethtown, N. Y.). The names *Mount Marcy, Whiteface,* and *Split Rock* [where published?] apply only to local differentiation and assimilation phases of the anorthosyte, of which *Marcy type* is most widespread and typical; and while term "Adirondack gneisses" has sometimes been loosely employed without definition for the Precambrian rocks of northern N. Y. as a whole, it lacks currency today and can have no claim against the appropriate application of *Adirondack* to the anorthosyte mass that constitutes all the high central peaks of true Adirondack Mtns. A cataclastic phase of this rock from S. of Ausable Forks, N. Y., has gone on market as "Adirondack granite."

Adirondack granite.

Trade name for a part of Adirondack anorthosyte of Chadwick.

Admiral formation. (In Wichita group.)

Permian: Central and central northern Texas.

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, pp. 192–195 and charts). *Admiral fm.*—Basal fm. of Wichita group. Includes all strata btw. top of Coleman Junction ls. memb. of underlying Putnam fm. and top of Elm Creek ls. Thickness 270 to 350 ft. Named for village of Admiral, Callahan Co. [For subdivisions see 1922 entry under *Coleman bed.*]

Admiralty drift.

Pleistocene (pre-Wisconsin): Western Washington (Puget Sound region) and British Columbia.

B. Willis, 1898 (Geol. Soc. Am. Bull., vol. 9, pp. 111+). *Admiralty till and clays.*—In order to give them distinctive names it appears desirable the term "till" should be restricted to the unstratified deposits and the simple term "clays" be applied to the stratified fms. Principal exposures in bluffs along shores of Admiralty Inlet.

Admiralty glacial epoch.

Pleistocene (pre-Wisconsin): Western Washington (Puget Sound region).

B. Willis, 1898 (Geol. Soc. Am. Bull., vol. 9, pp. 111+). *Admiralty glacial epoch.*—Covers Admiralty till and clays. Preceded Puyallup interglacial epoch.

Admire shale. (In Wabaunsee group.)

Pennsylvanian: Eastern Kansas, southeastern Nebraska, and southwestern Iowa (?).

G. I. Adams, 1903 (U. S. G. S. Bull. 211, p. 53). *Admire shales.*—Fossiliferous shales, 40 ft. thick, overlying Emporia ls. and underlying Americus ls. [C. S. Prosser (Jour. Geol., vol. 10, p. 707, 1902) gave thickness of rocks btw. Emporia and Americus lss. as 300 ft., consisting chiefly of shales but including many thin beds of coal, and ss.]

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 72, 81, etc.). *Admire sh. memb. (revised).*—Adams in proposing *Admire* in 1903 introduced it for the shales lying btw. Emporia ls. and Americus ls., with thickness of 40 ft. Just what bed or beds Adams erroneously correlated as Emporia ls. in arriving at thickness of 40 ft. is not known. It may have been Falls City ls., which is poorly exposed SW. of Admire [Lyon Co., Kans.], about 60 ft. below Americus ls. It could not have been Emporia ls., which is much lower in section and does not crop out in this vicinity. Only upper part of Admire as later recognized by Prosser, Haworth, Moore, and others is exposed at Admire, which means that *Admire* as now used is not properly applied. The Admire sh. of Kans. geologists extends from base of Americus ls. down to top of Emporia ls. The Nebr. Geol. Survey is to use *Admire sh. memb.* for the beds beneath Americus ls. down to base of Brownville ls., because this portion of the section constitutes about what Adams defined as a memb. The Brownville ls. outcrops on creek just NE. of Admire and Americus ls. is exposed SW. of it. The Admire sh. memb. as thus revised is here divided into (descending): (1) West Branch sh., 24± ft.; (2) Falls City ls., 4± ft.; (3) Aspinwall sh., 25± ft.; (4) Brownville ls., 4± ft.

R. C. Moore, 1929 (Kans. Geol. Surv. Bull. 12, p. 43, footnote). As revised by G. E. Condra, "Admire sh." as here used includes, in ascending order, Willard sh., Tarkio ls. (apparently absent in southern Kans.), McKissick Grove sh., and *Admire sh. (restricted).* The Kans. Geol. Survey accepts this revised classification.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3), discarded his 1929 definition of Admire sh., and adopted a still further restricted definition, i. e., for the beds *overlying* Brownville ls. and underlying Americus ls. (Brownville ls. being treated as a distinct unit); and divided it into (descending) West Branch sh., Falls City ls., and Aspinwall sh. Moore and Condra in their Oct. 1932 revised classification chart for Kans. and Nebr.

defined Admire sh. as underlying Americus ls. and overlying Brownville ls., but they transferred to it, at top, Houchen Creek ls. and Stine sh., which had previously been included in overlying Elmdale sh. They divided Admire sh. into (descending) Oaks sh., Houchen Creek ls., Stine sh., Five Point ls., West Branch sh., Falls City ls., Hawxby sh., Aspinwall ls., and Towle sh. Their Oaks sh. was apparently previously included in Elmdale sh., which overlies Americus ls.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, pp. 8–9), and R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 50), used *Admire group* to include the same subdivisions mentioned in 1932 definition above.

The Kans. and Nebr. Geol. Surveys now include the Admire in Perm. The U. S. Geol. Survey has not yet considered this change in bdy btw. Perm. and Penn. nor the restricted definitions of Admire. (See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.)

Admire group.

Name used by G. E. Condra (1935) in SE. Nebr., instead of *Admire sh.* For subdivisions see Kans.–Nebr. chart compiled by M. G. Wilmarth, 1936.

Adolphus formation.

Cambrian: British Columbia.

L. D. Burling, 1922 (Geol. Soc. Am. Bull., vol. 33, p. 109). *Adolphus fm.*, Camb., B. C. [In 1923 (Geol Soc. Am. Bull., vol. 34, pp. 725, 741) Burling called the fm. *Adolphus ls.*]

Aetna.

Permian: Western Oklahoma and Kansas.

F. W. Cragin, 1897 (Am. Geol., vol. 19, p. 353). *Aetna*, from Aetna (Barber Co.), is here proposed as common name for Glass Mtn and Cave Creek fms., expressing the genetic and chemical relationship btw. them. [In table is called *Aetna cycle of precipitation of gyp.*]

Includes Blaine fm. and upper part of Enid fm.

Afton terrane.

Pleistocene: Iowa and Kansas.

C. R. Keyes, 1912 (Iowa Acad. Sci. Proc., vol. 19, p. 148). *Afton terrane.*—Sands, 40 ft. thick, underlying Kansas till and overlying Nebraska till in Iowa.

Same as Aftonian of other geologists.

Aftonian stage of deglaciation (Pleistocene).

Aftonian stage is name applied to interglacial stage during which the Aftonian soil, gumbotil, vegetal and other interglacial deposits were formed. This stage followed the oldest or Nebraskan stage of glaciation and preceded the second or Kansan stage of glaciation. The name, which was introduced by T. C. Chamberlin (Jour. Geol., vol. 3, pp. 270–277, 1895), was derived from exposures btw. Afton and Thayer, Iowa.

Agamenticus complex.

Devonian (?): Southwestern Maine (York County).

A. Wandke, 1922 (Am. Jour. Sci., 5th, vol. 4, pp. 149, 152–154). *Agamenticus complex.*—Chiefly biotite granite (dominant phase), alkaline granite, and syenite, also the small stock of Berwick quartz diorite (apparently later than main biotite granite), and other small bodies, such as those along S. side of York Harbor [see York Harbor biotite granite] and along NE. side of Brave Boat Harbor [see Brave Boat Harbor granite]. Three of dominant rock types occur on slopes of Mount Agamenticus. Assigned to Dev. (?).

Agassiz.

Name applied to a glacial lake, of Pleist. age, in Great Lakes region.

Agassiz series.

Jurassic: Southwestern British Columbia.

N. L. Bowen, 1913 (12th Int. Geol. Cong. Guidebook 8, p. 258). *Agassiz series,* Paleozoic, B. C.

C. H. Crickmay, 1927 (Stanford Univ. Abstracts of Dissert. 1924–26, vol. 1, p. 132). *Agassiz series,* Jurassic, B. C.

Agassiz Prairie formation.

Upper Jurassic: Southwestern British Columbia (Harrison Lake region).

C. H. Crickmay, 1927 (Stanford Univ. Abstracts of Dissert. 1924–26, vol. 1, p. 132). *Agassiz Prairie fm.,* Jurassic, B. C.

C. H. Crickmay, 1930 (Geol. Mag., vol. 67, map, p. 487). *Agassiz Prairie fm.*—Argillite, 5,000 ft. thick, yielding *Anacardioceras perrini.* Assigned to Upper Jurassic. Uncon. underlies Peninsula fm. (Lower Cret.) and overlies Kent fm. (Upper Jurassic).

Agate Bay group.

Pre-Cambrian (Keweenawan): Northeastern Minnesota.

R. D. Irving, 1883 (U. S. G. S. 3d Ann. Rept., pl. 14, pp. 143–146). *Agate Bay group.*—Succession of relatively very thin beds with very highly vesicular stratiform amygdaloids, which must make up two-thirds of group; includes thin seams of reddish sss. and cgls. Overlies Lester River group and underlies Beaver Bay group, all included in Keweenaw series. Exposed on Agate Bay, NE. of Duluth.

Agathla sandstone.

Lower Triassic: Northeastern Arizona (Navajo County) and southeastern Utah.

D. Hager, 1924 (Min. and Oil Bull., vol. 10, No. 2, p. 137; No. 4, pp. 383–384, 423, 437). *Agathla ss.*—Pinkish ss., 10 to 15 ft. thick, a local representative of Moencopie beds. Uncon. underlies Shinarump cgl. near Agathla Peak, NE. Ariz. [N. part of Navajo Co.].

A. A. Baker and J. B. Reeside, Jr., 1929 (A. A. P. G. Bull., vol. 13, No. 11, p. 1441, etc.). [See note under *Agathla sh.*]

Agathla shale.

Lower Triassic: Northeastern Arizona (Navajo County) and southeastern Utah.

D. Hager, 1924 (Min. and Oil Bull., vol. 10, No. 2, p. 137; No. 4, pp. 383–384, 423, 437). *Agathla sh.,* 40 to 50 ft. thick, underlies Agathla ss. and overlies Kaibab ls. near Agathla Peak, NE. Ariz. [N. part of Navajo Co.]. Is local representative of Moencopie beds.

A. A. Baker and J. B. Reeside, Jr., 1929 (A. A. P. G. Bull., vol. 13, No. 11, pp. 1441, etc.). The Agathla ss., Agathla sh., Kaibab ls., Coconino ss., and underlying sh. of Hager's 1924 rept all belong to true Moenkopi fm.

Agawa iron-formation member (of Knife Lake slate).

Pre-Cambrian (Knife Lake series): Northeastern Minnesota (Vermilion district) and western Ontario.

J. M. Clements, 1903 (U. S. G. S. Mon. 45). *Agawa fm.*—Petrographically same as Soudan fm. Is iron bearing, 0 to 50± ft. thick. Conformably underlies Knife Lake slates and grades into underlying Ogishke cgl. Named for exposures on shores of Agawa Lake, Ont., 1½ mi. N. of int. bdy.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), included *Agawa iron-fm. memb.* and Ogishke cgl. memb. in Knife Lake sl., which they tentatively removed from Huronian series and assigned to their Knife Lake series (pre-Huronian and post-Laurentian).

†Agnotozoic era.

A term that has been used to include all pre-Camb. time, and also applied (originally) to the part of pre-Camb. time that was formerly called "Algonkian period." See U. S. G. S. Bull. 769, pp. 14–16.

†Agoniatite limestone.
†Agoniatites limestone.

Paleontologic terms applied in some early N. Y. repts. to a ls. occurring at a lower horizon in Marcellus sh. than Stafford ls. Disappears W. of Seneca Lake. Most fully developed in eastern N. Y. counties 20 to 30 ft. above base of Marcellus.

Agua sandstone member (of Santos shale).

Miocene (lower): California (Temblor Range).

L. M. Clark and A. Clark, 1935 (A. A. P. G. Bull., vol. 19, No. 1, p. 137). A ss. memb. in upper part of Santos sh., that is traceable from vicinity of Carneros Creek to mouth of Cedar Canyon, several mi. farther NW., and in places reaches thickness of 300+ ft., is here referred to as "Agua ss." It contains Vaqueros fossils at several localities.

Aguacate series.

Age (?): Costa Rica.

J. Romanes, 1912 (Geol. Soc. London Quart. Jour., vol. 69, p. 122).

Aguadulce formation.

Pleistocene: Panama.

O. H. Hershey, 1901 (Calif. Univ. Dept. Geol. Bull., vol. 2, p. 258).

Agua Fria.

Probably lower Mesozoic: Sierra Nevada, California.

N. L. Taliaferro, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 149). *Agua Fria slates, lss., cherts, and tuffs,* 2,000+ ft. thick. Top fm. of Tuolumne group (probably lower Mesozoic) on Merced River and southward into Indian Gulch quad.

Aguas Buenas limestone.

Cretaceous (?): Puerto Rico.

D. R. Semmes, 1919 (N. Y. Acad. Sci., Scientific survey of Porto Rico and Virgin Islands, vol. 1, p. 64).

Agueguexquite formation.

Miocene: Vera Cruz, Mexico.

H. E. Thalmann, 1935 (Geol. Soc. Am. Proc. 1934, p. 116).

Aguja formation.

Upper Cretaceous (Gulf series): Western Texas (Brewster County).

W. S. Adkins, 1933 (Univ. Tex. Bull. 3232, pp. 239, 271, 505). *Aguja fm.*—When in 1907 Dr. Udden described his "Rattlesnake" fm., the name had already been used for a fm. in Oreg. Pliocene. Accordingly the name *Aguja* is here substituted for Udden's name. Type loc. is Sierra Aguja (Needle Peak), in the flat in front of Santa Helena fault scarp, 6 mi. S. of Terlingua, Brewster Co. The slopes and surrounding flats contain a practically complete section of the beds, overlain by Tornillo clay, and situated close to Udden's original type loc. [Distribution and fossils discussed.] Upper part of fm. is of Navarro age and lower part of Taylor age.

Ahtell diorite.

Carboniferous: Southeastern Alaska (central Copper River region).

W. C. Mendenhall, 1905 (U. S. G. S. P. P. 41, p. 38, map). *Ahtell diorite.*—Intrusive. Chiefly quartz diorite or quartz diorite porphyry. Probably mainly upper Carbf. and perhaps extending into Perm. Composes hills drained by W. tributaries of Ahtell Creek.

Aibonito conglomerate.

Cretaceous: Puerto Rico.

C. P. Berkey, 1915 (N. Y. Acad. Sci. Annals, vol. 26, p. 61).

†Aiken beds.

Pliocene (?) and Upper Cretaceous: Western South Carolina (Aiken County).

E. Sloan, 1904 (S. C. Geol. Surv., ser. 4, Bull. 1, p. 72). *Aiken beds.*—The deposits exposed at Aiken, which include (descending) : Plio. (?), 40 ft. (divided into eolean sands, 8 ft.; Lafayette cobbles, 2 ft.; Lafayette loams, 10 ft.; Lafayette mottled clay, 6 ft.; coarse sands, 13 ft.; pebbles, 1 foot) ; Cret., 274 ft. (divided into Middendorf beds, 93 ft.; Upper Hamburg beds and Lower Hamburg beds, 181 ft.).

Ainoni volcanics.

Pleistocene (late) : Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and Gd. Water Res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Ainoni volcanics.*—Basalt and cinders. The basalt forms massive walls along Ainoni and Maunawili Streams and generally shows columnar jointing. Included in middle part of Honolulu volcanic series [q. v.]. Named for Ainoni Spring, which issues from E. margin of the basalt.

Ainslie sandstone.

Carboniferous (Mississippian) : Nova Scotia.

P. D. Trask and K. F. Mather, 1927 (Wash. Acad. Sci. Jour., vol. 17, p. 324).

Ainsworth formation.

Ainsworth series.

Paleozoic: British Columbia.

S. J. Schofield, 1919 (Canada Geol. Surv. Summ. Rept. 1919, pt. B, p. 60) ; 1920 (Canada Geol. Surv. Mem. 117, p. 11). *Ainsworth fm.* included in *Ainsworth series.*

Ainsworth formation.

Upper Cretaceous: Southwestern South Dakota and northwestern Nebraska.

F. Ward, 1922 (S. Dak. Geol. and Nat. Hist. Surv. Bull. 11). The Pierre of SE. part of Pennington Co. and SW. part of Jackson Co., S. Dak., includes at top 35 ft. of thin-bedded sandy sh., of predominantly yellow brown color but variegated with browner and purpler colors in upper part. These beds are called *Interior phase of Pierre.* The fossils warrant placing them in Pierre, although in field they were called *Fox Hills.* If accepted as Pierre the strong color contrast and sandier texture require explanation. The Nebr. Surv. has called these beds *"Rusty memb." of Pierre* (E. F. Schram, personal communication). They grade into underlying Pierre.

H. J. Cook, 1922 (Pan-Am. Geol., vol. 37, No. 5, pp. 421–424). The "Rusty" memb. of Pierre shales, or *Ainsworth fm.*, as it is sometimes called, uncon. underlies Chadron fm. to S. and E. of Black Hills uplift in S. Dak. and Nebr.

Air Point granite.

Pre-Cambrian: Southwestern Virginia (Roanoke County region).

A. I. Jonas, 1933 (Geol. Soc. Am. Bull., prel. list of titles and abstracts, vol. 44, pp. 29–30). *Air Point granite.*—Pink, orthoclase-microcline granite that intrudes granodiorite in Virginia Blue Ridge region. Is pre-Camb., as Lower Camb. sediments contain fragments of it.

A. S. Furcron, 1934 (Jour. Geol., vol. 42, pp. 407–410). *Air Point granite* was named by Jonas, from Air Point on Bent Mtn, Roanoke Co. Is widespread in Park area. Is probably youngest intrusive in dist., except some dikes, and is believed to be younger than Old Rag granite.

Aitkin formation.

Pre-Cambrian (upper Huronian) : Central Minnesota (Aitkin, Crow Wing, and Cass Counties).

C. Zapffe, 1930 (Lake Superior Min. Inst. Proc., vol. 28, pp. 101–106). The Upper Huronian (Cuyuna series) of Cuyuna dist. is lithologically divided into 3 conformable fms. (descending) Crow Wing fm., Aitkin fm., and basal cgl. The Aitkin fm. consists of gray slates and phyllites. It contains some iron carbonate, but extensive iron-bearing lenses are virtually lacking, and volcanics are absent.

It is nonmagnetic. It underlies large area in N. and E. parts of Aitkin Co., and extends into Crow Wing and Cass Counties.

†Ajax quartzite.

Middle Cambrian: Southeastern Arizona (Tombstone district).

J. A. Church, 1903 (Am. Inst. Min. Engrs. Trans., vol. 33, pp. 3–37). *Ajax qtzite*, 500 ft. thick, overlies [?] Randolph ls. and underlies Emerald ls.

F. L. Ransome, 1920 (U. S. G. S. Bull. 710D). "Ajax" qtzite of Church is Bolsa qtzite.

Ajax limestone.

Lower Ordovician: Central northern Utah (Tintic district).

G. F. Loughlin, 1919 (U. S. G. S. P. P. 107). *Ajax ls.*—In descending order: (1) Dark bluish gray cherty mag. ls., upper part calc., 440± ft.; (2) Emerald dol. memb. (30 to 40 ft. of cream white dol.); (3) dark-gray clouded dol. or highly mag. ls., partly cross-bedded and in part consisting of thin conglomeratic beds, also many thin lenses and nodules of light-gray chert, with qtzite and ls. cgl. at base, 90 ft. Grades into overlying Opohonga ls. and uncon. overlies Opex dol. Named for Ajax mine.

Ajibik quartzite.

Pre-Cambrian (middle Huronian): Northwestern Michigan (Marquette district).

C. R. Van Hise and W. S. Bayley, 1895 (U. S. G. S. 15th Ann. Rept., pp. 540+). *Ajibik qtzite.*—Has two main areas: A western one in which it rests upon Archean, and an eastern one in which it rests on Wewe sl. Where it rests on Archean the basal part is a cgl. or recomposed rock, the material of which is derived mainly from immediately subjacent fm. These basal cgls., slates, and graywackes quickly grade up into qtzite. Where the Ajibik rests on Wewe sl. there is usually an intermediate phase or interstratification of the two. In one exceptional locality (in sec. 6, T. 47 N., R. 25 W.) the basal memb. of the qtzite is a cgl. interstratified with sl., the fragments of the cgl. being mainly from Wewe sl. Central part of fm. in its ordinary phases is a rather pure, typical, vitreous qtzite. In some places this qtzite becomes conglomeratic and bears small pebbles of white quartz or red jasper. In other places it is interstratified with belts of mica sl. or graywacke. Thickness of fm. 700 to 900 ft. Conformably underlies Siamo sl. Typical exposures on Ajibik Hills, NE. of Palmer.

Akins shale member.

Pennsylvanian: Central eastern Oklahoma.

J. A. Taff, 1905 (U. S. G. S. Tahlequah folio, No. 122). *Akins sh. memb.*—Chiefly blue and black clay sh., with thin sss. Thickness 175 ft. Top memb. of Winslow fm.

C. W. Wilson, Jr., 1935 (A. A. P. G. Bull., vol. 19, No. 4, p. 503). The Atoka, Hartshorne, McAlester, and Savanna fms. and a part of Boggy sh. are directly traceable into Winslow fm. as heretofore mapped in Muskogee Co. [Wilson identified the subdivisions enumerated above and did not use *Winslow fm.*]

T. A. Hendricks, C. H. Dane, and M. M. Knechtel, 1936 (A. A. P. G. Bull, vol. 20, No. 10, p. 1347). *Winslow fm.* is now abandoned. Wilson has recognized in it Atoka, Hartshorne, McAlester, Savanna, and Boggy fms.

It is still undet. to which of fms. into which †Winslow fm. is now divided the Akins sh. memb. belongs. (H. D. Miser, personal communication Feb. 1937.)

Named for Akins, Sequoyah Co.

Akron dolomite.

Silurian (Cayugan): Western New York and Ontario.

A. W. Grabau, 1909 (Geol. Soc. Am. Bull., vol. 19, pp. 544, 550). *Bullhead or Akron ls.*—Probably =Amherstburg bed of Mich. and Cobleskill of eastern N. Y. Name derived from exposure in village of Akron, Erie Co., N. Y.

The equivalency of the Cobleskill and Akron was accepted by most geologists, who continued to apply *Cobleskill* to the dol. of western N. Y. as well as of other parts of the State. C. A. Hartnagel, 1912 (N. Y. State Hdb. 19, p. 57) stated: *Cobleskill ls.* is absent along its line of outcrop across the State only in part of Albany Co.; in different parts of State it rests on Bertie, Brayman, Rosendale, Decker Ferry, and "Hudson River" fms. In 1917, however, G. H. Chadwick (Geol. Soc. Am. Bull., vol. 28, pp. 173–174) revived *Akron dol.* for western N. Y., stating: "The correlation eastward of the Akron with the Cobleskill remains to be worked out anew, but it is now believed to be substantially correct." The Canada Geol. Survey appears to employ *Akron dol.* for this fm. (See M. Y. Williams, 1919, Canada Geol. Surv. Mem. 111; and Cole, 1925, Ontario Dept. Mines 34th Ann. Rept., vol. 34, pt. 2, p. 10), while U. S. Geol. Survey designates it *Cobleskill dol.* (See Niagara folio, No. 190.) Grabau stated it is same as his Greenfield ls. (See under *Greenfield ls.*)

H. L. Alling, 1928 (N. Y. State Mus. Bull. 275, p. 21), showed *Akron* as younger than Cobleskill, and gave the sequence of beds given by Chadwick: Akron, Williamsville, Scajaquada (=Cobleskill), Falkirk, Oatka, but stated: Position of Cobleskill is still a matter of doubt. G. H. Chadwick, 1930 (Geol. Soc. Am. Bull., vol. 41, pp. 80–82), continued to use *Akron dol.*

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 343–344). ***Cobleskill ls.*** is a typical coral facies, and while it does not show the reef character it has the reef species. To the dolomitic phase in Erie Co. the name ***Akron dol.*** has been applied. The Akron dol. is a little later faunal development than the Cobleskill. [Lists characteristic species of Cobleskill dol., also of ***Akron phase.***]

†Alabama period.

Tertiary: United States.

J. D. Dana, 1875 (Man. Geol., 2d ed., pp. 490–494, 509–510, 523). Time term to include, in Ala., the Vicksburg, Jackson, Claiborne, and Buhrstone, also contemp. deposits in other States. [He also used ***Alabama group.***]

†Alabama.

Eocene (middle): Alabama.

E. A. Smith, 1888 (Ala. Geol. Surv. Rept. Prog. 1884–88, geographic map of Ala.). [On this map the name ***Alabama*** (***Claiborne***) is applied to deposits underlying St. Stephens ls. and overlying the Lignitic, and the deposits thus designated are divided into Claiborne above and Buhrstone below.]

Replaced by Claiborne group.

Apparently named for exposures in Ala.

†Alabama white limestone.

Tertiary: Alabama.

T. L. Casey, 1902 (Phila. Acad. Nat. Sci. Proc., vol. 53, p. 513). White ls. exposed on Tombigbee River near St. Stephens and on Alabama River near Claiborne. [Same as †St. Stephens ls. (Olig. and upper Eo.).]

Alachua formation.

Pliocene (lower): Northern Florida.

W. H. Dall, 1892 (U. S. G. S. Bull. 84, pp. 127–130, 157, 320). ***Alachua clays.***—Deposits of clay containing bones of extinct mammalia. These clays occur in sinks, gullies, and other depressions in Mio., Upper Eo., and later rocks of Fla., especially on W. anticline in higher parts of Alachua Co., and along banks of many rivers and streams. They appear in Alachua Co. to have been subjected to denudation after deposition, so that only those parts protected by their depressed position in cavities or gullies of harder rock remain undisturbed. The clay is bluish or grayish and extremely tenacious, so that it is most difficult to discover remains embedded in it. Occurs in patches, usually in depressions, but occasionally in short ridges whose lateral buttresses of limerock have disappeared through dissolving agency of rain water and carbon dioxide. [Mentions many localities of its occurrence in Alachua Co.]

G. C. Matson and F. G. Clapp, 1909 (Fla. Geol. Surv. 2d Ann. Rept., p. 133). *Alachua clay* as here used includes "Peace Creek bone bed" of Dall, "which appears to be a local phase of the fm. which may have been eroded and redeposited in its present condition."

E. H. Sellards, 1914 (Fla. Geol. Surv. 6th Ann. Rept., pp. 161–162). *Alachua clay* and *Dunnellon fm.* are merely different facies of a single fm., and *Dunnellon* should not be used any longer.

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept.). *Alachua fm.* is here used to include "Dunnellon" fm., discarded by Sellards. The Alachua is a residual deposit derived from Hawthorn fm. and containing Plio. fossils. It uncon. overlies Ocala ls. or Tampa ls. and is overlain by loose wind-blown sand. The part of fm. to which name *Alachua* was originally applied consists chiefly of clay, accumulated in ponds or sinks, and at least 15 ft. thick. Great bulk of fm. that Sellards called "Dunnellon" is chiefly compact white or gray sand, closely resembling the sand in Hawthorn fm., from which it no doubt is derived. Greater part of Alachua fm. seems not to have been laid down under water. Sellards gives thickness of "Dunnellon" fm. as 75 to 100 ft.

Named for its many exposures in Alachua Co.

Alameda formation.

Pleistocene: Western California (San Francisco region).

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). *Alameda fm.*—Yellow sandy clay, of very uniform fine texture, which without much change in character passes into beds that carry marine shells. Intercalated with these marine deposits are nonpersistent beds of gravel of fluviatile origin, the conditions indicating delta formation alternating with marine or estuarine deposition. Thickness several hundred ft. Uncon. underlies San Antonio fm. and uncon. overlies Campus fm. Named for fact it is well developed at Alameda.

Alamito shale.

Pennsylvanian: New Mexico.

C. R. Keyes, 1906 (Jour. Geol., vol. 14, pp. 147–154), applied *Alamito shales* to beds said to uncon. overlie Lake Valley ls. Derivation of name not stated.

Alamitos zone.

A subsurface petroliferous zone, about 670 ft. thick, in Fernando group of Long Beach field, Los Angeles Basin, southern Calif. Is lower than Wilbur zone and higher than Brown zone. Includes Booth zone. Named for discovery well Alamitos No. 1.

Alamo sandstone member (of Yegua formation).

Eocene (middle): Northeastern Mexico (Tamaulipas).

W. G. Kane and G. B. Gierhart, 1935 (A. A. P. G. Bull., vol. 19, No. 9, pp. 1374, 1384). [See under *Mier ss. memb.*]

Alamosa formation.

Late Pliocene or early Pleistocene: Central southern Colorado (San Luis Valley).

C. E. Siebenthal, 1910 (Sci., n. s., vol. 31, p. 745; U. S. G. S. W. S. P. 240, p. 40). *Alamosa fm.*—Blue clays and interstratified sands; some gravel, and occasionally, in depth, boulders. Thickness 725 to 1,250 ft. Of late Plio. or early Pleist. (preglacial) age. Uncon. overlies Santa Fe fm. Occurs at foot of Conejos Range, at foot of Blanca Peak, and at other places. Occupies bottom of San Luis Valley proper. Named for Alamosa, Conejos Co., near center of valley.

†Alaqua phase.

Miocene (middle): Northwestern Florida.

L. C. Johnson, 1893 (Sci., vol. 21, pp. 90–91). *Alaqua phase of the Mio.* is the Chesapeake. It overlies Euchee phase, and has larger shells than the Euchee. It is the fm. of upper bluffs at Abes Spring, and is perfectly and largely developed on bluffs of Yellow River from Ala. line to Milligen, Fla., the most northern of these beds being the low shell landing at Oak Grove, 6 mi. S. of Ala. line.

According to studies of Julia Gardner these beds are Shoal River fm., and Johnson's Euchee phase is probably younger and belongs to Choctawhatchee fm.

Named for Alaqua Creek, Walton Co.

Alaska Bench limestone.

Carboniferous (Pennsylvanian or Mississippian): Central Montana (Big Snowy Mountains).

O. W. Freeman, 1922 (Eng. and Min. Jour.-Press, vol. 113, No. 19, pp. 826–827). *Alaska Bench ls.*—Excessively hard, gray, fossiliferous ls. that weathers red. Forms a series of hogbacks and sloping benches around Big Snowy Mtns. Well exposed on top of Alaska Bench, E. of the Snowies, where it is 100 to 150 ft. thick, and just below it are 300 ft. of white to red sss., interbedded with varicolored sh., here named *Tyler ss.* Is overlain by 100 ft. of nonfossiliferous black sh. usually classified as part of Quadrant but which may in part belong to Ellis fm. [In his generalized section of Quadrant fm. for central Mont., on p. 827, Freeman showed 100 ft. of gray sh. btw. Tyler ss. and Alaska Bench ls., and 100 ft. of black sh. above Alaska Bench ls., all of which he included in the Quadrant.]

Alazan shale.

Tertiary: Mexico.

E. T. Dumble, 1912 (Sci., n.s., vol. 35, p. 907). [Assigned to Eo.]

Many others assigned this fm. to Eo.; but T. W. Vaughan (Geol. Soc. Am. Bull., vol. 35, p. 731, 1924) and C. Schuchert (Hist. geol. Antillean-Caribbean region, 1935, p. 199) assigned it to Olig.

Albanian series.

A term proposed by C. [R.] Keyes to replace Albany ls. (Perm.) of north-central Tex., "until it is made certain the Albany ls. and Vidrio ls. are not one and the same fm." (See Pan-Am. Geol., vol. 57, pp. 350, 351, etc., 1932, and vol. 59, pp. 144, 146, etc., 1933.)

Albany clay.

Pleistocene: Eastern New York and western Vermont.

E. Emmons, 1846 (N. Y. Nat. Hist., Agric., vol. 1, pp. 202–204). ***Albany clay.***—At Albany this Tert. clay is an important material for making brick, and is 10 to 20 ft. thick. In excavations at Albany a boulder is sometimes found in the clay, but always near top. [He also described *Lake Champlain clays*, and stated that the Tert. of the valley of Hudson is continuous with that in the valley or basin of the Champlain, and does not differ essentially from it.]

Asa Fitch, 1850 (Historical, topographical, and agricultural survey of county of Washington [N. Y.], pt. 3, Rocks and soils, pp. 872–878, 890–891). ***Albany clay fm.***—This is the gray and blue clay of the Quat. Div. of Prof. Mather, the Tert. clay or Albany and Champlain clays of Dr. Emmons, in the volumes of the State Natural History. As neither its geological age or name is well settled, I prefer designating it *Albany clay*, a name by which more readers will obtain a definite idea respecting it than by any other. Is well developed at Albany, from thence it reaches N., forming bluffs or river hills upon both sides of the Hudson, and continuously to Fort Ann, if not to Whitehall, and onward through whole length of Champlain Valley, particularly upon its Vt. side. Throughout most of its extent it rests on Hudson River sl., though in places extensive beds of gravel, 30 ft. thick, intervene btw. it and the sl. Is overlain by Saratoga sand fm. Is of blue, brown, gray, and white colors, and 6 to 150 ft. thick.

W J McGee, 1888 (U. S. G. S. 7th Ann. Rept., p. 611). ***Albany clays*** overlie the boulder clay in vicinity of Albany, and both belong to second ice invasion of glacial period.

F. J. H. Merrill, 1903 (N. Y. State Mus. 21st Rept. State Geol., p. r12). The so-called *Albany clays* are somewhat earlier in age than the typical marine clays of Champlain Valley.

J. B. Woodworth, 1905 (N. Y. State Mus. Bull. 84, p. 220). The term "Albany clays" was specifically applied to the glacial rock flours of Hudson Valley N. and S. of Albany in 1846. Included in Hochelagan fm.

Has also been called "Lake Albany clays."

Albany granite.

Late Devonian or late Carboniferous: Northern New Hampshire (White Mountains in north part of Carroll County).

C. H. Hitchcock, 1874 (Geol. N. H., pt. 1, btw. pp. 508 and 545) and 1877 (Geol. N. H., pt. 2, pp. 143, etc.). *Albany granite.*—Porphyritic granite spotted with rounded feldspars. Has been called trachytic. Thickness 1,000 ft. Younger than Conway granite and older than Chocorua granite.

G. W. Hawes, 1881 (Am. Jour. Sci., 3d, vol. 21, pp. 21+) and 1901 (Yale Bi-Cen. Pub., Contr. Min. and Petrog., pp. 400–414). *Albany granite* is a spotted or trachytic eruptive granite, younger than Conway granite and younger than andalusite schist, and believed to be older than Concord granite. Named by Prof. Hitchcock on account of extensive development in Albany, N. H. [In N. part of Carroll Co.]

M. Billings, 1928 (Proc. Am. Acad. Arts and Sci., vol. 63, No. 3, map, pp. 67–137), divided *Albany group*, as he called it, into 3 petrographic types, placed it as older than his Chocorua and Conway groups of granite, and included all in *Dev. (?)*. In 1935 Billings assigned all of these intrusives to late Dev. or late Carbf.

M. Billings, 1935 (letter dated Aug. 27). *Albany granite* belongs to White Mtn magma series.

†Albany formation.

Permian: Northern Texas and southwestern Oklahoma.

E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, p. lxvii). *Coleman-Albany series.*—Shales, clays, and lss., barren of coal, overlying Waldrip-Cisco series and underlying Wichita beds.

W. F. Cummins, 1891 (Tex. Geol. Surv. 2d Ann. Rept., pp. 361–402). *Albany div.*—Largely lss. and shales, with some ss. at base. Thickness 1,180 ft. Overlies Cisco beds and is overlain by Clear Fork beds. [See 1891 entry under *Wichita fm.*] Well developed in vicinity of Albany, Shackelford Co., Tex.

Has for many years been considered same as Wichita fm., better established name. See further explanation under *Wichita fm.*

Albany black shales.

An abbreviated form of *New Albany sh.* used by C. [R.] Keyes. (See Pan-Am. Geol., vol. 48, p. 147, 1927.)

Albany conglomerate.

Pre-Cambrian: Michigan.

See *Albany and Boston cgl.*

Albany conglomerate.

Lower Ordovician: Northeastern Vermont (Orleans County).

C. H. Richardson, 1929 (16th Rept. Vt. State Geol., pp. 107–110). *Albany phase of Irasburg cgl.* is characterized by presence of Camb. marble, by porphyritic andesite boulders more than a foot in diam., and by large well smoothed boulders of pure quartz. The porphyritic andesite boulders are present in both Irasburg and Albany.

C. H. Richardson and J. E. Maynard, 1933 (18th Rept. Vt. State Geol., p. 343). The *Irasburg, Albany and Northfield cgls.* form base of Ord. in eastern Vt.

Albany porphyritic nordmarkite.

Devonian (?): New Hampshire.

L. Kingsley, 1931 (Am. Jour. Sci., 5th, vol. 22, p. 143).

Albany quartz syenite.

Late Carboniferous (?): New Hampshire.

C. R. Williams, 1934 (Appalachia, vol. 20, No. 4, Summer Mag. No., p. 73).

Albany and Boston amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. R. Marvine, 1873 (Mich. Geol. Surv. vol. 1, pt. 2, pp. 25–27, 80, 81, 85, and chart). Younger than Albany and Boston cgl. and older than Pewabic West cgl.

Belongs to Ashbed group. The mineralized part is the Albany and Boston lode.

Named for occurrence in Albany and Boston mine, Houghton Co.

†Albany and Boston conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. R. Marvine, 1873 (Mich. Geol. Surv. vol. 1, pt. 2, pp. 53–57, 61, 81, 84, 86 and chart). Is cgl. No. 15 of Houghton Co., and=Allouez cgl. of Keweenaw Co.

Is same as Allouez cgl., of Central Mine group.

Named for occurrence in Albany and Boston mine, Houghton Co.

Albany and Boston flow.

Includes Albany and Boston amygdaloid and underlying trap.

Albee formation.

Pre-Silurian (Upper Ordovician?): Northwestern New Hampshire (Ammonoosuc River region).

M. Billings, 1934 (Sci., Jan. 19, vol. 79, No. 2038, pp. 55–56). *Albee qtzite.*—Qtzite and sl., 4,000 ft. thick, underlying Ammonoosuc volcanics in Littleton and Moosilauke quads. No fossils, but are pre-Sil. and probably Upper Ord. [The name appears to replace Lisbon qtzite of his Feb. 1933 paper in Am. Jour. Sci., 5th, vol. 25, No. 146, p. 149.]

M. Billings, 1934 (Am. Jour. Sci., 5th, vol. 28, Dec., pp. 413–415), mapped *Albee fm.* (pre-Sil., Upper Ord. ?) at and around Albee Hill, Littleton quad. and other parts of Littleton and Moosilauke quads.

M. P. Billings, 1935 (Geology of Littleton and Moosilauke quads., N. H., maps and p. 9). *Albee fm.*—A group of black and green slates, argill. qtzite, and qtzite, typically exposed on Gardner Mtn. Type loc. is that part of Gardner Mtn. which lies btw. Hunt Mtn. (just SW of Littleton quad.) and Albee Hill [in Littleton quad.], from which name was chosen. Probably Upper Ord.

Alberca sandstone member (of Yegua formation).

Eocene (middle): Northeastern Mexico (Tamaulipas).

W. G. Kane and G. B. Gierhart, 1935 (A. A. P. G. Bull., vol. 19, No. 9, p. 1384). *Alberca ss.*—Massive gray ss., 80 ft. thick, lying 904 ft. below top of Yegua fm. and 559 ft. above base of the Yegua, in section from San Pedro de Roma on Mexican side of Rio Grande from Roma [Starr Co.], Tex. Lies 132 ft. above Alamo ss. memb. [Derivation of name not stated.]

Alberhill clay.

Eocene: Southern California (Riverside County).

P. H. Dudley, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, p. 223). *Alberhill clays (Eocene)*. [All there is about it. Paper describes area btw. towns of Riverside and San Jacinto and Corona and Elsinore.]

P. H. Dudley, 1935 (Calif. Jour. Mines and Geol., vol. 31, No. 4, map, pp. 491, 505). The Eo. Alberhill clays have recently been described in detail by J. C. Sutherland (Calif. State Div. Mines, State Min. Rept. 31, Calif. Jour. Mines and Geol., Jan. 1935). [On map Dudley assigns this clay to *Eocene (Martinez)*.]

Alberta shale.

Upper Cretaceous: Alberta.

C. S. Evans, 1930 (Canada Geol. Surv. Summ. Rept. 1929, pt. B, p. 27).

Later repts assign *Alberta fm.* to Upper and Lower Cret.

Albertan.

A name proposed by G. M. Dawson (Jour. Geol., vol. 3, 1895, pp. 507–511) for the pre-Kansan drift of Canada. Probably corresponds to Nebraskan drift of United States. Named for province of Alberta.

Albert Canyon division.

Pre-Cambrian: British Columbia.

R. A. Daly, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 170).

Albertian series.

Name suggested by C. [R.] Keyes (Pan.-Am. Geol., vol. 44, pp. 217, 218, 1925, and vol. 46, pp. 207–208, 1926) to cover basal part of his expanded Selkirkic period, but it "may not include all the strata of Early Selkirkic age." Named for exposures in Albert Canyon, in which Canadian Pacific Railway runs westward out of the Selkirks.

Albin shale.

Upper Cambrian: Northeastern Iowa.

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, pp. 319, 326). Berkey (Am. Geol., vol. 20, p. 373, 1897), in Minn., without defining either upper or lower limits, proposed *Franconia ss.* for this part of Mid Cambric succession as exposed at St. Croix Dalles. This name, after proper definition, might be retained were it not for fact that it was long ago preoccupied for a fm. in N. H. It therefore becomes invalid. Hence *Albin shales* is substituted. Uncon. underlies Allamakee dol. and uncon. overlies Dresbach ss. Named for fine exposures at Albin, Allamakee Co.

Albion gravel.

Pleistocene: Central northern Iowa.

S. W. Beyer, 1897 (Iowa Geol. Surv. vol. 7, pp. 210, 231). *Albion gravels.*—Stratified sands and gravels, 10 ft. thick, underlying Kansan till and forming base of section at Albion, Marshall Co. Assigned to Aftonian stage.

Albion schist member (of Westboro quartzite).

Pre-Cambrian: Eastern Rhode Island.

B. K. Emerson and J. K. Perry, 1907 (U. S. G. S. Bull. 311, pp. 8, 10–13, and map). *Albion schist memb. of Grafton (Westboro) qtzite.*—Quartz phyllite and fine-grained micaceous quartz schist upon which village of Albion stands. Of light gray color. Is a band down center of Grafton qtzite, which consists of two flanking bands of granular massive qtzite. The finer grain and presence of considerable beds of phyllite distinguish this memb. from rest of Grafton qtzite.

Albion sandstone.

Silurian (early): Western New York and Ontario.

E. O. Ulrich, 1913 (12th Int. Geol. Cong., Canada, pp. 26, 27, 30, 36, 49). *Albion stage* (also *Albion group*).—The need of a distinct formational name for upper Medina having become apparent in preparation of Niagara folio in course of publication by U. S. Geol. Survey, Dr. J. M. Clarke has cooperated by suggesting *Albion.* The fm. rests on lower Medina or Queenston. [This paper was in print and distributed at Toronto on or before the Cong. convened, which was Aug. 7, 1913.]

In U. S. G. S. Niagara folio (No. 190)—a small part of the edition of which was completed Aug. 17, 1913—the rocks btw. Queenston sh. and Clinton fm. were designated *Albion ss.*, of which Whirlpool ss. of Grabau constituted basal memb., the top beds ("Grey band" of early repts.) being named *Thorold ss. memb.*, the intervening beds consisting of red ss. and red and gray shales. This is classification still employed by U. S. Geol. Survey. Some geologists, however, have advocated abandoning *Albion* and restricting *Medina* to this upper part of original Medina. Others have recommended the use of *Cataract fm.* for lower 50 ft. of the Albion, and restriction of *Medina* to the beds above the Cataract. Others have recommended using *Cataract fm.* to include all beds included in Albion ss. Others have recommended restricting *Albion* to beds btw. Whirlpool ss. and Thorold ss. Others have recommended restricting *Albion* to beds btw. base of the Thorold and top of Queenston sh. (See fuller explanation under *Medina group, Cataract fm., Thorold ss. memb.*, and *Whirlpool ss. memb.*)

Albion moraine.

Pleistocene (Wisconsin stage): Western New York. Shown on moraine map (fig. 8) in U. S. G. S. Niagara folio (No. 190), p. 17. Named for Albion, N. Y.

Albion Range group.

Pre-Cambrian: Central and southern Idaho.

A. L. Anderson, 1934 (Jour. Geol., vol. 42, No. 4, pp. 377–379). The strata invaded by Cassia batholith are qtzites in lower part of the pre-Camb. *Albion Range group* here substituted for *Harrison series*, which is preoccupied. This group continues southward into Raft River Range of NW. Utah and resembles a series of pre-Camb. rocks in Wasatch Range, which Blackwelder has shown to underlie sss., cgls., and slates of late Algonkian age. Writer considers Albion Range group to be of pre-Beltian age. The group consists mainly of metaqtzites with some intercalated marbles and schist in its middle and upper parts. Lower part is more than 4,000 ft. thick and consists mainly of medium to fine-grained pure qtzite, completely recrystallized by dynamo-metamorphism.

†Albirupean formation.

Upper Cretaceous: Eastern Maryland and Virginia.

P. R. Uhler, 1888 (Am. Phil. Soc. Proc., vol. 25, p. 42 and map). *Albirupean fm.* here proposed for the great sandrock system lying uncon. beneath the greensand Cret. Is more decidedly marine than underlying Baltimorean. Excellent sections on Severn River show nearly all members of Albirupean fm. Thickness 200 ft.

B. L. Miller, E. B. Mathews, A. B. Bibbins, and H. P. Little, 1917 (U. S. G. S. Tolchester folio, No. 204, p. 6). The sands of Raritan fm. are in several places indurated by iron oxide or silica. The best examples of such sss. are the White Rocks near mouth of Patapsco River, which furnished Uhler with the name "Albirupean" for this series of strata.

Albirupean is derived from *albus*, white, and *rupes*, a rock.

Albirupean black marl.

Upper Cretaceous: Maryland.

P. R. Uhler, 1901 (Md. Acad. Sci. Trans., n. s., vol. 1, btw. pp. 185 and 201). *Albirupean black marl.*—A great marl bed which in many places forms summit of Albirupean fm.

Alboroto quartz latite (also **Alboroto group**). (In Potosi volcanic series.)

Miocene: Southwestern Colorado.

E. S. Larsen, 1917 (Colo. Geol. Surv. Bull. 13, pp. 20, 36). *Alboroto fm.*—A fm. of Potosi volcanic series. Underlies Huerto fm. and overlies Summitville fm. in Platoro-Summitville dist.

W. H. Emmons and E. S. Larsen, 1923 (U. S. G. S. Bull. 718). *Alboroto fm.*—In Platoro-Summitville dist. consists of 0 to 3,000 ft. of quartz latite and rhyolite flows with some tuff. Is overlain by Huerto fm. and rests uncon. on Summitville andesite. In Creede dist. the Alboroto becomes a *group*, divisible into 6 fms., and is uncon. overlain by Piedra fm. (the Huerto being absent) and rests uncon. on rocks much older than Summitville andesite.

E. S. Larsen, 1935 (U. S. G. S. Bull. 843), changed name to *Alboroto quartz latite*, and stated (p. 80) that the fm. is confined to N. and E. flanks of Alboroto dome.

Albright limestone. (In Conemaugh formation.)

Pennsylvanian: Northeastern West Virginia and western Maryland.

R. V. Hennen and D. B. Reger, 1914 (W. Va. Geol. Surv. Rept. Preston Co., p. 140). *Albright ls.*—Dark gray ls. 2 ft. thick. Underlies Bakerstown (Barton[?]) coal and rests on 5 to 20 ft. of fire clay sh. that overlies Pine Creek ls. Occurs at Albright, Preston Co., W. Va.

Md. Geol. Surv. (vol. 11, 1922) applied *Albright ls.* in Md. to a younger ls., underlying the fire clay beneath "Upper Bakerstown (Maynardier) coal," and lying a short distance above "Lower Bakerstown (Thomas) coal."

Albuquerquan series.

A term introduced by C. [R.] Keyes to designate part of the pre-Camb. rocks of N. Mex., "exposed to the extent of more than 2,000 ft. in the Tijeras Canyon, E. of Albuquerque." (See his Conspectus of geol. fms. of N. Mex., 1915, p. 4.)

Albuquerque marl.

Tertiary (late): Central northern New Mexico (Albuquerque region).

C. L. Herrick, 1898. [See 1st entry under *Rio Grande series.* As here used applied to upper 6 ft. of so-called Albuquerque series.]

A. B. Reagan, 1903 (Am. Geol., vol. 31, p. 86). In Rio Grande embayment the Plio. marls will be called *Albuquerque marls.* In Jemez region they are called *Jemez marls.* They are a continuation of Santa Fe marls of Cope. At Albuquerque they are 350 ft. thick; in Jemez region 100 to 250 ft. They are older than Placita marl (Pleist.), and rest on a series of alternating softer and harder calc. sss. and cgls., of white to deep green colors.

Albuquerque series.

See under *Rio Grande series, Tert.*

Alcona moraine.

Pleistocene (Wisconsin stage): Eastern Michigan (Alcona Co.). (See Mich. Geol. Surv. Pub. 11, 1912.)

Alcova limestone member (of Chugwater formation).

Triassic (?): Central Wyoming (Natrona County).

W. T. Lee, 1927 (U. S. G. S. P. P. 149, pp. 14, etc.) *Alcova ls. memb. of Chugwater fm.*—Name here proposed for 8-ft. bed of marine ls. lying 335 ft. below top of Chugwater fm. at Alcova. It is hard, resistant, purplish ls., which outcrops in conspicuous ledges. Was noted at all localities examined in Big Horn Basin. Lies 420 ft. below top of "Red Beds" at Thermopolis and 345 ft. below top near Rawlins. At W. end of Casper Mtn it is only 73 ft. below top of Chugwater. Occurs throughout Casper Range but not observed E. of this range nor SE. of Freezeout Hills. Is probably Lower Triassic

Alcyone trachyte.

Tertiary (middle or late): Northwestern Arizona (Oatman district).

F. L. Ransome, 1923 (U. S. G. S. Bull. 743). *Alcyone trachyte.*—Gray vitrophyre where moderately fresh, but much of rock is altered and mottled greenish gray. Mainly flows, but probably some green porphyritic varieties are intrusive. Thickness estimated at 2,800 ft., but may not be more than 1,000 ft. Locally separated from overlying Esperanza trachyte by 100 to 150 ft. of sandy beds. Rests in places on 200 ft. of coarse-grained breccia. Named for Alcyone mine.

Alden limestone.

Mississippian: Central northern Iowa.

F. M. Van Tuyl, 1925 (Iowa Geol. Surv. vol. 30, pp. 52, 92, 99). *Alden ls.*—Light-gray, thin-bedded, slightly oolitic ls., 30 ft. thick. Overlies Iowa Falls dol., with evidence of discon. Fossils poorly preserved, and exact age open to question. Tentatively referred to top of Kinderhook.

See *Gilmore City ls.*

Named for exposures in S. bank of Iowa River, just below wagon bridge at town of Alden, Hardin Co.

Alden limestone.

Ordovician: Southern Oklahoma (Arbuckle and Wichita Mountains).

C. E. Decker, 1933 (Tulsa Geol. Soc. Digest, pp. 55–57). [See this entry under *Simpson group*, which is only recorded use of this name.]

Alden moraine.

Pleistocene (Wisconsin stage): *Northern Wisconsin.*

R. T. Chamberlin, 1905 (Jour. Geol., vol. 13, p. 242). The oldest of the three terminal moraines in St. Croix Dalles quad. Named for occurrence in Alden Twp, Wis. [Local and not same as Alden moraine of N. Y.]

Alden moraine.

Pleistocene (Wisconsin stage): *Western New York.* Shown on moraine map (fig. 8) in U. S. G. S. Niagara folio (No. 190), p. 17. Named for Alden, Erie Co., N. Y.

Alderson limestone. (In Greenbrier limestone.)

Mississippian: Eastern West Virginia and southwestern Virginia (Giles County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 449, 462, 699). *Alderson ls.*—Usually a dark-gray calc. fm., weathering almost dirty yellow, 75 to 325 ft. thick, with abundant marine fossils and plants in chalky beds above middle. Top memb. of Greenbrier series [ls.]. Overlies Greenville sh. and underlies Lillydale sh. Type loc. on road toward Wolf Creek, ⅛ mi. S. of Alderson, Monroe Co., W. Va. Also observed in Summers Co., W. Va., and in Giles Co., Va. Can be traced NE. to Tucker Co., W. Va. Southward it corresponds to Glen Dean ls. and Golconda sh.

†Aldrich limestone.

Upper or Middle Cambrian: Central Alabama.

H. McCalley, 1897 (Ala. Geol. Surv. Rept. on Coosa Valley, Ala., pp. 41–42 and several later pp.). *Aldrich ls.*—Siliceous blue lss. and dolomites, 250 to 500 ft. thick, underlying Montevallo shales and sss. and overlying Weisner (Chilhowee) sss. and cgls. These lss. are typical near Aldrich, where they are 500 ft. thick. Are present in Shelby, Talladega, Calhoun, Cherokee, Cleburne, and Coosa Counties. Same as Beaver ls. of Hayes. [In Co. descriptions in this rept the ls. is called *Aldrich (Beaver) ls.*]

In several subsequent repts of Ala. Geol. Surv. (E. A. Smith and H. McCalley, Ala. Geol. Surv. Bull. 9, 1904; E. A. Smith, Ala. Geol. Surv. Undergd Water Res. Ala., 1907; W. B. Phillips, Ala. Geol. Surv., Iron making in Ala., 1912; and W. F. Prouty, Ala. Geol. Surv. Bull. 18, 1916) *Aldrich ls.* was applied to ls. underlying †Montevallo sh. and ss. and overlying Weisner ss. or qtzite. Later work by C. Butts led to discovery that the ls. at Aldrich is Conasauga ls., and that it *overlies* Rome (†Montevallo) fm., instead of underlies it; but elsewhere in Ala. and in NW. Ga. there is a ls. underlying Rome fm. and overlying Weisner qtzite that has proved to be the S. extension of Shady dol. of Tenn., and is now called by that name. The name *Conasauga ls.* has priority over *Aldrich ls.*, and latter name, as defined, having been misapplied, it has been discarded by U. S. Geol. Survey and Ala. Geol. Survey. (See C. Butts, 1926, Ala. Geol. Surv. Spec. Rept. No. 14, 1926, p. 51.)

Aldridge formation.

Pre-Cambrian: British Columbia.

S. J. Schofield, 1912 (The geology of East Kootenay, B. C.; Abstract of thesis, Mass. Inst. Tech., p. 3). Included in Purcell series.

Aldridge conglomerate.

Pre-Cambrian: British Columbia.

C. W. Drysdale, 1917 (Canada Geol. Surv. Summ. Rept. 1916, p. 59).

Alexandria syenite.

Pre-Cambrian: Northeastern New York (Alexandria Bay quadrangle).

H. P. Cushing et al., 1910 (N. Y. State Mus. Bull. 145, pp. 10, 39, map). *Alexandria syenite* is early pre-Cambric but younger than Laurentian gneiss. Named for Alexandria Twp, W. and N. of Redwood.

Alexandria type.

Name applied by A. F. Buddington (N. Y. State Mus. Bull. 281, pp. 52–104, 1929) to a nonporphyritic granite intrusive into Grenville series of NW.

Adirondacks, which was called *Alexandria batholith of Laurentian granite* by Cushing, and on Canadian side was referred to as *Mallorytown granite* by J. F. Wright (Geol. Surv. Canada Mem. 134, pp. 1-63, 1923). Derivation of name not stated. Age relations to porphyritic Hermon type of granite not determined.

Alexandria group.

A term used by some geologists instead of *Alexandrian series* used by other geologists.

Alexandrian series.

Silurian: Mississippi Valley.

T. E. Savage, 1908 (Ill. Geol. Surv. Bull. 8, p. 110). *Alexandrian.*—Time term to include Cape Girardeau ls. (40 ft. thick) and overlying beds containing *Dalmanites danae* and *Whitfieldella billingsana.* Thickness 44 ft. in Alexander Co., Ill. Uncon. underlies Clinton. Since there seems to be no direct time equiv. of these beds in the Ord. or Sil. as generally defined the horizons are classed as Middle Sil. strata that more or less completely bridge the lost interval btw. the Cincinnatian and the Clinton. The term to have same rank as *Cincinnatian.*

Savage later included in his *Alexandrian series* all beds beneath Bainbridge ls. and above Maquoketa sh. and Thebes fm., both of which he assigned to Ord. (Richmond group). He divided it into (descending) Sexton Creek ls. (=Brassfield ls.), Edgewood ls., Girardeau ls., and Orchard Creek sh. The Rept. 9th Ann. Field Conf. Kans. Geol. Soc., 1935, included in Alexandrian series of Savage the Kankakee and Edgewood of Ill. and Waucoma of Iowa, and showed it as absent in Wis. and Minn.

Alfred shale.

Upper Devonian: Western New York (Allegany County).

E. R. Eller, 1935 (Carnegie Mus. Annals, vol. 24, serial No. 164, art. 8, pp. 263-264). *Alfred sh.*—At Alfred Station consists of 2 beds, a layer of sh., about 5 ft. thick, very fine-grained, containing a large and diversified fauna of "Chemung" age, overlain by 40 ft. of barren siliceous sh., formerly used by nearby ceramic plants. Alfred sh. is overlain by 6 ft. of heavy calc. ss., which G. H. Chadwick (personal communication) considers to be top of Rushford ss. of Canadaway group. Search was made at outcrops where the ss. and sh. should have been found, but all attempts to trace these beds there [into Rushford ss?] have been unsuccessful. Possibly these rocks have changed in their lithological and paleontological characters or are only lentils which have not wide distribution. The fauna is limited to about 6 inches of the lower fine-grained sh.

Alger formation.

Silurian (Niagaran): East-central Kentucky and southwestern Ohio.

A. F. Foerste, 1905 (Ky. Geol. Surv. Bull. 6, p. 145) and 1906 (Ky. Geol. Surv. Bull. 7, pp. 27, 61). *Alger fm.*—Upper fm. of Crab Orchard div. (lower part of Niagaran div.) of east-central Ky. Essentially clay. Includes following members: Estill clay at top, Waco ls. in middle, and Lulbegrud clay at base; also Fiades clay, the equiv. of Estill clay and Waco ls. Overlain uncon. by Dev. ls. and underlain by Indian Fields fm. of Crab Orchard div.

The name *Alger sh.* was subsequently applied by some Ohio geologists to beds underlying West Union ls. and overlying Brassfield ls., also to beds underlying West Union ls. and overlying Dayton ls.

A. F. Foerste, 1935 (Denison Univ. Bull. Jour. Sci. Lab., vol. 30, pp. 127-140). In earlier studies *Alger clay* was used in Lewis, Adams, and Highland Counties to include not only the unfossiliferous clay shales overlying Dayton ls., but a higher series of similar clay shales interbedded with thin indurated shales, and which, on close search, frequently reveal distinct imprints of fossils belonging to *Mastigobolbina typus* fauna, which is at present unknown anywhere S. of Lewis Co. The name *Ribolt sh.* was proposed in 1931 for these upper shales, and *Alger clay sh.* was restricted to underlying unfossiliferous clay sh. Transition from Alger into Ribolt is not abrupt, and it is assumed that greater part if not all of Alger is also of upper Clinton age. [On p. 140 he says: No distinct line of separation has been observed btw. the Alger and Ribolt; therefore, since the Ribolt is known to be of upper Clinton age, the Alger also is referred to upper Clinton.] In Bath Co. rests on Oldham ls.; in Lewis Co. it underlies Ribolt sh. and rests on Dayton ls. Named for Alger, a station on R. R. btw. Panola and Irvine, about 1 mi. E. of Estill-Madison Co. line. Seems possible to trace *Alger clay* of southern Ohio into the clay at top of the Osgood of SE. Ind., but paleontologically this does not seem possible.

Algoma sand.

Pleistocene: Ontario.

W. E. Logan, 1863 (Canada Geol. Surv. Repts. 1843–63, pp. 887, 907–909). *Algoma sand.*—Yellow sand overlying Saugeen and Erie clays in part of country to N. of Lake Huron and btw. Georgian Bay and Ottawa River. Most largely developed along principal rivers of the dist. Much of region covered by it lies within dist. of Algoma, hence name. No fossils found. Relation to fossiliferous sands farther down the Ottawa, also to Artemisia gravel, is uncertain. [In table on p. 887 it is placed above Artemisia gravel.]

Algomah amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name locally in use many years. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. Younger than cgl. No. 8 (Bohemia cgl.). Belongs in Central Mine group, at or near horizon of Evergreen amygdaloid. The mineralized part is the Algomah lode.

Named for occurrence at Algomah mine, Ontonagon Co.

Algomah flow.

Includes Algomah amygdaloid and underlying trap.

Algoman revolution.

Term applied by A. C. Lawson to a pre-Camb. epoch of granitic intrusion which he considered to have immediately preceded the formation of the †Animikie rocks, but which some other geologists place at a lower horizon in the Huronian series, and which still other geologists regard as Laurentian. (See U. S. G. S. Bull. 769, pp. 123–124). C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), placed it below lower Huronian and above Knife Lake series (tentatively classified as pre-Huronian and post-Laurentian, but which may eventually prove to be lower Huronian).

Algoman granite.

Algoman gneiss.

Names that have been applied to the rocks intruded during the Algoman revolution.

Algomian revolution.

Same as Algoman revolution.

Algomic period.

C. [R.] Keyes, 1914 (Iowa Acad. Sci. Proc., vol. 21, p. 201). Latest period of Archeozoic era in Lake Superior region. Includes Soultan qtzites below, and unnamed lavas and granites above, separated by an erosion interval.

C. [R.] Keyes, 1917 (Iowa Acad. Sci. Proc., vol. 24, p. 56). [*Algomic* shown as older than Animikie, younger than his Soultan qtzites, and as including "Shuswap granites of Cordilleran region and Killarney granites of Interior region."]

†Algonkian period (or system).

A term that was for many years applied to the time (and the rocks) immediately preceding the Camb. period and succeeding the †Archean period, but which is no longer used by U. S. Geol. Survey, except in sense of a rock type, as *Algonkian type*, the meaning of which is "less highly metamorphosed than Archean type." For definition of "Algonkian period (or system)" see U. S. G. S. Bull. 769, pp. 103–127.

Algonquin.

Name applied to a glacial lake of Pleist. age in Great Lakes region. (See U. S. G. S. Mon. 53, 1915, p. 469.) Also to a Pleist. clay in Ontario. (See Ont. Bur. Mines Ann. Rept., vol. 18, pt. 1, 1909, p. 297.)

Aliamanu tuff.

Pleistocene (late): Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and Gd. Water Res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Aliamanu tuff.*—Included in lower part of Honolulu volcanic series [q. v.]. Exposed near Aliamanu Crater, from which it was erupted.

Replaces Lower Salt Lake tuff of Wentworth, according to H. T. Stearns.

Alibates dolomite lentil (of Quartermaster formation).

Permian: Panhandle of Texas.

C. N. Gould, 1907 (U. S. G. S. W. S. P. 191, pp. 17–20). *Alibates dol. lentil.*—Massive white dol. more or less flinty, usually in two ledges, the lower one 8 ft. thick and upper one 2 ft. thick, separated by 4 or more ft. of red clay. Total thickness 15 ft. Local lentil in Quartermaster fm., near top. Separated from underlying Saddlehorse gyp. lentil by 50 to 60 ft. of red sh. with white bands and ledges of soft ss.

C. N. Gould and F. E. Lewis, 1926 (Okla. Geol. Surv. Circ. 13, pp. 8–25). *Alibates dol.* is approx. = Day Creek dol. and we recommend "Alibates" be dropped.

C. N. Gould and R. Willis, 1927 (Geol. Soc. Am. Bull., vol. 38, p. 438). *Alibates dol.* of Panhandle of Tex. is same as Day Creek dol. of western Okla., which underlies Cloud Chief gyp. and overlies Whitehorse ss.

F. M. Bullard, 1928 (Okla. Geol. Surv. Bull. 47, pl. 8), mapped Day Creek dol., Whitehorse ss., and Dog Creek dol. in Hutchison, Carson, Potter, Moore and Oldham Counties, Tex., and did not show any Quartermaster fm. as present there. The exposures, however, are rather widely separated from the exposures of these fms. in Okla.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 167, 243), placed *Alibates dol.* and Saddlehorse gyp. in Quartermaster fm., stating that Alibates is in upper part of that fm. and the Saddlehorse 60 to 80 ft. above base of Quartermaster.

Named for Alibates Creek, Potter Co.

Alkali formation.

Recent: Central southern Oregon.

W. D. Smith, 1926 (Oreg. Univ. Commonwealth Rev., vol. 8, pp. 207–214). *Alkali fm.*—Salt incrustations, 1 inch to 15 ft. thick, occurring as calderas and mounds. Type loc. Alkali Lake and Alvord Basin, Lake Co.

Alkali Creek.

Name applied by W. Granger (Am. Mus. Nat. Hist. Bull., vol. 28, 1910, pp. 244, etc.) to very fossiliferous red stratum in midst of Wind River fm. along Alkali Creek near Lost Cabin, NE. corner of Fremont Co., Wyo.

Allamakee dolomite.

Upper Cambrian: Northeastern Iowa.

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, pp. 319–326). In proposing *Allamakee* for nether *dol.* of Cambric succession in Upper Mississippi valley it is with full cognizance of fact that for many years the fm. to which it is applied has been widely known as *St. Lawrence ls.* Latter designation is clearly a misnomer. [Keyes correlates typical St. Lawrence with Oneota.] Allamakee dol. seems to have as yet no recognizable representative in Minn. It uncon. underlies Waukon ss., and uncon. overlies Albin shales. Is older than St. Lawrence of Minn.

Probably named for exposures in Allamakee Co.

Allegany oil sand.

Drillers' term for an oil sand in Allegany Co., N. Y., which according to J. F. Carll, 1886 (2d Pa. Geol. Surv. Ann. Rept. 1885, chart opp. p. 4), lies about 50 ft. higher than Cherry Grove oil sand (of probable Chemung age), and according to C. A. Ashburner, 1888 (Am. Inst. Min. Engrs. Trans., vol. 16, chart opp. p. 958), lies 100 ft. below Cherry Grove oil sand.

Allegany drift.

A name applied by R. M. Deeley, 1913 (Geol. Mag. London, n. s., dec. 5, vol. 10, table opp. p. 14), to an old drift sheet in No. Am. Probably refers to the drift W. of Allegheny River in NW. Pa., which is now regarded by F. Leverett as probably of Illinoian age.

Allegany Park parvafacies.

Devonian or Carboniferous: Southwestern New York.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 28). The parvafacies of Big Bend magnafacies, which falls within boundaries of Venango stage and which is therefore coeval with Cattaraugus parvafacies of Smethport magnafacies, is herein termed *Allegany Park parvafacies*, for development in New York State Park of this name, S. of Salamanca, N. Y.

Allegheny formation.

Pennsylvanian: Pennsylvania, eastern Ohio, West Virginia, and western Maryland and Virginia.

H. D. Rogers, 1840 (Pa. Geol. Surv. 4th Ann. Rept. p. 150). *Allegheny series* (*Lower Coal Measures*).—Developed in valley of Allegheny River. Underlies Monongahela series, the bdy btw. the two series being marked by final outcrop of the shales exposed just above Ohio River at Pittsburg, and overlies fm. XII (coarse, massive white ss., about 100 ft. thick, which constitutes bottom of productive coal measures, and which appears to include at base the ss. on Tionesta Creek [Homewood ss. memb. of Pottsville fm.]. [The above definition includes Allegheny and Conemaugh fms. of present nomenclature.]

J. J. Stevenson, 1873 (Am. Phil. Soc. Trans., vol. 15, n. s., p. 16). *Lower Coal Group* (*Allegheny River series*).—Extends from the great cgl. [Pottsville fm.] (350± ft. thick) up to Mahoning ss. [This definition accords with current definition of *Allegheny fm.*, the shorter name.]

The present Pa. Geol. Survey classifies the Allegheny as a *group;* the U. S. Geol. Survey classifies it as a *fm.*

†Allegheny group.

Mississippian: Pennsylvania.

A. Sherwood, 1878 (Pa. Geol. Surv. Rept. G, pp. 11–42). *Vespertine or Upper* (*White*) *Catskill fm.*, consisting chiefly of gray ss., underlies Umbral (chiefly red shales) and overlies Lower (Red) Catskill group. The Catskill and Chemung are names well chosen. This is not quite the case with the Vespertine, unless we adopt the whole nomenclature of Rogers. As these rocks constitute the mass of the Allegheny Mtns I think the name *Allegheny group* would be more appropriate.

Corresponds approx. to Pocono fm., and name is also preoccupied.

Allegheny sand.

A subsurface sand lying lower in western Pa. section than Speechley sand and higher than Tiona sand. According to J. D. Sisler, 1933 (Pa. Geol. Surv., 4th ser., Bull. M19, p. 28), "this sand has been recognized for the first time by these correlations. It lies directly beneath the Speechley and above the Tiona. It first appears in records of wells on Allegheny

River north of Pittsburgh and seems to be continuous sand throughout the Allegheny River drainage basin. The Allegheny has locally been mistaken for the Speechley."

Allegheny system.

A term applied by F. Platt (2d Pa. Geol. Surv. Rept. L, 1876) to Allegheny fm. of present nomenclature.

†Allegheny River series.

See J. J. Stevenson, 1873, under *Allegheny fm.* Same as Allegheny fm., the shorter name.

†Allegheny River coal series.

Pennsylvanian and Mississippian: Pennsylvania and northern West Virginia.

J. P. Lesley, 1877 (2d Pa. Geol. Surv. Rept. H_3, p. XXIII). *Allegheny River coal series* includes all beds btw. top of Lower Barren Measures [Conemaugh fm.] and base of Pocono ss. Rests on Catskill ss. Underlies Upper Productive Coal Measures [Monongahela fm.].

Allegrippis sandstone member (of Chemung formation).

Upper Devonian: Central Pennsylvania (Huntingdon County).

I. C. White, 1885 (2d Pa. Geol. Surv. Rept. T_3, pp. 99–100). *Allegrippus cgl.*—White quartz pebbles in matrix of grayish white sand. Thickness 5 to 10 ft. Forms Allegrippus [Allegrippis] Ridge, Huntingdon Co. Overlain by olive shales and thin ss., and underlain by 450 ft. of shales, all belonging to Chemung fm.

C. Butts (U. S. G. S. Hollidaysburg-Huntingdon folio, No. 227, in press). *Allegrippis ss. memb. of Chemung fm.*—Three sss. separated by sh. Thickness 100 ft. Lies 1,400 ft. above Piney Ridge ss. memb. of Chemung, and a considerable distance below Saxton cgl. memb. of Chemung.

†Allen limestone member.

Pennsylvanian: Southeastern Kansas.

G. I. Adams, 1904 (U. S. G. S. Bull. 238, p. 20). *Allen ls.*—Ls., 10 to 25 ft. thick, underlying Vilas sh. and overlying Concreto [Lane] sh.

Same as Plattsburg ls. according to H. Hinds and F. C. Greene (1915) and N. D. Newell (1935). Discarded by U. S. G. S. in 1912. Discarded by R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22).

Named for Allen, Lyon Co.

Allendale sand.

A subsurface sand in Chester group (Miss.) of Wabash Co., SE. Ill.

Allens Creek facies.

Name applied by P. B. Stockdale (Ind. Dept. Cons., Div. Geol., Pub. 98, pp. 76, 249, etc., 1931) to a lithologic development of his Edwardsville fm. (early Miss.) in a part of southern Ind.

Allensville member.

Mississippian: Central and southern Ohio.

J. E. Hyde, 1912 (History of Fairfield Co., p. 211) and 1915 (Jour. Geol., vol. 23, pp. 656, 657, 764, 771, 775–778). *Allensville memb.*—Chiefly very coarse, rather loose, reddish sands, 0 to 39 ft. thick, uniformly bedded, with some interbedded fine-grained sands and in one place 4 to 8 ft. of fossiliferous sh. Middle memb. of Logan fm. Underlain by Byer memb. of Logan fm. and overlain by Vinton memb. Traced from Newark to Ohio River. Lowest occurrence of coarse beds adopted as base of memb. Is = cgl. II of Prosser.

Logan fm. as used by Hyde included upper part of Black Hand fm. of Ohio Geol. Survey and U. S. Geol. Survey. These beds are upper part of Black Hand fm.

Named for exposures at Allensville, Vinton Co.

Allentown limestone.

Upper Cambrian: Eastern Pennsylvania (Lehigh Valley district).

E. T. Wherry, 1909 (Sci., n. s., vol. 30, p. 416). *Allentown ls.*—White to gray, dolomitic ls., largely oolitic; 2,000 ft. thick. Full of Cryptozoon. Underlies Coplay ls. and overlies Leithsville fm. Assigned to Upper Camb.

Is a part of Conococheague ls.

Named for exposures along Lehigh and Jordan Creeks in vicinity of Allentown.

Allison formation.

Upper Cretaceous: Alberta, Canada.

J. D. MacKenzie, 1914 (Canada Geol. Surv. Summ. Rept. 1912, p. 239). *Allison (Belly River) fm.*, Cret., Alberta.

Allison barren member (of Mesaverde formation). (Also **Allison member.**)

Upper Cretaceous: Northwestern New Mexico (Gallup-Zuni Basin).

J. D. Sears, 1925 (U. S. G. S. Bull. 767). *Allison barren memb.*—Light-gray to white lenticular ss., light-gray clay sh., and thin irregular coal beds, but none of commercial importance. Thickness 800+ ft. Top memb. of Mesaverde fm. in Gallup-Zuni Basin. Overlies Gibson coal memb. and uncon. underlies Tert. deposits. Well exposed near village of Allison, McKinley Co.

C. H. Dane, in a rept (U. S. G. S. Bull. 860C) on Chacra Mesa-LaVentana coal field, N. Mex., which lies to E. of Gallup dist., revised the definition of Allison, by extending the unit upward to include all continental beds (including coal beds at top) up to marine sss. (Chacra ss. memb.) in top of Mesaverde fm. of this area. He called the beds in that area *Allison memb.* (instead of *Allison barren memb.*).

Allison Creek sandstone.

Cretaceous: Alberta.

W. W. Leach, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 198).

Alloa rhyolite.

Pre-Cambrian: South-central Wisconsin (Baraboo district).

J. T. Stark, 1932 (Jour. Geol., vol. 40, No. 2, pp. 120, 121, 126). *Alloa rhyolite.*—Flow rhyolite and breccia near Alloa, on SE. flank of syncline in sec. 3, T. 11 N., R. 8 E. Is exposed on both sides of an elliptical mound on Shanks farm, just NE. of United Presbyterian Church, Caledonia Twp. Assigned to pre-middle Huronian.

Allouez conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. R. Marvine, 1873 (Mich. Geol. Surv., vol. 1, pt. 2, pp. 53–57, 60, and chart). Is cgl. No. 15 of Keweenaw Co., and same as Albany and Boston cgl. of Houghton Co. Is 15 to 20 ft. thick at Central and Allouez mines.

Belongs to Central Mine group. The mineralized part is Allouez lode.

Named for occurrence in Allouez mine, Houghton Co.

Alloway clay.

Miocene (upper): Southwestern New Jersey.

H. B. Kümmel and G. M. Knapp, 1904 (N. J. Geol. Surv. vol. 6, p. 142). *Alloway clay.*—A continuous bed of clay without sand beds of sufficient extent to show in outcrop. Usually light brown, although some parts are white, yellow, and black. Thickness 0 to 80 feet. Underlies Shiloh marl and overlies a thin bed of micaceous white talc-like clayey sand near Woodstown and towards Ewan Mills. Continuous from near Swans Mill, S. of Mullica Hill, Gloucester Co., to a point 2 mi. S. of Alloway, Salem Co., and isolated outcrops have been seen as far S. as Stow Creek Twp., Cumberland Co.

Is a part of Kirkwood fm.

Allsboro sandstone. (In Chester group.)

Mississippian: Northeastern Mississippi (Tishomingo County) and northwestern Alabama.

W. C. Morse, 1928 (Jour. Geol., vol. 36, pp. 31–43). *Allsboro ss.*—Coarse-grained ss., in places decidedly contorted, thus differing from other sss. of region. At a few places contains a little asphaltic material. Thickness 8 ft. Named for small village in Ala., near Miss. line. Overlies Alsobrook fm. and underlies Southward Pond fm. Is correlated with Bethel ss. [not true Bethel, but Yankeetown chert; true Bethel ss. underlies Renault fm., with which Morse correlates his Alsobrook fm.]

W. C. Morse, 1930 (Miss. Geol. Surv. Bull 23). Thickness of *Allsboro ss.* varies from 3 to 9 ft. In N. end of Allsboro, Ala., it consists of 5 ft. of massive and contorted ss. and bluish gray sh. Well exposed N. and S. of village.

†Alma limestone. (In Council Grove group.)

Permian: Northeastern Kansas.

C. S. Prosser, 1894 (Geol. Soc. Am. Bull., vol. 6, pp 44–45). Light yellowish gray massive ls., 5½ ft. thick, quarried at Alma and locally known as *"Alma stone."* Same as Cottonwood or Manhattan ls.

Replaced by Cottonwood ls.

Named for Alma, Wabaunsee Co.

†Almagre beds.

Eocene (lower): Northwestern New Mexico.

See under †*Largo beds*.

Almond formation. (In Mesaverde group.)

Upper Cretaceous: Southwestern Wyoming (Baxter Basin, Sweetwater County).

A. R. Schultz, 1920 (U. S. G. S. Bull. 702). *Almond coal group.*—Soft white and brown sss., sandy sh. and clay, with many beds of coal and bituminous sh. Thickness 700 to 950 ft. Top subdivision of Mesaverde fm. in Rock Springs uplift, Sweetwater Co. Separated from underlying Rock Springs coal group (basal subdivision of Mesaverde fm.) by 800 to 1,000 ft. of massive white and yellowish ss., the upper third of which is conglomeratic, with fine black and gray quartz pebbles. Overlain by Lewis sh.

J. D. Sears, 1926 (U. S. G. S. Bull. 781, p. 20, pl. 5). In this rept. the Almond and Rock Springs coal groups are given rank of fms., and intervening body of white ss., 800 to 1,100 ft. thick, is named *Ericson ss.*, from excellent exposure near old Ericson ranch, on Salt Wells Creek, sec. 31, T. 16 N., R. 102 W., Wyo. The Blair, Rock Springs, Ericson, and Almond fms. compose Mesaverde group in Baxter Basin, but the Blair and Rock Springs fms. are=in time upper part of Mancos sh. of Moffat Co., Colo.

Almy formation. (In Wasatch group.)

Eocene (lower): Southwestern Wyoming.

A. C. Veatch, 1907 (U. S. G. S. P. P. 56). *Almy fm.*—Yellow and reddish yellow sandy clays, with irregularly bedded ss. and, near base, cgl. beds. Thickness 2,100 to 2,200 ft. Basal fm. of Wasatch group. Underlies Fowkes fm. and overlies Evanston fm. ("Upper Laramie"). Named for Almy (a town a few mi. N. of Evanston), where it is exposed in bluffs along E. side of Bear River, immediately overlying Evanston fm. (white beds).

Alnwick lake beds.

Tertiary (late Miocene or Pliocene): Eastern Colorado (Pikes Peak region).

W. Cross, 1894 (U. S. G. S. Pikes Peak folio, No. 7). *Alnwick lake beds.*—Fine-grained ss. and cgl., the latter containing pebbles representative of the volcanic series to W. Occurs in valley of Oil Creek about Alnwick. No fossils, but lake is younger than that at High Park, the deposits of which are named *High Park lake beds*. Assigned to Neocene.

Alpena limestone.

Middle Devonian: Northeastern Michigan.

A. W. Grabau, 1902 (Mich. Geol. Surv. Rept. 1901, p. 175). *Alpena ls.*, 25 to 34 ft. thick, underlies Thunder Bay series (Traverse upper shales) and overlies Traverse lower shales and lss.: all included in Traverse group.

R. A. Smith, 1916 (Mich. Geol. Surv. Pub. 21). *Alpena or "Middle" ls.* of Traverse fm. in Alpena dist. consists of 80+ft. of chiefly very massively bedded gray and buff high calcium ls. characterized by extensive system of coral reefs. Is more massive and resistant than overlying Thunder Bay series and than Long Lake series of Traverse fm., which it overlies.

W. A. VerWiebe, 1927 (Papers Mich. Acad. Sci., Arts, and Lett., vol. 7, pp. 181–192). *Alpena ls.* [*redefined*].—Hard crystalline ls., to which Grabau gave thickness in Churchill well as 25 to 35 ft., but there appears to be no good reason for placing bottom of this ls. at this depth, for same type of rock continues on down at least 80 ft., as clearly shown in quarry of Mich. Alkali Co. near Alpena, and drill core in N. part of this section gives thickness of 125 ft. of essentially same kind of rock. It would be more logical to draw base of Alpena ls. at base of No. 6 in Churchill well, which would give thickness of Alpena ls. 126 ft. This is definition used in this rept.

A. S. Warthin, Jr., and G. A. Cooper, 1935 (Wash. Acad. Sci. Jour., vol. 25, No. 12, pp. 524–526), restricted *Alpena ls.* as explained under *Traverse fm.*

Named for exposures at Alpena.

Alpine quartz diorite.

Late Jurassic or early Cretaceous: Southern California (San Diego and Imperial Counties).

W. J. Miller, 1935 (Calif. Jour. Mines and Geol., vol. 31, No. 2, pp. 115–141, map). *Alpine quartz diorite.*—Usually of more uniform composition, color, texture, and structure than Viejas gabbro diorite, although of about same age. Cuts Black Mtn volcanics. Typical occurrence in general vicinity of Alpine, southern Peninsular Range.

Alpreston quartzite.

Middle Cambrian: Western central Montana (Elkhorn region).

W. H. Weed, 1901 (U. S. G. S. 22d Ann. Rept., pt. 2, map, pp. 434, 435). *Alpreston qtzite.*—Nearly white altered ss. of great hardness. Thickness 125 ft. Forms crest of hill W. of Elkhorn. [This hill is also to W. of Alpreston Gulch.] Basal bed of Camb. Probably=Flathead qtzite.

Alsate shale.

Lower Ordovician (Beekmantown): Southwestern Texas (Brewster County).

P. B. King, 1931 (A. A. P. G. Bull., vol. 15, No. 9, pp. 1066, 1069–1070). *Alsate sh.*—In northern exposures is mostly sh., but to S. there are many ls. ledges. To SE. of Marathon the lss. come beneath the sh. beds, but as faunas show no great difference in age the two facies probably intergrade. Near type loc. the fm. consists of 25 to 50 ft. of indurated greenish sh., in part siliceous, containing nodular beds of dense yellow-weathering ls. and lenses of saccharoidal buff quartz ss., passing locally into fine cgl. At base is a coarse cgl. of irregular thickness, composed of rounded ls. and chert fragments. In Dagger Flat anticlinorium the fm. is 125 ft. thick. It underlies the coarse cgl. at base of Fort Peña fm. and overlies Marathon ls. Fossils are late Beekmantown. Named for Alsate Creek, which joins Peña Colorada Creek from W. at Fort Peña Colorada. Is well exposed in cut on creek 2½ mi. W.-SW. of Fort Peña, near road to Roberts ranch.

Alsen cherty limestone.

Lower Devonian: Eastern New York (Schoharie and Greene Counties).

A. W. Grabau, 1919 (Geol. Soc. Am. Bull., vol. 30, pp. 468–470). *Alsen cherty ls.* proposed for 20 to 50+ft. of cherty lss. which overlie the Becraft and contain a modified Becraft fauna. Are shown in hills above Alsen, at Becraft and Schoharie, and they are everywhere stratigraphically continuous with the Becraft. Have heretofore been classed as Port Ewen, but near Port Ewen Station the Port Ewen beds [restricted] rest discon. on the Alsen.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 190, 370, 377), adopted *Alsen ls.* for beds underlying Port Ewen ls. and overlying Becraft ls., and assigned all to the Helderberg.

Alsobrook formation. (In Chester group.)

Mississippian: Northeastern Mississippi (Tishomingo County) and northwestern Alabama.

W. C. Morse, 1928 (Jour. Geol., vol. 36, pp. 31–43). *Alsobrook fm.*—Upper 70 or 80 ft. at type loc. is clay sh. save for a thin layer of ss. near middle. A short distance S., on Cripple Deer Creek, upper third of fm. has changed to ss.—the Cripple Deer ss. memb. Basal bed of fm. is 1 to 10 ft. of ls., whose fossils (Chester) show it belongs with overlying beds, although lithologically it seems closely related to underlying Iuka fm., from which it is separated by large uncon. Underlies *Allsboro ss.* Named for Alsobrook homestead and Alsobrook bridge [Ala.], about which it is excellently exposed.

W. C. Morse, 1930 (Miss. Geol. Surv. Bull. 23, passim), gave many details of fm. and correlated it with Renault fm., which *overlies* true Bethel ss.

Alta formation.

Permian: Southwestern Texas (Shafter district, Presidio County).

J. A. Udden, 1904 (Univ. Tex. Min. Surv. Bull. 8, pp. 10–25). *Alta beds.*—Upper part yellow sand 1,500 ft. thick; lower part dark-colored mixture of silt, clay, and some sand, 2,000 ft. thick. Middle fm. of Chinati series. Underlies Cibola lss. and overlies Cieneguita beds. Few fossils.

P. B. and R. E. King, 1929 (A. A. P. G. Bull., vol. 13, p. 908). Cieneguita and Alta beds of Shafter region, formerly classed as Penn., proved to be of Leonard (Perm.) age. [See also C. L. Baker, 1929 (Univ. Tex. Bull. 2901, pp. 73+).]

Named for Sierra Alta Hill, on side of Sierra Alta Creek, Presidio Co.

†Alta shale.

Middle and Lower Cambrian: Central northern Utah (central Wasatch Mountains).

F. F. Hintze, Jr., 1913 (N. Y. Acad. Sci. Annals, vol. 23, p. 104). *Alta sh.*—Black or dark, micaceous, sandy sh., 150 to 200 ft. thick, uncon. underlying Maxfield fm. and conformably overlying Brigham qtzite. Walcott collected Middle and Lower Camb. fossils from this fm., which is named for its prominence at little town of Alta.

Replaced by *Ophir fm.*, "Alta" being preoccupied.

†Alta granodiorite.

A name that has been applied by some geologists to the stock of granodiorite (of late Cret. or early Tert. age) that crops out just E. of Alta, in central Wasatch Mtns, Salt Lake Co., Utah. (See F. F. Hintze, 1913, N. Y. Acad. Sci. Annals, vol 23, pp. 85–143.) As there is only one granodiorite in the region, the U. S. Geol. Survey has not adopted a geographic name for the rock, but uses the term *Alta stock* for the structural feature which it forms.

†Altamaha formation.

†Altamaha grit.

Miocene (lower): Southeastern Georgia, Alabama, and northern Florida.

W. H. Dall, 1892 (U. S. G. S. Bull. 84, pp. 81–82, 157, 320). *Altamaha grit* (*Mio.*).—The bluffs of Altamaha River at Rocky Hammock exhibit first example on the river of a fm. to which name *Altamaha grit* may be applied. The last bluff of the grit is only a few rods above the bridge across Altamaha River at Doctor Town. Btw. Rocky Hammock and Doctor Town all bluffs of Altamaha River (which are mostly on right bank of river and sometimes reach elev. of 70 ft. above river) are composed of the grit, sometimes extremely hard and flinty and at others more disposed to crumble, but always composed of angular grains of slightly worn quartz mixed with more or less clay as a matrix and with water-worn quartz pebbles. These grits are obviously of a perezonal nature and represent, for the Georgian embayment, the operation through the agency of the southeastern drainage of Ga. of the same forces and analagous circumstances to those which on the borders of Mississippi embayment produced the

Grand Gulf perezone. Though the contact with the oyster-bearing Hawthorne beds of House Creek was not observed by Mr. Burns, there can be little doubt that latter are overlain by the grit where they join, and that the grits, which contain no fossils except a little silicified wood, are consequently of Mio. age.

In 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, pp. 334–348) Dall assigned "*Altamaha grits* of Altamaha River, Ga.," to upper Olig.

C. J. Maury, 1902 (Bulls. Am. Pal., vol. 3, No. 15, pp. 67–69, 81). *Altamaha grits* of Ga. correspond lithologically and faunally with Hawthorne beds of central Fla. [typical Hawthorn], which are upper Olig. [lower Mio. now].

R. M. Harper, 1906 (N. Y. Acad. Sci. Annals, vol. 17, pt. 1). *Altamaha grit* of southern Ga. is thin to 200 ft. thick, yellowish on fresh exposure; weathers dull reddish brown. Lies just above Chattahoochee fm. and is overlain by Lafayette. Probably Plio. [Mapped across southern Ga.]

S. W. McCallie, 1908 (Ga. Geol. Surv. Bull. 15). *Altamaha grit* is probably a phase of the Lafayette and therefore Plio. It consists of heavy-bedded indurated sands with clay and silica matrix. Overlies Chattahoochee fm.

J. O. Veatch, 1908 (Sci., n. s., vol. 27, pp. 71–74). *Altamaha fm.*—Name applied by Dall in 1892 to a ss. or gritty clay fm. prominently exposed along Altamaha and Ocmulgee Rivers of Ga. Is most widespread fm. of coastal plain of Ga. Covers approx. 21,000 sq. mi. As a whole consists of yellow and red sand and both massive and stratified layers of gritty clay, with local areas of indurated grit or ss. and clay. In Ga. is believed to be identical with Lafayette of McGee. Thickness 100 to 500 ft. [In 1909 (Ga. Geol. Surv. Bull. 18) Veatch gave thickness of *Altamaha fm.* of Ga. as 350 ft. and assigned it to Plio. In 1910 (Ga. Geol. Surv. Bull. 23) S. W. McCallie gave thickness of *Altamaha grit* as 200 ft., placed it btw. †Chattahoochee fm. and †Lafayette, and assigned it to Mio.]

J. O. Veatch, 1911 (Ga. Geol. Surv. Bull. 26). *Altamaha (Lafayette?) fm.*—A widespread but relatively thin series of sands and clays covering much of central and southern Ga. Thickness 150(?) ft. Tentatively referred to Plio. Doubtless a part of it is contemp. with so-called Lafayette fm. Inadequacy of knowledge of age and strat. relations of Altamaha fm. is conceded. [In table and on map is placed above Charlton fm. and below Okefenokee fm. (Pleist.). As herein mapped covers major part of southern Ga., but the deposits along Altamaha River (type loc.) are *mapped as Alum Bluff fm.*]

L. W. Stephenson and J. O. Veatch, 1915 (U. S. G. S. W. S. P. 341, pp. 90–91). "Altamaha grit" as proposed by Dall in 1892 applies to same deposits as Alum Bluff fm. Dall regarded the typical beds along Altamaha River as contemp. in general way with the older Mio., which was later classified by him and by others as upper Olig. R. M. Harper in 1906 and J. O. Veatch in 1908 correlated the same deposits with Plio. Veatch and Stephenson in 1911 [Ga. Geol. Surv. Bull. 26] questionably referred the fm. to Plio., although they recognized that *Altamaha fm.* as used by them and as previously used by Harper and by Veatch, included strata ranging in age from Olig. to Pleist. Investigations of recent years have led to conclusion that bulk of deposits included by Harper, Veatch, and Stephenson in Altamaha fm. are of Olig. age and probably contemp. with part of Alum Bluff fm. [In this rept the deposits along Altamaha River are mapped as *Alum Bluff fm.* and the broad area mapped in previous repts as *Altamaha fm.* is herein mapped as *undiff. Olig. to Pleist., inclusive.*]

H. K. Shearer, 1917 (Ga. Geol. Surv. Bull. 31, pp. 7–18). Upper part of Alum Bluff fm. is so-called Altamaha grit, an extensive deposit of irregularly bedded sands, clays, and gravels, locally indurated.

C. W. Cooke, T. M. Prettyman, and H. S. Cave, 1923 (Ga. Geol. Surv. Bull. 40), mapped the deposits over most of southern Ga. (including those along Altamaha River from Doctortown westward, and also northward over western part of Screven Co.) as Alum Bluff fm. Later work by Cooke proved that the deposits mapped as Alum Bluff fm. in this 1923 rept are chiefly Hawthorn fm., which is = Chipola fm. (basal fm. of Alum Bluff group of NW. Fla.) but of different lithology, and they are now called *Hawthorn fm.* by U. S. Geol. Survey. The Altamaha grit of Dall is upper part of Hawthorn fm.

Named for exposures in bluffs of Altamaha River, especially btw. Rocky Hammock and Doctortown, Wayne Co., Ga.

Alta Mira limestone.

Jurassic (?): Mexico.

G. E. Anderson, 1926 (Am. Inst. Min. Met. Engrs. Trans. [preprint], No. 1551, p. 3).

Altamira shale member. (In Monterey shale.)

Miocene (middle and upper): Southern California (Palos Verdes Hills).

W. P. Woodring, M. N. Bramlette, and R. M. Kleinpell, 1936 (A. A. P. G. Bull., vol. 20, No. 2, p. 131). *Altamira sh. memb.*—Basal memb. of Monterey sh. in Palos Verdes Hills. Lower 280 ft. are chiefly silty sh., including Portuguese tuff bed at top. Middle part, 400 to 675 ft. thick, is chiefly porcelaneous and cherty sh., the basal 2 to 6 ft. of which is here named *Miraleste tuff bed.* Upper 150 ± ft. consists of porcelaneous and cherty sh. Rests on Mio. basalt and on Franciscan (?) fm. Underlies Valmonte diatomite memb. of Monterey sh. Is of upper and middle Mio. age. Type region, on S. slope of hills along and adjoining Altamira Canyon, Palos Verdes Hills [Los Angeles Co.].

Altamont limestone.

Pennsylvanian: Southeastern Kansas and northeastern Oklahoma.

G. I. Adams, 1896 (Kans. Univ. Geol. Surv. vol. 1, p. 22). *Altamont ls.*—Variable ls. at summit of ridge at Altamont, usually rough and unsuited for building purposes. Thickness 12 ft. Overlies Pleasanton shales.

In SE. Kans. was for many years treated as lower memb. of Parsons fm. (being the so-called "lower Parsons ls." of early repts). Is underlain by Bandera sh. and overlain by Nowata sh. In Okla is treated as a distinct fm. R. C. Moore has recently abandoned Parsons fm., and now treats Altamont ls. as a fm. in his Marmaton group. These changes have not been considered by U. S. Geol. Survey for its publications.

Named for exposures at Altamont, Labette Co., Kans.

Altamont moraine (also **morainic system**).

Pleistocene (Wisconsin stage): Minnesota, Iowa, South Dakota, North Dakota, Montana.

T. C. Chamberlin, 1883 (U. S. G. S. 3d Ann. Rept., pp. 378, 385, 393, 403). The first or outermost moraine is well displayed at Altamont, Deuel Co., [S.] Dak., and may fittingly be known as Altamont moraine.

Originally regarded as outermost moraine of Wisconsin drift of southern Minn. and S. Dak., but F. Leverett has shown that the moraine at Altamont, S. Dak., the type loc., is not the outer moraine, and has introduced *Bemis moraine* for the outer moraine and restricted *Altamont* to the next younger moraine. Both Altamont and Bemis are of late Wisconsin age, according to W. C. Alden.

†Alternating beds.

A descriptive term applied in a titular sense in some early Tex. repts to the Lower Cret. beds later named *Glen Rose ls.*

Alto formation.

Upper Devonian: Southwestern Illinois.

T. E. Savage, 1920 (Am. Jour. Sci., 4th, vol. 49, pp. 169–178). *Alto fm.*—Dark siliceous sh. and somewhat shaly ls., 40 to 75 ft. thick. Uncon. underlies Mountain Glen sh. and overlies Lingle ls. Is thought to represent Portage or Chemung. Named for exposure along a creek in NE. ¼ sec. 34, in Alto Twp, Union Co.

Alto coal group. (In Pottsville formation.)

Pennsylvanian: Central northern Pennsylvania (McKean County).

C. A. Ashburner, 1880 (2d Pa. Geol. Surv. Rept. R). *Alton coal group.*—Chiefly sh., sl., and fire clay; usually contains 3 well-marked coal beds—Alton upper, Alton middle, and Alton lower. No ls. or calc. beds. Thickness 20 to 35 ft. In Alton Basin, Lafayette Twp, McKean Co., it is 30 to 35 ft. thick. The lower coal is at base and its fire clay rests on Kinzua Creek [Connoquenessing] ss. Underlies Johnson Run [Homewood] ss. Is=Mercer coal group without question.

I. C. White, 1891 (U. S. G. S. Bull. 65, p. 201). The Alton coal group of Ashburner in McKean Co., Pa., probably represents Mercer coals.

Same as Mercer sh. memb. of Pottsville fm., the approved name.

Altona dolomite member (of Blaine gypsum).

Permian: Central Oklahoma.

C. N. Gould, 1902 (Okla. Geol. Surv. 2d Bien. Rept., pp. 42, 48). *Altona dol. memb. of Blaine div.*—Fossiliferous aren. dol. overlying a stratum of sh. (Jenkins clay of Cragin) and underlying Shimer gyp. memb., all of which are included in Blaine div.

C. N. Gould, 1906 (U. S. G. S. W. S. P. 154, p. 16), divided Blaine fm. of Okla. into (descending) Shimer gyp., red shales, Medicine Lodge gyp., red shales, and Ferguson gyp.; and ignored his previously named *Altona dol. memb.* and *Magpie dol. memb.*

C. N. Gould, 1927 (Obsolete Okla. geologic names: Univ. Okla. Bull., Proc. Okla. Acad. Sci., vol. 6, pt. 2, pp. 235–238). *Altona dol.* and *Magpie dol.*, proposed by Gould in 1902 for dol. members in Blaine fm., were abandoned on revision of Perm. in 1906. [The equivalents of these dol. beds not explained.]

Named for Altona, W. part of Kingfisher Co.

Altoona limestone.

Pennsylvanian: Southeastern Kansas.

E. Haworth and W. H. H. Piatt, 1894 (Kans. Univ. Quart., vol. 2, pp. 115–117). *Altoona ls.*—Heavy lss., 50 to 60 ft. thick, capping the hills along Verdigris River from a few miles above Coffeyville to vicinity of Altoona. Separated from overlying Iola ls. by 100 feet of shales with interbedded sss., and from underlying Independence ls. by 80 to 150 ft. of shales and sss. Believed to be same as Erie ls.

Named for Altoona, Wilson Co.

Above is only record of this name.

†Altuda granite.

Age (?): Western Texas (Brewster County).

J. A. Udden, 1907 (Univ. Tex. Bull. 93, Sci. ser. No. 11, p. 70). *Altuda granite.*—An intrusive granite boss lies uncovered over an area of somewhat more than a square mi. 4 mi. N. of Mount Ord, SW. of Altuda. It is a moderately coarse-grained rock of reddish gray color, and weathers into large blocks, sometimes 20 ft. in length. It rises in a hill several hundred ft. high. The Carbf. sediments which surround this hill dip away from it and have evidently at one time formed a continuous cover over whole area.

P. B. King, 1931 (Univ. Tex. Bull. 3038, p. 100). Largest igneous mass in Altuda Mtn area is at so-called Granite Mtn, or Granite Knob, 1 mi. W. of the James ranch and 2 mi. S. of summit of the mtn. This rock was called "Altuda granite" by Udden. This is not only a misnomer, but implies a formational name for the rock, when no special term appears justified. Actually the rock is a syenite or syenite porphyry. It outcrops on several rugged hills, covered with large exfoliating boulders, and occupies an area of about a sq. mile.

Altuda shaly member (of Capitan limestone).

Permian: Western Texas (Glass Mountains).

P. B. King, 1927 (Am. Jour. Sci., 5th, vol. 14, p. 217). *Altuda memb.*—Middle memb. of Vidrio fm. Thin-bedded dolomites, characterized by considerable amounts of sandy and shaly material. Thickness 0 to 400 ft. Is separated from underlying Word fm. by several hundred ft. of very massive cliff-forming dolomites, making up lower part of Vidrio fm. To W. these thin and gradually merge with Altuda memb. Overlain by 1,000± ft. of massive dolomites, which represent upper part of Vidrio fm. and interfinger with lower part of overlying Gilliam fm. Named for exposures in vicinity of Altuda section house.

P. B. King, 1931 (Tex. Univ. Bull. 3038, pp. 75, 131, 134, 136, quarto), treated *Altuda memb.* as a memb. of Capitan fm., and gave several detailed sections, in some of which he described it as chiefly ls. with considerable siliceous sh., and in others as almost wholly dol., and gave thicknesses of 347, 477, and 734 ft. [See 1931 entry under *Tessey dol.*]

P. B. King, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 4, p. 737), changed name to *Altuda shaly memb. of Capitan ls.*, and also treated the Vidrio, Gilliam, and Tessey as members of Capitan ls.

Alturas formation.

Pliocene (upper): Northeastern California (Modoc County).

E. Dorf, Sept., 1933 (Carnegie Inst. Wash. Pub. 412, pp. 6, 23). A small flora has been collected from Rattlesnake Butte, 4± mi. E. of Alturas, Modoc Co. The beds, which are here referred to as *Alturas fm.*, consist of gray sandy tuffs and shales containing both plant and vertebrate remains. The mammalian remains collected by Stock appear to indicate upper Plio. age.

R. S. LaMotte, 1936 (Carnegie Inst. Wash. Pub. 455). Upper Cedarville fm. (Plio.) of Modoc Co., Calif., is overlain by Alturas fm., but at Camp 49, Nev., the Alturas is absent, and Warner basalt rests on the Upper Cedarville.

Altyn limestone.

Pre-Cambrian (Belt series): Northwestern Montana (Glacier National Park) and southeastern British Columbia.

B. Willis, 1902 (Geol. Soc. Am. Bull., vol. 13, pp. 316, 321). *Altyn ls.*—Upper memb. consists of 600± ft. of argill. ferruginous ls., yellow, terra cotta, brown, garnet red; very thin bedded; well exposed in summit of Chief Mtn. Lower memb. consists of 800± ft. of massive ls., grayish blue, heavy bedded, somewhat siliceous, with many flattened concretions, rarely but definitely fossiliferous. Fossils suggest Grayson sh. Underlies Appekunny argillite. Type loc. in cliffs of Appekunny Mtn, btw. 6,000 and 7,400 ft. above sea, due N. of Altyn, in Swift Current Valley.

† Alum Bluff series.

Miocene (upper and middle): Northwestern Florida.

D. W. Langdon, 1891 (Ga. Geol. Surv. 1st Rept. Prog., pp. 91–97). *Alum Bluff series.*—Consists of (descending): (1) Black lignitic sand, much pyrites, and from efflorescence of ferrous sulphate arises name Alum Bluff, 10 to 15 ft.; (2) gray calc. sand filled with shells, *Mactra* leading, 10 to 15 ft.; (3) gray sand, slightly calc., 5 ft.; (4) light yellow sand, pockets of fossils, 35 ft. Overlies Chattahoochee series.

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept). The beds described by Langdon [in rept above cited] belong to fm. later named *Choctawhatchee*, which is younger than Alum Bluff group as now understood. All of deposits now assigned to Alum Bluff group were under water at time of Langdon's visit to Alum Bluff, and were not discovered until Dec. 1889.

Alum Bluff group.

Miocene (middle and lower): Florida, southern Georgia, and southeastern Alabama.

W. H. Dall, 1892 (U. S. G. S. Bull. 84, pp. 112–113, 122–123, 157, 158, 320). *Alum Bluff beds.*—The unfossiliferous sand and clay strata intervening btw. Chipola marl and the upper fossiliferous bed at Alum Bluff. Over the richly calc. rather ferruginous Chipola marl at Alum Bluff we find a total change of material and total disappearance of the fauna. There are from 5 to 15 ft. of gray siliceous sand and a little clay, without fossils, while above that a radical change of fauna is revealed by the fossils of *Ecphora* bed. To these transition strata I would apply the provisional name *Alum Bluff beds*, until such time as fuller information shall be available. That they represent in the series of Alum Bluff a period of important changes of level and probably of sea temperatures, and no inconsiderable portion of geologic time, is hardly open to dispute. Top fm. of older Mio.

G. C. Matson and F. G. Clapp, 1909 (Fla. Geol. Surv. 2d Ann. Rept.). *Alum Bluff fm.* as here defined is underlain by Chattahoochee fm. and overlain by Choctawhatchee marl. It includes Chipola marl memb. (= Chipola marl of Dall), Oak Grove sand of Dall, and, in upper part, *Shoal River marl memb.* (new).

Julia Gardner, 1926 (U. S. G. S. P. P. 142, p. 2). *Alum Bluff* is raised to rank of a *group*, divided into (descending): Shoal River fm. (including †Shoal River marl memb. of Matson & Clapp and other deposits); Oak Grove sand; and Chipola fm. (including †Chipola marl memb. of Matson and Clapp and other deposits). It uncon. underlies Choctawhatchee marl and uncon. overlies Chattahoochee fm. [now replaced by *Tampa ls.*]. Thickness varies from 0 to 400 ft. Is of marine origin.

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept.). At Alum Bluff, the type loc., the *Alum Bluff group* consists of Chipola fm., but there is possibility that 6 ft. of beds overlying the Chipola there may represent Oak Grove sand or Shoal River fm., or they may belong to the post-Alum Bluff Choctawhatchee fm. The Hawthorn fm. of Fla. and southern Ga. is contemp. with Chipola fm., but of different lithology, and it is now included in Alum Bluff group.

Named for exposures at Alum Bluff, on E. side of Apalachicola River, Liberty Co., Fla.

Alum Cave.

Pennsylvanian: Western and southwestern Indiana.

W. N. Logan, 1929 (Ind. Dept. Cons. 11th Ann. Rept., pp. 30 to 34), described the beds btw. coal V^a and coal V in W. and SW. Ind. as consisting of 35 ft. of shales and ls., to which he applied, in parentheses, the term *Alum Cave.* Derivation of name not stated.

Alvord formation.

Miocene (lower): Southeastern Oregon.

W. D. Smith, 1926 (Oreg. Univ. Commonwealth Rev., vol. 8, pp. 207–214). *Alvord fm.*—Coarse buff-colored tuffs and interbedded sands, more than 1,000 ft. thick, typically exposed on E. side of Alvord Valley, S. part of Harney Co. *Overlies Trout Creek fm.*

Alvord Creek beds.

Tertiary (middle Miocene): Southeastern Oregon (Steens Mountain).

R. E. Fuller, 1931 (Univ. Wash. Pub. Geol., vol. 3, No. 1, pp. 7–130). *Alvord Creek beds.*—Well stratified acidic tuffs, predominantly white; 800 to 1,000± ft. thick. Occur in scattered exposures, near base of Steens Mtn scarp btw. Cottonwood Creek and Little Alvord Creek. To N. of Alvord Creek consist of (descending): (1) White tuff, 100± ft.; (2) flow of basic andesite, 100± ft.; (3) white tuffaceous sediments, 200± ft.; (4) buff stratified tuff, 50 ft.; (5) brownish tuffs, 200± ft. Fossil leaves about 100 ft. below top of No. 3 demand correlation with Mascall fm. (middle Mio), according to Chaney. Underlie Pike Creek volcanic series in S. part of Steens Mtn and underlie Steens Mtn andesitic series in N. part of Steens Mtn.

Amargosan series.

C. [R.] Keyes, 1923 (Pan-Am. Geol. vol. 40, pp. 52, 78). *Amargosan series* is proposed for the thick succession of volcanics and cgls. best exposed in Amargosa Desert and in Furnace Canyon near Death Valley, and believed to be Early Tertic in age. In Nev. divided into Greenwater volcanics above and Grapevine cgl. below. Uncon. above Zunian series and uncon. below Furnacean series.

Amarillo sandstone.

Jurassic (?): Northeastern New Mexico.

C. R. Keyes, 1905 (Am. Jour. Sci., 4th, vol. 20, p. 424). *Amarillo sss.*, 200 ft. thick, underlie Pyramid shales and overlie Endee shales in eastern New Mex. Are correlated with Wingate sss. of western N. Mex. [Derivation of name not given.]

Amarillo Big lime.

A subsurface unit at Amarillo, Tex. Appears to lie 1,500 to 1,700 ft. lower than Big Lake Big lime (Perm.) of Pecos River region.

Amazonia limestone bed. (In Lawrence shale.)

Pennsylvanian: Northwestern Missouri.

H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines, vol. 13, 2d ser., pp. 31, 170, 179). *Amazonia ls. bed.*—A ls., which in places attains thickness of 16 ft. in Lawrence sh. memb. of Douglas fm. Lies 25 to 100 ft. below top of the Lawrence.

The overlying beds are prevailingly aren., the underlying chiefly argill. At Amazonia, Andrew Co. (the type loc.) the Amazonia bed is 9 ft. thick, and consists of gray ls., nodular at top, weathering buff.

Amber sand.

A subsurface sand in southern San Juan Co., SE. Utah, that lies in Hermosa fm.

Amboy stoneware clay.

Economic term for a clay bed, 30 to 80 ft. thick, forming top memb. of Raritan fm. in NE. N. J. Named for occurrence at South Amboy. (See N. J. Geol. Surv. vol. 6, 1904.) Also called *Amboy fire clay.*

†Amboy clays.

A term that has been loosely used to include Amboy stoneware clay, South Amboy fire clay, and other clays worked at Perth Amboy and South Amboy, N. J.

Amelia-Goochland quartz monzonite gneiss.

Pre-Cambrian: Central Virginia (Amelia, Goochland, Powhatan, and southern Louisa Counties).

A. A. Pegau, 1932 (Va. Geol. Surv. Bull. 33, pp. 15, 20–22, pl. 1). *Amelia-Goochland quartz monzonite gneiss.*—Principal rock in Amelia and Goochland areas. Is a light to dark-gray micaceous augen gneiss with irregular banding. Some of it is conglomeratic. Is oldest rock type in the area. [On 1928 Va. geol. map A. I. Jonas assigned it to pre-Camb.]

Ament Bay arkosites.

Pre-Cambrian: Kenora district, Ontario.

F. J. Pettijohn, 1935 (Geol. Soc. Am. Bull., vol. 46, pp. 1895, 1900, map, etc.).

American Falls lake beds.

Pleistocene: Southern Idaho (Power County).

H. T. Stearns, 1932 (Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932) and 1936 (Jour. Geol., vol. 44, No. 4, pp. 434–439). *American Falls lake beds.*—Buff, horizontal, evenly bedded, partly consolidated clay, sand, and silt, with an aphanitic, gray, pahoehoe basalt memb., 10± ft. thick, btw. American Falls and Gibson Butte, along N. side of Snake River. Thickness of fm. 150± ft. Older than Madson basalt and younger than Cedar Butte basalt. Type loc., bluffs along Snake River from American Falls dam, Power Co., to narrows, a distance of 5± mi.

American Flat latite.

Tertiary (Miocene): Southwestern Colorado (Ouray region).

W. Cross and E. Howe, 1907 (U. S. G. S. Ouray folio, No. 153). *American Flat latite.*—Light to dark gray porphyritic rock, notable for glistening biotite leaves. Intrusive into Henson tuff, topmost fm. of Silverton volcanic series. So closely resembles some of lower flows of Potosi volcanic series that in Silverton folio it was taken as basal flow of that series, but its intrusive character is now evident. Its largest known body is that of American Flat.

American Fork formation.

Cretaceous (Lower ?): Central southern Montana (Sweetgrass County).

E. Douglass, 1909 (Carnegie Mus. Annals, vol. 5, pp. 269–288). On Fish Creek, Sweetgrass Co., Mont., the Fort Benton fm. is underlain by several hundred ft. of clays, shales, and bedded sss., which until satisfactorily correlated with Dakota fm. may be called *American Fork fm.*, as they occur near American Fork of Musselshell River. They overlie Lower Cret. (?) red and somber clays containing bones of large dinosaurs and mollusks.

Probably=upper part of Kootenai fm.

American Nettie quartzite.

Upper Cretaceous: Southwestern Colorado (Ouray district).

J. D. Irving, 1905 (U. S. G. S. Bull. 260, p. 56). [In geol. section of Gold Hill on this page, the upper part of Dakota fm. is called *American Nettie qtzite.* It seems to be named for a mine.]

Americus limestone member (of Foraker limestone).

Pennsylvanian: Eastern Kansas, southeastern Nebraska, and central northern Oklahoma.

M. Z. Kirk, 1896 (Kans. Univ. Geol. Surv. vol. 1, p. 80). *Americus ls.*—Two layers of ls. (upper one thin and bluish, lower one light buff and 16 inches thick) separated by 4 ft. of sh. Separated from overlying Dunlap [Neva] ls. by 50 ft. of sh. and from underlying Emporia ls. by an extensive sh. bed.

A. J. Smith, 1902 (A bulletin on Lyon Co. geology, McCord and McCord Printers). *Americus ls. system.*—Consists of (descending): (1) flag ls., 6 in.; (2) sh., 6 ft.; (3) good building stone containing many Fusulina, 21 in. (is known as *Americus ls.* and quarried near village of Americus; color neutral drab; weathers light buff; texture even, compact, and semicrystalline); (4) sh., 8 ft.; (5) ls., 1 ft.; weathers to dry bone fm. Rests on 45 ft. of sh. containing red ss. in places, and is overlain by 8 to 26 ft. of black, blue, and buff sh.

C. S. Prosser, 1902 (Jour. Geol., vol. 10, pp. 703–737). *Americus ls.*—Consists of (descending): Ls., 6 in.; sh., 6 ft.; solid buff ls., 21 in. Is overlain by Elmdale fm. and underlain by sandy shales which are to be named by Adams.

G. I. Adams, 1903 (U. S. G. S. Bull. 211). *Americus ls.* underlies Elmdale fm. and overlies Admire shales (new name). Thickness 5 ft. Consists of (descending) (1) ls., (2) thin sh., and (3) ls., 16 in. thick.

L. C. Wooster, 1906 (Kans. Acad. Sci. Trans., vol. 20, pt. 1, pp. 75–82). *Americus beds,* 155 ft. thick, consist of Americus ls. and shales (above), 35 ft. thick, and Admire shales and lss. (below), 120 ft. thick. Underlie Elmdale beds and overlie Emporia beds.

E. Haworth and J. Bennett, 1908 (Univ. Kans. Geol. Surv. vol. 9). *Americus ls.,* 8 ft. thick, is quarried at Americus. Underlies Elmdale fm. and overlies Admire fm.

R. C. Moore and W. P. Haynes, 1917 (Kans. Geol. Surv. Bull. 3). *Americus ls.,* 8 ft. thick, is a rather persistent ls., which on outcrop breaks into large blocks which are strewn down slope beneath. Underlies Elmdale sh. and overlies Admire sh.

N. W. Bass, 1929 (Kans. Geol. Surv. Bull. 12, p. 45), divided the beds in Cowley Co., Kans., btw. Neva ls. above and Admire sh. below into (descending) Elmdale sh. restricted (80 ft. thick) and Foraker ls. (47 to 50 ft. thick), the latter including at base a ls., 2½ to 4 ft. thick, designated as *Americus (?) ls. memb.*

R. C. Moore, 1929 (Kans. Geol. Surv. Bull. 12, p. 45, footnote). Recent field work by G. E. Condra and me has shown definitely that Americus ls. of type loc. extends southward and constitutes basal part of the Foraker as described by Bass (Cowley Co. rept, Bull. 12 above cited) and by Heald [?] and others in Osage Co., Okla. [In footnote on p. 50 Moore states:] It is likely detailed strat. work will afford basis for definite determination of relations of type Foraker to Americus and Elmdale.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), transferred this ls. to Perm. and showed it as basal memb. of Foraker ls., and as consisting of two ls. beds separated by sh. This change in Perm.-Penn. bdy has not been considered by U. S. Geol. Survey for its publications.

Named for exposures near Americus, Lyon Co., Kans.

†Americus beds.

Pennsylvanian: Eastern Kansas.

L. C. Wooster, 1905 (The Carbf. rock system of eastern Kans.). *Americus beds.*—Includes Americus ls. and shales, 35 ft. thick, and Admire shales and lss., 120 ft. thick [upper part only of Admire sh.]. Overlies Emporia reservoir shales [lower part of Admire sh.].

Preoccupied and conflicts with original and established definitions.

Named for Americus, Lyon Co.

Ames limestone member (of Conemaugh formation).

Pennsylvanian: Eastern Ohio, Pennsylvania, Maryland, West Virginia.

E. B. Andrews, 1873 (Ohio Geol. Surv. vol. 1, pp. 235, 271, 296). *Ames ls.*—Fossiliferous ls., 1 to 5 ft. thick, in Coal Measures of Morgan, Athens, and Gallia Counties, Ohio, about 140 ft. below horizon of Federal Creek or Pomeroy coal.

Adopted as a memb. of Conemaugh fm. Replaces "Crinoidal ls." of early repts. In W. Va. Surv. repts the names *Upper Ames ls.* and *Lower Ames ls.* are used, for lss. 4 and 3 ft. thick, respectively, separated by 10 to 20 ft. of green sh. called Ames sh. (See R. V. Hennen and D. B. Reger, W. Va. Geol. Surv. Rept. Preston Co., 1914, and Rept. Marion, Monongalia, and Taylor Counties, 1918.)

Named for exposures near Amesville, in Ames Twp, Athens Co., Ohio.

Ames shale. (In Conemaugh formation.)

Pennsylvanian: Northern West Virginia.

R. V. Hennen and D. B. Reger, 1913 (W. Va. Geol. Surv. Rept. Marion, Monongalia, and Taylor Counties, p. 289). *Ames sh.*—Dark-green sh. with marine fossils; 15 ft. thick. Underlies Upper Ames ls. and overlies Lower Ames ls. [Later repts give thickness 10 to 20 ft. Probably named for occurrence in ls. identified as Ames ls.]

Ames red bed. (In Conemaugh formation.)

Pennsylvanian: Northern West Virginia and western Pennsylvania.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, pl. 6), applied *Ames red bed* to beds occurring some distance above Ames ls. and some distance below Barton coal at Morgantown, W. Va., and at Latrobe, Pa.

Ames monzodiorite.

Devonian or Carboniferous: New Hampshire (Belknap Mountains).

See 1936 entry (D. Modell) under *White Mtn magma series*. Occupies small area NW. of Ames station.

Ames Knob formation.

Silurian: Central southern Maine (Knox County).

G. O. Smith, E. S. Bastin, and C. W. Brown, 1907 (U. S. G. S. Penobscot Bay folio, No. 149, p. 4). *Ames Knob fm.*—Lss. and red shales; with several cgl. beds and a basal cgl. memb. 16 ft. thick. Contains Niagara fossils. Thickness 580 ft. Rests on North Haven greenstone. Overlain by volcanic rocks. Named for exposures on shore of Southern Harbor, just NW. of Ames Knob, which lies ½ mi. W. of village of North Haven, Knox Co.

On 1933 geol. map of Maine, by A. Keith, these rocks seem to be included in Ord. and Camb. block.

Amherst schist.

Carboniferous: Central Massachusetts, southwestern New Hampshire, and northern Connecticut.

B. K. Emerson, 1898 (U. S. G. S. Holyoke folio, No. 50; also U. S. G. S. Mon. 29, pp. 218, 219, 222, 224–225). *Amherst schist* (also *Amherst feldspathic mica schist*).—Coarse fibrolitic and feldspathic schist exposed in Mount Warner and across Amherst, Mass.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 60, 72–76, and map). On W. border of Central Upland of Mass. the Brimfield schist becomes a normal garnetiferous mica schist called *Amherst schist*. The Amherst is at base a coarse lead-gray mica schist, generally without accessory minerals. This is succeeded above by a finer-grained corrugated mica schist, which is dark gray from graphite and abounds in dark-red garnet and red-brown biotite, set transversely to bedding. On Mt. Warner the schist reverts to Brimfield type and becomes a highly fibrolitic rusty garnetiferous brown biotite schist.

Amherst sandstone.

Quarry term for a ss. of Upper Triassic age, outcropping in Connecticut Valley. (See A. A. P. G. Bull., vol. 19, No. 1, p. 9, 1935.)

Amherstburg dolomite member (of Detroit River dolomite).

Lower Devonian: Southeastern Michigan (Detroit region) and western Ontario.

W. H. Sherzer and A. W. Grabau, 1909 (Geol. Soc. Am. Bull., vol. 19, p. 542). *Amherstburg dol.*—Mag. calcarenite, 0 to 30 ft. thick. Included in Upper Monroe [Detroit River dol.]. Underlies "Lucas" dol. and overlies Anderdon coral ls. Named for fact it forms bottom of eastern channel of Detroit River, opp. Amherstburg, Ont. Also exposed in Sylvania dist., Ohio.

Amisk group (also series).

Pre-Cambrian: Manitoba.

A. Bruce, 1918 (Canada Geol. Surv. Summ. Rept. 1917, pt. D. p. 4).

Amity shale.

Devonian or Carboniferous: Northwestern Pennsylvania (Erie County).

G. H. Chadwick, 1925 (Geol. Soc. Am. Bull., vol. 36, pp. 457–464). [See definition under *Woodcock ss.*] Outcrops mentioned. The fossiliferous beds at Rock Creek Village seem to be in the Amity. On Sagamore Creek, in Cuyahoga Valley, Ohio, the lowest exposure is in the Amity. Included in Bradfordian and also treated as a memb. of Chagrin fm. [which U. S. Geol. Survey classifies as Upper Dev. Derivation of name not stated.]

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 203). *Amity sh. memb. of Cattaraugus fm. (Dev.)* underlies Watson ss. memb. (new name) and overlies Panama cgl. memb. (Le Boeuf, Venango 3d oil, Wolf Creek). [The U. S. Geol. Survey classifies Cattaraugus fm. as *Dev. or Carbf.* In 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61, p. 86) Caster replaced his *Watson ss. memb.* (preoccupied) with *Bimber Run cgl. memb.*]

Ammonoosuc volcanics.

Pre-Silurian (Upper Ordovician ?): Northwestern New Hampshire (Ammonoosuc River region).

M. Billings, 1934 (Sci., Jan. 19, vol. 79, No. 2038, pp. 55–56). *Ammonoosuc volcanics.*—Chlorite and sericite schists, of volcanic origin, 2,500 ft. thick, underlying Partridge sl. and overlying Albee qtzite in Littleton and Moosilauke quads. No fossils, but are pre-Sil. (Upper Ord. ?).

M. Billings, 1934 (Am. Jour. Sci., 5th, vol. 28, Dec., pp. 13–15), mapped the rocks of parts of Littleton and Moosilauke quads; and his map shows Ammonoosuc River flowing through his *Ammonoosuc volcanics* at and around Littleton and to southward. The name replaces what he called "Swiftwater-Lyman fm." in Feb. 1933 issue of Am. Jour. Sci., according to letter dated July 19, 1935.

M. P. Billings, 1935 (Geology of Littleton and Moosilauke quads., N. H., maps, pp. 10, 20). Type loc. of *Ammonoosuc volcanics* is in dist. bounded on N. by Slate Ledge School and Partridge Lake and on S. by Youngs Pond (Ogontz Lake) and Tinkerville. The fm. is also well exposed along Ammonoosuc River but with a different metamorphic character. Most of material would be classified as tuff, breccia, or volcanic cgl., and was largely deposited by streams flowing westward from active volcanoes to E. It includes a number of rock types which grade into one another. Believed to be Upper Ord.

Amnicon formation. (In Oronto group.)

Pre-Cambrian (upper Keweenawan): Northwestern Wisconsin (Douglas and Bayfield Counties).

F. T. Thwaites, 1912 (Wis. Geol. Nat. Hist. Surv. Bull. 25, pp. 50, 54). *Amnicon fm.*—Red and greenish shales, arkosic ss., and some cgl. Thickness 5,000 ft.; 1,050 ft. exposed. Top fm. of Oronto group. Overlies Eileen ss. and conformably underlies Bayfield ss. group. Exposed on Fish Creek, near Ashland, and on Middle and St. Louis Rivers in Douglas Co. [Derivation of name not stated. According to map the rocks of American River region are Orienta ss. and trap rocks.]

†Amphitheater dolomite.

Permian: Central Oklahoma (Blaine County).

F. W. Cragin, 1897 (Am. Geol., vol. 19, pp. 353, 358, 363). *Amphitheater dol.*—A lamina-built amphitheater ledge of dol. locally recognized below middle of Dog Creek fm. in Blaine Co.

C. N. Gould, 1927 (Obsolete Okla. geologic names: Univ. Okla. Bull., Proc. Okla. Acad. Sci., vol. 6, pt. 2, pp. 235–238). Amphitheater dol. of Cragin (1897) was never in common use.

Not a geographic name.

Amsden formation.

Pennsylvanian (some Mississippian locally): Wyoming (rather widespread) and Montana.

N. H. Darton, 1904 (Geol. Soc. Am. Bull., vol. 15, pp. 394–401). *Amsden fm.*—Red shales, white lss., and cherty and sandy lss. Thickness 150 to 350 ft. Underlies Tensleep ss. and overlies (without apparent uncon.) Little Horn ls. [Now replaced by *Madison ls.*] Named for Amsden Branch of Tongue River, W. of Dayton.

In some areas fossils of Miss. age have been found in basal part of what is considered to be Amsden fm.

See under *Big Snowy group*, which H. W. Scott (1935) states underlies Amsden fm. in central Mont.

C. C. Branson (1936) proposed to call Miss. part of Amsden fm. the *Sacajawea fm.*, as explained under that name.

Amsterdam limestone. (Of Black River group.)

Middle Ordovician: East-central and eastern New York.

R. Ruedemann, 1910 (N. Y. State Mus. Bull. 138, p. 72). [See 1st item under *Watertown ls.*]

R. Ruedemann, 1910 (N. Y. State Mus. Bull. 145, table on p. 97). [*Amsterdam ls.* shown as top fm. of Black River group in Mohawk and Champlain Valleys and Saratoga region, and as younger than Watertown ls. of Watertown region, but not occurring in same section with Watertown ls. Underlies Trenton ls. and overlies pre-Leray part of Lowville ls. in Mohawk Valley and beds=Leray ls. memb. of Lowville in Champlain Valley.]

H. P. Cushing, 1911 (Am. Jour. Sci., 4th, vol. 31, pp. 135–144). *Amsterdam ls.*—Is Mohawk ls. of Conrad, but that name was later abandoned, and this ls. was called "base of the Trenton." Vanuxem classed it with Black River ls., but it has of late years usually been referred to as Trenton, both along the Mohawk and at Saratoga; but it is older than anything in type section at Trenton Falls, and is properly referable to Black River, forming youngest div. of that group in N. Y. It is also a deposit in a different trough from that of type Trenton. On eastern Mohawk and Saratoga it rests on Tribes Hill or Little Falls. In Champlain Valley true Trenton ls. overlies it. Named for exposures along the Mohawk in vicinity of Amsterdam, Montgomery Co.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19), R. Ruedemann, 1929 (Geol. Soc. Am. Bull., vol. 40, p. 414), and W. Goldring, 1931 (N. Y. State Mus. Hdb. 10), assigned *Amsterdam ls.* to Black River group, which seems to be commonly accepted definition.

†Amyzon beds.

A paleontologic name applied by E. D. Cope (Am. Nat., vol. 13, 1879, p. 332, and Am. Phil. Soc. Proc., vol. 19, 1880, p. 61) to fresh-water Tert. beds in Elko Co., Nev., South Park, Colo., and central Oreg., which are characterized by sp. of fishes belonging to the genus *Amyzon*. The beds thus designated in central Oreg. underlie John Day fm., and are now known as Clarno fm., of lower Olig. and upper Eo. age.

Anacacho limestone.

Upper Cretaceous (Gulf series): Southwestern Texas.

R. T. Hill and T. W. Vaughan, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, p. 240). *Anacacho fm.*—Hard yellow and white lss., with interbedded marls and occasional ss. ledges. Thickness 279 ft. Overlies Austin chalk in Uvalde and Kinney Counties and occupies strat. position of Taylor marls to E.

L. W. Stephenson, 1928 (Am. Jour. Sci., 5th, vol. 16, p. 492). *Anacacho ls.* of Anacacho Mtn is uncon. overlain by Escondido fm. and underlain by a thin development of Upson clay, which rests on Austin chalk. In Medina River section the Anacacho is overlain by a thin development of Taylor marl and rests on Austin chalk.

Named for Anacacho Mtns, Kinney Co., which are capped by the fm.

Anadarche member (of Hoxbar formation).

Pennsylvanian: Central southern Oklahoma (Carter County).

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z, pp. 15–16). *Anadarche cgl.* lies 1,800± ft. above base of Hoxbar fm. It carries pebbles of chert and of early Penn. as well as pre-Penn. lss. Some 200 ft. higher in Hoxbar fm. is *Anadarche ls.*, a very dense, hard, bluish gray ls. up to 20 ft. thick.

C. W. Tomlinson, 1929 (Okla. Geol. Surv. Bull. 46, pp. 43–44). *Anadarche memb. of Hoxbar fm.* is 100 to 200 ft. thick. Consists, at top, of very dense, hard, bluish gray ls. up to 20 ft. thick, and, at base, of a ls. cgl., 0 to 10± ft. thick, which contains pebbles of pre-Penn. lss. and cherts and also of Penn. lss. [Does not describe the intervening strata of the memb.] Lies 500 to 800 ft. above Crinerville memb. and 400 to 600 ft. below Daube ls. memb. Type loc. is on Anadarche Creek, ⅛ mi. S. of NW. cor. of sec. 35, T. 5 S., R. 2 E.

Anadarche conglomerate. (In Hoxbar formation.)

Pennsylvanian: Central southern Oklahoma (Carter County).

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z, p. 16). (See under *Anadarche memb.*)

Anadarche limestone. (In Hoxbar formation.)

Pennsylvanian: Central southern Oklahoma (Carter County).

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z, p. 16). (See under *Anadarche memb.*)

Anaktuvuk group.

Lower Cretaceous: Northern Alaska (Anaktuvuk River region).

F. C. Schrader, 1902 (Geol. Soc. Am. Bull., vol. 13, p. 245). *Anaktoovuk series.*—Essentially heavy-bedded, impure, dark-gray or greenish, fine to medium grained ss. Lower Cret. fossils. Uncon. overlies Lisburne fm. (Dev.) and uncon. underlies Nanushuk series. Named for river, on which it occurs.

Analomink red shale.

Upper Devonian (Portage): Northeastern Pennsylvania (Monroe County).

B. Willard, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 8, p. 1206). [See 1935 entry under *Delaware River flags.*]

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 571, 588). *Analomink red sh.* is a local unit of 100 ft. of red beds at its type loc., Analomink, Monroe Co. It is probably confined to Pike and Monroe Counties, except doubtful identification on N. Y. side of Delaware River, near Hawks Nest. White mistook this red sh. for his much younger New Milford red sh. It is valuable only as defining base of Delaware River flags in this neighborhood. Where it is absent the Delaware River flags rest on Trimmers Rock ss. [Table on p. 571 shows following downward succession: Delaware River flags, Analomink red sh., and Trimmers Rock ss. Table on p. 606 shows Trimmers Rock ss.=Delaware River and Analomink.]

Anamosa dolomite.

Silurian (Niagaran?): Central eastern Iowa.

S. Calvin, 1895 (Iowa State Univ. Bull. Lab. Nat. Hist., vol. 3, No. 3, pp. 186, 189). *Anamosa ls.*—Earthy, finely and perfectly laminated dol. not highly crystalline, forming top memb. of Niagara fm. in eastern Iowa. Overlies LeClaire ls. [Latter fm. is now regarded by E. O. Ulrich as of post-Salina Cayugan age.]

W. H. Norton, 1895 (Iowa Geol. Surv. vol. 4, pp. 130–135). *Anamosa stage; Anamosa or Mount Vernon beds.*—[See under †*Mount Vernon beds.*] Overlie LeClaire beds and underlie Bertram beds.

A. H. Sutton, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 269, 276). There seems to be no question of contemporaneity of the Leclaire and Anamosa. The Leclaire represents the "reef" type and the Anamosa and overlying Bertram consist of the more normal type of sediments deposited away from the "reefs." Exposures show interfingering of Anamosa type of sediment with the "reef" type of the Leclaire. It is possible the Bertram may be in part at least younger than the youngest Leclaire. Anamosa is younger than Hopkinton and Racine.

See also under *Gower dol.*

Named for Anamosa, Jones Co.

Anarchist series.

Carboniferous (?): Southern British Columbia and central northern and northeastern Washington.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, maps 10, 11, 12, 118° to 120°). *Anarchist series.*—Qtzite, phyllitic shales, greenstones, with some ls. beds. Underlies Attwood series. [Mapped around Anarchist Mtn, B. C. on map 11.]

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 389).

Anastasia formation.

Pleistocene: Florida (east coast as far south as Broward County; west coast from Ten Thousand Islands as far north as Tampa).

E. H. Sellards, 1912 (Fla. Geol. Surv. 4th Ann. Rept., p. 18). The term *Anastasia fm.* is here applied to the extensive deposit of Coquina rock found along east coast of Fla. The rock is a mass of more or less water-worn shells, which in some localities are cemented to form a firm rock, but elsewhere may be slightly or not at all cemented. Some sand is frequently included in this fm. and the cementing material is calc. Typically exposed on Anastasia Island, also in cut made by Florida East Coast Ry on Tomora Creek near Ormond, and along the coast at Rockledge. Probably contemp., or partly so, with Miami ls. and other Pleist. fms. along southern coast.

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept.). Anastasia fm. redefined to include all marine deposits of Pleist. age that underlie lowest plain bordering E. coast of Fla. N of southern part of Palm Beach Co., and also including a local facies, consisting chiefly of shell marl irregularly hardened into sandy ls., which in some previous repts has been called "Palm Beach ls.," and which marks transition of Anastasia fm. into the contemp. Miami oolite. Most conspicuous part of Anastasia fm. is coquina containing a little quartz sand, and no doubt at some places the fm. may be almost wholly quartz sand. Thickness variable; near St. Augustine the coquina is 30+ ft. thick. It is probable the deposits referred to Anastasia fm. are not all of same age. It is not unlikely the fm. of the shell beds has been continuous since end of Plio., although the locus of deposition has been continually shifting. [The map accompanying this rept applied *Anastasia fm.* to the Pleist. marine beds of *west* coast of Fla. as far N. as Tampa Bay, and that is present accepted definition of name.]

Anawalt sandstone.

Mississippian: Southern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, p. 245). *Anawalt ss.*—Massive, hard, fine grained, gray, 15 ft. thick. Lies about 500 ft. below Pocahontas No. 3 coal. Older than Hartwell ss. Included in Mauch Chunk series. Exposed at SW. edge of town of Anawalt, McDowell Co.

Anchor limestone member (of Monte Cristo limestone).

Mississippian (lower): Southeastern Nevada (Goodsprings region).

D. F. Hewett, 1931 (U. S. G. S. P. P. 162, pp. 10, 17, etc.). *Anchor ls. memb.*—Massive gray ls. with numerous thin chert layers; in places large belts are altered to dol. Thickness 65 to 400 ft. Many lower Miss. fossils (listed). Underlies Bullion dol. and overlies Dawn ls.; all members of Monte Cristo ls. Well developed in region of Anchor mine, Goodsprings quad.

Anchor Mine tongue (of Mancos shale).

Upper Cretaceous: Eastern Utah (Book Cliffs coal field).

C. E. Erdmann, 1934 (U. S. G. S. Bull. 851, pp. 36–38). *Anchor Mine tongue* is one of the 3 westward-projecting tongues of Mancos sh. that inter-finger with basal Mesaverde strata. Its base or E. end lies in sec. 12, T. 10 S., R. 100 W., and in that vicinity it has typical Mancos lithology. Westward it changes from dark-gray sandy marine sh. into thin-bedded ss. and carbonaceous material representing deposition in shallower waters near shore. Near mouth of Hunter Canyon it separates upper and lower members of Sego ss. Is exposed at Anchor mines. Thickness ranges from 0 to 115± ft.

Anderdon limestone member (of Detroit River dolomite).

Lower Devonian: Southeastern Michigan (Detroit region) and western Ontario.

W. H. Sherzer and A. W. Grabau, 1908 (Sci., n. s., vol. 27, p. 408). *Anderdon ls.*—In most localities a more or less continuous coral and *Stromatopora* reef; very fossiliferous. Is middle memb. of Upper Monroe [Detroit River dol.].

W. H. Sherzer and A. W. Grabau, 1909 (Geol. Soc. Am. Bull., vol. 19, pp. 540+). *Anderdon coral ls.*—Pure calcarenite or lime sand rock with embedded corals. Thickness 0 to 38 ft. Older than Amherstburg dol. and younger than Flat Rock dol. Only exposure in Anderdon quarry, Anderdon Twp, Essex Co., Ont. [On a later page (553–556) thickness is given as 40 to 50 ft. Later repts give thickness 0 to 150± ft.]

Anderson sandstone. (In Pottsville group.)

Pennsylvanian: Eastern Tennessee.

A. Keith, 1896 (U. S. G. S. Briceville folio, No. 33). *Anderson ss.*—Sss., sandy and argill. shales, and coal beds, like preceding fms. [Scott, Wartburg, and Briceville]. Bottom of series is marked by massive sss. in beds from 20 to 50 ft. thick, with total thickness of 100 to 120 ft. Above these follow 300 to 400 ft. of shales interbedded with thin layers of massive ss. which are capped in higher mtns by thick, massive sss. like bottom layers. Appears on mtn tops. Original thickness unknown, but 650 ft. remain. Overlies Scott sh. Named because of its frequent occurrence in Anderson Co.

Anderson phyllite.

Pre-Cambrian: Southeastern Wyoming (Medicine Bow Mountains).

E. Blackwelder, 1926 (Geol. Soc. Am. Bull., vol. 37, pp. 620, 622, 641). *Anderson phyllite.*—Largely recrystallized dark-gray and black slaty rocks, with some calc. and a few sandy strata; much pyrite. Thickness 1,600 ft. Intergrades with overlying Ranger marble and with underlying Nash marble series. Named for old Anderson mining prospect, on Libby Creek, near contact of this fm. with Nash marble series. Assigned to early Algonkian.

Anderson clay.

A name applied to clay underlying Anderson coal in Jefferson Co., Ohio. Lies in Conemaugh fm. (Penn.), 15′2″ above Cambridge ls. (See R. E. Lamborn, Ohio Geol. Surv., 4th ser., Bull. 35, 1930, p. 134.)

Anderson Bay formation.

Triassic: British Columbia.

R. G. McConnell, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 70).

Anderson River group.

Age (?): British Columbia.

A. R. C. Selwyn, 1872 (Canada Geol. Surv. Rept. 1871–72, pp. 62–63).

Anderson-Spartanburg zone.

Pre-Cambrian: Northwestern South Carolina.

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2) and 1907 (Summary of mineral resources of S. C., pp. 6, 12). The *Anderson-Spartanburg zone* probably represents most prominent body of oldest phase of Archean exposed in S. C., to which all other rocks in State are probably junior, excepting tongues of the corresponding Carolina gneiss series which occupy portions of adjacent zones. It comprises a wide belt bounded on W. by Tiger zone along a line which irregularly extends from 82° long. on N. C. line to Brown's ferry on Savannah River; on N. by the State line; on E. by an irregular line which extends from a point approx. 1 mi. E. of Grover, along Whitaker Mtn Ridge, to mouth of Buffalo Creek, thence immediately N. of Gaffney to Thicketty Station, thence slightly W. of Thicketty Creek to West Mtn, thence to Graycourt Knob, thence near Wares Shoals (Saluda River), thence N. of Abbeville and immediately S. of Lowdensville, whence it proceeds along Rosses Creek to Savannah River, up which the bdy extends to Brown's ferry. It includes upper part of Cherokee, greater portion of Spartanburg, lower half of Greenville, lower three-fourths of Anderson, and a narrow northerly strip of Abbeville Counties. It is largely constituted of Carolina gneiss series and subordinately of Roan gneiss or hornblende series, and intrusive diabase and diorite. The rocks comprise granite, granitite, gneissoid slates, mica schists and slates, hornblende schists, graphite schists, etc. Pegmatization has been extensive. Many of rocks are garnetiferous.

Named for development in Anderson and Spartanburg Counties.

Andover granite.

Carboniferous (late): Northeastern Massachusetts.

C. H. Clapp, 1910 (Igneous rocks of Essex Co., Mass.). *Andover granite.*—Normal facies strongly resembles Squam granite. Includes a muscovite granite facies and aplite and pegmatite.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 86–87, 220–221, and map). *Andover granite.*—Typically a biotite-muscovite granite of moderately coarse and generally somewhat uneven grain. Generally more or less foliated and in many places strongly gneissic. Parts of it are porphyritic, and aplitic and pegmatitic phases abound. Color ranges from nearly white to dark gray. Composed essentially of feldspar, quartz, muscovite and biotite. Intrusive, and, with exception of few dikes, the youngest rock in region in which it occurs. Occupies large area around Andover.

†Andrew shale. (In Douglas formation.)

Pennsylvanian: Southwestern Iowa, northwestern Missouri, and eastern Kansas.

C. R. Keyes, 1899 (Am. Geol., vol. 23, p. 306). *Andrew sh.*—Upper memb. of Lawrence sh. [broad usage] in Mo. and eastern Kans. Overlies Iatan ls. memb. of Lawrence and underlies Plattsmouth ls.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936, for relations to present recognized units.

Named for Andrew Co., Mo.

Andrews schist.

Lower Cambrian: Western North Carolina, eastern Tennessee, and central northern Georgia.

A. Keith, 1907 (U. S. G. S. Nantahala folio, No. 143, p. 5). *Andrews schist.*—Calc. schist, 200 to 350 ft. thick. One of most conspicuous features is large number of crystals of ottrelite which spangle the rock. Muscovite and biotite also occur in frequent crystals, especially in upper parts of fm. The various micas are embedded in a fine matrix of carbonate of calcium of about same character as underlying Murphy marble. The feature which makes this schist of particular importance is development in it of deposits of brown hematite. At base the fm. grades into Murphy marble by interbedding and by diminution of amount of ottrelite. Upward it passes into Nottely qtzite, as the sandy material increases both in separate layers and as grains in the body of the schist.

Named for exposures at and in vicinity of Andrews, Cherokee Co., N. C. The town is situated on the schist.

Angela formation.

Cretaceous: Mexico.

W. F. Foshag, 1934 (Econ. Geol., vol. 29, No. 4, p. 333).

†Angelina series.

Tertiary: Eastern Texas.

R. T. Hill, 1902 (Franklin Inst. Jour., vol. 154, No. 2, pp. 153–154). *Angelina series.*—Later Eocene deposits of Tex. coastal plain. Overlies Camden series (earlier Eo.) and underlies Neocene. Includes Lufkin deposits (Yegua), Fayette sands, and Fleming beds (Frio clays). Thickness as given by Kennedy 1,407 ft.

Probably named for Angelina Co. or Angelina River.

†Angelina County beds.

Eocene: Eastern Texas.

See explanation under †*Lufkin beds.*

Angel Lake glacial stage.

A name applied by E. Blackwelder (Geol. Soc. Am. Bull., vol. 42, p. 918, 1931) to time covered by a Pleist. glacial deposit in Ruby Mtns, NE. Nev., which he correlates with Wisconsin stage. "The features of this stage can best be studied at Angel Lake, SW. of Wells" [Elko Co.].

Angola shale.

Upper Devonian: Western New York.

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, p. 24 and chart). ***Angola sh.***—Soft gray shales underlying Dunkirk sh. and overlying Rhinestreet sh. Included in Portage. [See also N. Y. State Mus. Mem. 6, 1903.]

D. D. Luther, 1903 (N. Y. State Mus. Bull. 69, pp. 1019–1029). ***Angola soft shales with concretions.***—Upper 100 ft. soft shales; lower 68 ft. concretionary sh. Underlie Silver Creek light soft shales and overlie Rhinestreet black sh. Included in Portage group of Lake Erie section.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 76 and chart). ***Angola sh.*** named for Angola, Erie Co., where it is exposed along Big Sister Creek. Overlain by Hanover sh. and underlain by Rhinestreet sh. The Hanover and Angola = Hatch sh. and flags to E.

G. H. Chadwick, 1919 (Geol. Soc. Am. Bull., vol. 30, p. 157). ***Angola shales*** are discon. overlain by Hanover shales and discon. underlain by Rhinestreet sh.

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69). ***Angola sh.*** is much younger than Hatch sh. and is = Gardeau sh. [narrow sense]. Is separated from overlying Hanover sh. [restricted] by Pipe Creek sh., with which it is discon. (?).

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60. No. 3, p. 193). ***Angola sh.*** overlies Hatch and underlies Wiscoy. Is = (ascending) Grimes ss., Gardeau sh. (restricted), Letchworth sh., and Portage ("Nunda") ss.

Anguilla formation.

Miocene (lower): West Indies.

T. W. Vaughan, 1918 (Wash. Acad. Sci. Jour., vol. 8, p. 271).

Anian period.

A term introduced by C. [R.] Keyes. Probably an abbreviated form of his Anianic period.

Anianic period.

A time term introduced by C. [R.] Keyes to cover what appears to be the erosion interval separating the pre-Camb. rocks formerly called "Archean system" and "Algonkian system." "Derived from Anian Straits, an illusory waterway the discovery of which long played chief incentive to early geographic exploration of North American continent." (See Iowa Acad. Sci. Proc., vol. 21, p. 201, 1914, also Iowa Acad. Sci. Proc., vol. 24, p. 56, 1917.)

Animas formation.

Tertiary? (Eocene?): Southwestern Colorado.

W. Cross, 1896 (U. S. G. S. Mon. 27, pp. 217–219). ***Animas River beds*** [*in heading*]; *Animas beds* [*in text*].—Yellowish brown clays, tuffs, sss., and cgls, in which andesitic material greatly predominates and presents a variety rivaling that in the Denver beds, of which they are considered the direct equiv. Thickness 700 or more ft. Overlie Laramie fm. and underlie Puerco fm. on Animas River below Durango.

J. B. Reeside, Jr., 1924 (U. S. G. S. P. P. 134). ***Animas fm. (restricted).***—Andesitic fluviatile deposits, of probable Eo. age, 0 to 2,670 ft. thick. Uncon. underlies Torrejon fm. and *uncon.* overlies McDermott fm.—an andesitic fm. 0 to 400 ft. thick, heretofore included in Animas fm., but believed to be of Cret. age. Animas fm. as here restricted appears to be present in only a limited area in SW. Colo.

In NW. New Mex. deposits believed to be approx. contemp. with it, but geographically separated from it and different lithologically, are here designated as *Ojo Alamo ss.*

†Animas interglacial epoch.

Pleistocene: Southwestern Colorado.

W. W. Atwood and K. F. Mather, 1912 (Jour. Geol., vol. 20, pp. 392–409), applied this name to interval preceding the Wisconsin (†Uinta) glacial stage and following the Durango (†Bighorn) glacial stage. The name *Animas* being preoccupied in same region, this interval was later (U. S. G. S. P. P. 166, 1932) described by them as *post-Durango and pre-Wisconsin interglacial stage.*

Animas moraine.

Pleistocene: Southwestern Colorado.

W. Cross and E. Howe, 1906 (Geol. Soc. Am. Bull., vol. 17, pp. 256–272), mention *Animas moraine* on several pages. The name is preoccupied in same region.

†Animas River beds.

Tertiary? (Eocene?): Southwestern Colorado.

See under *Animas fm.*

Animikean.

A term applied by some Canadian geologists to rocks formerly called "Animikie group" by other geologists. (See W. G. Miller and C. W. Knight, Ontario Bur. Mines Rept., vol. 22, pt. 2, 1914, p. 125.)

†Animikie group.

Pre-Cambrian (upper and middle Huronian): Canada, northern Michigan, Wisconsin, and Minnesota.

T. Sterry Hunt, 1873 (Am. Inst. Min. Engrs. Trans., vol. 1, pp. 331–395). *Animikie group.*—Dark-colored argillites and sss. underlying the great Keweenaw group and overlying Huronian crystalline schists along Thunder Bay (of N. shore of Lake Superior, in Canada). This is lower div. of upper copper-bearing series of Logan. Animikie is Indian name for Thunder Bay.

R. D. Irving, 1883 (U. S. G. S. 3d Ann. Rept., pp. 124, 135, 157–163), gave thickness of Animikie group (slates and qtzites) of the Huronian as 10,000 ft.

C. R. Van Hise, 1892 (U. S. G. S. Bull. 86), stated *Animikie series* is=upper Huronian; rests uncon. on lower Huronian; is uncon. overlain by Keweenawan series; and is=Penokee series.

C. W. Hayes, Robt. Bell, W. G. Miller, F. D. Adams, C. R. Van Hise, and A. C. Lane (composing the Special Committee of American and Canadian geologists appointed to determine the proper nomenclature for Lake Superior region), 1905 (Jour. Geol., vol. 13, pp. 89–104). *Animikie* (*Upper Huronian*) rests uncon. on Middle Huronian in Lake Superior region and is uncon. overlain by Keweenawan series.

Some geologists later restricted Huronian to pre-Animikie rocks, but the U. S. Geol. Survey continued to follow the definition adopted by the Special Committee in 1905, which included in it *Animikie group* (*upper Huronian*). Much has been written about the Animikie rocks and their correlation. R. C. Allen, 1915 (Jour. Geol., vol. 23, table opp. p. 703) transferred to middle Huronian the Animikie group, the Vulcan fm., the Felch schist, the †Hanbury sl., the Tyler sl., and the Quinnesec schist. In 1919 (Am. Inst. Min. and Met. Engrs. Bull. 153, pp. 2579–2594) he referred Quinnesec schist and upper part of †Hanbury sl. to upper Huronian, but included Vulcan fm. and lower part of †Hanbury in middle Huronian, and stated that his middle Huronian "carries the distinctive members of the old Animikie, the main iron-bearing series. Whether the name Animikie should be retained for the portion remaining as the Upper Huronian, or shall follow its most distinctive members into the Middle Huronian may be left for later decision."

A. C. Lawson, 1929 (Geol. Soc. Am. Bull., vol. 40, p. 383). The Animikie rests, at Thunder Bay, on the peneplain evolved in Eparchean interval, and therefore is not Huronian in any sense. Its correlative N. of Lake Huron is very uncertain and may be nonexistent.

A. Leith, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 325). There are a few iron fms. within the Upper Huronian. Among them are the fms. at Iron River, Crystal Falls, Florence, the W. part of Marquette dist., and probably in Cuyuna dist. The great producers, however, including the iron fms. of Marquette, Mesabi, Gogebic, and Menominee dists., are now considered to be of Middle Huronian age. Because of this new correlation it seems necessary to abandon the term *Animikie*, because it includes fms. of both Upper and Middle Huronian age, separated by an uncon. which, at least in Marquette dist., is of great magnitude.

†Animikie series.

Same as †*Animikie group*.

Ankareh shale.

Triassic (?): Northeastern Utah (Park City region) and southwestern Wyoming.

J. M. Boutwell, 1907 (Jour. Geol., vol. 15, pp. 439–458). *Ankareh sh.* (also *Ankareh fm.*).—Siliceous detrital deposits, chiefly red shales, which frequently become sandy through considerable thicknesses. Also includes a number of well-marked beds of rather coarse whitish gray ss., 20 to 55 ft. thick. A few fossiliferous grayish blue lss. a few ft. thick are also intercalated. Thickness of fm. 1,500 + ft. The div. line btw. Ankareh and underlying Thaynes fm. is made on lithologic grounds, calc. members characterizing the Thaynes and siliceous members characterizing the Ankareh. The basal memb. is taken as the coarse massive ss. that lies at base of the red sh. as a whole and immediately overlies a thin ls. Only a part of this fm. occurs in Park City dist., the highest part being marked by a prominent massive white ss. memb. Named for Ankareh Ridge, Park City dist., on which it attains its fullest and most characteristic development within the dist.

The same year (1907) that Boutwell introduced the name *Ankareh sh.* in Park City dist., Utah, A. C. Veatch introduced the name *Nugget ss.* for approx. equiv. deposits in SW. Wyo.

H. S. Gale and R. W. Richards, 1910 (U. S. G. S. Bull. 430), restricted both Nugget ss. and Ankareh sh. (See 1910 entry under *Nugget ss.*)

J. M. Boutwell, 1912 (U. S. G. S. P. P. 77, p. 59), redefined his Ankareh sh., as explained in 1912 entry under *Nugget ss.*, and called the upper part *Nugget ss.*

The name *Ankareh* is no longer used in SE. Idaho. (See 1916 and 1920 entries under *Nugget ss.*) According to G. R. Mansfield (U. S. G. S. P. P. 152, 1927) the Ankareh sh. of Park City dist., Utah, as restricted by Boutwell in 1912 is=lower part of Nugget ss. restricted of Mansfield plus underlying Wood sh., Deadman ls., Higham grit, and Timothy ss. of SE. Idaho.

Annabelle shale. (*In Monongahela formation.*)

Pennsylvanian: Northern West Virginia.

R. V. Hennen and D. B. Reger, 1913 (W. Va. Geol. Surv. Rept. Marion, Monongalia, and Taylor Counties, p. 250). *Annabelle sh.*—Greenish gray and brown sh., 10 to 12 ft. thick. Underlies Uniontown ss. and overlies Uniontown coal. At Annabelle, Marion Co., it largely replaces Uniontown ss.

Annapolis formation.

Triassic: New Brunswick and Nova Scotia.

S. Powers, 1915 (Geol. Soc. Am. Bull., vol. 26, p. 93).

Annona chalk.

Upper Cretaceous: Northeastern Texas, Louisiana, southeastern Oklahoma, and southwestern Arkansas.

R. T. Hill, 1894 (Geol. Soc. Am. Bull., vol. 5, p. 308). Pure white chalk, called *White Cliffs chalk* in Ark. and *Anona chalk* in Tex. Underlies marls called *Brownstown marls* in Ark. and *Kickapoo marls* in Tex. Overlies Taylor marls.

According to 1925 and 1926 work of L. W. Stephenson and C. H. Dane (U. S. G. S. Press Bull. 8823, Sept. 10, 1926; A. A. P. G. Bull., vol 11, p. 9, 1927; Ark. Geol. Surv. Bull. 1, p. 79, 1929) the Annona chalk in Ark. underlies Marlbrook marl restricted (mistaken for the older Brownstown marl in early repts) and overlies Ozan fm. (upper and uncon. part of Brownstown marl of early repts, which is=in age lower part of typical Taylor marl). In NE. Tex. the Annona rests uncon. on Brownstown marl restricted (=lower part of Brownstown marl of earlier usage) and uncon. underlies marl that is believed to be upper part of Taylor marl. According to L. W. Stephenson, 1937 (U. S. G. S. P. P. 186G, p. 135), Ozan fm. is=lower part of Annona chalk of Red River Co., NE. Tex., which lower part of Annona is=lower part of Taylor marl.

Named for outcrops about 2 mi. NW. of Annona, Red River Co., Tex.

Annville limestone.

B. L. Miller, 1925 (Pa. Geol. Surv., 4th ser., Bull. M7, pp. 124, 133). Trade name for belt of "Cambro-Ordovician" [Upper Camb.] lss., a few hundred ft. wide and about 15 mi. long, that passes through or very near Myerstown, Lebanon, Annville, and Palmyra, Lebanon Co., Pa. Quarried in vicinity of Annville.

Anoka moraine.

Pleistocene (Wisconsin stage): Southern Minnesota (Kandiyohi, Meeker, and Anoka Counties).

F. Leverett, 1932 (U. S. G. S. P. P. 161, pp. 84–85). Included in Crow River morainic system. Village of Anoka, Anoka Co., is on this moraine.

Anona chalk.

See *Annona chalk.*

† Anorthosite series.

Pre-Cambrian: Canada.

F. D. Adams, 1893 (Jour. Geol., vol. 1, pp. 332–335).

C. R. Van Hise and C. K. Leith, 1909 (U. S. G. S. Bull. 360, p. 59). As the area studied in Laurentide Mtns widened, a new fm. was found, a laminated gabbro. It was recognized as being largely composed of labradorite or anorthosite and so was first called "Anorthosite" or "Labradorian," and afterward "Norian." [For further particulars see index of Bull. 360.]

Antelope moraine (also **morainic system**).

Pleistocene (Wisconsin stage): Southern Minnesota, South Dakota, and North Dakota.

Named by T. C. Chamberlin, 1883 (U. S. G. S. 3d Ann. Rept., pp. 388, 393), *Antelope Hills or third moraine.* He believed it next succeeded the Gary moraine. Later the name was shortened to *Antelope moraine.* According to work of F. Leverett (U. S. G. S. P. P. 161, 1932) this moraine is not the third moraine. Named for Antelope Ridge or Antelope Hills, in SW. part of Lac qui Parle Co., Minn. Is of late Wisconsin age, according to W. C. Alden.

Antelope rhyolite.

Tertiary (?): Northwestern Arizona (Oatman dist., Mohave County).

C. Lausen, 1931 (Ariz. Bur. Mines Bull. 131, and map).

Antelope Creek bed. (In Strawn formation.)

Pennsylvanian: Central Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 374, 385, 386). *Antelope Creek bed.*—Variable ss., friable to hard, pure to clayey, with a little cgl.

and some clay. Local deposit. Memb. of Strawn div. Underlies Indian Creek bed and overlies Comanche Creek bed.

Named for Antelope Creek, San Saba Co.

† Antelope Hills moraine.

Name originally proposed by T. C. Chamberlin (U. S. G. S. 3d Ann. Rept. pp. 388, 393, 1883) for the Antelope moraine of modern literature.

† Anterior sandstones and shales.

Descriptive term applied in early repts to a lower part of Newark group in Conn.

† Anterior trap.

Descriptive term applied in early repts to a basalt flow in lower part of Newark group in Conn.

†Anthracolithic.

A European term synonymous with *Carboniferous period* as used by U. S. Geol. Survey and other American geologists, i. e., including Perm., Penn., and Miss. series. Introduced by William Waagen in 1891. For definition see U. S. G. S. Bull. 769, p. 78, 1925.

Anticosti group.

Silurian: Canada and New York.

E. Billings, 1857 (Canada Geol. Surv. Rept. Prog. 1853–1856, pp. 247–345). *Anticosti group*, divided into divisions C, D, E, and F.

W. E. Logan, 1863 (Canada Geol. Surv. Rept. 1843–1863, pp. 298–344). *Anticosti group* includes Oneida cgl., Medina ss., Clintonl group, and Niagara group.

C. Schuchert and W. H. Twenhofel, 1910 (Geol. Soc. Am. Bull., vol. 21, pp. 680, 704). "Anticosti group" of Billings included Oneida, Medina, Clinton, and Niagara sh. and ls., and is synonym of Niagara period of Dana, 1863 and 1895. "Billings' term 'Anticostian,' although a synonym for Niagaran, will be retained for local application and value."

G. H. Chadwick, 1918 (Geol. Soc. Am. Bull., vol. 29, p. 365). *Anticostian* is best available series name for the Eontaric as here defined, that is, including approx. Medina, lower Clinton, upper Clinton, and Rochester.

The U. S. Geol. Survey uses *Niagara group* to include Lockport dol. and Clinton fm. (in which Rochester sh. is included as a memb.), and treats the Medina as a distinct group.

Anticostian.

See under *Anticosti group.*

Antietam sandstone.

Lower Cambrian: West Virginia, Virginia, Maryland, and southeastern Pennsylvania.

A. Keith, 1893 (as reported by G. H. Williams and W. B. Clark, in Maryland, its resources, industries, and institutions, chap. 3, p. 68. The fm. was described, but not named, by Keith in Am. Geol. vol. 10, p. 365, 1892). *Antietam ss.*—Fine-grained white ss., 250 ft. thick, with scolithus and Lower Camb. fossils. Underlies Camb. ls. and overlies Harper's Ferry shales [Harpers sh. of present usage].

In SE. Pa. the lithologic character of fm. changes and it is there called *Antietam qtzite* in some areas and *Antietam schist* in other areas.

Named for exposures E. of Antietam Creek, in Harpers Ferry quad.

Antigua formation.

Tertiary: West Indies.

J. W. W. Spencer, 1901 (London Geol. Soc. Quart. Jour., vol. 57, pp. 497, 526) and 1902 (vol. 58, p. 357). [Assigned to Tert.]

Later writers have assigned it to Cret., to Olig., and to Mio.

Antioch sandstone.

Permian: Central southern Oklahoma (Garvin County).

D. A. Green, 1936 (A. A. P. G. Bull., vol. 20, No. 11, pp. 1465, 1466). South of Washita River the upper part of Garber-Wellington section again contains thick sss., as at Antioch, in T. 3 N., R. 2 W. These Antioch sss. grade northward into the sh. of Paoli area, thus indicating that they did not come from same direction as the Garber of Cleveland Co. Btw. the Antioch sss. and the Pontotoc on E. the lower section is similar to that E. of Paoli, the sss. being very lenticular. [On p. 1466 Green states that on S. side of Washita River, in area SW. of Maysville, a good sh. section, 160 ft. thick, lies btw. base of Purcell ss. lenses of Hennessey sh. and *Antioch ss.*]

Antler formation.

Mississippian: British Columbia.

W. A. Johnston and W. L. Uglow, 1926 (Canada Geol. Surv. Mem. 149, p. 22).

†Antlers sand.

Lower Cretaceous (Comanche series): Southeastern Oklahoma and northeastern Texas.

R. T. Hill, 1894 (Geol. Soc. Am. Bull., vol. 5, p. 303). Pack sand, at base of mtns in southern Ind. Ter., identical in character with that of Trinity and Paluxy sands of Brazos section in Tex., except that the lss. which there separate them have thinned out in country N. of the Brazos. Uncertain whether it represents either one or both of the sands of Trinity div. of Tex., so provisional name *Antlers sands* is used.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, p. 114). *Antlers sand* will be applied to equivalents of all the fms. of Trinity group (Paluxy, Glen Rose, and Travis Peak) as they coalesce along W. border region N. of Parker Co.

This name was many years ago discarded by Okla. Geol. Surv. and U. S. Geol. Survey, both of whom employ the older name *Trinity sand*, for the undiff. equivalent of Trinity group of Tex.

Named for Antlers, Pushmataha Co., Okla.

†Antoine dolomite.

Pre-Cambrian (lower Huronian): Northwestern Michigan (Menominee district).

C. R. Van Hise, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, pp. 16, 17, and U. S. G. S. Mon. 36, pp. XXV, XXVI). *Antoine dol.* of Menominee dist. overlies Sturgeon qtzite and underlies Vulcan iron fm.

C. R. Van Hise and W. S. Bayley, 1900 (U. S. G. S. Menominee folio, No. 62), and W. S. Bayley, 1904 (U. S. G. S. Mon. 46, on Menominee dist.), applied *Randville dol.* to the dol. overlying Sturgeon qtzite in Menominee dist., stating that it borders N. side of Lake Antoine for a part of its length, that it is uncon. overlain by Vulcan fm., the lower memb. of which consists of slates, cgls., qtzites, and jaspilites, and that Negaunee fm. is represented in Menominee dist. only by pebbles in the qtzite at base of Vulcan fm.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, p. 333 and chart opp. p. 598), applied *Randville dol.* to the dol. overlying Sturgeon qtzite in Menominee dist., stating that a belt of the dol. borders N. side of Lake Antoine for a portion of its length, and that it is overlain by middle Huronian qtzite (correlated with Ajibik qtzite, Siamo sl., and Negaunee fm.) which "in most of dist. is not separated from upper part of Randville dol."

Antonio slate.

Pre-Cambrian: Central northern New Mexico (Manzano Mountains).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257–259; Conspectus of geol. fms. of N. Mex., pp. 4, 5). *Antonio slates.*—Somewhat metamorphosed argill. beds, 2,000 ft. thick, which lie beneath Tijeras qtzite and are well displayed at N. end of Manzano Mtns. Underlain by other but as yet undet. sediments. [Derivation of name not given.]

Antonito limestone.

Pennsylvanian (?): Central northern New Mexico (Sandia Mountains).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257–259; Conspectus of geol. fms. of N. Mex., pp. 3, 5). *Antonito lss.*—Lowermost of heavy gray lss. exposed in fine sections at S. extremity of Sandia Range. Thickness 200 ft. Basal part of Maderan series and overlies Mosca ls. [Derivation of name not given.]

Antrim shale.

Upper Devonian: Michigan (Lower Peninsula).

A. C. Lane, 1901 (Mich. Miner, vol. 3, No. 1, p. 9). We are considering replacing *St. Clair* (preoccupied) by *Antrim,* the name of the county in which the shales are exposed.

A. C. Lane, 1902 (Mich. Geol. Surv. vol. 8, pt. 2, map at end). *Antrim.*—Mainly black sh., often bituminous. Underlies Berea grit and overlies Traverse [fm.].

R. B. Newcombe, 1933 (Mich. Dept. Cons., Geol. Surv. Div. Pub. 38, geol. ser. 32, pp. 47, 48), stated that *Antrim sh.* contains Miss. fossils in upper part.

Anvil ferruginous chert member (of Ironwood formation).

Pre-Cambrian (upper Huronian): Northwestern Michigan (Gogebic district) and northwestern Wisconsin.

W. O. Hotchkiss, 1919 (Eng. and Min. Jour. vol. 108, pp. 501, 505). *Anvil ferruginous chert memb.*—Dominantly wavy-bedded granular or fine-grained ferruginous cherts, 0 to 375 ft. thick. Top memb. of Ironwood fm. Eroded away in places. Overlies Pence ferruginous sl. memb. Named for Anvil mine, E. of Bessemer, Mich.

Anvil Rock sandstone member (of McLeansboro formation).

Pennsylvanian: Western Kentucky and southeastern Illinois.

D. D. Owen, 1856 (Ky. Geol. Surv. vol. 1, p. 45, and pl. showing section of Lower Coal Measures). *Anvil Rock ss.*—Massive ss., 31 ft. thick, separating Lower Coal Measures from Upper Coal Measures; universally known in SW. Ky. as "Anvil Rock," because of resemblance to an anvil of two conspicuous masses of the ss. situated on its northern escarpment on Hines Creek, Union Co.

G. H. Cady, 1926 (Ill. Acad. Sci. Trans., vol. 19, pp. 250–272). Anvil Rock ss. outcrops in Saline Co., SE. Ill., where it is 60±ft. thick and lies 5 to 20 ft. above base of McLeansboro fm. Relations to Bankston Fork ls. undet.

Anzar phase (of Santa Lucia series).

Paleozoic (provisionally): Southern California (San Benito County).

P. F. Kerr and H. G. Schenck, 1925 (Geol. Soc. Am. Bull., vol. 36, pp. 470, 471, and map). A metamorphic phase probably produced by serpentinization of basic phase of the igneous intrusion. There is a small area of red chert and granite associated with schist and gneiss W. of San Andreas fault in vicinity of Anzar Lake. The chert appears to be Franciscan and the serpentinized schist and gneiss an alteration of the granite; all are now confused in their relations because of faulting. In the accompanying strat. column they are included as *Anzar phase of Santa Lucia series.* Further study might show that the rocks of this limited region are either (1) entirely Franciscan, (2) a slight variation of the Santa Lucia, or (3) a separate series.

Apache group.

Pre-Cambrian: Central Arizona.

F. L. Ransome, 1903 (U. S. G. S. P. P. 13). *Apache group.*—Chiefly qtzites, with subordinate shales and cgls. Thickness 800 to 1,000 ft. Underlies Globe ls. and uncon. overlies Pinal schist. Divided into (descending): Dripping Spring qtzite, 400 ft.; Barnes cgl., 10 to 15 ft.; Pioneer sh., 200 ft.; and Scanlan cgl. 1 to 6 ft.

F. L. Ransome, 1911 (Min. and Sci. Press, June 3, 1911). Recent work in Ray quad., which adjoins Globe quad. on S., has revealed that Dripping Spring qtzite as mapped in Globe quad. included two qtzites, each 400 ft. thick, separated by 250 ft. of cherty ls. The name *Dripping Spring* is restricted to the lower qtzite.

F. L. Ransome, 1915 (Wash. Acad. Sci. Jour., vol. 5, pp. 380–385). The ls. overlying Dripping Spring qtzite restricted is here named *Mescal ls.* and the overlying qtzite, which comprises top fm. of Apache group, is here named *Troy qtzite.*

In 1932 N. H. Darton (Wash. Acad. Sci. Jour., vol. 22, No. 11, p. 319), removed Troy qtzite (which contains Upper and Middle Camb. fossils) from the nonfossiliferous underlying fms. of Apache group, which he assigned to Algonkian system (now discarded) because of their strong lithologic resemblance to Chuar and Unkar groups of Grand Canyon. The fms. now included in Apache group consist of (descending) Mescal ls., Dripping Spring qtzite, Barnes cgl., Pioneer sh., and Scanlan cgl.

Named for exposures on W. face of Apache Mtns.

†Apache sandstone.

Upper Cambrian: Grand Canyon.

D. Hager, 1924 (Min. and Oil Bull., vol. 10, p. 137). *Apache ss.*, a new name given me by Darton for beds below the Redwall. [Mr. Darton says (personal communication) that he referred to Tapeats ss., but that in conversation he may have called it Apache ss.]

Apache limestone.

Permian: Western Texas (Apache Mountains).

K. H. Crandall, 1929 (A. A. P. G. Bull., vol. 13, pp. 929, 939–940). In Apache Mtns, in SE. Culberson Co., there is exposed a ls. series about 1,000 ft. thick, which resembles Capitan ls. to marked degree. The local name *Apache ls.* has been applied to it. It consists of massive gray and white lss., exhibiting practically same lithological characteristics and fauna as the Capitan and an overlying, well-bedded pisolitic series resembling Carlsbad ls. No fossils found by writer, but Girty repts a few forms of Guadalupian age. It is almost certainly = Capitan and Carlsbad lss. The Apache ls. seems to be a barrier reef with accompanying lagoonal deposits.

Apache sandstone.

Upper Cretaceous: Eastern Colorado (Walsenburg district).

C. S. Lavington, 1933 (A. A. P. G. Bull., vol. 17, No. 4, p. 399). In Walsenburg dist. the basal zone of Pierre sh. contains a 20-ft. ss. memb. which H. W. C. Prommel in an unpublished rept has called *Apache ss.*

†Apalachicola group.

Miocene (middle and lower): Southern Georgia and northern Florida.

G. C. Matson and F. G. Clapp, 1909 (Fla. Geol. Surv. 2d Ann. Rept., table opp. p. 50, pp. 67–69). *Apalachicola group* was formerly designated *Chipolan stage* and *Chipola group*, but these names are abandoned because *Chipola* has been used to designate a marl belonging to the group. The group includes a number of beds differing widely in lithological character, though they are recognized by their fossils as integral parts of a single group. While lss. and marls predominate, the group also includes beds of nearly pure sand and clay. The entire period of deposition appears to have been characterized by accumulation of more or less terrigenous materials, and hence the lss. are usually rendered somewhat impure by an admixture of clay and sand. At certain times the conditions appear to have been especially favorable for development of organic life and some horizons, such as Chipola marl memb. of Alum Bluff fm. and the "silex bed" of Tampa fm., contain very large faunas. The Apalachicola group is separated into four fms.—Chattahoochee, Hawthorne, Tampa, and Alum Bluff. There is, however, some reason for believing that the first three are, in part at least, synchronous, though exact equivalence is difficult to determine where outcrops are widely scattered and faunal variations are slight. The Alum Bluff is clearly younger than Chattahoochee fm., upon which it rests. Assigned to Olig.

Includes Alum Bluff group and Tampa ls.

Named for exposures along Apalachicola River in western Fla.

Apishapa shale. (Of Colorado group.)

Upper Cretaceous: Eastern Colorado.

G. K. Gilbert, 1896 (U. S. G. S. 17th Ann. Rept., pt. 2, p. 567). *Apishapa fm.*—Chiefly argill. laminated sh., dark gray, weathering yellowish. Thickness 500 ft. Upper fm. of Niobrara group in Arkansas Valley of eastern Colo. Overlies Timpas fm. and underlies Pierre group. Named for Apishapa River.

The Niobrara and Benton are not now treated as groups by U. S. Geol. Survey, the broader term *Colorado group*, which includes them both, being considered the more useful group name. Where the Niobrara deposits and Benton deposits are not subdivided, they are called *Niobrara ls.* and *Benton sh.*, respectively.

Apison shale.

Lower Cambrian: Eastern Tennessee, western North Carolina, and northwestern Georgia.

C. W. Hayes, 1894 (U. S. G. S. Ringgold folio, No. 2; Kingston folio, No. 4; and Chattanooga folio, No. 6). *Apison sh.*—Brightly colored, slightly sandy or clayey shales, banded in red, purple, green, and yellow colors. A bed of gray siliceous ls. [†Beaver ls.] sometimes occurs btw. this and overlying Rome fm. Thickness of fm. more than 1,000 ft. Oldest fm. in region.

Named for exposures at Apison, James Co., Tenn.

According to C. E. Resser (personal communication May 1936) the Apison sh. is part of Rome fm., and so-called Beaver ls. of Knoxville folio is a ls. lentil in Rome fm.

†Appalachian group.

†Appalachian series.

†Appalachian system.

Paleozoic: Pennsylvania (Appalachian region).

H. D. Rogers, 1836 (Pa. Geol. Surv. 1st Ann. Rept., pp. 12–22), divided the Paleozoic rocks of Appalachian region into *Carboniferous system* and *Appalachian system*. In 1840 rept Rogers called the rocks *Appalachian system* and *Appalachian series*.

H. S. Williams, 1891 (U. S. G. S. Bull. 80, p. 60). Like objection exists to term "New York system" [as a name for *Paleozoic* in America]. While the base is well marked, the rocks of Pa. to top of Coal Measures should be added to them to complete the system. Adding the Carbf. system, as expressed in Pa., Ohio, and Va., a natural group of the first order is produced, which nearly corresponds to what we call *Paleozoic era*. Were we to adopt for this grand terrane the name *Appalachian group*, we should have a properly constituted name for an actual existing geologic group, free from theory, and its use would probably assist in the progress of science.

Appalachian revolution.

A period of mountain building and erosion in Appalachian region that is believed to have begun in late Penn. time and ended at beginning of Triassic time. (See C. Schuchert, Textbook of Geol., pt. 2, pp. 101, 427, 1924.) The 1933 edition of this Textbook, by C. Schuchert and C. O. Dunbar, assigns (p. 65) this revolution wholly to Perm. time.

†Appanoose beds.

Pennsylvanian: Central southern Iowa.

H. F. Bain, 1896 (Iowa Geol. Surv. vol. 5, pp. 378–394). *Appanoose beds.*—Shales, lss., coals, and clays forming lower part of Des Moines stage in Appanoose Co. Overlain by Chariton cgl. (top div. of Des Moines stage). *Includes Mystic coal.*

H. F. Bain, 1897 (Iowa Geol. Surv. vol. 7, pp. 426–469), divided Des Moines "stage" of Guthrie Co., Iowa, into (descending): (1) Sandy sh., 40–100 ft. (probably=Pleasanton sh. of Mo. and Kans.); (2) sh., sss., and lss. with 3 coals (probably=Appanoose fm. of Iowa and Henrietta fm. of Mo.); (3) sss., sandy sh., coals, etc. corresponding to Cherokee sh. of Kans.

H. F. Bain, 1905 (Iowa Geol. Surv. vol. 15, pp. 102–122). *Appanoose beds*, near middle of Des Moines fm., include Mystic or Centreville coal, also lss. known as "Bottom rock," "Cap rock," "Thirteen-foot ls.," and "Fifty-foot ls."

J. H. Lees, 1909 (Iowa Geol. Surv. vol. 19, pp. 598–604). *Appanoose fm.*=Henrietta fm. of Mo. Consists of (descending): *Lonsdale coal*, 1 to 2½ ft.; sh. with ls. and ss. seams, 25 to 100 ft.; coal and fine clay, 4 to 16 ft.; Chariton cgl., 15 to 25 ft.; shales and lss., 50 to 100 ft.; Mystic coal, 6 to 36 inches; fine clay, 1 to 8 ft.; ls., 15 to 35 ft. Underlies Pleasanton shales and overlies Cherokee beds.

Named for development in Appanoose Co.

Appekunny argillite.

Pre-Cambrian (Belt series): Northwestern Montana (Glacier National Park) and southeastern British Columbia.

B. Willis, 1902 (Geol. Soc. Am. Bull., vol. 13, pp. 316, 322). *Appekunny argillite.*—Prevailingly gray, black, and greenish; thin-bedded; ripple marked; interbedded with white qtzite; carries flattened concretions resembling fossils. Thickness 2,000± ft. Overlies Altyn ls. Underlies Grinnell argillite. It is possible more detailed strat. study may develop fact that Grinnell and Appekunny argillites are really phases of one great fm., and that line of distinction btw. them is one diagonal to the stratification. Excellent exposure occurs on NE. spur of Appekunny Mtn, Mont., but also well exposed in cliffs throughout Lewis and Livingston Ranges.

Appistoki member (of Appekunny argillite).

Pre-Cambrian (Belt series): Northwestern Montana (Glacier National Park) and southern Alberta.

C. L. and M. A. Fenton, 1931 (Jour. Geol., vol. 39, No. 7, pp. 670–679). *Appistoki memb.*—Middle memb. of Appekunny fm. Consists of 2,000 to 2,200 ft. of thin-bedded to thick-bedded metargillite, with minor beds of siliceous argillite and qtzite. On Rising Wolf and Appistoki Mtns, in S. part of Lewis Range, Mont., this memb. consists of a lower series of brownish to black metargillites and upper greenish series which forms heavy ledges and falls. Northward to Blackiston Brook, Alberta, the memb. becomes more highly siliceous, with beds of qtzite; the color becomes green in lower portions. Underlies Rising Wolf memb. and overlies Singleshot memb.

Appleton stage.

Pennsylvanian: Western Arkansas coal field and central eastern Oklahoma.

A. Winslow, 1896 (N. Y. Acad. Sci. Trans., vol. 15, pp. 51–52). *Appleton stage.*—Sss. and shales underlying Booneville stage and overlying Danville stage. Consists of (descending): Shales, few ft. to 40 ft.; Cross Plains ss., 50 to 200 ft.; Russellville shales, 500 to 600 ft.; and Washburn sss., 500 to 600 ft.

Represents middle part of Atoka fm.

Probably named for Appleton, Pope Co., Ark.

† Appomattox formation.

Pleistocene and Pliocene (?): Atlantic Coastal Plain, Virginia to Alabama.

W J McGee, 1888 (Am. Jour. Sci., 3rd, vol. 35, pp. 125, 328–330). *Appomattox fm.*—A series of predominantly orange-colored clays and sands of later Tert. age, regularly but obscurely stratified, sometimes interbedded with gravel or interspersed with pebbles. Thickness 0 to 100 ft. Typically exposed on and near Appomattox River from its mouth to some mi. W. of Petersburg. Rests on Potomac ss., from which it is readily distinguished by its greater homogeneity, the more complete intermingling of its aren. and argill. materials, its more regular stratification, and its more uniform and predominating orange color. It is as readily distinguished from overlying Columbia deposits by its vertical homogeneity, its comparatively regular stratification, distinctive color, and greater range in altitude, extending as it does from tide level to highest eminences of Piedmont escarpment btw. the Rappahannock and the Roanoke. Continues to thicken and expand S. of Appomattox River, until it forms the surface everywhere in vicinity of fall line save where it is cut away by erosion or concealed beneath Columbia deposits. Is typically exposed on the Roanoke opposite Weldon, N. C. Forms predominant surface fm. over a zone 40 or 50 mi. wide on the Roanoke, but attenuates and narrows northward, finally disappearing on Potomac Creek 4 or 5 mi. N. of Fredericksburg; and although it appears to thicken seaward it soon disappears beneath tide level and newer deposits. No fossils. Overlies Mio. and underlies Columbia fm. Fresh aspect and comparatively slight erosion indicate its age is much nearer Columbia fm. than Mio. It is probable it will be found to reach considerable volume in S. C., Ga., and Ala., and although precise relations have not been ascertained, it is indicated not only by physical considerations but by Fontaine's recent studies in Va. and Ala. that at least part of Orange Sand of Hilgard and other southern geologists is = Appomattox fm. of N. rather than Columbia, which is not known to extend much farther S. than N. C.

Includes equivalents of †Lafayette fm. (Plio. ?) and of Columbia group (Pleist.).

Apsey formation.

Lower Ordovician: Newfoundland.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4). *Apsey fm.*—Shales carrying 2 species of *Princetonia*, underlain by brown shales carrying *Shumardia*. Overlain by Maidment fm. and underlain by Brown Mead fm. Included in Clarenville series. [Derivation of name not stated.]

Apulia shale.

Apulia limestone.

Devonian: Central New York (Onondaga County).

T. A. Conrad, 1841 (N. Y. Geol. Surv. 5th Ann. Rept., p. 31). Sherburne group underlies Tully ls. and overlies *shales near Apulia* [Onondaga Co.], which rest on black sl.

W. W. Mather, 1843 (Geol. N. Y., vol. 1). Erie div. includes Ludlowville sh., Encrinal ls., Moscow sh., *Apulia and Sherburne shales*, and Cazenovia group. [Apulia sh. not described.]

G. A. Cooper and J. S. Williams, 1935 (Geol. Soc. Am. Bull., vol. 46, pp. 790–808). *Apulia memb. of Tully fm.*—*Apulia* was proposed by Conrad in 1841 for a part of Hamilton group, but was early discarded and nearly forgotten. Because of scarcity of local names in Tully Twp the name is here revived, with a new meaning. Type section is in the ravine adjacent to June's quarry, 1½ mi. SW. of Apulia Station, Tully Twp. It is hard, heavy-bedded, aren. ls. containing *Hypothyridina* in great numbers and at several levels. Thickness at type section, 17 ft. 3 in.; at Moravia, 12± ft.; at Ovid, 4± ft.; at Bellona, 2½ ft. Underlies West Brook memb. of Tully and overlies Tinkers Falls memb. of Tully.

Aquashicola formation.

Silurian: Northeastern Pennsylvania (Carbon and Northampton Counties).

B. L. Miller, 1911 (Pa. Topog. and Geol. Surv. Rept. No. 4, p. 51). *Aquashicola fm.*—Shales, chiefly red but in part olive colored, with occasional layers of sss., which are numerous in lower part but rare in upper part. Thickness 1,275 ft. in Lehigh Gap dist. Called *Clinton shales* in repts 2d Pa. Geol. Surv., but are more recent than Clinton, because they overlie Shawangunk fm., which carries Salina fossils at Otisville, N. Y. Believed to be same as High Falls fm. Named for occurrence in valley of Aquashicola Creek.

Aquia formation. (Of Pamunkey group.)

Eocene (lower): Eastern Virginia, Maryland, and Delaware.

W. B. Clark and G. C. Martin, 1901 (Md. Geol. Surv. Eocene vol., p. 58). *Aquia fm.*—More highly aren. and much more calc. than overlying Nanjemoy fm. Consists chiefly of greensands and greensand marls, frequently argill. Thickness 100 ft. Characterized by well-marked fauna representing a clearly defined paleontological stage. Is divided into Paspotansa memb. or substage above and Piscataway memb. or substage below, which are faunally separable over considerable parts of Md. and Va. Rests uncon. on Cret. This is an expanded definition of Aquia Creek stage or fauna, which did not include basal 60 ft. of unfossiliferous greensand. Is bottom fm. of Pamunkey group.

Type loc., Aquia Creek, Stafford Co., Va.

†Aquia Creek series.

Lower Cretaceous: Northeastern Virginia.

L. F. Ward, 1895 (U. S. G. S. 15th Ann. Rept., p. 326). *Aquia Creek series.*—Most typically developed within vicinity of Aquia Creek [Stafford Co., Va.], and I therefore decided to give that name to the memb. designated as "Brooke" by Prof. Fontaine. The materials were obviously derived to a great extent from the Rappahannock series. There is great difference in the fossil plants of Aquia Creek and Rappahannock series. The materials of Aquia Creek series, as well as their mode of deposition, are different from those of any of underlying members of Potomac fm., although they consist largely of redeposited sands, clays, and gravels of the earlier series. Uncon. underlies Iron Ore series of Potomac fm; and uncon. overlies Mount Vernon series of Potomac fm.

Ward later replaced *Aquia Creek series* with *Brooke fm.*, but the use of both of those names was discontinued years ago. According to later studies by W. B. Clark and B. L. Miller (Va. Geol. Surv. Bull. 4, 1912) the Aquia Creek series or Brooke fm. of Ward is included in Patapsco and Patuxent fms. of present nomenclature.

†Aquia Creek stage.

Eocene: Eastern Virginia and Maryland.

W. B. Clark, 1895 (Johns Hopkins Univ. Circ., vol. 15, No. 121, p. 3). The upper beds of Eo. of middle Atlantic slope may be designated *Woodstock stage*, and lower beds may be designated *Aquia Creek stage*. Fossils of Woodstock stage are closely related to "Claiborne" types, and those of Aquia Creek stage are decidedly "Lignitic."

W. B. Clark, 1896 (U. S. G. S. Bull. 141, pp. 54, 57; Am. Jour. Sci., 4th, vol. 1, pp. 369–370). *Aquia Creek stage or fauna*.—Greensands, 77 ft. thick, containing fauna resembling middle Lignitic. Named for Aquia Creek, Va. Separated from overlying Woodstock stage or fauna by 117 ft. of greensands and argill. sands, and from underlying Rancocas fm. (Cret.) by 60 ft. of greensand, at times argill., with basal pebble bed. [This 60 ft. of greensand was included in *Aquia fm.* as defined by W. B. Clark and G. C. Martin in 1901.] All included in Pamunkey fm.

The foregoing definitions apply to upper part only of Aquia fm. of present nomenclature.

Aquia Creek freestone.

Trade term for ss. quarried from Potomac group in vicinity of Aquia Creek, Stafford Co., Va. See under †*Rappahannock series*.

†Aquidneck series.

†Aquidneck shales.

Carboniferous: Southeastern Rhode Island and southeastern Massachusetts (Narragansett Bay region).

A. F. Foerste, 1899 (U. S. G. S. Mon. 33, pp. 348–364 and map, pl. 31). *Aquidneck series* (mapped as *Aquidneck shales*).—Chiefly dark-blue fissile shales, with isolated thin beds of ss. and cgl., 3,000+ft. thick, overlain, in part of area, by 150 to 250 ft. of greenish sh. On E. side of Sakonnet River, and across Portsmouth and Middletown (on W. side of Sakonnet River), the upper greenish sh. is represented by Sakonnet ss., mapped as separate fm. The Aquidneck series grades into underlying Kingstown series through a series of "transition rocks" (mapped separately), and is overlain by Purgatory cgl. It forms almost whole of Aquidneck Island (near Newport, R. I.).

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, map), mapped Aquidneck shales of Foerste as Rhode Island fm.

Aquilonian.

Lower Cretaceous: California.

F. M. Anderson, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 6, p. 1253). *Aquilonian*, Upper Jurassic [of European classification], included in Knoxville series.

The U. S. Geol. Survey classifies Knoxville as Lower Cret.

Aquinnah conglomerate.

Pleistocene: Southeastern Massachusetts (Marthas Vineyard).

J. B. Woodworth and E. Wigglesworth, 1934 (Harvard Coll. Mus. Comp. Zool. Mem., vol. 52, p. 160). *Aquinnah cgl.*—Semiconsolidated quartzose cgl. with numerous cetacean bones. Thickness 0 to 1½ ft. In previous repts called "osseous cgl."

and referred to Mio., but it contains the remains of a Pleist. horse. Underlies Dukes boulder bed at Gay Head Cliffs fold, on Marthas Vineyard, the only place it is known to occur. Is nonglacial and preglacial, and probably is an old stream gravel. *Aquinnah* is Indian name for *Gay Head.*

Arago group.

Eocene: Southwestern Oregon.

J. S. Diller, 1896 (U. S. G. S. 17th Ann. Rept., pt. 1, pp. 458–462, 475). *Arago beds.*—Great mass of shales containing here and there much material of igneous origin. Well exposed at Cape Arago [Coos Bay quad.]. Fossils relegate them definitely to position high in Eo. Uncon. overlain by Empire beds (Mio.).

W. H. Dall, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, pp. 336–343). *Arago beds.*—Name suggested by Diller. Consist of sss. and shales, containing fossils that suggest correlation with Clabornian of Gulf region. Are apparently newer than blackish rocks of region about junction of Little River and the North Umpqua. [Further along he calls latter beds *Umpqua beds.*] The Arago beds, which were not at first discriminated from those of the Umpqua, now appear, from differences in fauna, to require separation as a distinct series of beds.

J. S. Diller, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, pp. 319–320). *Arago fm.* occupies almost all of Coos Bay region. Is composed of sss. and shales. The coal-bearing strata of the Arago, which contain fresh and brackish water fossils, are here named *Coaledo fm.*, and the older and main body of the Arago, which contains only mere traces of coal and few strata containing brackish water fossils, is here named *Pulaski fm.* The Arago underlies Empire fm. (Mio.).

J. S. Diller, 1901 (U. S. G. S. Coos Bay folio, No. 73). Thickness of Arago fm. (divided into Coaledo and Pulaski fms.) 10,000 ft. Uncon. underlies Empire fm. and uncon. overlies Myrtle fm. [In Port Orford folio, No. 89, 1903, Diller gave thickness of Arago fm. in that quad. as 5,000± ft.]

R. Arnold, 1909 (Jour. Geol., vol. 17, No. 6). *Arago* includes (descending) Coaledo, "Pulaski," and Umpqua.

W. H. Dall, 1909. [See 1909 entry under *Tunnel Point ss.*]

R. Arnold and H. Hannibal, 1913 (Am. Phil. Soc. Proc., vol. 52, pp. 565–595), gave thickness of Arago fm. as 10,000 to 15,000 ft. "May be = Ione of Calif."

R. Arnold and H. Hannibal, 1914 (Sci., n. s., vol. 39, pp. 906–908). *Arago or Ione fm.* is younger than any Tejon in Tejon or Puget Basins, which includes Olequa and Chehalis fms. Ione has priority over Arago. In Upper Umpqua Basin Arago fm. is 10,000 ft. thick, and consists of tuffaceous and arkose ss. Farther N., on Santiam River, it consists of coarse basic tuffs.

W. D. Smith and E. L. Packard, 1919 (Univ. Oreg. Bull., vol. 16, No. 7, and Jour. Geol., vol. 27). Lower part of Arago group may be = part of Umpqua fm. and Tyee ss. Has been considered by several to be later than Umpqua fm.

Harrison & Eaton (firm), 1920 (Min. Res. Oreg., Oreg. Bur. Min. and Geol., vol. 3, No. 1, pp. 5–14, 25–31). Eocene of western Oreg. divided into (descending): Coaledo fm. (=Ione), 4,000 ft.; Tyee fm. (=Tejon), 2,000–5,000+ ft.; and Umpqua fm., 5,000 ft. [Did not explain relations of Tyee and Umpqua to Pulaski fm. of Diller.]

L. G. Hertlein and C. H. Crickmay, 1925 (Am. Phil. Soc. Proc., vol. 64, No. 2, pp. 225–242). Umpqua beds are of approx. same horizon as *Siphonalia sutterensis* zone of Marysville Buttes, Calif., and are probably eastern equiv. of Arago fm., although they may be slightly lower than the Arago.

W. D. Smith, 1924 (Econ. Geol., vol. 19, No. 5) and 1926 (Commonwealth Rev. Univ. Oreg., vol. 8, No. 3), divided Eo. of western Oreg. into (descending) Coaledo, Tyee, and Umpqua.

Aragon formation.

Eocene (lower): Mexico.

W. L. F. Nuttall, 1930 (Jour. Pal., vol. 4, No. 3, p. 277).

Arapahoe formation.

Upper Cretaceous: Eastern Colorado (Denver Basin).

G. H. Eldridge, 1888 (Colo. Sci. Soc. Proc., vol. 3, pt. 1, p. 97). [See †*Willow Creek beds, Tert.*]

W. Cross, 1893 (Int. Cong. Geol., Compte Rendu, 5th sess., pp. 437–438). *Arapahoe beds* are a fresh-water deposit whose most prominent memb. is a cgl. free from volcanic materials, containing pebbles of sed. rocks recognized as belonging to various horizons from the Laramie down to the red sss. of the Trias.

The age of this fm. was changed by U. S. Geol. Survey from *Tert.* (?) to *Upper Cret.*, in Dec. 1935, as explained under *Lance fm.*, last entry.

Named for development in Arapahoe Co.

Arbuckle limestone.

Cambrian and Ordovician: Central southern and southwestern Oklahoma.

J. A. Taff, 1902 (U. S. G. S. Atoka folio, No. 79). *Arbuckle ls.*—Chiefly massive and thin bedded, white and light-blue lss. with cherty concretions, but with 500 to 600 ft. of dull-blue, massive and thin lss. in lower part, and 200 to 300 ft. of thin, sandy lss. at base. Total thickness 4,000 to 6,000 ft. Overlies Reagan ss. and underlies Simpson fm.

J. A. Taff, 1903 (U. S. G. S. Tishomingo folio, No. 98). *Arbuckle ls.*, 5,000 to 6,000 ft. thick, consists of (descending): (1) Medium and thin-bedded lss., 450 ft.; (2) massive, compact, mag. ls., 3,500 to 4,000 ft.; (3) thin-bedded granular ls. and compact blue ls., 250 ft.; (4) heavy-bedded, dull bluish, and cream-colored dolomites, 200 to 400 ft.; (5) thin-bedded siliceous ls., 50 ft.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pp. 624, 642, 661, 666, pl. 27), introduced *Honey Creek ls. memb. of Reagan ss.* for lss. which he stated were originally included in Arbuckle ls. but are now transferred to Reagan ss.

H. D. Miser, 1926 (Okla. geol. map), followed Taff's original definitions of Arbuckle ls. and Reagan ss. and included Ulrich's Honey Creek ls. in Arbuckle ls.

In 1932 E. O. Ulrich raised *Honey Creek ls.* to rank of a fm. (See 1932 entry under *Reagan ss.*, also see under *Honey Creek ls.*) The U. S. Geol. Survey now recognizes Honey Creek ls. as a distinct fm., which is a slight restriction of Arbuckle ls.

Named for Arbuckle Mtns, of which it composes major part of central mass.

Arbuckle group.

Ordovician and Cambrian: Southern Oklahoma (Arbuckle and Wichita Mountains).

C. E. Decker, 1933 (Tulsa Geol. Soc. Digest, pp. 55–57). *Arbuckle group* divided into (descending) Wolf Creek dol., McKenzie Hill ls., Chapman's Ranch dol., Signal Mtn ls. (may be a part of Fort Sill), Royer marble, and Fort Sill ls. Rests on Timbered Hills group, top fm. of which is Honey Creek fm.

†Arcadia marl.

Pliocene (lower): Southern Florida.

W. H. Dall, 1892 (U. S. G. S. Bull. 84, pp. 131–132, 157, 320). Yellowish sandy marl, comprising a putty-like mixture of lime and sand, with minute phosphatic pebbles, a few small shark's teeth, and obscure prints of Ostrea, Spondylus, and other bivalves. When exposed to the air, away from the water, the marl hardens rapidly, sometimes forming a very hard and brittle rock, which splinters and rings almost like chert under the hammer. Thickness on Peace Creek about 9 ft. Assigned to Plio. Overlain by Peace Creek bone bed.

Now considered to be a facies of Caloosahatchee marl.

Named for exposures near Arcadia, De Soto Co., on Mare Branch, a tributary of Peace River, about 6 mi. N. of Arcadia.

†Arcadia clays. (In Claiborne group.)

Eocene (middle): Louisiana, Texas, Mississippi, Arkansas.

O. Lerch, 1893 (La. Geol. Surv., pt. 2, p. 85). *Arcadia clays.*—Well stratified gray marine clays, conformably underlying Jackson group and resting uncon. on upper lignitic. May provisionally be called "Arcadia clays" from town on Vicksburg, Shreveport & Pacific R. R. nearly centrally located in area they occupy in La.

As defined the clays occupy strat. position of Yegua (†Cockfield) fm., which name has priority. In some early repts the St. Maurice fm. was called "Upper Lignitic" and the Wilcox was called "Lower Lignitic."

Named for Arcadia, Bienville Co., La.

Arcadian amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

L. L. Hubbard, 1898 (Mich. Geol. Surv. vol. 6, pt. 2, pp. 78, 131, 132, 133, pl. 10, etc.). Same as Isle Royale amygdaloid.

Belongs to Central Mine group, and according to B. S. Butler (personal communication) is probably same as Isle Royale amygdaloid. The mineralized part is the Arcadian lode.

Named for occurrence at Arcadian mine, Houghton Co.

Arcadian flow.

Includes Arcadian amygdaloid and underlying trap.

Arcadia Park formation.

Upper Cretaceous (Gulf series): Eastern Texas (Trinity and Brazos River regions).

W. S. Adkins, 1933 (Univ. Tex. Bull. 3232, pp. 239, 270, 425). *Arcadia Park fm.* (from W. L. Moreman's unpublished description).—Type loc., Arcadia Park station, 7 mi. W. of Dallas, on Fort Worth-Dallas interurban. Thickness 100± ft.; thins to S. and N.; about 10 ft. thick at Austin. Type section consists of 20 ft. of blue clay at base, overlain by 1 to 3 ft. of thin ls. flags forming escarpment and dip-slope; upper 75 ft. consists of blue sh. containing numerous calc. concretions of various sizes. On Red River the upper part is sandy and lower part blue shaly clay with a few thin scattered ss. seams. In McLennan and Bell Counties the unit is laminated marl. At Austin the lower part is flaggy, laminated marl and upper part is blue sh. Is uncon. overlain by Austin chalk; the transition zone, Taff's "Fish Bed Cgl.," consists of clay containing gyp., phosphatic pebbles, and reworked pelecypods and fish remains. Is upper part of Eagle Ford. Overlies Britton fm.

†Archean period (or system).

A term that was for many years applied to the time (and the rocks) preceding the Algonkian period (now discarded) and covering the oldest known rocks, but which is no longer used by U. S. Geol. Survey, except in the sense of a rock type—that is, *Archean type*, the meaning of which is "very highly metamorphosed." For definition of the period see U. S. G. S. Bull. 769, pp. 127–135, 1925.

†Archeozoic era.

A time term covering part of Proterozoic era of U. S. Geol. Survey and other geologists. As originally defined it included all pre-Camb. time. In later usages it was applied: (1) To what for many years was known as "Algonkian period;" (2) to what for many years was known as "Archean period;" and (3) to Cambrian, †Algonkian, and †Archean periods combined. For original definition and diversity of usage see U. S. G. S. Bull. 769, pp. 17–20, 1925.

†Archer beds.

Pliocene (lower): Northeastern Florida.

W. B. Scott, 1894 (Geol. Soc. Am. Bull. 5, pp. 594–595). *Archer beds* contain mammalian fauna much older than those of Peace Creek beds, and represent a very different fauna. For strat. reasons Dall regards the Archer deposits as Plio.

Replaced by *Alachua fm.*, the older name.

Named for exposures at Archer, Alachua Co.

Archer County sand.

Same as Gose sand. Subsurface, Archer Co., Tex.

†Archimedes group.

†Archimedes limestone.

Mississippian: Southwestern Illinois, eastern Missouri, northwestern Arkansas, and northeastern Oklahoma.

Paleontologic names applied in early Mo. repts to Chester, Meramec, and Osage groups of present terminology or to parts of these groups. "First Archimedes ls." (also "Upper Archimedes ls.") was applied to the beds above Aux Vases ss. and beneath a ss. at Chester, Ill., called by Swallow "Chester ss.," which S. Weller stated is Palestine ss. of modern nomenclature; "Second Archimedes ls." was applied to Ste. Genevieve ls.; "Third Archimedes ls." was applied to Warsaw ls., also to Warsaw and Keokuk lss., and to Keokuk ls. alone. "Lower Archimedes ls." was also applied to the lower lss. (See B. F. Shumard, 1873, Mo. Geol. Surv. Rept. 1855–71, pp. 292–293.) In NW. Ark. and E. Okla. "Archimedes ls." was in early repts applied to Pitkin ls.

Archuleta shale.

Upper Cretaceous: Northwestern New Mexico (San Juan region).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, p. 260; also Conspectus of geol. fms. of N. Mex., pp. 2, 5). *Archuleta shales* is here proposed for *Animas fm.* of San Juan region, which is preoccupied. [On p. 2 he states it consists of 250 ft. of cgl., uncon. underlying Puerco fm. and uncon. overlying Maxwell shales. Derivation of name not stated.]

Corresponds to Ojo Alamo ss. and McDermott fm. (both Upper Cret.) of current nomenclature.

Arcola sand.

A subsurface sand in either Rico fm. or Hermosa fm. of southern San Juan Co., SE. Utah.

†Arctic Miocene.

Name applied in early repts to plant-bearing rocks in Greenland that are now classified as Eocene.

Arctomys formation.

Upper Cambrian: Alberta and British Columbia.

C. D. Walcott, 1920 (Smithsonian Misc. Coll., vol. 72, No. 1, p. 15). *Arctomys fm.*, Camb., Alberta. [Walcott fully defined this fm. in Smithsonian Misc. Coll., vol. 67, No. 8, pp. 461–462, Mar. 5, 1923. Underlies Sullivan fm.; uncon. overlies Murchison fm.; is 1,386 ft. thick; is Upper Camb.]

Arcturus limestone.

Pennsylvanian: Eastern Nevada (Ely region).

A. C. Lawson, 1906 (Univ. Calif. Pub., Bull. Dept. Geol., vol. 4, No. 14, p. 294). Argill. and in part sandy ls. which may be designated *Arcturus shaly ls.*, although the shaly character is not always apparent. Is easily distinguished by abundance and yellow color of its regolith. Thickness 900 to 1,000 ft. Underlies Ruth ls. and overlies Ely ls.

A. C. Spencer, 1917 (U. S. G. S. P. P. 96, pp. 26, 28, map). *Arcturus ls.* was named for Arcturus mining claim, on which the fm. occurs. It is 400± ft. thick, and lies in the broad central syncline of Ely dist. and in SW. corner of Ely quad. In both places it is partly covered by rhyolite flows or by volcanic tuff. Fossils listed. Overlies Ely ls. The "Ruth" ls. of Lawson is same as Ely ls.

Ardmore limestone member (of Cherokee shale).

Pennsylvanian: Northwestern and north-central Missouri and southeastern Kansas.

C. H. Gordon, 1893 (Mo. Geol. Surv. Sheet Rept. No. 2 (vol. 9) p. 20). *Ardmore ls.*—Irregular marly and concretionary fossiliferous ls. in Lower Coal Measures of Bevier quad. (covering parts of Macon, Randolph, and Chariton Counties), separated from underlying Lower Ardmore coal by 25 to 30 ft. of sh. with few interstratified ls. beds, and from overlying Bevier coal by 6 to 18 inches of clay. [Later repts give thickness 0 to 10 ft. Is †Hydraulic ls. of Swallow.]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 56). Most important ls. in Cherokee sh. is in upper part. *Ardmore ls.* has priority for this bed, but Okla. name *Verdigris ls.* has usage.

Named for Ardmore, Macon Co., Mo.

Ardness formation.

Mississippian: Nova Scotia.

M. Y. Williams, 1911 (Canada Geol. Surv. Summ. Rept. 1910, p. 244).

Arecibo formation.

Tertiary: Puerto Rico.

C. P. Berkey, 1915 (N. Y. Acad. Sci. Annals, vol. 26, pp. 10–17). Includes San Sebastian shales, Ponce chalky lss., Juana Diaz marls, Juana Diaz shales, Guanica coral reefs, and Quebradillas reef lss.

Arenal formation.

Eocene: Mexico.

J. L. Tatum, 1931 (A. A. P. G. Bull., vol. 15, p. 880). [Assigned to Eo.]

Arendtsville fanglomerate lentil (in Gettysburg shale).

Upper Triassic: Central southern Pennsylvania (Adams County).

G. W. Stose, 1929 (U. S. G. S. Fairfield-Gettysburg folio, No. 225). *Arendtsville fangl. lentil.*—Coarse cgl. of rounded cobble and boulders of qtzite, ss., quartz, and some aporhyolite in matrix of red sand, which extends for 20 mi. along foot of South Mtn in NE. part of Fairfield quad., NW. corner of Gettysburg quad. and SE. part of Carlisle quad. Estimated thickness 0 to 500± ft. It forms the large hills SW. and W. of Arendtsville, whence its name. In Carlisle quad. it passes into ls. cgl. (unnamed). Is top memb. of Gettysburg sh.

Argenta limestone.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, p. 37). Lss., 150 ft. thick, underlying Park sss., uncon. overlying Bingham qtzite, and composing basal fm. of Aubreyan series in Utah. [Derivation of name not stated.]

Argentine limestone.

Pennsylvanian: Eastern Kansas.

R. C. Moore, 1931 (Kans. Geol. Soc. 5th Ann. Field Conf. Guidebook, correlation chart). *Argentine ls.*, new name. Underlies Island Creek sh. and overlies Lane sh. Basal part of Lansing group redefined.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 92, 97). [See under *Wyandotte ls.* Derivation of name not stated. On p. 46 *Argentine ls.* is described as consisting of 10 to 32½ ft. of white irregularly bedded ls. On p. 92 Moore states that Argentine ls. replaces what had been called Iola ls. at Kansas City.]

G. E. Condra, 1933 (Nebr. Geol. Surv. Paper No. 4, p. 11). Argentine ls. is the "Iola" at Kansas City, but according to Kans. geologists it is higher in section than Iola at type loc.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pp. 18, 59–60). *Argentine ls. memb. of Wyandotte ls.* consists of 20 to 30 ft. of light-gray, thin-bedded, wavy ls., underlying Island Creek sh. memb. and overlying Quindaro sh. memb. Named for Argentine railway station, Kansas City, *Kans.* Type exposure in a quarry S. of 26th and Metropolitan Ave. Comprises main part of so-called Iola ls. of Mo. and NE. Kans., which is younger than true Iola ls.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), stated that Newell is author of this name.

†Arickaree shale.

Upper Cretaceous: Northwestern Kansas.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, p. 52). *Arickaree shales.*—Light-colored, olive, yellowish, and brownish fossiliferous gray shales referred to lower part of Fox Hills div. Overlie Lisbon shales.

Conflicts with better established name (Arikaree) for a Mio. fm. These beds belong to Pierre sh. No beds of Fox Hills age are known in Kans.

Named for *Arikaree* River, Cheyenne Co.

Arido sandstone.

Jurassic: Northeastern Arizona.

C. [R.]Keyes, May, 1936 (Pan-Am. Geol. vol. 65, No. 4, pp. 303, 306). *Zunian series* divided into (descending) McElmo shales, Lohali ss., Montezuma shales, and *Arido ss.* The latter 3 fms. correspond to LaPlata beds of Cross. The Arido replaces Gregory's preoccupied name *Navajo ss.*, and is named for Arido Creek, in N. part of Navajo Reservation.

This ss. appears to correspond to Wingate ss. of U. S. G. S. classification. (See A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1936, U. S. G. S. P. P. 183, chart opp. p. 37.)

†Arietina bed.

A paleontologic name applied in some early Tex. repts. to the Lower Cret. beds later named *Del Rio clay.*

Arikaree sandstone.

Miocene: Western Nebraska, southeastern Wyoming, southern South Dakota, and northeastern Colorado.

N. H. Darton, 1899 (U. S. G. S. 19th Ann. Rept., pt. 4, pp. 732, 735, 742, 743–748, pls. 82, 83, 84, 85, 88). *Arikaree fm.*—Series of gray sands, everywhere characterized by layers of dark-gray concretions which often have a tubular form, underlying Ogallala fm. in western Nebr. with distinct erosional uncon. and overlap. Rests (usually conformably) on Gering fm., where that fm. is present; where Gering is absent, on Brule clay. There is possibility upper memb. of Gering fm. may be basal part of Arikaree fm. The Arikaree enters Nebr. from Wyo., and thins out beneath Ogallala fm. in E. part of Banner Co. Thickness 400 ft. in Scotts Bluff Co. and 500 ft. in Sioux and Dawes Counties, the thickness increasing as the Arikaree displaces the Ogallala fm. northward. Extensively exposed along Niobrara River, apparently to E. of Valentine, and occasionally seen along W. edge of sand-hill dist., but not yet distinctly recognized in region drained by Loup Forks or along Platte River E. of Cheyenne Co. In upper part are beds containing the large *Daemonelix* of Barbour. The fm. includes large amount of volcanic ash as a general admixture in its sediments as well as in beds of considerable extent and thickness. Also contains a number of channels filled with cgl. The name *Arikaree* is applied to the fm. because Arikaree Indians were at one time identified with area in which it is most largely developed.

N. H. Darton, 1903 (U. S. G. S. P. P. 17), mapped *Arikaree fm.* across western northern Nebr. up to S. Dak. line, but did not show any Ogallala above it in that area. In 1909 (U. S. G. S. W. S. P. 227) Darton mapped *Arikaree fm.* across southern S. Dak. from near Fall River Co. on W. to beyond Missouri River on E., did not show any younger fm., and did not mention presence of Ogallala fm. in S. Dak.

According to H. F. Osborn, 1909 (U. S. G. S. Bull. 361, p. 65), the Arikaree of NW. Nebr. and SE. Wyo. is all of lower Mio. age, while the Arikaree of northern Nebr. and adjacent Little White River region, S. Dak., includes upper Mio. and late middle Mio. deposits equiv. to lower part of Ogallala fm. of SW. Nebr., and these late middle Mio. deposits are separated from beds equiv. to lower Mio. Arikaree of NW. Nebr. and SE. Wyo. by a big hiatus.

H. F. Osborn, 1912 (Geol. Soc. Am. Bull., vol. 23, pp. 247, 249), assigned Arikaree fm. of S. Dak. to Mio. and Olig. In 1918 (Am. Mus. Nat. Hist. Mem., n. s., vol. 2, pt. 1, pp. 9, 12) he stated that Arikaree fm. includes some Plio., lower Mio., and possibly some upper Olig.

E. L. Troxell, 1922 (Geol. Soc. Am. Bull., vol. 33, p. 210), stated that study of vertebrate fossils in Marsh collection leads to conclusion Arikaree fm. is upper Olig.

See also *Oak Creek fm.*, *Little White River beds*, and *Ogallala fm.*

H. J. and M. C. Cook, 1933 (Nebr. Geol. Surv. Paper No. 5), stated that vertebrates of "Arikaree" fm. are Mio. and upper Olig. But G. E. Condra, preface to same book, stated that he believes the Gering (the equiv. of lower part of Arikaree) is Mio. and not Olig., as classified by H. J. and M. C. Cook. This would assign all of Arikaree to Mio., which is present age designation of U. S. Geol. Survey.

Arisaig series.

Silurian: Nova Scotia.

J. W. Dawson, 1860 (Canadian Nat., vol. 5, pp. 135–137).

†Arizona slates.

†Arizonan.

†Arizonian slate.

Pre-Cambrian: Southeastern Arizona.

W. P. Blake, 1883 (Eng. and Min. Jour., vol. 35, p. 254). *Arizonian sl.*—An extensively developed fine-grained mica sl. This fm. is very ancient, and is lithologically and to all appearance the equiv. of the Taconic slates of Berkshire, Mass., and the Vermont extensions. It is extensively developed in Ariz., and being one of the primal series of fms. and fundamental bedrocks of the territory, in and upon which such a variety of later fms. are grouped, it deserves the distinguishing name of *Arizonian sl.,* which I shall apply to it. It is extensively exposed to view along the sides of Queen Creek Valley, W. of town of Pinal, where it may be seen in a highly contorted, twisted condition traversed by innumerable veins of white quartz, also contorted, and often doubled back and forth upon themselves. This sl. extends to SW., flanking the granitic masses of Pinal Range, and is there much traversed and broken up by granitic intrusions. This rock finally disappears, westward, under the post-tertiary fms. of Gila plains.

Same as Pinal schist. Has also been spelled *Arizonan* and called "Arizona slates."

Arkadelphia marl. (In Navarro group in Texas.)

Upper Cretaceous (Gulf series): Southwestern Arkansas, northwestern Louisiana, and northeastern Texas.

R. T. Hill, 1888 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 2, pp. 53–56, 188). *Arkadelphia shales.*—Alternating bands of marine blue clay and white or orange-colored sands, 5 ft. thick. Uncon. overlies Washington or High Bluff (Cret.) greensands, and underlies Quat. gravels and clays. Basal fm. of Eocene Camden series.

A. C. Veatch, 1906 (U. S. G. S. P. P. 46, p. 28). The dark laminated clays which overlie Nacatoch sand and form the "blue dirt" of well drillers along line of Iron Mtn Ry from Arkadelphia to Texarkana were named by Hill in 1888 the Arkadelphia shales, from outcrops at Arkadelphia, Clark Co., Ark. These beds contain uppermost Cret. fossils for 100 to 200 ft. above Nacatoch sands, the fossil-bearing beds being well developed on Yellow Creek 3 to 4 mi. NW. of Fulton, 5 to 6 mi. N. of Hope, N. and NW. of Emmet, and at Arkadelphia. Thus far no fossils have been found in upper portion of this fm., which extends without any apparent break to the Eocene sand beds forming the sandy hills S. of Iron Mtn Ry. Thickness 200 to 300 ft. at Arkadelphia, 500 ft. at Lanesburg, 500 to 600 ft. at Hope and Spring Hill, and 500 ft. at Texarkana and Shreveport.

C. H. Dane, 1929 (Ark. Geol. Surv., Bull. 1). The outcrops near Arkadelphia are now known to be upper part of the Nacatoch, which is unusually well stratified and consists of alternating clay and sand in this vicinity. The outcrops along Mine Creek are part of the clay phase of Tokio fm. Exact location of outcrops cited [by Hill] in southern Hempstead Co. is not known to writer, but a locality about half way btw. Fulton and Washington might be either in uppermost Nacatoch or possibly in lowest part of marl now defined as Arkadelphia. The "dark laminated clays" which according to Veatch are well developed on Yellow Creek 3 to 4 mi. NW. of Fulton, 5 to 6 mi. N. of Hope, N. and NW. of Emmet, are not the "blue clay and yellow sand outcropping in vicinity of Arkadelphia" to which Hill first applied the name Arkadelphia, and a new name would have been desirable.

The name, however, has now become firmly entrenched in geologic literature, although somewhat modified from the sense in which it was used by Veatch; and it now seems best to retain it, although with the clear understanding that the fm. typically outcrops 2 to 3 mi. NW. of Fulton and at numerous localities 5 to 7 mi. N. and NW. of Hope. Thickness 120 to 160 ft. It is possible basal few ft. of fm. outcrops, though not typically, at Arkadelphia; and this is an additional reason for retention of the name.

Top fm. of Upper Cret. or *Gulf* series in SW. Ark. Uncon. overlies Nacatoch sand and uncon. underlies Midway fm. According to 1925 and 1926 studies of L. W. Stephenson and C. H. Dane, *marl* is more appropriate lithologic designation than either *shale* or *clay*, by both of which names it has been called.

Arkadelphia clay.

Same as Arkadelphia marl, the present adopted name.

†Arkansan series.

Pennsylvanian: Western Arkansas and eastern Oklahoma.

C. R. Keyes, 1901 (Iowa Acad. Sci. Proc., vol. 8, pp. 119–132). *Arkansan series.*—Series of coal measures, 0 to 18,000 ft. thick, representing practically uninterrupted deposition, and locally underlying Des Moines series and overlying Mississippian series. Limited above by base of Cherokee sh., or base of Grady coal in Okla., and limited below by top of Miss. Includes (descending) Sebastian, Spadra, Norristown, Boonville, Appleton, Danville, and Millstone grit terranes. Represents, locally, lower part of Penn. series. [In 1931 Keyes replaced this name with *Yellian series.*]

Named for valley of Arkansas River, Ark. and Okla.

†Arkansas marls.

Miocene (upper) and Pliocene: Central southern Colorado.

F. V. Hayden, 1869 (U. S. Geol. Surv. Colo. and N. Mex. 3d Ann. Rept., pp. 75–91). In valley of the Arkansas N. of Poncha Pass is a fine development of light-colored marls, doubtless of same age as Santa Fe marls, which I have designated by name of *Arkansas marls.* They occupy entire valley of the Arkansas, which is 40 mi. long and 5 to 10 mi. wide. Assigned to Plio.

Same as *Santa Fe fm.*, of upper Mio. and Plio. age.

†Arkansas sandstone.

Pennsylvanian and Permian: Central southern Colorado.

F. M. Endlich, 1874 (U. S. Geol. and Geog. Surv. Terr. 7th Ann. Rept., p. 312). *Arkansas ss.*—Red ss., 5,000± ft. thick. In Sangre de Cristo Range the sss. are interstratified with lss. and shales and rest directly on granite. Assigned to Carbf. Is overlain by gray and bluish lss. and underlain by gray saccharoidal ls. Named for proximity to Arkansas River.

F. M. Endlich, 1878 (U. S. Geol. and Geog. Surv. Terr. 10th Ann. Rept., p. 129). *Arkansas ss.* assigned to Upper Carbf. Thickness 2,400 to 4,000 ft. Consists of red sss. and shale. Occurs along Arkansas River and in Sangre de Cristo Range.

C. E. Siebenthal, 1910 (U. S. G. S. W. S. P. 240, p. 35). Looking up valley of Willow Creek Park, SE. of Crestone, is a ledge of cgl., here called puddingstone cgl., because many of the bowlders in it are themselves conglomeratic, which was called "Arkansas ss." by Endlich.

Arkansas novaculite.

Middle and Upper (?) Devonian: Southwestern Arkansas and southeastern Oklahoma.

L. S. Griswold, 1892 (Ark. Geol. Surv. Ann. Rept. 1890, vol. 3, pp. 57–61, 69, 85, 87–113). *Arkansas stone* [also repeatedly called *Arkansas novaculite*].—True novaculite which occurs associated with shales into which it grades through opaque flinty layers. Resembles chert in structure, composition, and manner of occurrence. Thickness 500 or 600 ft., which generally includes some flinty shales and soft shales or sss. The novaculites proper are the prominent members, however, and occur in massive beds from few inches to 12 or 15 ft. thick. All highly siliceous rock except occasional sss. is novaculite or flinty sh.; there is no true chert or flint, although hard spots or masses are called flint by quarrymen. The Arkansas stone is a typical memb. of the novaculite fm., in which the two stones (Arkansas novaculite and Ouachita stone) occur.

A. H. Purdue, 1909 (Slates of Ark., Ark. Geol. Surv., pp. 30, 39–40). *Arkansas novaculite*.—Massive white and variegated novaculite with alternating flint and sh. layers in upper half. Lower 300 ft. wholly novaculite. Thickness 0 to 800 ft. Uncon. underlies Fork Mtn sl. and overlies Missouri Mtn sl.

H. D. Miser, 1917 (U. S. G. S. Bull. 660, p. 66). *Arkansas novaculite* consists of 3 lithologic divisions: A lower one made up almost entirely of massive white novaculite, at whose top is one of the two manganese horizons; a middle one consisting mainly of thin layers of dense dark-colored novaculite interbedded with sh. and having a cgl. of local distribution at its base; and an upper one consisting chiefly of massive, highly calc. novaculite which also yields manganese. Thickness 250 to 950 ft. Uncon. underlies Stanley sh. and overlies Missouri Mtn sl. Some sh. at base of Stanley sh. has in places been altered to sl., to which name "Fork Mtn sl." has been earlier applied.

The upper part of lower memb. contains Middle Dev. fossils; the lower part of middle memb. contains fossils that were identified by E. O. Ulrich as Upper Dev. (Genesee); the upper memb. may be post-Dev. (See H. D. Miser and A. H. Purdue, U. S. G. S. Bull. 808, 1929, pp. 57–59.)

C. L. Cooper, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 211). At Caddo Gap, Montgomery Co., west-central Ark., the *Arkansas novaculite* is 900 ft. thick and typical of the fm. in Ouachita Mtns. It is divisible into 3 lithologic units (descending): (1) Mostly massive calc. novaculite; (2) interbedded dark-colored dense novaculite and sh.; (3) almost entirely massive thick-bedded novaculite. Ulrich, on basis of fossils from novaculite beds near Ti, Okla., holds that the lower div. is of Onondagan age. Evidence furnished by conodonts indicates upper and middle divisions are Miss. Of 45 sp. in the novaculite, 27 occur in the Woodford, 13 in the Hardin, and 17 in the Chattanooga. The fm. therefore should be redefined. Writer suggests *Caddo Gap* for Miss. part when necessary detailed mapping has been done. [Proof that the beds referred to are Miss. is lacking. The U. S. Geol. Survey still classifies them as Dev. (?).]

Named for quarries in Ark. and for fact that the quarried rocks have long been known to the trade as *Arkansas novaculite*. It is the principal fm. of Ouachita Mtns.

Arkansas black marble.

Trade term for very fine-grained, even-textured, and uniformly shaded black marble occurring in large quantities in Fayetteville and Pitkin fms. (both of Miss. age) of northern Ark.

Arkona.

Name applied to a glacial lake, of Pleist. age, in Great Lakes region. (See U. S. G. S. Mon. 53, 1915, p. 469.)

Arkona beds.

Devonian: Ontario.

A. W. Grabau, 1917 (Jour. Geol., vol. 25, p. 341).

Arlington formation.

Mississippian: Northern California (Taylorsville and Lassen Peak regions).

J. S. Diller, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 370–394). *Arlington beds.*—Slates and sss. with traces of cgl.; 5,700 ft. thick. No fossils, but as they lie beneath Shoo Fly beds at one end and are associated with Sil. slates at the other, they are regarded as probably belonging to upper Paleozoic. Older than Shoo Fly beds and younger than Taylor[s]ville slates.

J. S. Diller, 1908 (U. S. G. S. Bull. 353). *Arlington fm.*—Chiefly fine, gray, thin-bedded ss., with some sh. in part silicified and a few beds of cgl. In lower memb. yellowish shales prevail and grade up into the shaly and thin-bedded greenish gray ss. of middle memb., which is well exposed in bold escarpment of Arlington Heights. In upper memb., which is well exposed about Crystal Lake, slaty gray shales are most abundant, with local cgls. and highly silicified red jaspery portions near top. Measured thickness 5,700 ft. Is separated from overlying Shoo Fly fm. by great thickness of Taylor meta-andesite. Is younger than Taylorsville fm.

Named for Arlington Heights, Plumas Co., which is composed of the fm., and where middle memb. is well exposed.

Arlington lake beds.

Pleistocene and late Tertiary: Central northern Oregon.

E. T. Hodge, 1930 (Monthly Weather Rev., vol. 58, pp. 405–441). *Arlington lake beds.*—Lake beds and stream gravels of white ash, diatomaceous material, and gray silts, 200 ft. thick. Furnish evidence of period of extensive flooding of Cascade Range at a time contemp. with deposition of The Dalles and Madras fms. Underlie extensive morainal deposits and bear on their surface enormous glacial erratics. Occur on S. side and very close to Columbia River. Greatly eroded. Once extended as far S. as Willamette, as far W. as The Dalles beds, as far N. as N. side of Columbia River, and unknown distance to E. Conviction prevails that Dalles, Madras, and Arlington fms. represent a period of aggradation during first glacial stage.

E. T. Hodge, 1931 (Geol. Soc. Am. Bull., vol. 42, No. 3, pp. 924–968). Early Pleist. fossils in gravels of *Arlington fm.* near Umatilla. Uncon. overlies Columbia River basalt (Mio.).

E. T. Hodge, 1932 (Univ. Oreg. Pub., Suppl. to Geol. Ser., vol. 1, No. 5). *Arlington lake beds.*—Pleist. fossils in older gravels. Perhaps part of fm. is Recent. The name is not wholly distinctive of this fm., and in later publications we propose to call it *Shutler fm.* On E. side of Deschutes River the fm. intergrades with Madras fm. Lies uncon. on Columbia River basalt. The lake beds and gravels occur as erosional remnant patches up to elev. of 1,750 ft.

The town of Arlington is near Shutler.

†Arlington traps.

Name applied by N. H. Darton (U. S. G. S. Bull. 67, 1890), to several small sheets of Palisade diabase (intrusive) near Arlington, Hudson Co., N. J.

Arlington moraine.

Pleistocene (Wisconsin stage): Northeastern Illinois. (See M. M. Leighton, 16th Int. Geol. Cong. Guidebook 26, 1932, pl 2.)

Arlington Heights moraine.

Pleistocene (Wisconsin stage): Northeastern Illinois. (See M. M. Leighton, 16th Int. Geol. Cong. Guidebook 26, 1932, p. 15.) See also *Tinley Park moraine.*

Armendaris limestone.

Ordovician: New Mexico.

C. R. Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 259, 260). *Armendaris lss.*—Lss., 300 ft. thick, underlying Montoyan series and uncon. overlying late Camb. qtzites (Lone terrane) in N. Mex. The main body of Early Ordovicic lss. well displayed in Sierra de los Caballos. [Derivation of name not stated.]

Armenia limestone lentil (of Oswayo formation).

Devonian or Carboniferous: Central northern Pennsylvania (Bradford County).

H. S. Williams and E. M. Kindle, 1905 (U. S. G. S. Bull. 244). *Armenia ls. lentil of Oswayo fm.*—Is No. 29 of Armenia Mtn section, Bradford Co. Contains probably not more than 25 per cent of lime, but since no other bed in section above the Chemung contains an appreciable quantity of lime, it is regarded as a ls. Thickness 10 to 26 ft. Lies 149 ft. below top of Oswayo fm. Contains Carbf. fish remains.

Armstrong member (of Cuyahoga formation).

Mississippian: North-central Ohio (Wayne County).

G. W. Conrey, 1921 (Ohio Geol. Surv., 4th ser., Bull. 24, p. 54). *Armstrong memb. of Cuyahoga fm.*—Greenish buff, fine-grained ss., 25 to 35 ft. thick. Upper part in layers 2 to 6 inches thick; lower 25 ft. massive, irregularly bedded, with marked tendency toward lenticular beds. Underlies Black Hand memb. and overlies Burbank memb. Named for exposure near village of Armstrong, Wayne Co.

Armuchee chert.

Lower and Middle Devonian: Northwestern Georgia.

C. W. Hayes, 1902 (U. S. G. S. Rome folio, No. 78, p. 3). *Armuchee chert.*—Rusty, sandy, bedded chert, at places grading into ferruginous ss. Thickness 0 to 50 ft. Underlies Chattanooga sh. and overlies Rockwood fm., on N. side of Coosa Valley, NW. of Coosa fault. Probably contemp. with Frog Mountain ss., of Oriskany age, which is present in only SW. corner of Rome quad.

C. Butts, 1927 (U. S. G. S. Bessemer-Vandiver folio, No. 221, p. 10). Typical *Frog Mtn ss.* is all of Onondaga age. It extends NE. into Ga., where it is present in Lavender Mtn and in Horseley Mtn, about 1 m. W. of Rome, and was mapped by Hayes in *Armuchee chert.* In both of these mtns this ss. is immediately underlain by fossiliferous chert which belongs to Armuchee chert of Hayes as described in Rome folio.

Named for exposures around Armuchee, Floyd Co.

Arnheim shale. (In Richmond group.)

Upper Ordovician: Southwestern Ohio, southeastern Indiana, and west central Kentucky and Tennessee.

A. F. Foerste, 1905 (Sci., n. s., vol. 22, p. 150). *Arnheim bed* introduced to replace preoccupied name *Warren.* Consists of sh. and clay, with nodular clay layer at top. Thickness 63 ft. Underlies Waynesville bed and overlies Mount Auburn bed [upper part of McMillan fm.].

Adopted to include at top beds called by A. F. Foerste *Fort Ancient div. of Waynesville,* which, because of fauna and strat. break at their top more properly belong to Arnheim than to overlying Waynesville, according to E. O. Ulrich and C. Butts. Foerste also originally stated that his Fort Ancient div. is more closely related faunally to Arnheim than to Waynesville. In Ohio the Arnheim is chiefly sh. and is called *Arnheim sh.;* in Ind. and Ky. it consists of clay and sh. with ls. layers and is called *Arnheim fm.;* in Tenn. it is wholly ls. and is called *Arnheim ls.* Basal fm. of Richmond group.

Named for Arnheim, Brown Co., Ohio.

Arnheim limestone.

Upper Ordovician: Western Tennessee. See under *Arnheim sh.*

Arnold amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Local name, in use many years. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. Is same as Ashbed amygdaloid. The mineralized part is the Arnold lode.

Named for occurrence in Arnold mine, Keweenaw Co.

Arnold flow.

Includes Arnold amygdaloid and underlying trap.

Arnold member (of Deese formation).

Pennsylvanian: Central southern Oklahoma (Carter County).

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z, p. 15). *Arnold memb.,* near middle of Deese fm., N. of Ardmore, includes a fossiliferous ls. up to 50 ft. thick.

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 46, pp. 36–38). *Arnold memb.*, near middle of Deese fm., consists of (descending): (1) Medium-grained massive buff ss., 50 ft.; (2) sh., 50± ft.; (3) ls. (fossiliferous, thin-bedded, more or less earthy and lumpy, interbedded with calc. sh., and carrying lenses of smoky chert), 50± ft.; (4) 100± foot interval; (5) richly fossiliferous shales associated with float or smoky chert. Named for Arnold's Reef, on Arnold farm, in sec. 33, T. 3 S., R. 1 E. [Columnar section on pl. 18 shows 1,900± ft. of strata btw. Arnold memb. and underlying Devil's Kitchen memb. of Deese fm.]

See also C. W. Tomlinson, A. A. P. G. Bull., vol. 18, No. 8, 1934, p. 1085.

Arnoldsburg sandstone. (In Monongahela formation.)

Pennsylvanian: Western West Virginia and eastern Ohio.

R. V. Hennen, 1911 (W. Va. Geol. Surv. Rept. Wirt, Roane, and Calhoun Counties, pp. 57, 202, 505). *Arnoldsburg ss.*—Coarse brown and gray ss. forming high pebbly cliffs. Thickness 25 to 45 ft. Lies 40 to 50 ft. below Uniontown ls. and overlies Lower Uniontown coal. Named for Arnoldsburg, Calhoun Co., W. Va.

Arnoldsburg limestone. (In Monongahela formation.)

Pennsylvanian: Eastern Ohio and northern West Virginia.

W. Stout, 1929 (W. Va. Acad. Sci. Proc., vol. 3, pp. 140, 143). *Arnoldsburg ls.* (new) is a buff hard stratum occupying most of interval btw. Fulton green sh. and Arnoldsburg ss. in northern pan-handle region of W. Va. and belonging just below horizon of Lower Uniontown coal. Thickness 0 to 15 feet. Named for association with Arnoldsburg ss.

R. E. Lamborn, 1930 (Ohio Geol. Surv., 4th ser., Bull. 35, pp. 181, 244–247). In many parts of W. Va. and eastern Ohio the ls. btw. Uniontown coal and Fulton green sh. is divided into 2 well-defined ls. horizons separated from each other by aren. sh. or ss. The lower part of this ls. lies in contact with or closely above Fulton sh., and upper part is usually a few ft. below Uniontown coal. D. B. Reger of W. Va. Geol. Surv. proposes to restrict *Uniontown ls.* to that part which lies closely below Uniontown coal and to use *Arnoldsburg* for the ls. which lies close above Fulton green sh. The term *Arnoldsburg* is hereby accepted by Ohio Geol. Surv. and will be used in this and subsequent repts on Monongahela series of this State. The Uniontown ls. formerly included Arnoldsburg ss. and Arnoldsburg ls. horizons. [Thicknesses of Arnoldsburg ls. given by Lamborn range from 3 to 12 ft. in Jefferson Co., Ohio, but in some sections the name *Uniontown ls.* is applied to all the lss. and shales overlying Fulton green sh.]

D. B. Reger, 1931 (Ill. Geol. Surv. Bull. 60, pp. 217–239), in generalized section of Monongahela fm. of W. Va., gave following downward succession: Uniontown coal, 0 to 2; gray or red sh., 0 to 10; Uniontown ls., 0 to 15; red or green sh. with thin sss. and lss., 44 to 59; Arnoldsburg ss., 25 to 30; sh., 0 to 5; Lower Uniontown coal, 0 to 1; *Arnoldsburg ls.*, yellow, fresh-water, 0 to 5; Fulton green sh., 0 to 5.

W. Stout, 1931 (Ill. Geol. Surv. Bull. 60, p. 212), in generalized section of Monongahela fm. of Ohio, gave following downward succession: Uniontown coal, 10 inches; Uniontown sh. and ls., 5 ft.; Arnoldsburg ss., 8 ft.; Arnoldsburg coal absent; Arnoldsburg ls. and calc. sh., 37 ft.; Fulton green sh., 4 ft.

Arnott moraine.

Pleistocene (Illinoian): North-central Wisconsin.

S. Weidman, 1907 (Wis. Geol. and Nat. Hist. Surv. Bull. 16). Named for Arnott, Portage Co.

Aroostook limestone.

Silurian: Northeastern Maine (Aroostook County).

H. S. Williams, 1900 (U. S. G. S. Bull. 165, pp. 21, 44–45). Under name *Aroostook ls.* are grouped the calc. shales and slates covering large part of eastern twp of Aroostook Co. The Aroostook River cuts them from Wade Twp to its junction with the St. John. The few fossils indicate Clinton age. Is regarded as older than Sheridan ss. and Ashland sh. and ls. and as representing base of Sil. in this region.

Aroostook Falls diabase.

Age (?): Northeastern Maine (Aroostook County).

H. E. Gregory, 1900 (U. S. G. S. Bull. 165, pp. 115, 175–177). *Aroostook Falls diabase.*—Dark-gray rock, with characteristic lamprophyric appearance. Occurs in a number of dikes cutting the blue ls. of the region. Named for occurrence at Aroostook Falls, Aroostook Co.

On 1933 geol. map of Maine, by A. Keith, the diabase of Aroostook Co. is mapped in block designated "mainly Sil., but some of Dev. age."

Arpin conglomerate and quartzite.

Pre-Cambrian (upper Huronian): Central northern Wisconsin (Wood County).

S. Weidman, 1907 (Wis. Geol. Nat. Hist. Surv. Bull. 16, p. 366). *Arpin cgl. and qtzite.*—Qtzite, probably 200 to 500 ft. thick, which resembles Baraboo qtzite. Exposed immediately S. of Arpin, Wood Co. Contains pebbles of Powers Bluff qtzite. Is either upper or middle Huronian.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, chart opp. p. 598), assigned this fm. to "Animikie group (upper Huronian)."

Arrastre quartzite.

Probably Lower Cambrian: Southern California (San Bernardino County).

F. E. Vaughan, 1922 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 13, No. 9, pp. 344, 351, 352–365, and map). *Arrastre qtzite*—The oldest sedimentaries positively identified as such in the region. Qtzites and quartzose schists, chiefly thin bedded, in beds less than 6 inches thick. Differs from Saragossa qtzite in that it contains no beds up to 5 and 10 ft. thick, of pure qtzite, no pure saccharoidal qtzite, no coarse angular grits, pebble cgl., or cross bedding. No fossils found. Grades into Furnace ls. above. Floor on which it was laid down has been destroyed by granite intrusions.

Named for Arrastre Creek, San Bernardino Co.

Arriban series.

A time term applied by C. R. Keyes (Sci., n. s., vol. 23, p. 921, and Am. Jour. Sci., 4th, vol. 21, pp. 298–300; 1906) to 500 ft. of sss, said to underlie his Llano Estacadan series, to overlie his Wasatchan series in N. Mex., and to include Santa Fe fm. and Galisteo ss. Derivation of name not stated.

Arrowhead limestone member (of Monte Cristo limestone).

Mississippian (middle): Southeastern Nevada (Goodsprings region).

D. F. Hewett, 1931 (U. S. G. S. P. P. 162, pp. 9, 18, etc.). *Arrowhead ls. memb.*—Alternating layers of thin-bedded blue and gray ls. and gray sh.; highly fossiliferous; no chert. Thickness 10 to 20 ft. Underlies Yellowpine ls. and overlies Bullion dol., all members of Monte Cristo ls. Named for Arrowhead prospect, sec. 9, T. 24 S., R. 58 E., Goodsprings quad. Fossils (listed) are middle Miss., according to G. H. Girty.

†Arrowmink arkosic gneiss.

Pre-Cambrian: Southeastern Pennsylvania (Philadelphia region).

F. Bascom, 1904 (Am. Jour. Sci., 4th, vol. 17, p. 143). *Arrowmink arkosic gneiss* correlated with Baltimore gneiss. [In U. S. G. S. Philadelphia folio, No. 162, 1909, Baltimore gneiss was used, and Miss Bascom states (Dec. 5, 1936) that later work has not changed this identification.]

Arroyo formation. (In Clear Fork group.)

Permian: Central Texas (Taylor and Runnels Counties region).

J. W. Beede and V. V. Waite, 1918 (Univ. Tex. Bull. 1816, pp. 45–46). [See 1918 entry under *Abilene fm.*]

Most geologists (including U. S. Geol. Survey and Tex. Geol. Survey, Sellards, 1933) now include Arroyo fm. in Clear Fork group, but some geologists have included it in Wichita group.

Arroyo Seco gravel.

Pleistocene: Northern California (Mokelumne River Basin).

A. M. Piper, H. S. Gale, and H. E. Thomas (U. S. G. S. W. S. P. 780, in press). *Arroyo Seco gravel*—Water-worn cobbles, gravel, and sand derived chiefly from pre-Cret. crystalline rocks. Is a pediment gravel that mantles the dissected Arroyo Seco pediment in Arroyo Seco Land Grant, along W. front of Sierra Nevada. Thickness 0 to 19 ft. Contemp. sediments presumably exist to much greater thickness beneath cover in axis of California trough. Underlies Victor fm. and uncon. overlies Laguna fm. (Plio. ?).

Artemisa limestone.

Cretaceous: Cuba.

J. W. Lewis, 1932 (A. A. P. G. Bull., vol. 16, p. 537). [Assigned to Jurassic or Cret.]

Artemisia gravel.

Pleistocene: Great Lakes region (Ontario and Michigan).

W. E. Logan, 1863 (Canada Geol. Surv. Repts 1843–63, pp. 887, 908–909). *Artemisia gravel.*—A belt of loose gravel, stretching southward across the peninsula of western Canada from near Owen Sound to Brantford, a distance of 100 mi. Average breadth of belt 23 mi. Covers total area of more than 2,000 sq. mi. The gravel is all well rounded and generally coarse; often constitutes what might properly be called shingle, being loose and free from any admixture of clay; and it is distinctly stratified. After forming a northward spur in Euphrasia Twp it reaches Beaver River in the N. of Artemisia. Relations to Algoma sand and to Saugeen clay not fully determined. [In table on p. 887 it is placed btw. Saugeen clay below and Algoma sand above.] Near Brantford it rests on Erie blue clay.

J. W. Spencer, 1890 (Geol. Soc. Am. Bull., vol. 1, pp. 85–86). *Artemisia gravel* of Canadian Survey includes sand, gravel, and even till deposits of all kinds and ages. The term should be restricted to the ridges occupying position of the very high-level beaches. Named for Artemisia Twp, Ontario.

Artesia sand.

Subsurface sand, of Perm. (probably Capitan) age, in Artesia field, Eddy Co., N. Mex.

Arthrodiran sandstone.

Upper Devonian: Central Arizona.

See *Sycamore Creek ss.*, also *Jerome fm.* Paleontologic name, based on content of fishes of group *Arthrodira.*

Artibonite group.

Miocene: Haiti.

W. P. Woodring, 1922 (Haiti Geol. Surv., Strat. and structure of central plain, Washington). Includes Las Cahobas fm., Thomonde fm. and Maïsade tongue, and Madame Joie fm.

Arundel formation. (Of Potomac group.)

Lower Cretaceous: Eastern Maryland.

W. B. Clark, 1897 (Md. Geol. Surv. vol. 1, pp. 156, 190). *Arundel fm.*—Series of large and small lenses of iron-ore bearing clays which occupy ancient depressions in surface of Patuxent fm. The largest lenses nearly 125 ft. thick. The clays are highly carbonaceous. Lignitized trunks of trees are often found in upright position with their roots still intact. Vast quantities of nodules of iron carbonate are scattered through the tough dark clays. In upper part of fm. the carbonate ores have changed to hydrous oxides of iron. Fossils mainly dinosaurian remains. Uncon. underlies Patapsco fm. Included in Potomac group. Named for Anne Arundel Co.

Arvonia slate.

Upper Ordovician: Central Virginia (James River region).

T. L. Watson and S. L. Powell, 1911 (Am. Jour. Sci., 4th, vol. 31, pp. 36–43). West of Blue Ridge the Martinsburg sh. [Upper and Middle Ord.] was laid down at about same time as *Quantico and Arvonia belts of sl.*

T. L. Watson, 1916 (Va. Geol. Surv. geol. map of Va.). [Map explanation states that the Ord. (Cincinnatian) block "Includes the Arvonia and Quantico slates of the Piedmont Plateau province."]

A. I. Jonas, 1927 (Geol. Soc. Am. Bull., vol. 38, p. 119, abstract). At the James River, in Va., *Arvonia slates*, of Chazyan age, are infolded in a continuation of the Peach Bottom syncline.

A. I. Jonas, 1927 (Geol. Soc. Am. Bull., vol. 38, pp. 841–842). *Arvonia sl.*—Blue slates which uncon. overlie Peters Creek fm. and Precambrian granite, with a basal cgl. present in part of area. Have been previously mapped and described but not named. Writer proposes name *Arvonia slates* for these beds. Bassler classifies fossils as probably of Chazy [Lower Ord.] age. Exposed at Arvonia.

A. I. Jonas, 1932 (Va. Geol. Surv. Bull. 38, p. 25). Fossils have been found in *Arvonia sl.* by Darton (Am. Jour. Sci., 3d, vol. 44, pp. 50–52, 1892) and others in an old quarry E. of Arvonia Station. They include crinoids, brachiopods and trilobites of late Ord. (Maysville) age, according to personal communication from C. Schuchert and R. S. Bassler. Sl. of same age occurs near Quantico [Quantico sl.] and Dumfries, in NE. Va. The Arvonia sl. is similar in character to Peach Bottom sl. of Md. and Pa., whose age is not known because no fossils have been found in it.

†Arvonian.

A term applied in some early repts to the felsites and quartz porphyries of lower part of Huronian series. The name was imported from Wales. (See J. D. Whitney and M. E. Wadsworth, 1884, Harvard Coll. Mus. Comp. Zool. Bull., vol. 7, geol. ser. vol. 1, No. XI, pp. 561, 562; also C. R. Van Hise and C. K. Leith, 1909, U. S. G. S. Bull. 360, p. 88 and index.)

Asbury clay.

Miocene (upper): Eastern New Jersey (Monmouth County).

H. B. Kümmel and G. N. Knapp, 1904 (N. J. Geol. Surv. vol. 6, p. 145). *Asbury clay.*—Dark clay with thin laminæ of sand. Thickness 0 to 12 ft. Believed to lie below the great mass of "fluffy sand," which underlies Alloway clay in Gloucester and Salem Counties. Present in Monmouth Co., but absent in Burlington Co. and SW. to Salem Co. Not certainly known whether Asbury clay forms a single well-defined bed of wide extent and varying thickness, or is a series of overlapping lenses, some thin, some thick, separated by beds of fine, loose, light sand, all occupying about same general horizon. Evidence seems most to favor latter view. Rests uncon. on Eocene marl. Named for development just W. of Asbury Park.

Is a part of Kirkwood fm.

Ashawa till.

A term employed by C. [R.] Keyes to cover the Wisconsin till of Iowa, also (Pan-Am. Geol., vol. 58, p. 203, 1932) to a single till sheet of Wisconsin stage.

Ashawan.

Name proposed by C. [R.] Keyes (Pan-Am. Geol., vol. 45, pp. 150–151, 1926) to replace *Wisconsin*, as applied to the late Pleist. till of Keewatin glacier, with suggestion that Wisconsin be restricted to the late Pleist. till of the Labradoran glacier.

Ashbed amygdaloid. (In Ashbed group.)

Pre-Cambrian (Keweenawan): Northern Michigan.

A. R. Marvine, 1873 (Mich. Geol. Surv. vol. 1, pt. 2, pp. 56, 58, 102, 116, 129, and chart). Scoriaceous amygdaloids called "Ash-bed." Probably = Hancock or South Pewabic bed of Houghton Co. Thickness about 180 ft.

R. D. Irving, 1883 (U. S. G. S. Mon. 5, p. 173). The amygdaloid of bed 65 is the layer so well known as the Ashbed, though the name is certainly a misnomer so far as it means to indicate an origin in the condition of volcanic ash.

Belongs to Ashbed group and has been worked in old Ashbed mine, Keweenaw Co. The mineralized part is Ashbed lode.

Ashbed flow.

Includes Ashbed amygdaloid and underlying trap.

Ashbed group.

Pre-Cambrian (Keweenawan): Northern Michigan.

R. D. Irving, 1883 (U. S. G. S. Mon. 5, pp. 172–173, 178, 186, pls. 17 and 18). A series of diabase and diabase amygdaloid flows, including cgls., underlying Marvine's group C and overlying the Greenstone group. Thickness 618 ft.

According to A. C. Lane (Mich. Geol. and Biol. Surv. Pub. 6, geol. ser. 4, 1911) the Ashbed group is 1,239 to 2,400 ft. thick.

It underlies Eagle River group and overlies Central Mine group, the top fm. of which is the Greenstone flow.

Apparently named by Irving for fact it includes the Ashbed amygdaloid, but according to A. C. Lane (1911) it occurs in old Ashbed mine, Keweenaw Co., so that it has a geographic significance.

Ashcroft rhyolite porphyry.

Tertiary (Oligocene?): British Columbia.

C. W. Drysdale, 1914 (Canada Geol. Surv. Summ. Rept. 1912, p. 141), and 1916 (Summ. Rept. 1915, p. 87).

Asher formation.

Permian: Central and central southern Oklahoma.

G. D. Morgan, 1924 (Bur. Geol. [Okla.] Bull. 2, pp. 141–142, pls. 3, 27, and map). *Asher fm.*—Typical red beds. Basal 30 ft. consists of a series of coarse, red and brownish-red sss. that cap N. bluff of Canadian River from bridge S. of Asher to northern edge of Stonewall quad. Contains no arkosic material, but arkose is characteristic of underlying Pontotoc terrane [group]. The portion of fm. present in NW. corner of quad. is 250 ft. thick. No upper limit is here defined. No fossils found, but upon evidence afforded by color and position in section is referred to lower Perm. Next younger fm. is Guertie sand, of Pleist. age.

The top of Asher fm. as defined by H. D. Miser (geol. map of Okla., 1926) is base of Enid fm. as first defined.

Named for development at and W. of Asher, Pottawatomie Co.

Ashland limestone.

Silurian: Northeastern Maine (Aroostook County).

H. S. Williams, 1900 (U. S. G. S. Bull. 165, pp. 21, 51, 52–54). *Ashland ls.*—Mainly pure gray ls., much fractured. The fragmental, brecciated condition is common to it wherever seen. Contains fauna correlated with Niagara of N. Y. Appears to be younger than Ashland shales and older than Square Lake ls. Named for exposures in Ashland village (in a ledge opposite Ashland Hotel), Aroostook Co.

Ashland shale.

Silurian: Northeastern Maine (Aroostook County).

H. S. Williams, 1900 (U. S. G. S. Bull. 165, pp. 21, 45, 49–51). *Ashland shales.*—In Ashland village, along road opposite the hotel, and southward toward Masardis, are several outcrops of lss., calc. shales, and sss, which present strat. relationship to one another, but on account of shear planes and semislated structure, as well as intervals unexposed, some doubt must be held regarding accuracy of interpretation. The irregular, block-like masses of ls. opposite the hotel are met on S. side by yellowish, weathered shales. There is an interval of several hundred ft. showing no rock exposures. On E. side of road there is a rock cut about 400 ft. S. of hotel. The rocks in this exposure are calc., thin-bedded shales, somewhat nodular and weathering yellowish from iron oxide. Some layers contain nearly pure argill. shales, others are calc. The calc. layers are all somewhat aren., showing pebbles of quartz, jaspers, and siliceous slates, mingled with broken calc. shells, and an approach to the conditions of Sheridan ss. Writer's interpretation, with his present knowledge of facts, is that the shales are older than the lss., and that Sheridan sss. are of same age as [or older, p. 21] the shales. Fauna correlated with Niagara of N. Y. Regarded as younger than Aroostook ls.

Ashland mica schist.

Pre-Cambrian: Eastern Alabama.

E. A. Smith and H. McCalley, 1904 (Ala. Geol. Surv. Bull. 9, p. 8). ***Ashland mica schists.***—Metamorphic sediments of undet. age, probably Paleozoic. Older than Talladega slates and younger than the older (probably pre-Camb.) mica schists.

G. I. Adams, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14, map, pp. 32–33). ***Ashland mica schist.***—Schists, chiefly garnetiferous biotite schist and siliceous, more or less graphitic, muscovite schist, the two types intergrading. Contains some qtzite. Is penetrated by both basic and acid intrusives, not separable on map. Thickness probably 10,000 ft. Assigned to Algonkian, but without definite proof.

In view of fact that "Archean system" and "Algonkian system" have been discarded, this fm. is now classified by U. S. Geol. Survey as pre-Camb.

Named for development around Ashland, Clay Co.

†Ashland Leptostrophia zone.

Term applied by H. S. Williams (Sci., n. s., vol. 24, pp. 365–372, 1906) to *Leptostrophia* zone at top of Wellsburg ss. memb. of Chemung fm. in Ithaca region, N. Y., because of outcrops in Ashland Hills.

The U. S. Geol. Survey does not apply geographic names to faunal zones.

Ashland limestone.

Pennsylvanian: Southeastern Nebraska.

G. E. Condra and N. A. Bengston, 1915 (Nebr. Acad. Sci. Pub., vol. 9, No. 2, pp. 7, 24). *Ashland ls.*—Main body light gray, massive, hard. Basal 3½ ft. interbedded lss. and shales. Thickness 12 ft. Lies 16 to 18 ft. above South Bend ls. Is top memb. of Braddyville fm. in Nebr. Named for town.

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, 2d ser., p. 11). *Ashland ls.* abandoned, as another name has priority. The Ashland ls. is the Weepingwater ls.

†Ashley marl.

†Ashley River beds.

†Ashley River marl.

†Ashley-Cooper beds.

†Ashley-Cooper phase.

†Ashley-Cooper marl.

†Ashley and Cooper beds.

†Ashley phosphate beds.

Eocene (upper): Southern South Carolina (Dorchester County).

M. Tuomey, 1848 (Agric. Surv. S. C. 1st Rept., pp. 162–169, 190, 211). [See quotation under *Cooper marl.*]

All of the above names, used in foregoing and subsequent repts., are replaced by *Cooper marl*, which is of Jackson age. The Ashley marl of E. Sloan, 1908 (S. C. Geol. Surv., ser. 4, Bull. 2), which he defined as younger than Cooper marl, is interpreted by C. W. Cooke (U. S. G. S. Bull. 867, 1936) as including in part Hawthorn fm. (lower Miocene) and in part Cooper marl (upper Eocene).

Named for exposures along Ashley River, Dorchester Co.

Ashley Hill limestone.

Cambrian: Eastern New York (Columbia County).

T. N. Dale, 1893 (U. S. G. S. 13th Ann. Rept., pt. 2, p. 312). *Ashley Hill Camb. ls.* [in heading].—Another ls. belt associated with grits and shales occurs at Ashley Hill, in NE. corner of Chatham Twp, Columbia Co., about 1 mi. N. of Rayville or Rider's Mills Station on Lebanon Springs R. R., and 2 mi. S. of Brainard, in Nassau. This ls. belt cannot be connected with other ls. belts in this region, as they trend differently and are separated by masses of grit.

Ashnola gabbro.

Carboniferous (?): Southwestern British Columbia and central northern Washington.

R. A. Daly, 1906 (Geol. Soc. Am. Bull., vol. 17, pp. 329–376). *Ashnola gabbro.*—A long slab of gabbro, ranging with Cathedral Fork of Ashnola River. Is a roof pendant to Remmel batholith, and older than Remmel granodiorite. Extends for 5 mi. May be contemp. with Kruger schists (probably late Carbf.), or may be Triassic.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, map 13). [The mass mapped as Ashnola gabbro lies 2 mi. E. of Ashnola River, B. C. and Wash.]

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 435).

Ashokan beds.

Middle Devonian: Eastern New York (Ulster and Greene Counties).

A. W. Grabau, 1917 (Geol. Soc. Am. Bull., vol. 28, p. 954). *Ashokan beds.*—Nonmarine terminal phase of Hamilton in Ulster Co. region. Shales and sands 500 to 600 ft. thick. No fossils except plants. Form principal bluestone fm. of Ulster Co. Prosser erroneously called these beds Sherburne in his monograph on Hamilton and Portage beds of eastern N. Y. Overlie *Mount Marion beds,* the lower fossiliferous Hamilton beds of Ulster Co. region.

A. W. Grabau, 1919 (Geol. Soc. Am. Bull., vol. 30, pp. 468–470). *Ashokan fm.*—The so-called Sherburne ss. of the Helderbergs. Shales and flags 500± ft. thick. Underlies Oneonta fm. in Ulster and Greene Counties. No fossils. I am satisfied this fm. is a continental phase of Upper Hamilton and therefore beneath base of typical Sherburne ss. Rests on Mount Marion beds without strat. break. Named for exposures in Ashokan dist., W. of Kingston.

G. H. Chadwick (1932) has named the beds overlying *Ashokan bluestone* in Catskill area the *Kiskatom red beds.*

Ashtabula moraine.

Pleistocene (late Wisconsin): Northern Ohio and northwestern Pennsylvania. Included in Lake Escarpment morainic system. Named for Ashtabula, Ohio. (See U. S. G. S. Mon. 41.)

†Ashton schists.

Pre-Cambrian: Northeastern Rhode Island.

J. B. Woodworth, 1899 (U. S. G. S. Mon. 33, pp. 106, 107). *Ashton schists.*—Argill. rocks of Blackstone series, which succeeded the deposition and partial erosion of Cumberland qtzites. Characterized as a whole by greenish color. Some of rocks included in the schists are probably of igneous origin. Occur at Ashton, Providence Co.

B. K. Emerson and J. H. Perry, 1907 (U. S. G. S. Bull. 311, p. 11). "Ashton schists" of Woodworth included Marlboro fm. and Albion schist memb. of Westboro qtzite, of present classification. [Woodworth also called these rocks "Ashton series."]

Ashton zone.

A zone in lower part of Fernando group in Huntington Beach oil field of Orange Co., southern Calif. Consists of 1,200 to 2,000 or more ft. of sticky brown sh., sandy shales, sands, and hard shells. Some producing wells have penetrated it to depth of at least 1,750 ft., according to S. H. Gester. H. S. Gale (A. A. P. G. Bull., vol. 18, No. 3, 1933, p. 330) assigned it to Repetto siltstone (lower Plio.).

Ashville beds.

Cretaceous: Manitoba.

S. R. Kirk, 1930 (Canada Geol. Surv. Summ. Rept. 1929, pt. B, p. 117).

†Aspalaga clay.

†Aspalaga marl.

†Aspalaga phase of †Waldo formation.

†Aspalaga phase of †Chattahoochee formation, or lower layer.

Miocene (lower): Florida and southern Georgia.

L. C. Johnson, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 128–132). ***Aspalaga clays.***—Tough calc. clays or altered marls, brown and dark-colored, including residuum after lime of shells is leached away. Thickness 60 ft. at Aspalaga [Liberty Co.], Fla. (where they underlie Lafayette fm.). Overlie 40 ft. of ls., the upper layers of which are full of fossils, corals, and lamellibranchs, and *Orbitulites floridana*, and which for sake of distinction we may call the ***Aspalaga phase of Waldo fm.*** On Sweetwater Creek, Fla., the ***Aspalaga marl,*** 20 to 40 ft. thick, is overlain by Alum Bluff or Chipola marl and underlain by ***Aspalaga phase*** or upper layer (30 ft. thick) of Chattahoochee fm.

A. F. Foerste, 1894 (Am. Jour. Sci., 3d, vol. 48, pp. 41–54). ***Aspallaga clays*** (marl), 67 ft. thick, not seen at type loc., but well exposed at Rock Bluff [Liberty Co., Fla.?]. Whether they belong to Chattahoochee or Chipola will no doubt be settled as investigations go on. I am inclined to consider them as top of the Chattahoochee [Tampa ls.]. Overlie Griffin bed.

W. H. Dall and J. Stanley-Brown, 1894 (Geol. Soc. Am. Bull., vol. 5, p. 154). "***Aspalaga marl***" of Johnson is physically continuous with the sands of Alum Bluff beds. "***Aspalaga clays***" of Johnson are 20 ft. thick and belong to Chipola marl.

C. J. Maury, 1902 (Bulls. Am. Pal., vol. 3, No. 15, p. 70). No real discrimination could be made btw. so-called "Aspalaga clays" of Johnson and the Chattahoochee ls. The clays appear to be merely argill. beds of ls.

G. C. Matson and F. G. Clapp, 1909 (Fla. Geol. Surv. 2d Ann. Rept.) and G. C. Matson, 1913 (U. S. G. S. W. S. P. 319). "Aspalaga marl" is a part of Chattahoochee fm.

Aspen shale.

Upper Cretaceous: Southwestern Wyoming.

A. C. Veatch, 1907 (U. S. G. S. P. P. 56). ***Aspen fm.***—Black and gray shales containing abundant fish scales. Often weathers silvery gray. Thickness 1,500 to 2,000 ft. Underlies Frontier fm. and overlies Bear River fm. Is of Benton age. Named for exposures near Aspen Station [Uinta Co.].

Aspermont dolomite.

Permian: Central northern Texas (Stonewall County).

W. E. Wrather, 1917 (SW. Ass. Pet. Geol. Bull., vol 1, sec. opp. p. 96). ***Aspermont dol.***, 1 ft. thick, lies 105± ft. below top of Greer fm.

M. G. Cheney, 1929 (Univ. Tex. Bull. 2913, pl. 1). ***Aspermont dol.*** is older than Royston fm. and younger than McCaulley dol.; all included in Double Mtn group.

G. H. Norton, 1929 (A. A. P. G. Bull., vol. 13, pp. 955–956). Some geologists correlate Guthrie dol. with Aspermont dol.; others believe Guthrie is older than Aspermont.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 168). ***Aspermont dol.*** is same as Guthrie dol. and is discarded, Guthrie having been more commonly used. It is in Blaine fm.

Probably named for Aspermont, Stonewall Co.

Asphalto lake bed.

Pliocene: Southern California (northwestern part of Kern County).

J. G. Cooper, 1894 (Calif. Acad. Sci. Proc., 2d ser., vol. 4, p. 168). ***Asphalto lake bed.***—A small fresh-water deposit of fossiliferous blackish marl, about 40 mi. SE. from Kettleman lake bed, 18 mi. NW. of Buena Vista Lake, and 1,100 ft. above sea level.

Probably named for exposures at or near Asphalto, a village near McKittrick, Kern Co.

Asphaltum sandstone.

Pennsylvanian: Central southern Oklahoma (Jefferson County).

J. R. Bunn, 1930 (Okla. Geol. Surv. Bull. 40PP, pp. 10+). ***Asphaltum ss.***—A series of gray to buff, yellow, calc. sss., generally massive, friable, and medium-grained, but locally laminated and thin-bedded, separated by sh. beds. Thickness 20 to 50+ ft. Underlies Claypool fm. [On cross section lies 200± ft. higher than Oscar ss.] Is exposed in vicinity of town of Asphaltum, Jefferson Co.

Aspidella slate.

Pre-Cambrian: Newfoundland.

A. Murray, 1881 (Geol. of Newfoundland, pp. 280–288).

Aspinwall limestone. (In Admire shale.)

Aspinwall shale. (In Admire shale.)

Pennsylvanian: Southeastern Nebraska.

G. E. Condra and N. A. Bengston, 1915 (Nebr. Acad. Sci. Pub., vol, 9, No. 2, pp. 9, 17, 29). *Aspinwall ls.*—Usually in 1 bed; massive, light brown, mottled. Thickness 1–2 ft. Type loc. is at Aspinwall. Separated from underlying Brownville ls. by 10 to 25 ft. of bluish calc. sh. and from overlying Falls City ls. by 18 to 37 ft. of bluish calc. sh. Included in Admire (?) fm.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 73, 82, 89), applied *Aspinwall sh.* to all beds (25 ft. thick in Nebr. and greater in Kans.) btw. Falls City ls. and Brownville ls., thus including Aspinwall ls. of 1915 rept., which, however, he did not mention and appears to have discarded. Named for Aspinwall (now abandoned), SE. of Nemaha City, Nemaha Co. Included in Admire sh.

R. C. Moore and G. E. Condra, 1932 (Oct. 1932 revised classification chart of Penn. rocks of Kans. and Nebr.), divided the rocks underlying Falls City ls. and overlying Brownville ls. into (descending) Hawxby sh., *Aspinwall ls.*, and Towle sh., thus discarding Aspinwall sh. and restoring Aspinwall ls.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 9). *Aspinwall ls. fm.* underlies Hawxby sh. fm. and overlies Towle sh. fm. [This classification was followed by R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), but Moore transferred all beds above Brownville ls. to Perm. (See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.)]

Assiniboian series.

Name suggested by C. [R.] Keyes (Pan-Am. Geol., vol. 43, pp. 287–302, 1925) to cover post-Dakota and pre-Fox Hills Cret. rocks of Western States. Derived from Canadian province of Assiniboia.

Assiniboine series.

A term employed by C. [R.] Keyes to cover the post-Dakota Cret. rocks of Iowa.

Astoria shale.

Miocene: Northwestern Oregon and southwestern Washington.

E. D. Cope, 1880 (Am. Nat., vol. 14, pp. 457–458, and Am. Phil. Soc. Proc., vol. 19, p. 62). The unpublished notes of Prof. Condon, formerly State Geologist, state that backbone of Coast Range consists of argill. shales, which contain invertebrate and vertebrate fossils, frequently in concretions. To this fm. Dr. Condon gives the name *Astoria shales*. Fossils are Mio.

W. H. Dall and G. D. Harris, 1892 (U. S. G. S. Bull. 84, pp. 223–227). *Astoria shales.*—Clayey or sandy shales of various colors and degrees of consolidation. Weather soft and clayey, and so appear along banks of river at Astoria. Most prominent on left or S. bank. Included in Astoria group (Mio.). Overlies Aturia bed (Eocene). [See under *Astoria group.*]

W. H. Dall, 1909 (U. S. G. S. P. P. 59), assigned *Aturia* zone to Olig. and excluded it from Astoria sh.

C. W. Washburne, 1914 (U. S. G. S. Bull. 590), included *Aturia* zone in Astoria sh., and assigned a thickness of 400 ft. to the zone (which he assigned to the Olig.) and a thickness of 1,000± ft. to the overlying part of Astoria sh., which he assigned to Mio.

L. G. Hertlein and C. H. Crickmay, 1925 (Am. Phil. Soc. Proc., vol. 64, No. 2, pp. 259–260). Recently Howe (unpublished thesis Leland Stanford Univ., 1922) investigated Astoria locality and states that the 2 sss. present there (one underlying Astoria shales and one overlying the shales) have been confused by several writers. He states that by careful mapping the beds containing ***Aturia*** and the places from which Dall lists his fossils are middle Mio. and not Olig. as thought by Dall. Also that 54 per cent of the species present in the shales are also present in the sss., and that 43 per cent of the species at Astoria are also found in Monterey-Temblor (middle Mio.) of Calif.

H. V. Howe, 1926 (Pan-Am. Geol., vol. 45, pp. 295–306), assigned Astoria sh. and *Aturia* zone to middle Mio., and listed fossils.

W. D. Smith, 1926 (Oreg. Univ. Commonwealth Rev., vol. 8, p. 269), assigned Astoria sh. and *Aturia* zone to Mio.

The U. S. Geol. Survey now classifies Astoria sh., including ***Aturia*** zone at base, as Mio.

†Astoria sandstone.

Miocene: Northwestern Oregon and southwestern Washington.

W. H. Dall and G. D. Harris, 1892 (U. S. G. S. Bull. 84, pp. 223–227). *Astoria sss.*—Series of sss. on both sides of river above Astoria, though best developed on N. or right bank. The sss. are granular, brittle, or friable, sometimes very compact and hard, usually brownish. Included in Astoria group. Dana regards the sss. as more recent than Astoria shales, which is strengthened by fact that fissures in shales are filled with sand resembling that of which the sss. are composed. [See also under †*Astoria group.*]

†Astoria group.

Miocene: Northwestern Oregon and southwestern Washington.

W. H. Dall and G. D. Harris, 1892 (U. S. G. S. Bull. 84, pp. 223–227). *Astoria group.*—The *Astoria shales* and *Astoria sss.* appear to form part of a single series varying in character according to fluctuations in sedimentation, the shales being more argill., the sss. more aren., neither possessing an exclusive character, the fossils appearing to be the same Mio. species in both, with tendency to form concretions around them in the sh. and to be represented by casts in the sss. The name *Astoria group* (from Astoria, Clatsop Co.) is proposed to include them both, but not the subjacent Eocene Aturia bed. Dana regards the sss. more recent than the shales, and this is strengthened by fact that fissures in the shales are filled with sand resembling that of which the sss. are composed.

Has been discarded, because *Astoria sh.* has priority and is more useful name. The *Aturia* zone is now considered to be Mio., and is included in Astoria sh.

Atane beds.

A name long in use for Upper Cret. rocks in Greenland that underlie Patoot beds (also Upper Cret.) and overlie Kome beds (Lower Cret.).

†Atascadero formation.

Upper Cretaceous: Southern California (San Luis Obispo region).

H. W. Fairbanks, 1904 (U. S. G. S. San Luis folio, No. 101). *Atascadero fm.*—Thick and thin-bedded ss. with small amount of cgl. and sh. Thickness 3,000 to 4,000 ft. Is local representative of Chico group. Represents all of Chico deposits present in the area. Uncon. underlies Vaquero[s] ss. and uncon. overlies Knoxville. Named for exposures along Atascadero Creek, San Luis Obispo Co.

Replaced by Chico fm.

†Atchison shale.

Pennsylvanian: Northwestern Missouri, southwestern Iowa, and southeastern Nebraska.

C. R. Keyes, 1899 (Am. Geol., vol. 23, p. 309). *Atchison shales,* 500 ft. thick, extend from top of Forbes ls. to base of Cottonwood ls.

Includes Wabaunsee fm. and large part of underlying Shawnee fm. Named for Atchison Co., Mo.

Athabasca sandstone.

Pre-Cambrian: Canada.

R. G. McConnell, 1893 (Canada Geol. Surv., n. s., vol. 5, pt. 1, p. 51D). [Assigned to Camb., but for many years this ss. has been assigned to pre-Camb. in Canada repts.]

Athelstane granite.

Name applied by C. C. Wang (Geol. Soc. China Bull., vol. 11, No. 4, pp. 426–428, 1932) to a pre-Camb. granite in Wis. (area not stated).

Athens marble.

Silurian: Central western Illinois (Menard County).

A. H. Worthen, 1882 (Econ. Geol. Ill., vol. 1, pp. 102–103). Compact gray ls., quarried at Athens and generally known as *Athens marble.* Included in Niagara ls.

Athens shale. (In Blount group.)

Lower Ordovician: Eastern Tennessee, northern Alabama, western North Carolina, and western Virginia.

C. W. Hayes, 1894 (U. S. G. S. Kingston folio, No. 4, p. 2). *Athens sh.*—East of Tennessee River the upper part of Chickamauga ls. is replaced by calc. shales weathering yellow, from 300 to 500 ft. thick. Eastward beyond edge of this sheet this fm. increases to several thousand ft., where the strata represent the rapid and variable accumulation of sediment near the shore. Underlies Rockwood fm. and rests on a part of Chickamauga ls. [The area here described adjoins type loc.]

C. W. Hayes, 1895 (U. S. G. S. Cleveland folio, No. 20, p. 3). In belt extending from NE. corner of Cleveland tract toward SW., across Hiwassee River, a part of Chickamauga ls. is replaced by Athens sh., from 850 to 1,100 ft. thick, in some places sandy, but generally calc., dark blue when fresh, but weathering yellow. Increases in thickness to 2,500 or 3,000 ft. along E. side of valley, and includes a bed of calc. ss. 250 to 700 ft. thick about 500 ft. above base. [In columnar section of this folio this ss. is called *Athens ss.*] Underlies Tellico ss. and overlies part of Chickamauga ls. [This area includes type loc.]

The commonly accepted definition of Athens sh. in Tenn. applies to beds underlying Tellico ss. and overlying Holston marble, but Ulrich (1929) defined it as overlying his newly proposed Whitesburg ls., which he stated in places intervenes btw. Athens sh. and Holston marble. Fauna is considered to be of Normanskill age. In northern Ala. C. Butts (Ala. Geol. Surv. Spec. Rept. No. 14, 1926) identified Athens sh. as underlying Little Oak ls. and overlying Lenoir ls. Based upon work of C. Butts in Appalachian Valley of Va., the U. S. Geol. Survey now uses *Athens sh.* (or *Athens ls.*, where the fm. becomes so calc. as to be a ls.) across Appalachian Valley of Va., from Tenn. to W. Va. line. This use of *Athens ls.* displaces the local name *Liberty Hall ls.*

Named for exposures at Athens, McMinn Co., Tenn.

Athens group.

Pennsylvanian: Appalachian Basin.

J. J. Stevenson, 1907 (Geol. Soc. Am. Bull., vol. 18, p. 178). *Athens* and *Wheeling* proposed for groups of the Pennsylvanian lying btw. Dunkard group and Pottsville group [but no limits were assigned to either group]. The term "Athens" refers to the county of that name in Ohio, and "Wheeling" to the stream which flows through W. portions of Greene and Washington Counties of Pa. and Marshall and Ohio Counties of W. Va., localities in which the respective columns are shown in their full extent.

†Athens sandstone.

See under *Athens sh.*

Atherton clay.

Mississippian: Northwestern Kentucky and southern Indiana.

A. F. Foerste, 1910 (Ky. Geol. Surv. Rept. Prog. 1908 and 1909, pp. 76, 83, 84). *Atherton bed.*—Chiefly fossiliferous clay [thickness not stated] underlying St. Louis ls. in southern Ind. In northern Ky. overlies Harrodsburg ls., the Salem ls. not being recognized. Carries about same fauna as Salem ls. Thins out before reaching central Ind. [On p. 84 he stated his *Atherton bed* may be represented in part by the darker rock, 105 ft. thick, in bottom part of St. Louis ls. Derivation of name not stated.]

Athol shale.

Middle Devonian: Western New York (Eighteen-Mile Creek).

A. W. Grabau, 1930 (Sci. Quart. Nat. Univ. Peking, China, vol. 1, No. 4, pp. 322–326). *Athol shales.*—Separated from underlying black Marcellus sh. by 8½ ft. of Stafford ls. Underlie Avery shales. Thickness 45 ft. Appear to be 26 ft. thick in Livonia salt shaft, 70 mi. to E. Exposed on the Lake shore (18-Mile Creek region) at Athol Springs and Bay View. Are not black, like Marcellus sh., but fauna of Marcellus sh. continues up into Athol shales. [Fossils listed.]

According to G. A. Cooper (personal communication Jan. 1934) Grabau's Athol sh. is same as Levanna sh. of Cooper.

Atic Oban series.

Pre-Cambrian: Ontario.

W. H. C. Smith, 1893 (Geol. Soc. Am. Bull., vol. 4, p. 334).

Same as *Atikokan series*, the commonly accepted spelling.

†Atikokan series.

Pre-Cambrian (Keewatin): Ontario.

A. C. Lawson, 1912 (Canada Geol. Surv. Mem. 28, p. 14).

C. R. Van Hise and C. K. Leith, 1909 (U. S. G. S. Bull. 360), spelled the river, dist., range, and rocks *Atikokan*, and stated that the spellings *Aticokan* and *Atic Oban* have also been used.

†Atkinson limestone.

A shortened form of *Fort Atkinson ls.* employed by C. [R.] Keyes.

Atlantic period.

Atlantic system.

Pre-Cambrian: New Hampshire.

C. H. Hitchcock, 1874 (Geol. N. H., pt. 1, p. 522), divided his *†Eozoic era* into (descending): Huronian period; Labrador period; uncon.; *Atlantic period;* and Laurentian period. His Atlantic period was divided into (descending): Franconia breccia group; Montalban or White Mtn gneiss; Winnipiseogee gneiss; and Bethlehem group.

Some authors attribute this name to Featherstonhaugh, 1835, but as it has fallen into disuse the compiler has not searched for the original usage. The terms *Atlantic group, Atlantic series*, and *Atlantic gneiss* have also been used by Hitchcock for rocks in N. H., which he assigned to "Archean."

Atlantic amygdaloid. (In Ashbed group.)

Pre-Cambrian (Keweenawan): Northern Michigan.

Name locally in use many years. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. Is same as Ashbed amygdaloid. The mineralized part is the Atlantic lode.

Named for occurrence in Atlantic mine, Houghton Co.

Atlantic flow.

Includes Atlantic amygdaloid and underlying trap.

Atlantic oil sand.

Subsurface sand in midst of Penn. section in Graham field, NW. part of Carter Co., Okla., 75 to 244 ft. below Johnson oil and gas zone and 78 to 125 ft. above Ricketts oil sand.

†Atlantic group.

Tertiary: Atlantic Coastal Plain.

O. Meyer, 1888 (Am. Geol., vol. 2, pp. 88–89, 93–94). The marine Tert. is extensively developed along the coast from N. Y. to Tex. The eastern Tert. may be divided into two groups, one the *Atlantic group*, comprising the Atlantic States proper from N. J. to Fla., the other the *Gulf group*, including the states from Ala. to Tex. In the first group the younger Tert. fms. are extensively developed. It comprises mostly younger Tert. strata. The Gulf group comprises the old Tert. strata.

Atlantic Coast series.

Cambrian: Canada.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 195).

†Atlantosaurus beds.

A paleontologic term applied in early repts to Morrison fm. and also to lower part only of the Morrison.

Atlas formation.

Quaternary (?): Southern California (Kern County).

A. C. Lawson, 1906 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 4, pp. 431–462). *Atlas fm.*—Ancient alluvium, made up of angular fragments of rocks of bed-rock complex, including schists, quartz diorite, granite, quartz, and arkose, well cemented. Older than Tank volcanics.

Derivation of name not stated and not known.

Atoka formation.

Pennsylvanian (Pottsville): Eastern Oklahoma, western Arkansas coal field, and southwestern Arkansas.

J. A. Taff and G. I. Adams, 1900 (U. S. G. S. 21st Ann. Rept., pt. 2, p. 273). *Atoka fm.*—Alternating sss. and shales, 7,000 ft. thick, with, at intervals of 1,000 to 1,200 ft., four groups of ss. strata each nearly 100 ft. thick. Underlies Hartshorne ss. Is basal fm. of Coal Measures.

J. A. Taff, 1901 (U. S. G. S. Coalgate folio, No. 74). *Atoka fm.*, 3,100 ft. thick, underlies Hartshorne ss. and overlies Wapanucka ls.

The fm. (of Penn. age) underlying Atoka fm. in area S. and E. of Ti Valley-Choctaw belt of Ouachita Mtns, Okla., and extending into Scott Co., Ark., is now known as *Johns Valley sh.*, and the fm. underlying it in parts of the Ti Valley-Choctaw belt of Ouachita Mtns, Okla., is Wapanucka ls., but in other places the Wapanucka ls. and underlying Springer fm. are absent, and the Atoka appears to rest on the older Caney sh. (now restricted to beds of Miss. age). The fm. that underlies it in Arkansas Valley of Ark. is Jackfork ss. (See H. D. Miser, A. A. P. G. Bull., vol. 18, No. 8, 1934.)

Named for Atoka, Atoka Co., Okla., which is situated on outcrop of fm.

Atolia quartz monzonite.

Jurassic (?): Southern California (Randsburg quadrangle, Kern and San Bernardino Counties).

C. D. Hulin, 1925 (Calif. State Min. Bur. Bull. 95, pp. 33–42, map). Intrudes Rand schist and the undiff. Paleozoic series of El Paso Mtns, which may be in part Carbf. Uncon. underlies middle Mio. sediments (Rosamond series). Is undoubted correlative of plutonic rocks of Sierra Nevada and is probably of late Jurassic age. Named for exposures at and around Atolia, San Bernardino Co.

Atrypa limestone.

Upper Devonian: Eureka district, Nevada.

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 52, 78). *Atrypa ls.*, 2,000 ft. thick, underlies Woodpecker lss. and overlies Lamoureaux shales. Lithologically embraces the massively bedded portion of the local Dev. section. Included in Nevadan series [Nevada ls.]. Name derived from Atrypa Peak, in Eureka dist.

Attalla chert conglomerate member (of Chickamauga limestone).

Lower Ordovician (early Chazy): Northern central Alabama.

C. Butts, 1910 (U. S. G. S. Birmingham folio, No. 175). *Attalla cgl. memb.*—Medium-grained ss. to coarse cgl. or breccia; in general composed mostly of rather small angular fragments of chert embedded in a siliceous matrix composed of comminuted chert or quartz. Thickness 20 to 40 ft. Basal memb. of Chickamauga ls. in central and NE. Ala.

At request of C. Butts the name was in 1926 changed to *Attalla chert cgl. memb.*

Named for exposures at Attalla, Etowah Co.

Attawapiskat coral reef.

Silurian: Canada.

T. E. Savage and F. M. Van Tuyl, 1919 (Geol. Soc. Am. Bull., vol. 30, pp. 341, 356, 363, 368).

Attawapiskat limestone.

Silurian: Ontario.

A. F. Foerste and T. E. Savage, 1927 (Denison Univ. Bull., Sci. Lab. Jour., vol. 22, pp. 5, 16).

Attica shale.

Upper Devonian: Western New York.

G. H. Chadwick, 1919 (Geol. Soc. Am. Bull., vol. 30, p. 157), and 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69). [Showed (in tables) that the sh. of Lake Erie section that has been called *Rhinestreet sh.* includes at top the Hatch sh. of Genesee River section, and is therefore a larger unit than typical Rhinestreet sh. (which lies btw. Cashaqua sh. below and Hatch sh. above). He therefore (1923 citation) named the so-called Rhinestreet of Lake Erie region *Attica sh.*, probably from exposure at Attica, Wyoming Co.]

Attleboro sandstone.

Carboniferous: Southeastern Massachusetts and Rhode Island.

J. B. Woodworth, 1899 (U. S. G. S. Mon. 33, pp. 134, 144, 151–152). *Attleboro ss.*—Fine-grained massive ss., green to brown, the latter color evidently due to oxidation. Named for exposures in town of North Attleboro; also exposed in vicinity of Deantown, in Attleboro Twp. Is embedded in Wamsutta red beds.

Attwood series.

Carboniferous (?): Southern British Columbia and northeastern Washington.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, map 10, 118° 30′ to 119°). *Attwood series.*—Argillite, qtzite, ls. Overlies Anarchist series. [Mapped at and around Attwood Mtn, B. C.]

O. E. LeRoy, 1912 (Canada Geol. Surv. Mem. 21, pp. 19, 26, 32).

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 382).

Aturia bed.

Aturia formation.

Paleontologic names applied in early repts to the *Aturia* zone, composing lower 400 ft. of Astoria sh. (Mio.) of Oreg., which is characterized by the genus *Aturia*. In some early repts excluded from Astoria sh. and assigned to Eocene, also to Olig. W. H. Dall repeatedly assigned it to Olig., but B. L. Clark (1918) and recent writers assign it to Mio. (See under *Astoria sh.* and †*Astoria group.*)

Atwater Creek shale.

Upper Ordovician: Eastern New York (Black River Valley).

R. Ruedemann, 1921 (N. Y. State Mus. Bull. 227, 228, pp. 124–126, 130). [See under *Deer River sh.*]

R. Ruedemann, 1925 (N. Y. State Mus. Bull. 258, pp. 51, 60, 62, 63, 76, 147, 148, 150). The northern Frankfort [sh.] is thus not younger than the typical Frankfort, but older, and either of later Utica or early Frankfort age. We will for that reason distinguish it as *Atwater Creek sh.* Is the zone of *Glossograptus quadrimucronatus, forma typica.* Consists of black and gray shales. Overlies Deer River sh. (of basal Lorraine age and=basal part of Frankfort sh.), and on charts is correlated with a part of Frankfort sh. [In some parts of this rept *Atwater Creek sh.* is applied to beds below Whetstone Gulf sh. and in other parts of rept the Atwater Creek is included in Whetstone Gulf fm.]

Atwell sand.

Upper Devonian: Central northern Pennsylvania (Tioga County).

M. L. Fuller, 1902 (U. S. G. S. 22d Ann. Rept., pt. 3, p. 591). *Atwell sand.*—Fine-grained, very dark brown or almost black ss. called by driller black sand. Thickness 12 to 24 ft. Included in Chemung fm. of Gaines oil region, Tioga Co., lying 700 ft. below top of Chemung. Named in honor of owner of first producing well, on Atwell farm, E. of Watrous.

Aubrey group.

Permian and Pennsylvanian: Northern Arizona, southern Utah, and southeastern Nevada.

G. K. Gilbert, 1875 (U. S. Geog. and Geol. Surv. W. 100th Mer., vol. 3, pp. 176–185, 197). *Aubrey group.*—Consists of (descending): (1) Cherty lss., 200 to 820 ft. (*Aubrey ls.*); (2) massive, cross-bedded yellow sss. 300 to 1,000 ft. (*Aubrey sss.*); (3) red and white shales and sss. 800 ft. Overlies Red Wall ls. group and underlies Lower Triassic marls [now called Moenkopi fm.]. The Aubrey ls. and sss. constitute Aubrey Cliff, which faces Aubrey Valley, in northern Ariz. and stretches SE. nearly to Camp Apache.

N. H. Darton, 1910 (U. S. G. S. Bull. 435, pp. 21–30). The 3 fms. included in *Aubrey group* in Ariz. require individual names according to present methods of nomenclature, so that I shall here introduce the terms *Kaibab ls.* (to replace "Aubrey" ls. of early repts); *Coconino ss.* (for the cross-bedded gray to white ss. of Aubrey group, which is so conspicuous in walls of Grand Canyon); and *Supai fm.* (for the red sss. and shales constituting lower part of Aubrey group in northern Ariz. In previous literature the Supai fm. and Coconino ss. have usually been referred to as "Aubrey ss. series."

L. F. Noble, 1922 (U. S. G. S. P. P. 131B). The upper 235± ft. of thin-bedded lss. which form top memb. of Redwall ls. and are said to contain Penn. fossils, are here included in Supai fm., and *Redwall* is restricted to Miss. part of original Redwall.

Aubrey group is now generally divided into (descending) Kaibab ls., Coconino ss., Hermit sh., and Supai fm.

†Aubrey limestone.

Permian: Northern Arizona, southern Utah, and southeastern Nevada.

G. K. Gilbert, 1875 (U. S. G. S. and G. S. W. 100th M., vol. 3, pp. 171–187, figs. 81, 82). [See under *Aubrey group.*]

Replaced by *Kaibab ls.*

†Aubrey sandstones.

Permian: Northern Arizona, southern Utah, and southeastern Nevada.

G. K. Gilbert, 1875 (U. S. G. S. and G. S. W. 100th M., vol. 3, pp. 171–187, figs. 81, 82). [See under *Aubrey group.*]

Replaced by *Coconino ss.* and *Supai fm.*

Aubreyan series.

A term employed by C. R. Keyes instead of *Aubrey group.*

Auburn shale. (In Wabaunsee group.)

Pennsylvanian: Eastern Kansas and southeastern Nebraska.

J. W. Beede, 1898 (Kans. Acad. Sci. Trans., vol. 15, p. 30). *Auburn sh.*—Fossiliferous olive-colored sh., 8 to 20 ft. thick, included in Upper Coal Measures of Shawnee Co. [From statement on p. 28 appears to underlie Elmont ls. and overlie Wakarusa ls.]

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., p. 66). *Auburn sh.* is 20 ft. thick in Nebr. It overlies Wakarusa ls. and underlies Emporia ls. Is top bed of Humphrey sh. memb. of Wabaunsee fm. The name was free at time it was used by Beede and should be retained for this unit.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 10). *Auburn sh. fm.*—Gray, red, and bluish gray zones, quite calc. and fossiliferous near top, 18 to 30 ft. thick. Underlies Reading ls. (older than Elmont ls.) and overlies Wakarusa ls. fm.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 222). Condra (1927) has used *Auburn sh.* for a lower bed than Beede's Wakarusa ls. Because greater importance is attached to usage in recent literature than to priority in the case of a term that has been unused except in original rather obscure paper, we follow Condra's placement of Auburn sh. Type loc. not designated, but undoubtedly it is in vicinity of Auburn, Shawnee Co., Kans. Good exposures along Wakarusa Creek near NE. cor. sec. 26, T. 13 S., R. 14 E., SW. of Auburn. Thickness 20 to 70 ft. Continuous from SE. Nebr. across Kans. into Okla.

Auburn chert.

Middle Ordovician: Central-eastern Missouri.

R. R. Rowley, 1908 (Mo. Bur. Geol. and Mines vol. 8, 2d ser., pp. 14, 16). *Auburn chert.*—Intensely hard bluish ls., with soft chert bands full of fossils, forming surface stone of Auburn, Lincoln Co. Included in Trenton ls.

A. F. Foerste, 1920 (Denison Univ. Bull., Sci. Lab. Jour., vol. 19, pp. 175–194), correlated *Auburn chert* with Decorah sh., and stated that it "apparently lies at about same horizon as Bryant ls."

J. H. Bradley, Jr., 1925 (Mo. Bur. Geol. and Mines vol. 2, 2d ser., p. 66), stated that *Auburn chert* is included in Plattin fm.

C. L. Fenton (1928) and S. Weller and S. St. Clair (1928). See under *Plattin ls.*

J. Bridge, March 1937 (personal note). *Auburn chert* is = Decorah or possibly is slightly younger.

Auburn moraine.

A Pleist. moraine in central N. Y. (See H. L. Fairchild, Geol. Soc. Am. Bull., vol. 43, No. 3, pp. 627+, 1932.)

†Aucella beds.

A paleontologic term that has been applied to Lower Cret. and Jurassic rocks of Oreg., because of profusion in them of species of the genus *Aucella.*

Auger conglomerate lentil (of Wichita formation).

Permian: Southwestern Oklahoma (Tillman County).

M. J. Munn, 1914 (U. S. G. S. Bull. 547, pp. 23–26). *Auger cgl. lentil.*—Clay-ls. cgl. and associated beds, consisting of clay, ss., and cgl., forming basal memb. of Wichita fm. Thickness 20 to 78 ft.

Named for Old Fort Auger and Auger Creek, Tillman Co.

Auger limestone member.

A name applied by geologists of mining companies, in their company repts, to basal 100 ft. of Lake Valley ls. (Miss.) in Santa Rita dist., SW. N. Mex.

†Augusta limestone.
†Augusta group.
†Augusta stage.

Mississippian: Iowa, Missouri, and Illinois.

C. R. Keyes, 1893 (Iowa Geol. Surv. vol. 1, pp. 59–71). *Augusta ls.* introduced to include rocks btw. Kinderhook group below and St. Louis ls. [broad usage] above. Includes what has been called Warsaw shales and ls., Geode bed, Keokuk ls., Upper Burlington ls., and Lower Burlington ls. Uncon. underlies St. Louis ls. [In subsequent repts Keyes and others called these rocks "Augusta stage" and "Augusta group." *Augusta ls.* has also been applied to *Burlington ls.*]

Includes all of Osage group except Fern Glen ls., and part of overlying Meramec group.

Named for Augusta, Des Moines Co., Iowa.

†Auriferous slates.

Term in common use by Whitney (Geol. Surv. of Calif.) and subsequent writers for undiff. Paleozoic and Mesozoic strata in Sierra Nevada.

†Auriferous slate series.

A descriptive term used in folios and other early repts on Gold Belt region of northern Calif., to include Mariposa sl. and Calaveras fm., in contradistinction to †Superjacent series, a descriptive term applied to the Cret., Tert., and Quat. deposits of the region.

Auriferous gravels.

A descriptive term that has had considerable usage in northern Calif. for gravels of Cret., Eocene, and Pleist. age. (See under *Weaverville fm.*)

Aurora formation.

Cretaceous (Lower): Mexico.

R. H. Burrows, 1909 (Min. and Sci. Press, vol. 99, p. 324), and 1910 (Soc. Geol. Mexicana, Bol., t. 7, p. 96).

Aurora sandstone member (of Orangeville shale).

Mississippian: Northeastern Ohio.

C. S. Prosser, 1912 (Ohio Geol. Surv., 4th ser., Bull. 15, pp. 123, 209, 211). *Aurora ss. memb.*—Blue, fine-grained ss. with some thin sh. partings, forming middle memb. of Orangeville fm. in Cuyahoga and Chagrin valleys, NE. Ohio. Underlain by black Sunbury sh. memb. of Orangeville and overlain by Brecksville sh. memb. of Orangeville.

The Sunbury sh. is now excluded from Orangeville sh., so that Aurora ss. is basal memb. of the Orangeville.

Named for exposures on Aurora Creek, in NW. part of Portage Co.

†Auroral series.

Nongeographic name introduced by H. D. Rogers in 1858 (Geol. Pa., vol. 1, pp. 105, 123–124, 208–245, 251–257, 261; and vol. 2, p. 752). Divided into (descending): (1) *Auroral mag. ls.* 2,500 to 5,500 ft. ("The Chazy and Black River lss. of N. Y. are parts of this formation."); (2) *Auroral calc. ss.* (*Calciferous ss.* of N. Y.), which occurs chiefly in Northampton, Centre, and Huntingdon Counties, and is 60 ft. thick at Easton.

Later the Auroral ls. of Rogers was replaced by *Shenandoah ls.*, which is now subdivided in most areas into several named units.

†Auroral limestone.
†Auroral sandstone.

See under †*Auroral series.*

†Ausable granite.

Pre-Cambrian: Northeastern New York (Essex County).

J. F. Kemp, 1894 (N. Y. State Mus. 47th Ann. Rept.). The anorthosite quarried near Keeseville [Essex Co.] is called "Ausable granite." Probably to be classed in Algonkian of U. S. G. S. geologists.

H. P. Cushing, 1897 (N. Y. State Geol. 15th Ann. Rept., vol. 1, p. 546). The more feldspathic portions of the anorthosite are quarried near Keeseville and placed on market under name of "Keeseville granite."

J. F. Kemp, 1897 (N. Y. State Geol. 15th Ann. Rept., vol. 1, p. 583). The great quarries at Keeseville have made this anorthosite widely known as "Ausable granite."

Ausable sandstone.

Upper Cambrian: Eastern New York.

H. I. Alling, 1919 (N. Y. State Mus. Bull. 207, 208, pp. 113-145). "Au Sable ss." is applied by some authors to coarse cgl. known as *Potsdam basement bed* and underlying the so-called "white Potsdam" ss., which recent work seems to indicate is not same as Potsdam ss.

Ausable syenyte.

Pre-Cambrian: Eastern New York (Adirondack Mountains).

See under *Adirondack anorthosyte.*

Austin chalk.

Upper Cretaceous (Gulf series): Eastern Texas.

B. F. Shumard, 1860 (St. Louis Acad. Sci. Trans., vol. 1, pp. 583, 585). ***Austin ls.***—Fossiliferous cream-colored and bluish earthy ls.; 100 ft. exposed in vicinity of Austin. Some beds soft and crumble on exposure, other beds moderately hard and furnish handsome building rock. At base shaly layers of fossiliferous dark bluish gray calc. ss. Overlies *Exogyra arietina* marl [Del Rio clay] and underlies Comanche Peak group.

C. A. White and R. T. Hill, 1887 (Phila. Acad. Nat. Sci. Proc. 1887, p. 40). *Austin ls.*—Includes strata named Austin ls. by B. F. Shumard in 1860, but true relations not then recognized. Underlies Navarro beds [as here used included at base the Taylor marl] and overlies Eagle Ford shales.

The present generally recognized definition of *Austin chalk* applies to the beds below Taylor marl and above Eagle Ford clay. But to NE. the upper part of the chalk (Gober tongue) overlies Brownstown marl, and basal part of the chalk (Ector tongue) underlies Bonham clay (formerly erroneously included in Eagle Ford clay). (See L. W. Stephenson, U. S. G. S. P. P. 186G, 1937.)

†Austin marble.

Lower Cretaceous (Comanche series): Southeastern Texas.

R. T. Hill, 1889 (Tex. Geol. Surv. Bull. 4, p. xxii). *Austin marble.*—Massive ls., often metamorphosed into marble, composed almost exclusively of calcified shells of *Requienia* (*Caprotina*), *Nerinea*, etc. Thickness 20 ft. Overlies 10 ft. of flagstones. Assigned to Washita div. but may represent close of Fredericksburg div.

Conflicts with Austin chalk. Is a bed at top of Edwards ls., the top fm. of Fredericksburg group.

Named for occurrence at Austin.

†Austin rock.

Trade term for a fine-grained sandrock or shaly sandrock, of Dev. age, quarried at Austin, Mower Co., Minn.

Austin Brook quartz porphyry.

Post-Ordovician: New Brunswick.

G. A. Young, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 219).

Austinburg sand.

A subsurface sand in NE. Ohio (Austinburg pool, Ashtabula Co.) that has been correlated with both Sylvania ss. of Ohio and with Oriskany ss. of N. Y.

Autocene.

Recent: New England.

J. B. Perry, 1872 (Boston Soc. Nat. Hist. Proc., vol. 15, pp. 55–56). "Autocene" is introduced into the table, in place of "Recent" or "Present," merely for sake of uniformity. *Autocene* means *emphatically new,* thus appropriately designating the latest times.

Aux Sable limestone.

Upper Ordovician (Richmond): Northeastern Illinois.

J. R. C. Evans, 1926 (Chicago Univ., Abstracts of Theses, Sci. ser., vol. 2, pp. 199–200). The Richmond of NE. Ill. may be subdivided into 3 main members: (1) A lower sh. memb.; (2) a middle dominantly ls. memb.; and (3) an upper dominantly sh. memb. The lower and upper members are nonfossiliferous. The middle memb. contains abundant fossils. In it 6 horizons can be recognized, which are named (ascending order): (1) *Aux Sable ls.*, which corresponds faunally to lower part of the Waynesville of Ind.; (2) *Millsdale ls.,* which contains a few poorly preserved fossils representatives of which occur in the Waynesville and lower Liberty of Ind.; (3) *Treat ls.*, practically unfossiliferous; (4) *Du Page ls.*, fossils, poorly preserved, occur in Waynesville and lower Liberty; (5) *Rock Run ls.*, fossils, poorly preserved, occur in Waynesville and lower Liberty; (6) *Wilmington ls.*, highly fossiliferous, and fossils very similar to upper Waynesville and Liberty of Ind. [Lithology and type localities of these named faunal zones not stated.]

Aux Vases sandstone. (Of Chester group.)

Mississippian: Eastern Missouri and southwestern Illinois.

C. R. Keyes, 1892 (Geol. Soc. Am. Bull., vol. 3, p. 295). *Aux Vases* ss.—Fine-grained ferruginous ss., 10 to 100 ft. thick, the "ferruginous ss." of Shumard and others. Overlies Ste. Genevieve ls. and underlies Kaskaskia ls.

The fm. overlying Aux Vases ss. is now known as *Renault fm.*, and Aux Vases rests uncon. on Ste. Genevieve ls. (See also under *Ste. Genevieve ls.*)

Named for exposures on Aux Vases River, Ste. Genevieve Co., Mo.

Auxvasse Creek sandstone member (of Callaway limestone).

Devonian: East central Missouri (Callaway County).

F. B. Conselman, 1935? (Mo. Acad. Sci. Proc., vol. 1, pp. 105, 108–113, 119). *Auxvasse Creek ss. memb.*—Basal memb. of Callaway ls. (Dev.) in Auxvasse Creek quad., Callaway Co. The uncon. btw. Callaway ls. and underlying Mineola ls. is evidenced by the thinning or absence in places of the Mineola and by presence of Auxvasse Creek ss. memb. in S. part of quad. The Auxvasse ss. is white, friable, calc. ss.; rarely fossiliferous; 16 in. to 5 ft. thick. On E. side of Auxvasse Creek it reaches thickness of nearly 5 ft. and is well exposed a short distance N of the gravel road in NE. 1/4 sec. 8, T. 46 N., R. 8 W. and in NW. 1/4 sec. 9 of same twp., E. of where it apparently disappears. Is also absent in central part of area. Some early workers mistook this ss. for St. Peter ss., but it is St. Peter reworked by Dev. seas.

Ava shale. (In Pottsville formation.)

Pennsylvanian: Southwestern Illinois.

T. B. Root, 1928 (Ill. Geol. Surv. Rept. Invest. No. 16, pp. 9, 10, pls. 1, 2). In upper part of Pottsville fm. [110± ft. below top on pl. 1] is a fairly persistent and extensive sh. bed, which for convenience is called *Ava sh.* Can be identified in many outcrops and well records. Throughout greater part of area (Ava-Campbell Hill area, in parts of Randolph, Perry, and Jackson Counties) the Ava sh. has been used as key horizon for contour map which shows structure of Penn. beds. Although Ava sh. is irregular in thickness and locally is missing in both outcrops and well logs, it was found to be best horizon to use over so large an area. [Contour map shows it surrounding village of Ava, Jackson Co.]

Avalon group.

A term applied to ancient rocks of Newfoundland. Assigned to "Algonkian" by C. D. Walcott, 1899 (Geol. Soc. Am. Bull., vol. 10, p. 218) and C. R. Van Hise and C. K. Leith, 1909 (U. S. G. S. Bull. 360, p. 43). For Walcott's original definition see under *Terranovan*. Type loc. is on Avalon Peninsula.

Avalonian formation.

Pre-Cambrian (Huronian): Newfoundland.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4). *Avalonian fm.*—Slates, tuffs, aggls., cgls., and lavas. Fossil worms (?). Basal fm. of Huronian. Underlies Signal Hill fm. (Huronian). [Derivation of name not stated.]

Avant limestone member (of Ochelata formation).

Pennsylvanian: Central northern, northeastern, and northern central Oklahoma.

D. W. Ohern, 1910 (Okla. State Univ. Research Bull. 4, pp. 31, 37). *Avant ls. lentil*.—Bluish semicrystalline ls., often thin-bedded, from a few ft. to 40 ft. thick. Stratigraphically about 85 ft. above Dewey ls. along 96th meridian S. of Bartlesville. Included in Copan memb. of Wann fm. in northern area and in Ramona fm. in southern area.

In northern Okla. is now treated as a memb. of Ochelata fm.; in Bristow quad. is treated as a memb. of Copan fm.

Named for Avant, Osage Co.

Avenal sandstone.

Eocene: Southern California (Diablo Range).

F. M. Anderson, 1905 (Calif. Acad. Sci. Proc., 3d ser., vol. 2, pp. 164–168). *Avenal sss.*—A great thickness of ss. exposed in canyon of Canoas Creek, with a thin basal bed of cgl., 6 to 10 ft. thick, resting on Lower Cret. shales. Upper 400 ft. consists of very fossiliferous concretionary sss., below which occur thin-bedded ss. The Avenal wells at Tar Springs are drilled to penetrate these sands, which are exposed at Tar Springs on E. and at Sulphur Springs on Zapato Chino Creek to W. Underlie Kreyenhagen shales.

F. E. von Estorff, 1930 (A. A. P. G. Bull., vol. 14, No. 10, pp. 1321–1336). The 500 ft. of ss. underlying Kreyenhagen sh. in canyon of Canoas Creek is Domengine ss., of upper middle Eo. age. The type loc. of Domengine is N. of Coalinga.

Averill granite.

Age (?): Northeastern Vermont (Essex County).

R. A. Schroeder, 1921 (Vt. State Geol. Rept. 1919–20, pp. 39–42). *Averill granite*.—Pink, two-mica granite of medium grain, with subporphyritic texture. Intrudes a muscovite-biotite schist; the contact being well exposed on summit of Averill Mtn and in bed of Averill Stream 100 yds below the granite bridge of Norton Mills road. Underlies and surrounds Big Averill Lake and all but a small part of Little Averill Lake.

Avery shale.

Middle Devonian: Western New York (Eighteen-Mile Creek).

A. W. Grabau, 1930 (Sci. Quart. Nat. Univ. Peking, China, vol. 1, No. 4, pp. 323–326). *Avery shales*.—Do not differ markedly from underlying Athol shales, on which they rest. On 18-Mile Creek are 30 to 40 ft. thick and underlie Wanakah sh. In Livonia salt shaft, 70 mi. to E., they appear to be 147 ft. thick. Contain pronounced Hamilton fauna, but many typical Marcellus species continue. [Derivation of name not stated.]

According to G. A. Cooper (personal communication Jan. 1934) Grabau's Avery sh. is same as Ledyard memb. of Cooper.

Avilton conglomerate.

Upper Devonian: Western Maryland.

C. K. Swartz et al., 1913 (Md. Geol. Surv. Middle and Upper Devonian vol., pp. 352, 383–385). The flat-pebble jasper cgl. in Chemung ss. memb. of Jennings fm. of northern Garrett Co., Md., is named *Avilton cgl.* because of its occurrence in immediate vicinity of post office of that name on Pea Ridge. It is possibly same as Stevenson's Upper Chemung cgl. of Pa. Is overlain by the upper sh. and ss. beds of Chemung memb. and underlain by the middle sh. and ss. beds of that memb.

Avis sandstone memb. (of Thrifty formation).

Pennsylvanian: Central northern Texas (Brazos River region).

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31). *Avis ss.*, basal memb. of Thrifty fm. in May-Coleman and Strawn-Baird sections. Lies discon. on Graham fm.

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, pp. 125, 131–136, 152–158). *Avis ss. memb. of Thrifty fm.*—Persistent but variable deposit of coarse-grained ss., grit, or cgl., ranging in thickness from 5 to 40+ ft. Basal memb. of Thrifty fm. in Brazos River valley. Lies 35 to 80 ft. below Ivan ls. memb. In places rests on Wayland sh. memb. of Graham fm.; in other places on underlying Gunsight ls. memb. of Graham. Correlated by Plummer with Trickham bed of Drake, in Colorado River valley. Named for town of Avis, Jack Co. Typically developed in Jack, Young, and Stephens Counties.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 103), treated Avis ss. as basal memb. of Thrifty fm.

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501, p. 232), used *Avis ss.* for the beds underlying Breckenridge ls. and overlying Speck Mtn ls. in Colorado River Valley (McCulloch Co.), and stated that Parks Mtn cgl. of Drake (the type loc. of which is in adjoining Coleman Co.) is a conglomeratic phase of Avis ss.

The U. S. Geol. Survey at present treats Avis ss. as basal memb. of Thrifty fm. in Brazos River region, and Parks Mtn ss. memb. of Colorado River region as much younger, lying immediately below Chaffin ls. and resting on Lohn sh. memb. of Thrifty.

Avis limestone. (In Hinton formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 296, 347). *Avis ls.*—Steel gray, hard, with shaly streak near middle; marine fossils. Thickness 20 to 45 ft. Name introduced to replace *Hinton ls.* of Krebs, because of conflict with Hinton group [fm.]. Type loc. in vicinity of Avis and Hinton, Summers Co.

Avis shale. (In Hinton formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 296, 346–352). *Upper Avis sh.*—Green or yellow, calc., usually fissile, 20 to 100 ft. thick, abundant marine fossils. Underlies Avis ss. and overlies Avis ls. *Lower Avis sh.*—Yellow, calc., 15 to 30 ft. thick; marine fossils; underlies Avis ls. and overlies Payne Branch ss. All members of Hinton group [fm.]. Type loc., region around Avis, Hinton, and Bellepoint, Summers Co. Also observed in Mercer Co.

Avis sandstone. (In Hinton formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 296, 345). *Avis ss.*—Greenish gray, micaceous, massive or shaly, persistent, 10 to 35 ft. thick. Underlies Low Gap sh. and overlies Upper Avis sh., all members of Hinton group [fm.]. Type loc. high up sides of mtns in vicinity of Hinton and Avis, Summers Co. Also observed in Mercer Co.

Avoca limestone. (In Lecompton limestone.)

Pennsylvanian: Southeastern Nebraska, northeastern Kansas, and northwestern Missouri.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 44, 45, 47). *Avoca ls.*—Top unit in Lecompton ls. Dense bluish ls. in 2 or 3 beds. Thickness 2 to 9 ft. in Nebr.; 1+ ft. in Mo. and Kans. Overlies King Hill sh. (in Lecompton ls.). Named for exposure in South Fork Weeping Water Creek about 3 mi. E. of Avoca, Otoe Co., Nebr.

Avon shale and limestone. (In Pottsville formation.)

Pennsylvanian: Central western Illinois (Fulton County).

T. E. Savage, 1927 (Am. Jour. Sci., 5th, vol. 14, pp. 307–316), applied *Avon sh. and ls.* to beds underlying Colchester (No. 2) coal and overlying his Bernadotte ss. He included these beds in Carbondale fm., as he proposed to expand that name; but they belong to Pottsville fm. of U. S. Geol. Survey and other authors. Thickness and derivation of name not stated, but probably named for Avon, Fulton Co.

†Avondale limestone.

Pre-Cambrian: Southeastern Pennsylvania (Chester County).

P. Frazer, 1883 (2d Pa. Geol. Surv. Rept. C_4, pp. 307, 321, 322), casually alludes to *Avondale ls.*, and accompanying map (of Chester Co.) shows a belt of "Siluro-Cambrian ls." running through Avondale, Kennett Square, and other places in Chester Co.

A quarry rock in Cockeysville marble is now locally known as "Avondale ls."

Avondale volcanics.

Pre-Cambrian: Newfoundland.

A. F. Buddington, 1919 (Jour. Geol., vol. 27, p. 456).

†Avondale series.

A name used by A. C. Hawkins (Am. Jour. Sci., 5th, vol. 7, pp. 355–364, 1924) to denote Glenarm series in vicinity of Avondale, Chester Co., Pa.

Avon River limestone.

Mississippian: Nova Scotia.

W. A. Bell, 1921 (Am. Jour. Sci., 5th, vol. 1, p. 166).

Aweres formation.

Pre-Cambrian: Ontario.

R. G. McConnell, 1926 (Ont. Dept. Mines, 35th Ann. Rept., vol. 35, pt. 2, p. 16).

Axemann limestone. (In Beekmantown group.)

Lower Ordovician: Central Pennsylvania (Center and Blair Counties).

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pp. 552, 653, 657, 660, 674, pl. 27). *Axeman* [*n*] *ls.*—Thick and thin-bedded, nearly pure ls., of dark color, frequently stained with iron oxide, and ranging from compact to distinctly crystalline. Thickness 158 ft. Underlies Bellefonte dol. and overlies Nittany dol.

The ls. at Axemann, Center Co., is Stonehenge ls., which underlies Nittany dol., but the ls. named *Axemann* crops out 1 mi. E. of Axemann. The Bellefonte, Axemann, Nittany, and Stonehenge compose Beekmantown group of central Pa.

Ayer granite.

Carboniferous or post-Carboniferous: Eastern Massachusetts, southeastern New Hampshire, and northeastern Connecticut.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 86, 223–228 and map). *Ayer granite.*—Biotite-muscovite granite of moderately coarse grain. In many places coarsely porphyritic, containing feldspar phenocrysts 1 to 3 inches long or blotched with large patches of feldspar crystals. Extends through Ayer, Mass.

Aylesworth limestone member. (In Pottsville formation.)

Pennsylvanian: Northwestern Illinois (McDonough County).

T. E. Savage, 1930 (Ill. Acad. Sci. Trans., vol. 22, p. 498). [Columnar section of Macomb region shows *Aylesworth ls. memb.* located about midway in *Avon sh. and ls.*, the upper part of Pottsville fm. Derivation of name not stated.]

Aylmer formation.

Ordovician (Lower): Ottawa Valley, Canada.

P. E. Raymond, 1905 (Carnegie Mus. Annals, vol. 3, p. 380, and Am. Jour. Sci., 4th, vol. 20, p. 364, etc.). *Aylmer fm.*—Name proposed for the Chazy of Ottawa Valley, which is very late Chazy, and differs in lithology and fauna from typical Chazy.

†Azoic era.

In its earlier and in some of its later usages this term was applied to all pre-Paleozoic time. In other later usages it was applied (1) to all pre-Potsdam time; (2) to Huronian epoch of †Algonkian period plus the †Archean period; (3) to †Archean period only; and (4) to a hypothetical interval preceding all known rocks. (For full definition see U. S. G. S. Bull. 769, pp. 20–26, 1925.)

Azotea tongue (of Carlsbad limestone).

Permian: Southeastern New Mexico (Pecos Valley).

W. B. Lang, 1937 (A. A. P. G. Bull., vol. 21, No. 7). The part of Carlsbad ls. that caps western Azotea Mesa and overlies Seven Rivers gypsiferous memb. of Chalk Bluff fm. is here named *Azotea tongue*.

Aztec sandstone.

Jurassic(?): Southeastern Nevada (Goodsprings quadrangle).

D. F. Hewett, 1931 (U. S. G. S. P. P. 162, pp. 9, 35, etc.). *Aztec ss.*—Massive ledge of reddish or buff ss., minutely cross bedded. Is made up of many lenses, mostly 10 to 25 ft. thick, each lens in turn made up of smaller laminae ½ to 2 inches thick. Thickness 2,100 ft. Rests on Chinle fm. and is overlain by Quat. deposits. Name is derived from Aztec Tank, a natural depression in the ss. several hundred ft. E. of Contact mine, in which water accumulates at times of heavy rain.

Aztecan series.

A term introduced by C. [R.] Keyes and applied by him in Colo., N. Mex., and Ariz., to cover "a thick, post-Laramian succession of Cretacic sediments in the San Juan region." (See his Conspectus of geol. fms. of N. Mex., 1915, pp. 2, 5.)

Azuero formation.

Pre-Pleistocene: Panama.

O. H. Hershey, 1901 (Univ. Calif. Dept. Geol. Bull., vol. 2, p. 237).

Azure River series.

Pre-Cambrian(?): British Columbia.

N. F. G. Davis, 1930 (Canada Geol. Surv. Summ. Rept. 1929, pt. A, p. 285).

Baby sand.

A subsurface sand near top of Rico fm. (Perm.) in southern San Juan Co., SE. Utah.

Babylon cyclical formation.

A name applied by H. R. Wanless (Ill. Geol. Surv. Bull. 60, 1931, pp. 179–193) to basal part of Pottsville fm. (Penn.) of central-western Ill., based upon the rhythmic-cycle theory of sedimentation. Derivation of name not stated, but there is a village of that name in Fulton Co.

Bachelor Creek limestone.

Pennsylvanian: Southern Kansas.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 94, 96). Members of Howard ls. have been assigned names as follows, ascending: *Bachelor Creek ls., Aarde sh.* (containing Nodaway coal), *Church ls., Winzeler sh.*, and *Utopia ls.* [Derivation of names not stated. On p. 21 *Bachelor Creek ls.* is described as consisting of 1.35 ft. of blue ls. weathering brown and shaly.]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 205–207). *Bachelor Creek ls.*, lowest memb. of Howard ls., is developed in southern Kans. from Greenwood Co. southward. It is hard, somewhat sandy, impure, bluish gray ls. ranging in thickness up to 3± ft. Occurs below Aarde sh. memb., in which Nodaway coal lies near base. Type loc., Bachelor Creek, sec. 33, T. 25 S., R. 11 E., about 5 mi. E. of Eureka, Kans.

Backbone limestone.

Lower Devonian: Southwestern Illinois (Jackson County).

T. E. Savage, 1920 (Am. Jour. Sci., 4th, vol. 49, pp. 169–178). *Back-bone ls.*—Rather thick-bedded coarsely crystalline lss., 0 to 70± ft. thick, uncon. underlying Clear Creek chert in SW. Ill. and uncon. overlying Bailey ls., of New Scotland age. Fauna appears to be closely related to that of Becraft ls. of N. Y. No separate name was applied by Worthen to this ls. Is well exposed near S. end of Devil's Back-bone Ridge, a short distance N. of Grand Tower, Jackson Co.

T. E. Savage, 1925 (Am. Jour. Sci., 5th, vol. 10, pp. 139–144), replaced his *Back-bone ls.* (of supposed Helderberg age) with Weller's *Little Saline ls.* (of known Oriskany age), being satisfied of Oriskany age of his Backbone ls. and its equiv. to Little Saline ls.

†Bad limestone.

See 1st entry under *Bad River ls.*

Bad Axe member (of Franconia sandstone).

Upper Cambrian: Western Wisconsin and southeastern Minnesota.

A. C. Trowbridge, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., figs. 1, 2, pp. 81, 92, 134, 140, 159, 431, 446, 449, etc.). *Bad Axe memb. of Franconia fm.*—Greensand and siltstone, 21 to 25± ft. thick, underlying St. Lawrence memb. of Trempealeau fm. and overlying Hudson memb. of Franconia fm. at Victory, Trempealeau Mtn, Skillet Falls, Goodenough Hill, Hudson, Afton, and other places in western Wis. Named for Bad Axe River, near Franconia, Chisago Co., Minn. [On p. 309 of this book G. O. Raasch stated that *Bad Axe memb.* is lower *Dikelocephalus* zone. *St. Lawrence memb.* as used in above definition of *Bad Axe memb.* included not only St. Lawrence ls. (dol.) memb. of Ulrich but the underlying basal greensand and cgl. memb. as well.]

Above definition was repeated and somewhat amplified by W. H. Twenhofel, G. O. Raasch, and F. T. Thwaites, Nov. 30, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 11, pp. 1702, etc.), who, however, treated the basal cgl. and greensand memb. overlying Bad Axe memb. as distinct from their St. Lawrence dol. memb. They gave thickness of Bad Axe memb. as ranging btw. 20 and 50 ft.

Baden sandstone.

Pennsylvanian: Central eastern Missouri (St. Louis County).

H. A. Wheeler, 1895 (St. Louis Acad. Sci. Trans., vol. 7, p. 125). *Baden ss.*—Gray to drab ss., 2 to 10 ft. thick, coarse-grained, porous, cross-bedded. Occurs near base of Coal Measures at Baden, North St. Louis. Equiv. of "Ferruginous" ss. Underlain by 3 to 5 ft. of shales which rest uncon. on St. Louis ls.

Named for exposures at Baden, St. Louis Co.

Bader formation. (In Council Grove group.)

Permian: Southeastern Nebraska and northeastern Kansas.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, pp. 4, 7). *Bader ls. fm.*, about 24½ ft. thick, includes (descending) Middleburg ls., Hooser sh., and Eiss ls. of Council Grove group. [Derivation of name not stated.]

Badger Creek formation.

Cambrian or pre-Cambrian: British Columbia.

W. L. Uglow, 1922 (Canada Geol. Surv. Summ. Rept. 1921, pt. A, p. 76).

Bad Heart sandstone member.

Cretaceous: Alberta.

F. H. McLearn, 1926 (Canada Geol. Surv. Bull. 42, p. 119). Included in Smoky River fm.

Bad Hole sand.

A subsurface sand of early Penn. (Cherokee) age in central eastern Okla., which is reported to correspond to one of sands of Dutcher sand series. In Timber Ridge pool, Muskogee Co., it lies at a depth of 1,385 to 1,407 ft. and the Muskogee sand lies at 1,480 to 1,510 ft. C. W. Wilson, Jr., says (A. A. P. G. Bull., vol. 19, No. 4, 1935, pp. 505, 515) this sand corresponds to Georges Fork ss. memb. of Atoka fm., and that it is one of the Dutcher sands.

Badito formation.

Pennsylvanian: Central southern Colorado (Walsenburg region).

R. C. Hills, 1900 (U. S. G. S. Walsenburg folio, No. 68). *Badito fm.*—Upper part consists of 100 ft. of brick-red ss., massive or thick bedded but sometimes shaly on weathered surface. This ss. probably corresponds to some part of Fountain fm. Lower part consists of coarse brownish red cgl. that is=Sangre de Cristo fm. [See also 1900 entry under *Sangre de Cristo fm.*]

Probably named for Badito Peak or town of Badito, just W. of Walsenburg quad. and in Huerfano Park quad.

†Bad River sandstone.

Pre-Cambrian (Keweenawan): Northwestern Wisconsin (Ashland County).

E. T. Sweet, 1876 (Wis. Acad. Sci., Arts., and Lett. Trans., vol. 3, pp. 40–55). *Bad River ss.*—Sss. and shales forming upper beds of Copper-bearing series [Keweenawan]. Largely represented on Bad River.

†Bad River gabbro.

Pre-Cambrian (Keweenawan): Northwestern Wisconsin (Ashland County) and northern peninsula of Michigan.

R. D. Irving, 1883 (U. S. G. S. 3d Ann. Rept., pp. 115, 134, 135, 186; also U. S. G. S. Mon. 5, pp. 40–41, 144, 155, 377, 435). Very coarse gabbro, largely developed in Bad River region, Ashland Co., Wis., and exposed on Bad River, Iron Co., Wis. Forms base of Keweenawan series.

Bad River dolomite.

Pre-Cambrian (lower Huronian): Northwestern Michigan and northwestern Wisconsin (Penokee-Gogebic district).

C. R. Van Hise, 1901 (U. S. G. S. 21st Ann. Rept., pt. 3, p. 338). *Bad ls.*—Cherty ls., of Lower Huronian age. Uncon. underlies Palms fm. and uncon. overlies Archean granite and gneiss in Penokee-Gogebic dist.

A. C. Lane and A. E. Seaman, 1907 (Jour. Geol., vol. 15, btw. pp. 680–695). *Bad River fm.* of Gogebic Range is=Kona dol. and Randville dol.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, pp. 225, 228). *Bad River ls.*—Chiefly ls., heavily mag., in places approaching dol., intermingled and interstratified with chert. Thickness 200 to 300 ft. Grades into underlying Sunday qtzite. Top eroded. Overlain by Palms fm.

Named for occurrence at Bad River, in Penokee Gap section.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), adopted *Bad River dol.* as the name of this fm.

Badshot formation.

Pre-Cambrian: British Columbia.

J. F. Walker, 1929 (Canada Geol. Surv. Summ. Rept. 1928, pt. A, p. 126).

Bad Vermilion Lake granite.

Pre-Cambrian: Ontario.

A. C. Lawson, 1913 (Canada Geol. Surv. Mem. 40, p. 51).

Baffin till.

C. [R.] Keyes, 1926 (Pan-Am. Geol., vol. 45, p. 151). The Greenlandian ice-center of today and the Patrician ice-center of Hudson Bay may both prove to be parts of what we call the Labradoran glacier. If the first is really a distinct polarine ice-cap its deposits should be distinguished by some such title as *Baffin till*. In either case the Greenland glacier is a hold-over remnant of Wisconsin glaciation.

Bagley andesite.

Lower (?) Jurassic: Northern California (Redding quadrangle).

J. S. Diller, 1906 (U. S. G. S. Redding folio, No. 138). *Bagley andesite.*—Includes the lavas and pyroclastics of a succession of volcanic eruptions of similar general character. Commonly filled with an abundance of small phenocrysts of plagioclase, and rarely also with dark grains in a greenish groundmass. Composed chiefly of andesitic tuff, sometimes coarse, almost agglomeratic, but generally fine and stratified, with occasional traces of marine fossils. More than three-fourths of Bagley Mtn area is occupied by tuff. The lavas are most abundant near summit and whole mass has thickness of about 1,000 ft. Both areas [Bagley Mtn and along Pit River] of Bagley andesite lie practically on border btw. Potem and Modin fms., but do not necessarily indicate an uncon. These areas represent centers of greater accumulation of volcanic material near points of eruption during beginning of Potem epoch. Between the two points the contemp. sediments contain some detritus from both centers, but apparently the greater portion comes from a different source. For this reason the intermediate sediments were included in the Potem.

Bagnell till.

Name introduced by C. [R.] Keyes for a very old sheet of glacial till (pre-Nebraskan) in Mo. "that has been called Nebraskan till by Leverett." (See Pan-Am. Geol., vol. 58, pp. 203, 208, 217, 1932.)

Bailey limestone.

Lower Devonian (Helderberg): Eastern Missouri and southwestern Illinois.

E. O. Ulrich, 1904 (Mo. Bur. Geol. and Mines vol. 2, 2d ser., p. 110). *Bailey ls.*—Argill. lss. and shales containing New Scotland Helderbergian faunas at Red Rock landing and above. Overlies Bainbridge ls. and underlies Clear Creek ls. [restricted]. Thickness 100± ft.

Named for exposure at former Bailey's Landing, on Mississippi River, Perry Co., Mo., a short distance above present Red Rock Landing.

Bailey Spring limestone.

Pennsylvanian (early) and Mississippian (late): Eastern Nevada (Pioche district).

L. G. Westgate and A. Knopf, 1932 (U. S. G. S. P. P. 171, pp. 7, 21, etc.). *Bailey Spring ls.*—Gray, medium-bedded ls., some cherty layers; basal beds consist of olive-brown fossiliferous ls. weathering to reddish debris, which passes up into gray-black fossiliferous ls. that weathers to mottled red and yellow. These basal beds are probably not very thick. Thickness of fm. 2,275 ft. Overlies Scotty Wash qtzite. Is youngest Carbf. fm. in Pioche dist. Top is eroded. Is overlain by igneous rocks of Tert. (?) age. Fossils are lower Penn. and late Miss., according to G. H. Girty. The fm. occurs in several large areas SE. of Bailey Spring, on W. side of Bristol Range, Pioche dist.

†Bainbridge marl.

Eocene (upper): Southwestern Georgia.

A. F. Foerste, 1894 (Am. Jour. Sci., 3d, vol. 48, pp. 41-54). *Bainbridge marl.*—Very calc. bed containing many fossils, chiefly Orbitoides. Exposed at water level

E. and W. of Steamboat landing at Bainbridge. Lies 150 ft. below top of Vicksburg group, in which it is included.

According to later studies of C. W. Cooke this marl is part of Ocala ls. of Jackson (upper Eocene) age, which name has priority.

Named for exposures at Bainbridge, Decatur Co.

†Bainbridge residual beds.

Miocene and Oligocene: Southwestern Georgia.

W. H. Dall and J. Stanley Brown, 1894 (Geol. Soc. Am. Bull., vol. 5, p. 170). The *Bainbridge residual beds* correlate with Chipola marl and with upper part of underlying Chattahoochee beds. [Not defined.]

C. J. Maury, 1902 (Bulls. Am. Pal., vol. 3, No. 15, pp. 67-69, 81). The upper part of *Bainbridge residual beds* correlates with Alum Bluff beds, the middle part with Chipola marl, and lower part with Chattahoochee clays and lss. [Not defined.]

Conflicts with another fm. The lower bed belongs to Flint River fm. and upper bed to Alum Bluff group, according to recent studies of C. W. Cooke.

Named, apparently, for exposures at or in vicinity of Bainbridge, Decatur Co.

Bainbridge limestone.

Silurian (Niagaran): Eastern Missouri and southwestern Illinois.

E. O. Ulrich, 1904 (Mo. Bur. Geol. and Mines vol. 2, 2d ser., p. 110). *Bainbridge ls.* proposed to embrace all Sil. lss. beneath Bailey ls. in river bluffs for some miles above and below Bainbridge, Mo., also above and below Thebes, Ill. [For next older fm. Ulrich adopted Girardeau ls. in above rept.]

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 28), restricted *Bainbridge ls.* to beds of late Niagaran age, lying uncon. below Bailey ls. (Helderbergian) and uncon. above Brassfield ls. This is present generally accepted definition.

Named for Bainbridge, Cape Girardeau Co., Mo.

Baird shale.

Mississippian: Northern California (Redding region).

H. W. Fairbanks, July 1894 (Am. Geol., vol. 14, p. 28). *Baird sh.*—Black siliceous sh., probably 500 ft. thick, the lowest horizon recognized at United States fisheries on McCloud River. Fauna considered by J. P. Smith to be analogous to the Waverly, but strat. position is higher. The shales outcrop most prominently on W. side of river just above Baird P. O., where they are in places highly metamorphosed by dikes of diabase and diabase porphyrite.

J. P. Smith, Sept.-Oct. 1894 (Jour. Geol., vol. 2, pp. 588-612). *Baird sh.*—Black siliceous shales 500 ft. thick. Older than McCloud ls. and younger than Sacramento fm. [Kennett fm.].

According to J. S. Diller (U. S. G. S. Redding folio, No. 138, 1906) the Baird sh. overlies Bragdon fm. and underlies McCloud ls.

Baitoa formation.

Miocene: Dominican Republic.

C. W. Cooke, 1920 (Geol. Soc. Am. Bull., vol. 31, p. 219)

†Baker limestone.

Silurian (early); Western Tennessee.

A. F. Foerste, 1901 (Geol. Soc. Am. Bull., vol. 12, pp. 397, 402). *Baker ls.*—White crinoidal ls., 0 to 25 ft. thick in Tenn. Same as Clinton ls. of Ind. and Ky. Basal Sil. fm. in W. Tenn. Underlies South Tunnel bed (Osgood shaly clay). Included in Clifton ls.

Replaced by Brassfield ls., better established though later name. Is considered to be of Albion age.

Named for Baker, Davidson Co.

Baker gabbro.

Cretaceous (?): Southern British Columbia.

R. A. Daly, 1914 (Canada Geol. Surv. Dept. Mines Mem. 38, map 9, 118° to 118°30'). *Baker gabbro, Cret.* (?). [Mass lies just N. of Baker Creek (which empties into Christina Lake) and at headwaters of the creek.]

Baker sand.

A subsurface sand in Pottsville group of eastern Ky.

Baker member (of Richfield formation).

Pre-Cambrian: British Columbia (Cariboo district).

G. Hanson, 1935 (Canada Dept. Mines, Geol. Ser., Bur. Econ. Geol. Mem. 181, No. 2396, p. 4).

Bakerstown sandstone. (In Conemaugh formation.)

Pennsylvanian: Southwestern Pennsylvania (Allegheny County).

J. P. Lesley, 1878 (2d Pa. Geol. Surv. Rept. Q, pp. xix (preface) and 305–308, index). *Bakerstown ss.*—Underlies Bakerstown coal and overlies Lower Barren Measure red shales, which rest on Pine Creek coal. [Only recorded use of name.]

Bakerstown clay.

A term that has been applied to clay underlying Bakerstown coal in Conemaugh fm. of W. Va.

Bakersville gabbro.

Triassic (?): Western North Carolina.

A. Keith, 1903 (U. S. G. S. Cranberry folio, No. 90, p. 5). *Bakersville gabbro.*—Unmetamorphosed massive gabbro, of black and brown color. Intrusive into Roan gneiss and Carolina gneiss. [Named for Bakersville, Mitchell Co.]

W. S. Bayley, 1923 (Tenn. Div. Geol. Bull. 29, p. 41), assigned this gabbro to pre-Camb.

Bakoven shale.

Middle Devonian: Eastern New York (Catskill Mountains).

G. H. Chadwick, 1933 (Am. Jour. Sci., 5th, vol. 16, pp. 480, 483). The black sh. heretofore passing as "Marcellus," below Mount Marion fm., since it remains unidentified by Dr. Cooper with any of his Hamilton units, is here called *Bakoven sh.* (bok-o-fen), from local Dutch name of valley it produces, with its type section (partial) where Catskill-Palenville road crosses Kaaters Kill.

†Balaklala rhyolite.

Jurassic (?): Northern California (Redding quadrangle).

J. S. Diller, 1906 (U. S. G. S. Redding folio, No. 138). *Balaklala rhyolite.*—A succession of irregular lava flows and tuffs which have been so compressed and folded as to render very obscure the original layered arrangement of the mass. Thickness about 500 ft. Clearly underlies Kennett ls. and sh. and penetrates and overlies Copley meta-andesite. Named for fact it forms the hills about Balaklala mine.

Later work by L. C. Graton (U. S. G. S. Bull. 430, pp. 81–85, 1910) proved these rocks to be intrusive alaskite porphyry and same as so-called †Bully Hill rhyolite. Both geographic names have therefore been discarded as unnecessary. This porphyry cuts rocks as young as Pit sh (Middle and Upper Triassic).

†Bald Eagle conglomerate.

Upper Ordovician: Central Pennsylvania (Blair County).

A. W. Grabau, 1909 (Jour. Geol., vol. 17, p. 235). *Bald Eagle cgl.*—Gray to white, rarely red, cgl. and quartz ss., 550 to 1319 ft. thick. Characterized by extensive cross bedding. Generally called Oneida by Pa. geologists. Is of Lorraine age. Underlies Juniata fm. and overlies Eden ss. Was originally named "Tyrone," but that name is preoccupied. Named for Bald Eagle Mtn at Tyrone, Blair Co.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27). *Oswego (Bald Eagle)* underlies Juniata ss. in central Pa. and rests on Reedsville sh., the upper part of which is of Eden age.

A. W. Grabau, 1913 (Geol. Soc. Am. Bull., vol. 24, pp. 408-410). *Bald Eagle cgl.*—The Oswego ss. must represent upper part of the Bald Eagle. Ulrich makes Bald Eagle exact equiv. of Oswego ss. without giving reasons for this correlation. To E. the ss. begins earlier and rests on lower beds than to NW. In Bald Eagle Mtn it rests on lowest Pulaski if not Frankfort; in Buffalo and Pulaski region it is post-Lorraine.

C. Butts, 1918 (Am. Jour. Sci., 4th, vol. 46, pp. 533, 536). *Bald Eagle ss.* of Grabau and Oneida cgl. of 2d Pa. Geol. Surv. replaced by Oswego ss.

Baldface phase.

See 1928 entry under *Conway granite*.

M. Billings, 1935 (letter dated July 19). Type loc. for *Baldface phase of Conway granite* is South Baldface Mtn, in NE. corner of North Conway quad., White Mtns region, N. H.

Bald Hill granite gneiss.

Pre-Cambrian: Southeastern New York (Poughkeepsie region).

C. E. Gordon, 1911 (N. Y. State Mus. Bull. 148, pp. 11, 14-16, 20-21, 32, 34, 40). *Bald Hill granite gneiss* is of igneous origin and certainly Precambric. Covers about 11 sq. mi. E. of the Hudson. Composes Bald Hill. Remarkably homogeneous. In outcrops it is commonly drab colored and granitelike.

Bald Hill shale. (In Henshaw formation.)

Pennsylvanian: Western Kentucky (Webster County).

L. C. Glenn, 1922 (Ky. Geol. Surv., ser. 6, vol. 5, p. 118). *Bald Hill shales.*—Shales, dominantly argill. and marly and usually leaden or green, with a hint of purplish mottling in some places. Several thin coals in upper part. Thickness 60 to 125 ft. Underlies Vanderburg ss. and overlies Dixon ss., all included in Dixon [Henshaw] fm. Named for Bald Hill, just E. of Dixon.

Bald Hill limestone. (In Tradewater formation.)

Pennsylvanian: Southeastern Illinois (Saline County).

G. H. Cady, 1926 (Ill. State Acad. Sci. Trans., vol. 19, p. 263). *Bald Hill ls.* lies in interval btw. Bald Hill coal and Bald Hill ss. Is exposed in railroad cut E. of Stonefort as a discontinuous layer a few inches thick, but is more typically developed at Bald Hill, about 2 mi. SE. of Stonefort on N. side of Big Four R. R.

Bald Hill sandstone. (In Tradewater formation.)

Pennsylvanian: Southeastern Illinois (Saline County).

G. H. Cady, 1926 (Ill. State Acad. Sci. Trans., vol. 19, pp. 258, 263). Bald Hill ss. occurs along crest of hill N. of Stonefort, that is, Stonefort Hill, and is exposed on low knoll upon which Mitchellville is located. It lies 100 ft. or more above Curlew ls.

Baldie granite.

Jurassic (?): British Columbia.

W. L. Uglow, 1922 (Canada Geol. Surv. Summ. Rept. 1921, pt. A, p. 81).

Bald Knob shale. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

C. E. Krebs and D. D. Teets, Jr., 1915 (W. Va. Geol. Surv. Rept. Boone Co., p. 497). *Bald Knob sh.*—Dark gray, slaty sh. containing small marine fossils. Thickness 1 to 8 ft. Lies 25 to 34 ft. below Stockton ls. and 0 to 3 ft. above Matewan coal. Named for Bald Knob P. O., Boone Co.

Bald Mountain limestone.

Lower Ordovician (Beekmantown): Eastern New York (Mohawk Valley).

W. W. Mather, 1843 (Geol. N. Y., vol. 1, p. 367). *Bald Mountain ls.* is synonym of Black River ls.

A. Fitch, 1850 (Historical, topographical, and agricultural survey of county of Washington [N. Y.], pt. 3, pp. 841-852). *Bald Mtn ls.*—Blue ls., composing most of Bald Mtn, which rises 600 or 700 ft. above level of surrounding county. At Bald Mtn and its immediate vicinity we have both the Sparry ls. and the stratum beneath it.

J. M. Clarke, 1912 (N. Y. State Mus. Bull. 158, p. 21). *Bald Mtn ls.*, of Beekmantown beds; provisionally named because so distinct from Beekmantown beds of Champlain Valley. Underlies "Trenton" lss. Field work by R. Ruedemann.

R. Ruedemann, 1914 (N. Y. State Mus. Bull. 169, pp. 66–99). *Bald Mtn ls.*—Fine-grained, light bluish gray ls. with many white crystalline spots; aren. bands in lower part. Top fm. of Beekmantown age in eastern trough at Saratoga Springs and vicinity. Fauna distinct from Fort Cassin fauna, and indicates this ls. is older than Normanskill sh. and that it overlies Deep Kill sh., but it may come from an entirely different trough or basin that was originally E. of Levis trough. Thickness 100 ft. [In chart on p. 140 he shows it uncon. beneath Normanskill sh. Map shows that it occurs on Bald Mtn, Washington Co. This definition was repeated by Ruedemann in 1929 (Geol. Soc. Am. Bull., vol. 40, No. 2, p. 414) and 1930 (N. Y. State Mus. Bull. 285, p. 27).]

Bald Mountain dacite.

Tertiary: Central southern Colorado (Custer County).

W. Cross, 1896 (U. S. G. S. 17th Ann. Rept., pt. 2, p. 295). *Bald Mtn dacite.*—Named for Bald Mtn. Clearly later than Rosita andesite and is cut by rhyolite, but relations to other igneous rocks of Silver Cliff-Rosita Hills dist. not known.

Bald Mountain gneiss.

Pre-Cambrian: Northeastern Oregon.

W. D. Smith and E. L. Packard, 1919 (Univ. Oreg. Bull., vol. 16, No. 7, p. 105; Jour. Geol., vol. 27, p. 105). *Bald Mtn gneiss*, Archean(?), eastern Oreg. [Oldest fm. given in table of eastern Oreg. fms.]

Bald Mountain lake beds member (of Esmeralda formation).

Miocene (upper): Central Nevada (Manhattan district).

H. G. Ferguson, 1924 (U. S. G. S. Bull. 723). *Bald Mtn lake-beds memb.*—Cgls., tuffaceous sss., and shales; at top a few ft. of fangl. Sediments twice broken by volcanic activity, as two members of rhyolitic tuff are included. Thickness 500± ft. Lies 700+ ft. below top of Esmeralda fm., the intervening beds consisting of a quartz latite memb. Overlies Diamond King memb. Composes upper part of Bald Mtn to within 400± ft. of its top.

Bald Peak basalt.

Pliocene: Western California (San Francisco region).

A. C. Lawson and C. Palache, 1902 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 2, map at end). *Bald Peak basalt.*—Top fm. of Berkeleyan series [Berkeley group]. Forms large part of Bald Knob, E. of Berkeley.

Bald Rock conglomerate member (of Lee formation).

Pennsylvanian: Southwestern Virginia (Wise County).

J. B. Eby, 1923 (Va. Geol. Surv. Bull. 24, p. 65). *Bald Rock cgl. memb.*—Middle memb. of Lee fm. in Wise Co., SW. Va. Thickness 15 to 200 ft. Is 70 ft. thick at Bald Rock, in vicinity of Miller Yards, about 4 mi. W. of Dungannon, Wise Co. Underlies Starns coal and overlies Burton Ford coal.

Baldwinsville limestone. (In McLeansboro formation.)

Pennsylvanian: Central eastern Illinois (Edgar County).

See 1934 entry under *La Salle ls. memb.*, where is cited only known use of name. Derivation unknown.

Ballard.

Cretaceous: Jamaica.

R. T. Hill, 1899 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 34, p. 42).

Ballard Harmon sandstone.

Mississippian: Southern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, p. 244). *Ballard Harmon ss.*—Massive, hard, fine-grained, gray; 15 ft. thick. Lies about 500 ft. below Pocahontas No. 3 coal. Included in Mauch Chunk series. Has been quarried on SW. side of Tug Fork, just below mouth of Ballard Harmon Branch, McDowell Co.

†Ballast Point silex bed.

Miocene (lower): Central Florida.

Term used in some early repts of W. H. Dall to designate the very fossiliferous siliceous bed (4 to 10 ft. thick) in Tampa ls. that has also been called "Tampa silex bed" and "Orthaulax bed."

Named for exposures at Ballast Point, Tampa.

Ballena gravel.

Eocene: Southwestern California (San Diego County).

W. J. Miller, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 10, pp. 1556–1561). *Ballena gravel* (*or cgl.*) has been cause of considerable discussion and has been differently interpreted. It has an important bearing on geomorphologic history of Peninsular Range. Was first described [but not named] by H. W. Fairbanks (Calif. State Min. Bur. 11th Ann. Rept., 1893, pp. 91–92). [Fairbanks named the whaleback-shaped hill but not the deposit.] Occurs in 10 or more areas, extending SW. from near Witch Creek (at 3,000 ft.) to SW. of Ballena (at 2,400 ft.), and W. to San Vicente Valley (at 2,000 ft.) in Ramona quad. to W. and NW. of Padre Barona Valley (at 1,800± ft.) in Cuyamaca quad. The largest area, several mi. long, is SW. of Ballena, where the gravel caps ridges 300 to 500 ft. high. This may be regarded as type loc. All the areas were doubtless once continuous. Consists largely of pebbles and boulders of red and gray porphyritic lava, considerable qtzite, and some schist. Thickness 100 ft. or more. Striking similarity btw. the pebbles and boulders of Ballena gravel and Poway cgl. (marine) strongly indicates their former continuity. Assigned to late Eocene. Deposited locally. Probably = Poway cgl.

Ballou clay. (In Allegheny formation.)

A name applied in some early Ohio repts to the clay underlying Upper Freeport coal and overlying Upper Freeport ls. in Muskingum Co., Ohio.

Balltown oil sand.

Drillers' term for a sand in NW. Pa.; probably = Cherry Grove oil sand and of Chemung age. Lies lower than Tiona sand and higher than Sheffield sand, and is said to correspond to Gartland and Garfield sands.

Balmville limestone member (of Wappinger limestone).

Middle Ordovician: Southeastern New York (Orange County).

F. Holzwasser, 1926 (N. Y. State Mus. Bull. 270, pp. 38–41, 43). *Balmville ls.*, uppermost memb. of Wappinger ls. in Newburgh quad., underlies Hudson River slates and overlies typical Wappinger ls. of this area. Consists of more than 50 ft. of dark bluish gray coarsely crystalline ls., in places changing below into a conglomeratic facies consisting of about 20 ft. of fossiliferous cgl. crowded with pebbles. Outcrops N. of Balmville, Orange Co. Has been called Trenton ls. Is of either uppermost Black River or early Trenton age.

Balsora limestone. (In Palo Pinto formation.)

Pennsylvanian: North-central Texas.

G. Scott and J. M. Armstrong, 1932 (Univ. Tex. Bull. 3224, p. 24). *Balsora ls.*, in Palo Pinto fm., lies 70± ft. below Bridgeport coal and 7 to 10 ft. above Sanders Bridge ls. Thickness 0 to 4± ft. Named for outcrop in valley of a small stream 1 mi. W. of Balsora, Wise Co. Also occurs along Boone Creek. To NE. it lenses out into shales. Not present in section exposed at Martin Lake.

Baltic amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

L. L. Hubbard, 1898 (Mich. Geol. Surv. vol. 6, pt. 2, pp. 135, 136). The Baltic mine is in an amygdaloid bed [called by Hubbard *Baltic amygdaloid*], whose strike, according to Mr. Theodore Dengler, Mining Engineer of the Atlantic and Baltic mines, is N. 60°30′ E. (magn.). This bed crosses the line btw. secs. 20 and 21, T. 54, R. 34, about 200 ft. N. of the quarter post.

A. C. Lane, 1906 (Mines and Minerals, vol. 27, pp. 204–206). The Baltic lode occurs a short distance above Baltic (No. 3) cgl. on Keweenaw Point, Mich.

Belongs to Bohemian Range group. Is younger than Baltic cgl. and older than Baltic West amygdaloid. The mineralized part is Baltic lode.

Named for occurrence in Baltic mine, Houghton Co.

Baltic flow.

Includes Baltic amygdaloid and underlying trap.

Baltic conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. C. Lane, 1906 (Mines and Minerals, vol. 27, pp. 204–206). Baltic cgl. (No. 3) lies a short distance below Baltic lode.

Belongs to Bohemian Range group.

Named for occurrence in Baltic mine, Houghton Co.

Baltic sandstone.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. C. Lane, 1911 (Mich. Geol. and Biol. Surv. Pub. 6, geol. ser. 4, pp. 495, 499, fig. 47). "*Baltic sandstone,*" an amygdaloid cgl. with much red sandy matrix, which I am inclined to identify with Marvine's cgl. No. 5.

Belongs in Bohemian Range group.

Probably named for its occurrence near Baltic mine or at or near town of Baltic, Houghton Co.

Baltic West amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name locally in use for many years. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. Is younger than Baltic amygdaloid. Belongs in Bohemian Range group. The mineralized part is the Baltic West lode. Named because it is usually the first amygdaloid W. of Baltic lode.

Baltic West flow.

Includes Baltic West amygdaloid and underlying trap.

Baltimore gneiss.

Pre-Cambrian: Northern Maryland and southeastern Pennsylvania.

G. H. Williams and N. H. Darton, 1892 (U. S. G. S. map of Baltimore and vicinity, to accompany "Guide to Baltimore," prepared for Baltimore meeting Am. Inst. Min. Engrs. Feb. 1892, pp. 88–139). [*Baltimore gneisses,* also *Baltimore gneiss,* here used to include gneiss overlying Cockeysville marble and the hornblende gneiss underlying Setters quartz schist, and text says *Baltimore gneisses* embrace a great variety of types. The gneiss that overlies Cockeysville marble is in Wissahickon fm.]

G. H. Williams and W. B. Clark, 1893 (Maryland, its resources and institutions, chap. III, pp. 55–88). *No certain traces of clastic origin have ever been detected in Baltimore gneisses,* although their sed. character may be inferred from their rapid alternations of beds of different composition, and from nature of other rocks intercalated in them, like the marbles and quartz schists.

W. B. Clark, 1904 (Md. Geol. Surv. Harford Co. Atlas, geol. map). *Pre-Cambrian (Baltimore).*—Highly crystalline gneisses with bands varying from micaceous qtzite to biotite and hornblende schists. Includes metamorphosed sediments and igneous masses. [Placed beneath Setters qtzite. Columnar section on map reads:

"*Baltimore gneiss* 5,000 (?) ft. Banded mica and hornblende gneiss with intruded aplite, pegmatite, and granite."]

E. B. Mathews, 1904 (Am. Jour. Sci., 4th, vol. 17, pp. 141–159). *Baltimore gneiss.*—Banded gneiss, highly crystalline. All agree that it is pre-Camb. Usually in eastern Md. it is separated from other metamorphosed sed. rocks by igneous masses, but in vicinity of Baltimore and in Phila. area, as shown by Dr. Bascom, these banded gneisses immediately underlie the qtzite (Chickies qtzite or Setters quartz schist). Apparently of sed. origin.

E. B. Knopf and A. I. Jonas, 1923 (Am. Jour. Sci., 5th, vol. 5, pp. 40–62). *Baltimore gneiss* is restricted to sed. gneiss, and the intrusive gneiss is here named *Hartley augen gneiss.* The Baltimore uncon. underlies Setters fm.

E. B. Knopf and A. I. Jonas, 1929 (Md. Geol. Surv. Baltimore Co. Rept., pp. 105, 140–152). *Baltimore gneiss* (early pre-Camb.) consists of biotite and hornblende gneiss that shows some cataclastic deformation. Varies in appearance from a heavily bedded, granitoid gneiss of white or gray color to a thinly layered ribbon gneiss of alternating light and dark bands. Named for fine outcrops in city of Baltimore, along banks of Jones Falls and Gwynns Falls.

F. Bascom, 1932 (U. S. G. S. West Chester-Coatesville, Pa., folio, No. 223). *Baltimore gneiss* includes a nongraphitic facies and a graphitic facies. Latter was formerly treated as distinct fm. and called "Pickering gneiss," but this name is now abandoned, as the rocks are only a graphitic facies of Baltimore gneiss. Assigned to Archean.

In 1934 the U. S. Geol. Survey decided to adopt *Pickering gneiss* for the pre-Camb. sed. rocks associated with Franklin ls. (a white coarsely crystalline ls. or marble, more or less contemp. with Pickering gneiss), with which it is found interbedded as well as apparently overlying. For description of Pickering gneiss see last entry under *Pickering gneiss.*

The Baltimore gneiss was formerly classified by U. S. Geol. Survey as "Archean," but that term having been discarded as a time term the fm. is now classified as *pre-Camb.*

†Baltimorean formation.

Lower Cretaceous: Eastern Maryland.

P. R. Uhler, 1888 (Am. Phil. Soc. Proc., vol. 25, p. 48). *Baltimorean fm.*—Gravels, sands, and clays, 500+ ft. thick. Is probably lowest alluvial fm. discovered in Md. Rests on Archean rocks. Underlies Albirupean fm. Well developed in city of Baltimore.

B. L. Miller, 1917 (U. S. G. S. Tolchester folio, No. 204). "Baltimorean" of Uhler included Patuxent, Arundel, and Patapsco fms., which compose Potomac group.

Banbury volcanics.

Pliocene (upper): Southern Idaho (Twin Falls County).

H. T. Stearns, 1932 (Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932) and 1936 (Jour. Geol., vol. 44, No. 4, pp. 434–439). *Banbury volcanics.*—Massive dark-brown weathered basalt flows and fragmental tuff beds, 360± ft. thick. Older than Hagerman lake beds and younger than Raft lake beds. There are thick exposures of fm. near Banbury Hot Spring, sec. 33, T. 8 S., R. 14 E., Twin Falls Co. At old Riverside Ferry there is a cone from which the tuffs issued.

Bandbox Mountain type.

Name applied by L. V. Pirsson (U. S. G. S. 20th Ann. Rept., pt. 3, pp. 543–546, 1900) to dikes of analcite basalt on Bandbox Mtn, Little Belt Mtns, Mont.

Bandera shale.

Pennsylvanian: Southeastern Kansas and northeastern Oklahoma.

G. I. Adams, 1903 (U. S. G. S. Bull. 211, p. 32). *Bandera sh.*—Shales, 100 ft. thick, carrying considerable thin-bedded ss. and some coal, overlying Pawnee ls. and underlying Parsons ls.

Adopted by U. S. Geol. Survey many years ago as a fm. of Pleasanton group in Kans., overlying Pawnee ls. and underlying Altamont ls., basal memb. of Parsons fm. But R. C. Moore has recently abandoned Parsons fm., and now treats Bandera sh. of Kans. as a distinct fm. in his Marmaton group. This changed classification has not yet been considered by U. S. Geol. Survey for its publications.

Named for Bandera, Bourbon Co., Kans., near which it is quarried.

Banff series.

Carboniferous and Devonian(?): Alberta.

R. G. McConnell, 1887 (Canada Geol. Surv., n. s., vol. 2, pp. 15D, 17D, 19D). [Assigned to Carbf.]

Later repts assign these rocks to Dev., to Miss., to Miss. and Dev., and to Penn. and Miss.

Banffian series.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 42, pp. 285, 288). *Banffian series.*—Lss., 1,400 ft. thick, composing all of Late Devonic of Banff, Alberta. Underlie Banff shales, of Early Carbonic (Kinderhookian) age. The title *Banff* should be restricted to the Late Devonic beds, or some part of them in case it is found that this is not a single series.

Bangor limestone. (Of Chester group.)

Mississippian: Alabama, central and eastern Tennessee, and northwestern Georgia.

E. A. Smith, 1890 (Ala. Geol. Surv. Rept. on Cahaba coal field, pp. 155–157 and map). The Sub-Carbf. of Ala. is divided into "Upper or Calc. memb. (named Oxmoor ss. and shales and Bangor ls.)" and "Lower or Siliceous memb. (named Fort Payne chert)." The upper calc. member is variable in composition. In North Ala. it is chiefly a ls., called Mountain ls., from fact it forms flanks of most mtns in that section that are capped by Coal Measures. Within this ls. there is interbedded a layer of ss. [Hartselle] of variable thickness, perhaps 100 ft. max. in Tenn. Valley, while the over and underlying lss. are many times that. As we come southward the ss. (which we have often called La Grange ss., but that name is preoccupied, which has caused us to replace it by name *Oxmoor,* where the rocks are well exposed and where the shales are more conspicuous than at La Grange) becomes more important; and lower section of the ls. appears to give way to, or to be replaced by, a series of black shales [Floyd sh.] closely resembling those of the Dev. but many times more massive. In many places in the anticlinal valleys, and especially the further S. we go, the upper ls. also appears to be wanting or to be replaced by the shales and sss. above named. The ls. which comes next below the Coal Measures is well exposed at many places, as at Bangor, Blount Springs, and Trussville, where it is extensively quarried, but S. of latitude of Birmingham it is very rarely seen, and in its stead we find the black shales mentioned. These shales are often interstratified with dark-colored lss. and sometimes with tolerably pure lss., but these are unimportant in thickness as compared with the shales and sss. The greater part of Shades Valley is based upon these sss. and shales, though the ls. appears in several places.

Later mapping by C. Butts resulted in restriction (Ala. Geol. Surv. Spec. Rept. No. 14, 1926) of *Bangor* to the ls. above Hartselle ss. and below Pennington sh. In Shades Valley the Bangor restricted is overlain by an upper tongue of Floyd sh. In the broad sense in which Bangor ls. was originally defined and subsequently used it included all Miss. rocks above Fort Payne chert. In some early repts it was used to include the rocks later named *Tuscumbia ls.*, while in some other repts these rocks were included in Fort Payne chert. A name became necessary for the ls. above Hartselle ss., for which the name *Bangor* is especially appropriate, while the use of the name in the broad sense became unnecessary, the rocks having been subdivided. The Bangor restricted belongs to Chester group. (See also under *Hartselle ss.*)

Named for development at Bangor, Blount Co., Ala.

Bangor beds. (In Martinsburg shale.)

Upper Ordovician: Southeastern Pennsylvania (Northampton County).

C. H. Behre, Jr., 1926 (Jour. Geol., vol. 34, pp. 485–487) and 1927 (Pa. Geol. Surv., 4th ser., Bull. M9, pp. 33, 104–107, and maps). [See under *Pen Argyl beds.*]

Bankston Creek limestone.

See under *Bankston Fork ls.*

Bankston Fork limestone. (In McLeansboro formation.)

Pennsylvanian: Southeastern Illinois (Saline County) and southwestern Illinois (Perry County).

G. H. Cady. 1926 (Ill. State Acad. Sci. Trans., vol. 19, pp. 257, 261, 262). [*Bankston Creek ls.* in columnar section on p. 257; *Bankston Fork ls.* elsewhere in rept.].—The ls. which I have chosen to call *Bankston Fork ls.* lies in lower part of McLeansboro fm., about 40 ft. above Herrin No. 6 coal, top memb. of underlying Carbondale fm, It is a fairly pure, slightly brownish or pinkish, hard, dense ls., which commonly breaks with a fracture somewhat concnoidal, Contains fossils. Thickness 0 to 15± ft. Is discontinuous, possibly because locally displaced by Anvil Rock. The strat. relation of these two strata is not very certain in mind of writer. One of best exposures is along S. side of valley of *Bankston Creek,* just E. of Saline Co. line.

A. H. Bell, C. Ball, and L. McCabe, 1931 (Ill. Geol. Surv. Press Bull. No. 19). *Bankston Fork ls. memb.*—Argill., dark blue, massive, fossiliferous ls.; weathers brown. Thickness 2½ to 7 ft. in Perry Co. Top lies 5 to 7 ft. below Galum ls. memb. Base lies 25± ft. above Herrin (No. 6) coal. Named by G. H. Cady (Trans. Ill. Acad. Sci., vol. 19, p. 261).

Bannock volcanic formation.

Cambrian (?): Southeastern Idaho (Pocatello).

A. L. Anderson, 1928 (Idaho Bur. Mines and Geol. Pam. 28, p. 3). *Bannock volcanic fm.*—Ancient volcanic rocks, including several flows of lava of probable andesitic composition, tuff beds, and breccias, thin beds of impure ls., calc. sh., ss., qtzite, and cgl., all so highly sheared, mashed, and altered that they may be pre-Camb., but writer has tentatively left them at base of Camb. until further study. Thickness 1,200+ ft.; base not exposed, Top has been taken to include the sh. beneath Black Rock ls. No definite fossils found. Named because its only known occurrence is in Bannock Range. The lavas are purplish, greenish, and reddish, and best described as greenstones.

†Baptanodon beds.

A paleontologic name applied by O. C. Marsh (1891) to beds underlying †Atlantosaurus beds (Morrison fm.) in the West. Is same as *Sundance fm.*, according to J. B. Reeside, Jr.

Baraboo quartzite.

Pre-Cambrian (middle? Huronian): Central southern Wisconsin (Sauk and Columbia Counties).

R. D. Irving, 1877 (Geol. Wis., vol. 2, pp. 504–519, 539, 542). *Baraboo qtzite ranges.*—The rock constituting the great body of the Baraboo ranges is a qtzite of nongranular, usually flaky, texture, and of color from nearly white, through gray, pink, and amethyst, to purplish red and even brick-red, the gray and deep red being most common, the white the least common. Very rarely a distinct granular texture is seen. The qtzite is very distinctly laminated, the lamination contorted. Next in abundance to the qtzite, and merging into it, are heavy beds of a fine metamorphic cgl., usually of grayish to amethystine color; the matrix and pebbles of qtzite are not always well defined from one another. A peculiar greasy-surfaced quartz schist forms thin layers btw. the thick layers of qtzite. Other quartz schists of different character form the lowest layers of the north qtzite range.

R. D. Irving, 1892 (U. S. G. S. Mon. 19, pl. 1), mapped *Baraboo qtzites.*

C. R. Van Hise, 1892 (U. S. G. S. Bull. 86, p. 195), referred *Baraboo qtzites* to upper Huronian.

S. Weidman, 1904 (Wis. Geol. Nat. Hist. Surv. Bull. 13). Thickness of *Baraboo qtzite* is 3,000 to 5,000 ft. Rests on floor of rhyolite, granite, and diorite. Underlies Seeley sl., without evidence of uncon. Is mainly qtzite, but contains small amount of quartz porphyry cgl. at base, and in several places is accompanied by red sl., hardened and semi-metamorphosed, making the well-known catlinyte of Pipestone and Baraboo Counties.

S. Weidman and A. R. Schultz, 1915 (Wis. Geol. Nat. Hist. Surv. Bull. 35, pp. 274–275). *Baraboo qtzite* forms E. end of Baraboo bluffs in W. part of Columbia Co.

C. R. Van Hise and C. K. Leith, 1909 (U. S. G. S. Bull. 360, p. 720), stated that Baraboo qtzite, Seeley sl., and Freedom dol. might be middle Huronian.

Baraboo series.

Pre-Cambrian: Central southern Wisconsin (Sauk County).

S. Weidman, 1904 (Wis. Geol. and Nat. Hist. Surv. Bull. 13, Econ. ser. No. 8, pp. 4, 22, 161, 162, 169–171), used *Baraboo series* to include (descending) Freedom fm., Seeley sl., and Baraboo qtzite in Baraboo region.

A. Leith, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., fig. 216, pp. 329–331), used *Upper Baraboo series* to include, in Baraboo dist., Rowley Creek sl. and Dake qtzite, and *Lower Baraboo series* to include Freedom fm., Seeley sl., and *Baraboo qtzite.*

Barachois slate.

Cambrian: Nova Scotia.

H. Fletcher, 1900 (Canada Geol. Surv., Descriptive note on Sydney coal fields, p. 5).

Barberie andesite.

Devonian: New Brunswick,

W. V. Howard, 1926 (Geol. Soc. Am. Bull., vol. 37, p. 479).

Barbican formation.

Pleistocene: Jamaica.

R. T. Hill, 1899 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 34, p. 42).

†Barclay limestone.

Pennsylvanian: Eastern Kansas.

J. W. Beede, 1902 (Kans. Univ. Sci. Bull., vol. 1, p. 175). *Barclay ls.*—Proposed by G. I. Adams, in unpublished ms., for lss. interbedded with shales, about 70 ft. thick, intimately connected faunally. Overlies Burlingame [Scranton] shales and underlies Willard shales.

This name fell into disuse years ago. As defined it included several lss. According to R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 215), Barclay ls. of Beede extended from top of Scranton sh. up to base of Willard sh. (just as defined by Beede), but Moore's Willard sh. is a younger sh. than the Willard of current literature. Moore discarded this name.

Probably named for Barclay, Osage Co.

Bardstown coral reef. (In Liberty formation.)

Upper Ordovician: Southwestern Ohio and north-central Kentucky.

A. F. Foerste, 1909 (Denison Univ. Sci. Lab. Bull. 14, p. 280). *Bardstown coral reef.*—Coral horizon forming base of Liberty bed of Richmond fm. in Ohio and Ky.

Named for Bardstown, Nelson Co., Ky.

Bar Harbor series.

Silurian and pre-Cambrian: Southeastern Maine (Mount Desert Island).

N. S. Shaler, 1889 (U. S. G. S. 8th Ann. Rept., pt. 2, pp. 1037, 1047–1052, 1060 and map). *Bar Harbor series.*—Thick-bedded flaggy slates and associated bedded qtzites and felsites with very numerous injections of various igneous rocks. In main quartzose and argill. slates, shales, and flags. Near Rodick's Cove and in some other places they consist in the main of bluish green and purple shales; at some points the beds are crowded with siliceous concretions. Found on N. and E. shores of Mount Desert from Rodick's Cove to the Ovens. No trace of fossils. I am disposed to think this small series represents beds deposited at a later period than any other on the island. The greater part of Mount Desert rocks are probably Camb. or older.

F. Bascom, 1919 (Geog. Soc. Phila. Bull., vol. 17, No. 4, pp. 117–122). *Bar Harbor series.*—Chiefly qtzites, slates, and flagstones, red, purple, and green; 700 to 1,000 ft. thick. Not very highly metamorphosed, but no organic remains have been found. Some of them may prove to be volcanics. Well exposed at Bar Harbor landing, whence the name. Skirt N. and E. shores of Mount Desert Island from Thomas Bay (east side) to Cromwell Cove at SE. end of Bar Harbor. Are perhaps next younger than Bartlett Island series. Are Lower Camb. or earlier.

On 1933 geol. map of Maine, by A. Keith, the rocks extending along shore of Mount Desert Island from E. side of Thomas Bay to S. of Bar Harbor are included in block of igneous rocks labeled "mainly Sil. but some Dev.;" and the rocks on SW. side of Thomas Bay are mapped as pre-Camb. sediments.

F. W. Toppan, 1932 (Geol. of Maine, Dept. Geol. Union Coll., Schenectady, p. 50), assigned these rocks to Camb.

†Barker formation.

Upper and Middle Cambrian: Central northern Montana (Fort Benton region).

W. H. Weed, 1899 (U. S. G. S. Fort Benton folio, No. 55). *Barker fm.*—The oldest sed. rocks of quad. Comprise all of Camb. Subdivisions can not be mapped separately on scale of map. Consist of (descending): (1) Yogo ls., 100 ft.; (2) Dry Creek sh. (brick-red sh. and lss.); (3) Pilgrim ls. (massively bedded), 140 ft.; (4) Park shales and ls. cgls., several hundred ft.; (5) Meagher lss., 110 ft.; (6) Wolsey sh. (purple and green micaceous sh. containing small ls. nodules bearing fossils), 125 ft.; and (7) Flathead ss. (coarse ss. composed of small pebbles and coarse grains of quartz and feldspar and occasional pebbles of gneiss, grading into hard sss. which often form a true qtzite. The rocks are well exposed near Barker, also in broad valley of Pilgrim Creek and in cliffs to N. Rest on Archean gneiss and schist. Overlain by Monarch fm. (Sil.? and Dev.).

The subdivisions mentioned above are now treated as fms., and the inclusive unit "Barker fm." has been discarded.

Barker porphyry.

Post-Cretaceous: Central Montana (Little Belt Mountains).

W. H. Weed, 1899 (U. S. G. S. Little Belt Mtns folio, No. 56). *Barker porphyry.*—Granite porphyry, usually gray or pale brown, weathering reddish. Forms Big Baldy Mtn, to S. of Barker. Assigned to post-Cret. [Also forms Barker Mtn, in Fort Benton quad.]

Barker syenite.

A name applied by L. V. Pirsson (U. S. G. S. 20th Ann. Rept., pt. 3, pp. 465–468, 1900) to the rock that forms the intrusive mass N. of Barker, Cascade Co., Mont.

Barker sand.

A subsurface sand of Chester (Miss.) age in Ind. that has been correlated with Elwren ss. of Malott.

Barker quartzite.

Lower Cambrian: Southwestern Vermont (Rutland County).

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 401). *Barker qtzite.*—One of key rocks of Taconic sequence, being readily identifiable and making sharp hills and ridges. Is generally of light or white color on weathered surfaces, but usually is more or less green when freshly broken. Varies from dense rock with very fine grains of quartz to coarse qtzite and locally a fine cgl. The coarser facies contain pebbles of various slates, qtzites, and a little ls., probably derived from older Camb. fms. Thickness varies from 100± ft. at Barker Hill (4 mi. E of N. from Castleton) and nearby Wallace Ledge down to thinness that is barely recognizable. Underlies Bull sl. and overlies Hubbardton sl.

Barker shale.

Cambrian: Alberta.

C. E. Michener, 1934 (Jour Geol., vol. 42, No. 1, p. 47).

Barkerian series.

A term applied by C. [R.] Keyes to all Camb. fms. of Mont. (See Pan-Am. Geol., vol. 46, 1926.) Corresponds to Barker fm. of Weed, a term long ago discarded by U. S. Geol. Survey.

Barkerville formation.

Pre-Cambrian: British Columbia.

W. A. Johnston and W. L. Uglow, 1926 (Canada Geol. Surv. Mem. 149, p. 14).

Barkley quartzites.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, p. 38). *Barkley qtzites.*—Qtzites, 1,400 ft. thick, composing upper fm. of Panamintan series (Early Cambric) in Utah. [Derivation of name not stated.]

Barlow sand.

A subsurface oil sand of Miss. age in western Ky. that has been identified as Bethel or Sample ss. by D. B. Chisholm (Ky. Geol. Surv., ser. 6, vol. 41, p. 220, 1931) and W. L. Russell (A. A. P. G. Bull., vol. 16, No. 3, p. 244, 1932).

Barlow lime.

A subsurface oil zone of Miss. age in western Ky. that has been identified as basal part of Paint Creek ls., of Chester group. (See D. B. Chisholm, Ky. Geol. Surv., ser. 6, vol. 41, p. 220, 1931; and W. L. Russell, A. A. P. G. Bull., vol. 16, No. 3, p. 244, 1932.)

Barlow.

Name applied to a glacial lake, of Pleist. age, in Canada, north of Great Lakes region.

Barnard gneiss.

Cambrian: Southeastern Vermont (Windsor County).

C. H. Richardson, 1924 (Vt. State Geol. Rept. 1923–24, pp. 91–92). *Barnard gneiss.*—Acid intrusive gneiss forming continuous outcrop for several mi. in Barnard Twp. Composes prominent ridge on W. side of Locust Creek N. of village of Barnard, but before it enters Bethel, on N., it forms prominent ridge on both sides of Locust Creek. Is light gray, tinged with green from presence of a little chlorite and epidote. Of gneissoid structure and medium to coarse grained texture. Exact age unknown. That it is pre-Ord. seems certain, and it may be pre-Camb.

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), assigned this fm. to Upper Camb., but without discussion.

Barnegat limestone. (Has also been spelled *Barnegate.*)

Middle Ordovician to Lower Cambrian: Southeastern New York.

W. W. Mather, 1838 (N. Y. Geol. Surv. 2d Rept., pp. 168–169). The first continuous range of ls. of much magnitude that is seen in Columbia and Dutchess Counties, in passing from W. to E., is that which crosses the Hudson at Barnegat [now called Stoneco]. It extends from Barnegat up Wappingers' Creek, by Pleasant Valley and Pine Plains into Columbia Co., and on S. it passes from Milton to Newburgh; on the W. down the great valley through N. J.

into Pa. Varies in character from sandy, granular, subcrystalline texture, to perfect compact ls. with conchoidal fracture. Is usually gray, granular, and subcrystalline. Is said to contain fossils, but no fossils were found. Is sometimes distinctly stratified, and even slaty near its junction with the sl. rocks. Essentially synonymous with "Wappinger ls."

J. D. Dana, 1879 (Am. Jour. Sci., 3d, vol. 17). The ***Barnegat or Wappinger Valley ls.*** contains Trenton fossils and is a southward extension of Copake ls.

W. B. Dwight, 1883 (Am. Ass. Adv. Sci. Proc., vol. 31, pp. 384–387). The ***Wappinger*** *(or Barnegat) lss.* of Dutchess and neighboring counties, N. Y., contain Trenton and Calciferous fossils at several places.

W. B. Dwight, 1886 (Am. Jour. Sci., 3d, vol. 31, pp. 125–133). The ***Wappinger Valley*** *(or "Barnegat") lss.* at Fishkill and Stissing Mtns include lss. now known to be Trenton and Calciferous. In outskirts of Poughkeepsie a ledge of rock in Wappinger Valley ls. proved rich in Potsdam fossils. It must be over 300 ft. thick. Is exceedingly variable, but everywhere calc. and more or less aren. [In some places he called it *Potsdam ls.*] Rests on calc. qtzite of Potsdam group.

W. B. Dwight, 1887 (Vassar Bros. Inst. Trans. Sci. Sec., vol. 4, pt. 2). The ***Wappinger Valley*** *(or "Barnegat") lss.* of Dutchess Co. include Trenton ls. resting conformably on Rochdale group (the rocks which in previous papers I have called Calciferous).

E. C. Eckel, 1902 (N. Y. State Geol. 20th Ann. Rept., pp. r144–r150). Though there seems to be little doubt of essential equiv. of Barnegat and Stockbridge lss., it seems best to retain both names, as the Stockbridge probably includes Trenton beds, which in the less metamorphosed area of Orange Co. and N. J. can be differentiated from the Barnegat.

F. J. H. Merrill, 1902 (U. S. G. S. New York City folio, No. 83), used ***Stockbridge ls.*** for supposedly Ord. and Camb. lss. underlying Hudson [Manhattan] schist and overlying Poughquag [Lowerre] qtzite. The ls. of this area is now considered to be pre-Camb. and is known by local name ***Inwood ls.***

C. P. Berkey, 1907 (N. Y. State Mus. Bull. 107, pp. 361–378). ***Wappinger ls.***—Fine-grained blue and white banded ls. 1,000 ft. thick. Contains Lower Siluric [Ord.] and Cambric fossils. Conformably underlies Hudson River slates in Highlands of SE. N. Y. and rests conformably on Poughquag qtzite.

J. M. Clarke, 1909 (N. Y. State Mus. Bull. 133, pp. 14–17). *Wappinger ls.*—First called "Barnegate ls." by Mather, but now named for Wappinger Creek, Dutchess Co. Hard, blue, medium bedded lss., carrying brachiopods with an occasional trilobite, all of apparent Trenton affinities. [The belt of ls. that runs through town of Fishkill was in this rept. named *Fishkill ls.* and excluded by Clarke from Wappinger ls.] The belt can be traced beyond the road from Fishkill Village to Wappingers Falls.

C. E. Gordon, 1910 (N. Y. State Mus. Bull. 140, pp. 16–20). *Wappinger ls.*—Occurs in two well-defined masses in Poughkeepsie quad. the composite Wappinger Creek belt and the Fishkill ls. Is older than Beekmantown ("Calciferous," Rochdale group), but whether Cambric or Canadian could not be determined. [Gives reason for thinking much of the ls. is older than Trenton and perhaps Camb. or early Ord.]

C. P. Berkey, 1911 (N. Y. State Mus. Bull. 146, pp. 32–57). *Wappinger ls.*—Compact, fine texture, dark gray, either massive or strongly bedded ls., 1,000 ft. thick in area of N. Y. City aqueduct. Assigned to Cambro-Ordovicic. Generally supposed = Inwood ls. (or dol.) S. of the Highlands.

C. E. Gordon, 1911 (N. Y. State Mus. Bull. 148). *Wappinger (Barnegate) ls.*—In Poughkeepsie quad. is conglomeratic, aren., lutaceous, siliceous, and dolomitic lss. The western belt is Barnegate ls. of Mather, but now commonly referred to as Wappinger Creek or New Hamburg belt. It includes Trenton, Beekmantown (Calciferous-Rochdale group), Potsdam, and Georgian. The eastern belt of Wappinger ls. is known as ***Fishkill ls.***, as it lies chiefly in town of Old Fishkill. It includes Trenton, Beekmantown, and Lower Cambric (Georgian) fossils. Overlies Poughquag qtzite and underlies Hudson River sl. group.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 29). ***Barnegat ls.*** = Wappinger (Valley) ls. The name was from Barnegat, now called Stoneco, Dutchess Co. The Fishkill ls. is in part = Wappinger ls.

R. Ruedemann, 1914 (N. Y. State Mus. Bull. 169, pp. 66–99). ***Wappinger ls.*** includes ls. of Hoyt, Beekmantown, and Mohawkian ages.

C. P. Berkey and Marion Rice, 1921 (N. Y. State Mus. Bull. 225, 226). *Wappinger ls.* is about 1,000 ft. thick in West Point quad. Is finely crystalline ls. Conformably underlies Hudson River series and conformably overlies Poughquag qtzite. Belongs to Cambro-Ord. series.

E. B. Knopf, 1927 (Am. Jour. Sci., 5th, vol. 14, pp. 429–458). The Ord. and Camb. rocks of E. part of Dutchess Co. ("Wappinger ls." of Dwight and Dana) are divided as follows: (1) Lss. of early Trenton and Black River age; (2) Copake ls. (of Beekmantown age), 0 to 400 ft.; (3) Rochdale ls. (of Beekmantown age), 600 ft. in Wappinger Valley; (4) Hoyt dol., 300 ft. (the "Potsdam ls" of Dwight); (5) Stissing dol., 200 ft. (Middle ? and Lower Camb.); (6) Lower Camb. ("Poughquag") qtzite.

Has also been called *Newburgh ls.*

See also under *Stockbridge ls.*

Barnes conglomerate. (Of Apache group.)

Pre-Cambrian: Central Arizona.

F. L. Ransome, 1903 (U. S. G. S. P. P. 12). *Barnes cgl.*—Cgl., 10 to 15 ft. thick, composed of well-rounded pebbles of hard white or pink qtzite with some reddish jasper and white vein quartz. Overlies Pioneer sh. and underlies Dripping Spring qtzite. Forms a conspicuous strat. girdle about Barnes Peak, Globe dist. Included in Apache group.

Barneston formation. (In Chase group.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., p. 41). *Barneston fm.* is erected to include Florence flint and Fort Riley ls., *which are in contact, except at a few places where a thin sh. intervenes.* The Florence or lower memb. is distinguished from the Fort Riley by its abundant chert content. The members are usually mapped together as *Fort Riley-Florence*. Their average combined thickness from southern Kans. to Nebr. is 50 ft. or more. They constitute a strong fm. which produces bold rounded escarpments. Type loc. of Barneston fm. is in bluffs W. and SW. of Barneston, Gage Co., Nebr.

Barnett shale.

Mississippian: Central Texas (mineral region).

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 25–26). *Barnett sh.*—Yellowish gray to black bituminous sh., 0 to 50 ft. thick. Underlies Marble Falls ls. and overlies Ellenburger ls. Absent at type loc. of Marble Falls ls. Sharp faunal change btw. Barnett sh. and Marble Falls ls. Named for Barnett Springs, E. of San Saba [San Saba Co.].

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132). *Barnett sh.*, 0 to 150 ft. thick, consists chiefly of black petroliferous, fissile sh., overlain by thin layers of brownish, concretionary, petroliferous ls., and with distinctly conglomeratic beds at base, where it rests on Ellenburger ls. Previously called "Lower Bend" sh. Is basal fm. of Bend group. Overlain by massive beds of Marble Falls ls. The thin lss. at top contain fossils of Miss. aspect. [See also under †*Bend series.*]

Barnett sand.

A subsurface sand correlated with upper part of Cherokee sh. (Penn.) of Ponca City field, Kay Co., Okla. Is older than Markham sand and younger than Bartlesville sand.

†Barnstable series.

Pleistocene: Southeastern Massachusetts (Barnstable County).

N. S. Shaler, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, pp. 503–593). *Barnstable series.*—Dark-colored clays, in part at least laid down in salt water. Appears to have been laid down after Nashaquitsa series and before Truro series.

J. B. Woodworth and E. Wigglesworth, 1934 (Harvard Coll. Mus. Comp. Zool. Mem., vol. 52). Shaler's "Barnstable series" included clays, boulder clays, sands, and gravels, and represents several Pleist. fms. of Long Island.

Named for occurrence at Barnstable, Barnstable Co.

Barnwell sand. (In South Carolina.)
Barnwell formation. (In Georgia.)

Eocene (upper): Coastal Plain of western South Carolina and eastern Georgia (Savannah drainage).

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2) and 1907 (Summary of mineral resources of S. C., pp. 12, 17). [*Barnwell buhr sands* in table; *Barnwell phase* in heading.] The littoral line of Barnwell phase irregularly overlaps upper margin of Santee marls, which extend from Shell Bluff easterly by Tinkers Creek, Orangeburg, Keitt Ravine and thence southerly along E. ridge of Santee River; along some ridges this littoral line extends almost to the fall line. The area along Savannah River extends southerly to Johnson's Landing, where it passes under King's Creek Silex, which near Cohens Bluff passes under Brier Creek marl (explored on Ga. side along Brier Creek by Lyell and by Vaughan). From Johnson's Landing the line of southerly exposures of this fm. passes near Fairfax, and thence probably curves, in obscurity of surface sands, towards Scotchmans Bluff; but it has been conclusively discriminated nowhere near St. Georges anticline S. of Orangeburg. The materials consist of silicified shells and decomposed glaucenite sands, partly indurated to ss.

E. Sloan, 1908 (S. C. Geol. Surv., ser. 4, Bull. 2), showed *Barnwell buhr-sands* and *Barnwell phase* as overlying his Santee marl and as separated from his Cooper marl by Mount Hope phase, but stated that position of the Barnwell was uncertain.

J. O. Veatch and L. W. Stephenson, 1911 (Ga. Geol. Surv. Bull. 26, p. 285). *Barnwell sand.*—Sloan has used name Barnwell "buhr sands" or Barnwell "phase" for red, ferruginous sands that immediately overlie McBean fm. as defined in this rept. Type area is in Barnwell Co., S. C., where its strat. position is as stated. Sloan, who has also studied the area in Ga. adjacent to Savannah River, states that Barnwell "phase" is represented by the sands that overlie the fossiliferous marls of Shell Bluff [*Ostrea georgiana* zone]. The Barnwell sand directly overlies McBean fm. and is in contact with both the marls and the Congaree clay, the basal memb. of McBean fm. and of Claiborne group (p. 268).

C. W. Cooke and H. K. Shearer, 1918 (U. S. G. S. P. P. 120C), modified the definitions of Barnwell sand and of McBean fm. as explained in 1918 entry under *McBean fm.* They showed Ocala ls. and Barnwell fm. as contemp., but stated that they are very different in lithology and present different faunal facies; also that they interfinger and merge laterally into each other. They stated: Barnwell fm. as here defined applies to a less homogeneous composite of materials than Barnwell sand of Veatch and Stephenson, including, in addition to Barnwell sand of Veatch and Stephenson, their so-called "Congaree clay" and the *Ostrea georgiana* zone of their McBean fm.; and it extends in a broad belt from Savannah River nearly to Flint River, but in W. half of this belt, the area lying W. of Oconee River, the fm. is intermediate in character btw. the typical Barnwell and the Ocala ls., merging into Ocala ls. to the S., or seaward, and toward the SW.

C. W. Cooke, 1936 (U. S. G. S. Bull. 867, on Coastal Plain of S. C.). Study of fossils has shown that many of the localities specifically referred by Sloan to the Barnwell really belong to McBean fm., and it is difficult to specify any particular locality in S. C. that can be considered as the original type. However, *Barnwell* has been adopted in this rept. in what is deemed to be its original significance, namely, an Eocene fm. composed chiefly of sand that overlies uncon. the McBean fm. This usage is same as that followed by Cooke and Shearer in their description of the deposits of Claiborne and Jackson age in Ga. [As mapped by Cooke in this rept the fm. covers N. half of Barnwell Co.]

Barrack Mountain granite gneiss.

Pre-Cambrian (?): Northwestern Connecticut.

W. M. Agar, 1929 (Am. Jour. Sci., 5th, vol. 17, pp. 204, 211+). *Barrack Mtn granite gneiss.*—Coarse, irregularly banded granite gneiss with variably spaced foliation planes due to discontinuous bands of biotite. It is a cataclastic gneiss with frequently a well-developed mortar texture. The minerals are quartz, microcline, microperthite, a little oligoclase, brown pleochroic biotite, much less muscovite, usually a little epidote, and a good deal of a second generation of quartz in larger elongated crystals. Feldspars characteristically poikilitic; the potash feldspar usually white but when present in large crystals it shades towards pink. The rock forms Barrack Mtn, 1 mi. S. of Falls Village, Litchfield Co. The Grenville schists and gneisses and the Barrack Mountain gneiss are so intimately intermingled over large areas that it is necessary to map the resulting gneiss separately as a mixture of the two and disregard the many minor variations. *Intrudes all older rocks. Assigned to pre-Camb.*

W. M. Agar, 1934 (Am. Jour. Sci., 5th, vol. 27, p. 362). Writer previously (this Jour., 17, p. 211, 1929) called the most granitic type of this latter rock [mixed gneisses] the *Barrack Mtn granite gneiss* and regarded it as an older intrusive forming the igneous component of the widespread mixed gneiss series. He has abandoned that view at present and regards the Becket magma as a widespread impregnating agent.

Barranca division.

A term applied by E. T. Dumble (Am. Inst. Min. Engrs. Trans., vol. 29, pp. 122–152, 1900) to a series of shales, slates, sss., and cgl. or breccia, with beds of graphite and coal, in Sonora, Mexico. Assigned by him to Triassic, and said to overlie Carbf. lss. and dolomites.

R. E. King, 1934 (Am. Jour. Sci., 5th, vol. 28, pp. 89, 101), assigned these rocks to Upper Triassic and Liassic. (The latter is included in Lower Jurassic by U. S. Geol. Survey.)

Barranquitas shaly limestones.

Early Cretaceous (?): Puerto Rico.

C. P. Berkey, 1915 (N. Y. Acad. Sci. Annals, vol. 26, p. 61).

Barre granite.

Devonian: Northeastern Vermont (Washington County).

C. H. Richardson, 1902 (3d Rept. Vt. State Geol., btw. pp. 61 and 98). Of the eruptives in Washington ls. [Waits River ls. of current literature] the *Barre granite* plays most important part. The area is about 8 mi. long and 4 mi. wide, *mostly in Barre but with a small area in Williamstown. It is a fine granite,* composed of quartz, feldspar, and mica, and of lower Trenton age.

C. H. Richardson, 1908 (6th Rept. Vt. State Geol.). *Barre granite,* Dev., intrudes Waits River ls.

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), assigned *Barre granite* to Dev.

Barre moraine.

Pleistocene (Wisconsin stage): Western New York and southern Ontario. Named for South Barre, Orleans Co., N. Y. Replaces †Lockport moraine. Is shown on moraine map (fig. 8) in U. S. G. S. Niagara folio (No. 190), p. 17.

Barré limestone.

Devonian: Quebec.

J. M. Clarke, 1915 (N. Y. State Mus. Bull. 177, p. 150).

Barree limestone.

Silurian: Central Pennsylvania (Huntingdon County).

I. C. White, 1885 (2d Pa. Geol. Surv. Rept. T_3, pp. 132–133). *Barree lss.*—Thin beds of light-gray bluish gray ls. streaked with calcite, with some greenish gray sh. partings. Thickness 175 ft. Underlie Clinton upper shales and overlie Barree shales. Outcrop belt crosses Little Juniata River at Barree forge, and it is quarried for flux at Barree furnace [Huntingdon Co.].

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 2, pp. 825–827), called the shales above *Barree ls. group* the *Barree Upper shales* and the shales below that ls. the *Barree Lower shales.*

These ls. beds are basal part of McKenzie fm., as identified by C. Butts in U. S. G. S. Hollidaysburg-Huntingdon folio (No. 227).

Barree shales.

Silurian: Central Pennsylvania (Huntingdon County).

I. C. White, 1885 (2d Pa. Geol. Surv. Rept. T_3, p. 133). *Barree shales.*—Green shales; 60 to 75 ft. thick, with thin, limy, fossiliferous layers. Underlie Barree lss. and rest on 10 ft. of ore ss. [Keefer ss. memb.]. Included in Clinton fm. [Form upper part of Clinton fm. as identified in U. S. G. S. Hollidaysburg-Huntingdon folio (No. 227).]

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 2, pp. 826–827). *Barree Upper shales*, top memb. of Clinton fm., 60 ft. thick, overlie Barree ls. group (175 ft. thick), which rests on *Barree Lower shales* (75 ft. thick, green in color, with thin limy fossiliferous layers almost entirely confined to upper half, and exposed along river bank below Barree furnace, Huntingdon Co.). All included in upper part of Clinton fm. [The Barree Upper shales and Barree ls. of this rept form basal part of McKenzie fm. of U. S. G. S. Hollidaysburg-Huntingdon folio (No. 227), and the Barree Lower shales form upper part of Clinton fm. of that folio.]

Barrelian series.

Cambrian: California.

C. [R.] Keyes, 1931 (Pan-Am. Geol., vol. 56, p. 76).

Barrel Spring formation.

Middle Ordovician: Central eastern California (Inyo Range).

F. B. Phleger, Jr., 1933 (Southern Calif. Acad. Sci. Bull., vol. 32, pt. 1, pp. 1–6). *Barrel Spring fm.*—A succession of qtzites, impure lss., and argill. shales of Middle Ord. age. The fm. is well exposed in Barrel Spring Canyon and in each of next 4 canyons to N. Consists of (descending): (1) Argill. sh., dark gray to black, weathers reddish brown, highly fossiliferous at certain localities, 64 ft.; (2) nonfossiliferous dark-gray impure ls. that weathers lighter gray, 25 ft.; (3) basal qtzite, white, nonfossiliferous, 41 ft. Conformably overlies Mazourka fm. (of Chazy age) and conformably underlies Dev. qtzite that weathers white to buff. Five of the 7 forms that are present in fauna of Barrel Spring fm. are either identical with or are closely related to species of Trenton age.

†Barren Measures.

A descriptive term used in early repts (see J. P. Lesley, Manual of coal, 1856 ed.; H. D. Rogers, Geol. Pa., vol. 2, pt. 1, pp. 474–477, 1858) to include the rocks of western Pa. above the Mahoning ss. Subsequently "Upper Barren Measures" was applied to the rocks later named *Dunkard group*, and "Lower Barren Measures" was applied to the rocks later named *Conemaugh fm.* The coordinate descriptive term "Upper Productive Coal Measures" was applied to the intervening Monongahela fm., and the term "Lower Productive Coal Measures" to the Allegheny fm.

Barrett shale.

Lower Cretaceous: Northeastern Wyoming and western South Dakota (Black Hills).

W. P. Jenney, 1899 (U. S. G. S. 19th Ann. Rept., pt. 2, p. 593, fig. 122, and map). *Barrett shales (Lower Cret.)*.—Shales and massive sss., uncon. underlying Oak Creek beds and overlying (without positive evidence of uncon.) Hay Creek coal fm. in Black Hills. Formerly included in Dakota ss. (Upper Cret.). Thickness 45 to 75 ft. [Mapped at and around Barrett, Crook Co., Wyo.]

Barrett sand.

A subsurface sand, of Upper Dev. (Chemung?) age, in NW. Pa., which is believed to lie lower than Bayard sand and higher than Elizabeth sand.

Barrière formation.

Cambrian or pre-Cambrian: British Columbia.

W. L. Uglow, 1922 (Canada Geol. Surv. Summ. Rept. 1921, pt. A, p. 78).

Barrington clays.

Pleistocene (Wisconsin stage): Rhode Island (Barrington).

J. B. Woodworth, 1896 (U. S. G. S. 17th Ann. Rept., pt. 1, pp. 987–988, chart opp. p. 988, and pl. 62). *Barrington clays.*—Grayish to bluish clays present in town of Barrington, R. I. Are more sandy in upper than in lower part. Used for making brick. Underlain by glacial gravel and sands and overlain by glacial sands. Thickness 60 to 65 ft.

Is a local deposit of clay of Wisconsin age.

Barron quartzite.

Pre-Cambrian (Keweenawan): Northwestern Wisconsin (Barron County).

N. H. Winchell, 1895 (Am. Geol., vol. 16, pp. 150–162). The Sioux qtzite, New Ulm qtzite, Baraboo qtzite, and *Barron County qtzites* are of same age, and are pre-Keweenawan and post-Mesabi.

S. Weidman and A. R. Schultz, 1915 (Wis. Geol. Nat. Hist. Surv. Bull. 35, pp. 234, 235), mentioned *Barron qtzite* as present in E. part of Barron Co., resting on pre-Camb. granite.

W. O. Hotchkiss et al., 1915 (Wis. Geol. Nat. Hist. Surv. Bull. 44, econ. ser. 19, p. 85 and map). *Barron qtzite.*—The three main phases are the purplish pink, well-cemented qtzite, the yellowish somewhat less well-cemented qtzite, and the striped or stain-banded phase. A very minor phase widely famed, however, because of its use by the Indians, is the pipestone or catlinite, which occurs in thin shaly beds. It includes at least two separate uncon. qtzite fms., trap rocks, and probably both acid and basic intrusives. Thickness 600 ft. Assigned to Keweenawan. Rests uncon. on Huronian slates.

Barron County quartzite.

See under *Barron qtzite*.

Barryville member.

Upper Devonian: Southeastern New York and northeastern Pennsylvania (Wayne and Pike Counties).

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 571, 586–587). *Barryville memb.*—Lower memb. of Shohola fm. Underlies Paupack ss. (upper memb. of Shohola fm.) and overlies Delaware River flags. Consists of 700 ft. of olive and gray shales and sss., cross bedded, weathering often to deeply pitted surfaces, and containing red interbeds and glomerate layers of mud chips and fish fragments. Evidently this memb. corresponds to, and is a thickened continuation of, the beds below Paupack ss. which so puzzled I. C. White [but to which he applied the name *Paupack shales and ss.*]. Exposed on Delaware River in Pike Co., but better displayed on N. Y. side of the river, in vicinity of Barryville, Sullivan Co. Is continental correlate of marine Chemung. Is not recognized beyond central Monroe Co., along Brodhead Creek.

Barstow formation.

Miocene (upper): Southern California (San Bernardino County).

O. H. Hershey, 1902 (Am. Geol., vol. 29, pp. 360–370). *Barstow series.*—A thin valley fm. made under arid conditions. Occurs at several points in Mohave River valley, notably along railroad about 1½ mi. E. of Barstow [San Bernardino Co.]. Type section near Barstow consists of:

1. Stratified, hard brown material due to arid condition but composition not determined. Persistent over considerable area, 20 ft.
2. Yellow and light gray silt, 4 ft.
3. Stratified, fine gravel and sand of dull red color and containing red lava fragments, 15 ft.
4. Structureless bed of white tuff with angular and subangular fragments of various other rock species embedded in it, 20 ft.

Is extensively developed on low hills on N. side of valley btw. Barstow and Daggett. Uncon. overlies Rosamond and Escondido series. Extensively eroded. Overlain uncon. by Quat.

J. C. Merriam, 1915 (Pop. Sci. Monthly, vol. 86, pp. 252–254). The term *Barstow fm.* is used for the beds containing the Upper Mio. vertebrate fauna.

J. C. Merriam, 1919 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 11, No. 5, pp. 441–448). *Barstow fm. or group.*—Mainly bluish gray to yellowish brown, slightly indurated strata, composed largely of fine arkose with considerable percentage of volcanic ash. In an earlier publication (Calif. Univ. Pub., Dept. Geol. Bull., vol. 6, p. 168, 1911) writer referred to fauna of Barstow syncline as the *Mohave fauna,* this name being considered mainly as a geographic designation. Later, in order to avoid confusion with other Tert. faunas occurring in Mohave area, the name *Barstow* has been used for this faunal assemblage, and *Barstow fm.* for the beds containing the Upper Mio. or Barstow fauna. This fm. comprises the uppermost of the five divisions [of Rosamond series] in Barstow syncline, described by Baker [Calif. Univ. Pub., Dept. Geol. Bull., vol. 6, 1911] as fossiliferous tuff memb., and any other beds which may be recognized as representing the horizontal or vertical extension of the same depositional unit. The limits of Barstow fm. may be found to correspond with those of the fossiliferous tuff memb., or they may include a greater range of sediments above and below. It is possible the Barstow fauna occurs in all strata of Barstow syncline. It is also possible the lowest strata of that section will be discovered to contain a faunal assemblage much older than the particular Upper Mio. assemblage known as the fossiliferous tuff. The resistant breccia memb. immediately below the fossiliferous tuff in Baker's Barstow syncline section seems to contain a representation of Barstow fauna, and may ultimately be included in Barstow fm. Should the resistant breccia be recognized as a distinct fm. the name *Barstow group* may be used for the sequence of fms. Excepting marine deposits of Eocene age, the oldest Tert. rocks in Mohave area of which the age is certainly known are included in Barstow fm. Fauna [listed] is distinctly older than Ricardo fauna. Assigned to Upper Mio.

Bartlesville sand.

Name that has been applied to one and to several productive sands in lower part of Cherokee sh. of eastern part of Osage Co., NE. Okla., some of which have been correlated with Bluejacket ss. memb. of Cherokee sh. (Penn.). The name has been used to include Red Fork sand at top and Glenn sand at base, with intervening beds, the whole aggregating 200 or more ft. in thickness; and it has also been applied to the lower sand only, the upper sand being called *Burbank (Red Fork) sand.* According to N. W. Bass, the lower sand, which lies 50 to 100 ft. below the higher sand, is now regarded as true Bartlesville, which is the producing sand near town of Bartlesville, Washington Co., Okla., and is separated from Mississippi lime by a small thickness of sh. The sand formerly called *Bartlesville sand* in Kans. is now designated *Burbank sand.*

Bartlett barren member (of Mesaverde formation).

Upper Cretaceous: Northwestern New Mexico (Gallup-Zuni Basin).

J. D. Sears, 1925 (U. S. G. S. Bull. 767). *Bartlett barren memb.*—Light-gray to white lenticular ss., light-gray clay sh., and thin irregular coal beds, but none of commercial importance. Thickness 330 to 400 ft. Underlies Gibson coal memb. and overlies Dilco coal memb., all belonging to Mesaverde fm. Named for excellent exposures near old Bartlett shaft mine, which penetrates lower half of the memb.

Bartlett Island series.

Pre-Cambrian and later: Southeastern Maine (west of Mount Desert Island).

N. S. Shaler, 1889 (U. S. G. S. 8th Ann. Rept., pt. 2, pp. 1037, 1038–1041, 1060). *Bartletts Island series.*—Thick layer of micaceous, chloritic, and sometimes gneissoid schists, which lie on W. side of island, extending from Thomas Bay, on N. side of island, to Nutter's Point, the extremity of SW. shore. A series of schists, qtzites and sss.; no lss. Consists of contorted schist, aren. and argill., with frequent bed of qtzite, a material often assuming a gneissoid aspect with the associated injections of igneous rocks. Thickness not less than 2,000 ft. and may be twice as much. Rocks lie low in Paleozoic. It may be found that a portion or whole of Bartlett's Island series is to be placed with that found about Bar Harbor [which he named *Bar Harbor series*].

F. W. Toppan, 1932 (Geol. of Maine, Dept. Geol. Union Coll., Schenectady, p. 48). *Bartlett's Island series* is Camb. or possibly pre-Camb.

On 1933 geol. map of Maine, by A. Keith, the rocks of Bartlett Island are mapped as pre-Camb. gneisses and schists, Sil. or Dev. igneous rocks, and Carbf. granite.

Named for development on Bartlett Island, off W. coast of Mount Desert Island.

Barton group. (In Conemaugh formation.)

Pennsylvanian: Southwestern Pennsylvania.

J. J. Stevenson, 1877 (2d Pa. Geol. Surv. Rept. K_2, p. 67). *Barton group.*—Includes Morgantown ss. at top and Crinoidal or Green Fossiliferous ls. [Ames] at base. This portion of section is so constant and shows such slight variation in general character that it deserves to be especially distinguished.

Barton gneiss.

Pre-Cambrian: Northeastern New York (Essex County).

J. F. Kemp, 1898 (Am. Inst. Min. Engrs. Trans., vol. 27, p. 178, map and cross sections). *Barton gneiss forms summit of* Barton Hill; is darker than underlying Orchard gneiss. Both occur near Port Henry [Essex Co.].

Barton beds.

Silurian: Ontario (Hamilton).

M. Y. Williams, 1914 (Canada Geol. Surv. Summ. Rept. 1913, pp. 179–188). *"Barton beds."*—Thin to thick-bedded dol. with interbedded sh. (in part bituminous), occurring in upper part of Lockport memb. of Niagara fm. Locally known in vicinity of Hamilton, Ont., as "Barton beds." At Ancaster about 10 ft. thick, and rest on 15 ft. of chert beds, which in turn rest on Gasport ls. memb. of the Lockport. [Derivation of name not stated.]

M. Y. Williams, 1919 (Canada Geol. Surv. Mem. 111, No. 91 geol. ser.). *"Barton beds."*—The 80 to 90 ft. of the Lockport overlying the chert beds and underlying Guelph dol. in vicinity of Hamilton are decidedly argill. and contain sh. beds at some horizons. Spencer and Grant called these beds "Barton beds," after the name of township in which Hamilton is situated. The name "Barton" has never been recognized to any extent in geological literature as it was preoccupied in Tertiary of England; it has, however, considerable local significance. As will be seen later, the upper 35 ft. of "Barton beds" belong to Erasmosa dol. [Name applied in this rept. to upper 12 to 50 ft. of Lockport dol., exclusive of Guelph.] The lower part is well defined by its argill. character from Mount Albion to Ancaster.

Barton sandstone. (In Conemaugh formation.)

Pennsylvanian: Western Maryland (Allegany and Garrett Counties).

C. K. Swartz, W. A. Price, and H. Bassler, 1919 (Geol. Soc. Am. Bull., vol. 30, p. 573). *Barton ss.*—Underlies Barton rider coal and overlies Barton coal; all included in Conemaugh fm.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, pl. 6), applied *Barton ss.* to sss. both overlying and underlying Barton rider coal, but on p. 65 he stated: "A thick ss. is found locally over the Barton coal at Barton and elsewhere which is named the Barton ss. from its position." On p. 114 he showed 30 ft. of *Barton ss. and sh.* underlying Wellersburg ls. and fire clay and overlying Barton rider coal in Castleman Basin.

Barton limestone. (In Conemaugh formation.)

Pennsylvanian: Western Maryland (Allegany and Garrett Counties).

C. K. Swartz, W. A. Price, and H. Bassler, 1919 (Geol. Soc. Am. Bull., vol. 30, p. 573). *Barton ls.*—Underlies Barton coal and overlies Upper Grafton ss.; all included in Conemaugh fm.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, p. 115), gave thickness of *Barton* ls. in Castleman Basin as 5 ft. and in Georges Creek Basin as 1 ft.

Barton red shale. (In Conemaugh formation.)

Pennsylvanian: Western Maryland.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, p. 65). *Barton red sh.*—Red sh. found above Barton coal in drill holes in Potomac basin.

Barton clay. (In Conemaugh formation.)

Pennsylvanian: Central eastern Ohio (Jefferson County).

R. E. Lamborn, 1930 (Ohio Geol. Surv. Bull. 35, pp. 137–138). *Barton clay*, 3' 2" thick, underlies Barton coal, which in Jefferson Co. is represented by 2 in. of black carbonaceous clay.

Named for association with Barton coal.

†Barton Creek limestone.

Lower Cretaceous (Comanche series): Central Texas (Travis County).

R. T. Hill and R. A. F. Penrose, Jr., 1889 (Am. Jour. Sci., 3d, vol. 38, p. 470). *Barton Creek or Caprina ls.*—Estimated thickness 1,000 ft. Exposed on Barton Creek [near Austin] above the ford, also in high bluffs of the Colorado at and opposite Johnson's quarry; also in W. bluff of Mount Bonnel. Included in Comanche series.

Same as Edwards ls., later name but affording better type loc.

Barton Creek limestone. (In Millsap Lake formation.)

Pennsylvanian: Central northern Texas (Palo Pinto County).

F. B. Plummer, 1929 (Tex. Bur. Econ. Geol., geol. map of Palo Pinto Co.). *Barton Creek ls.*, in lower part of Mineral Wells fm., lies lower in section than Santo ls.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 106). *Barton Creek ls. memb. of Garner fm.* is preoccupied by Barton Creek ls. of Cret. of Tex. and is discarded. [It is listed as basal memb. of Garner fm., the name *Mineral Wells fm.* being restricted to upper part of the original Mineral Wells fm. Does not say what name replaces it.]

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534), do not refer to this name under their description of geol. of Palo Pinto Co., nor on map of that Co., but under description of "Underground water" of Palo Pinto Co., they state (p. 162) that their newly proposed *Buck Creek ss.* lies in interval btw. Brannon Bridge and Barton Creek ls. members of *Millsap Lake fm.*, which underlies Garner fm.

basement complex.

"Basement complex" and "Bedrock complex" are descriptive terms that have been rather loosely applied in the literature to the basement rocks of a region, regardless of whether they are or are not of complex structure.

Bashi formation. (In Wilcox group.)

Eocene (lower): Southern Alabama and southeastern Mississippi.

A. Heilprin, 1882 (Phila. Acad. Nat. Sci. Proc. for 1881, pp. 158–159). [See quotation under †*Eo-lignitic*.]

E. A. Smith and L. C. Johnson, 1887 (U. S. G. S. Bull. 43, pp. 43–47). *Wood's Bluff or Bashi series.*—Consists of (descending): (1) Wood's Bluff or Bashi marl, 15 to 30 ft. thick; (2) 25 ft. of gray sandy clays containing toward base 4 or 5 thin seams of lignite; (3) 35 to 40 ft. of yellowish cross-bedded sands; and (4) lignite bed 2 ft. thick. Underlies Hatchetigbee series and overlies Bell's Landing series [Tuscahoma sand of modern nomenclature].

Is next to youngest fm. of Wilcox group in Ala., and contains deposits of both marine and nonmarine origin. Extends a short distance into Miss. Is believed to occupy a position btw. Grenada fm. and Holly Springs sand, but occurs 80 mi. SE. of the outcrops of those fms.

Named for exposures on Bashi Creek, Clarke Co., Ala., especially at Wood's Bluff, Tombigbee River, just below mouth of Bashi Creek.

†Bashi marl.

Eocene (lower): Southwestern Alabama.

E. A. Smith, 1887 (U. S. G. S. Bull. 43, pp. 39, 43–46, 69). *Wood's Bluff or Bashi marl.*—Marl, with marine fossils and much greensand, 15–30 ft. thick, forming top memb. of Wood's Bluff or Bashi series. Overlain by purplish brown sandy clays forming basal part of Hatchetigbee series.

Conflicts with Bashi fm., of which it is top memb.

Named for exposures on Bashi Creek, Clarke Co.

†Basic claystone. (In Claiborne group.)

Eocene (middle): Southeastern Mississippi.

E. N. Lowe, 1919 (Miss. Geol. Surv. Bull. 14, pp. 74-75). *Basic claystone.*—Marine beds, consisting of (descending): (1) White qtzite, 20 ft. (to W. these beds characterize the claystone and pass into soft ss.); (2) yellowish white claystone, 100 ft.; (3) semi-indurated grayish glauconitic sand, 10 ft. A phase of Tallahatta fm. Rests conformably on Winona sand phase of Tallahatta fm.

Is a facies of Tallahatta fm. for which a geographic name is considered unnecessary. The true Winona sand has been proved, by later work of C. W. Cooke, to be a memb. of Lisbon fm.

Named for exposures at Basic City, Clarke Co.

Basin shale.

Upper Cretaceous: Northern Wyoming (Basin and Greybull oil fields).

F. F. Hintze, 1915 (Wyo. State Geol. Bull. 10, on Basin and Greybull oil and gas fields, Bighorn Co., Wyo., pp. 17, 24-29). *Basin sh.*—Marine shales, dark colored, containing calc. concretions and many Niobrara fossils in upper half. The large brown sandy concretions at base are highly fossiliferous. There is at base a persistent cgl. 2 ft. thick. Thickness of fm. 900-1,000 ft. Rests discon. (erosion) on Torchlight ss. memb. of Benton, and underlies Pierre sh., which is overlain by Eagle ss. [Parkman ss.]. [In Wyo. State Geol. Bull. 11, 1915, on Little Buffalo Basin, Hintze gave thickness as 1,200 to 1,250 ft.]

As above defined, this unit includes Carlile and Niobrara shales of present nomenclature, the overlying so-called Pierre sh. of Hintze being the Steele sh. of current nomenclature.

Bas Obispo formation.

Eocene or older: Panama Canal zone.

D. F. McDonald, 1913 (Geol. Soc. Am. Bull., vol. 24, p. 708).

Basque formation.

Jurassic: British Columbia.

C. H. Crickmay, 1930 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 19, No. 2, p. 33).

Bass limestone. (Of Unkar group.)

Pre-Cambrian: Northern Arizona (Grand Canyon).

L. F. Noble, 1914 (U. S. G. S. Bull. 549). *Bass ls.*—White crystalline ls. alternating with beds of argill. and calc. red sh. containing sun cracks. Thickness 335 ft. Cut by a thick sill of intrusive diabase. Conformably underlies Hakatai sh. and conformably overlies Hotauta cgl., all of which belong to Unkar group. Named for Bass Canyon, where typically exposed.

Bassand member (of Bearpaw shale).

Upper Cretaceous: Alberta.

L. S. Russell, 1932 (Roy. Soc. Canada Trans., 3d ser., vol. 26, sec. 4, p. 126).

Bassendorf shale.

Oligocene (?): Southwestern Oregon (Coos Bay district).

H. G. Schenck, 1927 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 16, No. 12, pp. 454, 457, 459). *Bassendorf sh.*—Sh., characterized in part by presence of diatoms and foraminifera. Estimated thickness 1,900 ft. Rests on Coaledo fm. as here restricted, and is overlain by Tunnel Point ss. No angular uncon. btw. Bassendorf sh. and Coaledo fm. could be established with certainty. Typical exposure at Bassendorf Beach, shown on U. S. Coast and Geodetic Survey chart No. 5984, in sec. 3, T. 26 S., R. 14 W. Contains microfossils and a few mollusks. Assigned to lower Olig.

H. G. Schenck, 1928 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 18, p. 16). There is some indication that an angular uncon. may exist btw. Bassendorf sh. and underlying Coaledo fm.

H. G. Schenck and R. M. Kleinpell, 1935 (Pan-Am. Geol., vol. 64, No. 1, p. 76). Microfossils and strat. relations suggest Bassendorf and Keasey shales are late Eo.

Bassick agglomerate.

Tertiary: Central southern Colorado (Custer County).

W. Cross, 1896 (U. S. G. S. 17th Ann. Rept., pt. 2, p. 307). *Bassick aggl.*—Volcanic aggl., 1,400± ft. thick, composing Bassick Hill and greater part of Mount Tyndall. The rock that is predominant among the fragments of the aggl. is an andesite closely allied to both Rosita and Bunker types. Seems likely to be last of sequence of igneous rocks of Silver Cliff-Rosita Hills region.

†Bassimenan Lake granite.

Pre-Cambrian (Laurentian): Northeastern Minnesota (Vermilion district).

N. H. Winchell, 1899 (Minn. Geol. Nat. Hist. Surv. Final Rept., vol. 4). *Bassimenan Lake or Basswood granite* is same as Saganaga granite. Well exposed on islands and along S. shores of Bassimenan Lake.

U. S. Geographic Board gives *Basswood* (not *Bassimenan*) as correct name of the lake.

Bass Islands dolomite.

Silurian (Cayugan): Southeastern Michigan, northern Ohio, and western Ontario.

A. C. Lane, C. S. Prosser, W. H. Sherzer, and A. W. Grabau, 1909 (Geol. Soc. Am. Bull., vol. 19, p. 554). *Bass Islands series or Lower Monroe.*—Named for group of islands in western Lake Erie. Discon. underlies Sylvania ss. Overlies Salina. Includes (descending): Raisin River dol., 200± ft.; Put-in-Bay dolomites, 100+ ft.; Greenfield dol., 100+ft.; and Tymochtee shales and lss. of Ohio, 100+ft. which may represent in part one or more members recognized elsewhere. [See under *Tymochtee sh.*]

Type loc. of Greenfield dol. is in SW. Ohio.

Bass Mountain diabase.

Mississippian: Northern California (Redding quadrangle).

J. S. Diller, 1906 (U. S. G. S. Redding folio, No. 138). *Bass Mountain diabase.*—Nonporphyritic, dark, somewhat greenish, compact lava, occasionally vesicular and more frequently fragmental. Is contemp. and partly interbedded with upper part of Bragdon fm. Named for fact it forms southern slope of Bass Mtn.

†Basswood granite.

Pre-Cambrian (Laurentian): Northeastern Minnesota (Vermilion district).

A. Winchell, 1888 (Minn. Geol. Nat. Hist. Surv. 16th Ann. Rept.). *Basswood granite* occupies all the Minn. shores of Basswood Lake except SW. shore of Arm 1.

N. H. Winchell, 1899 (Minn. Geol. Nat. Hist. Surv. Final Rept., vol. 4). *Basswood granite* intrudes Lower Keewatin and is of same age as Saganaga granite.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, p. 128). The *granite of Basswood Lake* is same as granite locally known as "Saganaga Lake granite."

The U. S. Geol. Survey uses *granite of Basswood Lake*, in a geographic sense.

Basswood Creek formation.

Ordovician: Quebec.

T. H. Clark, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 1, p. 6).

Bastard limestone.

A term applied in some early N. Y. and Pa. repts to a ls. in Helderberg group, because of its impure or siliceous character.

I. C. White, 1883 (2d Pa. Geol. Surv. Rept. G7, pp. 97–98). *Bastard ls.*—Buffish-gray impure mag. ls. 10 to 25 ft. thick. Overlies Bossardville ls. (basal part of

Lower Helderberg) and underlies Stormville ls. "Seems to represent Stormville cement bed as well as Decker's Ferry group of Pike and Monroe Counties."

Bastion schist.

Pre-Cambrian: British Columbia.

R. A. Daly, 1913 (12th Int. Geol. Cong. Guidebook 8, p. 124) and 1914 (Canada Geol. Surv. Summ. Rept. 1912, p. 158). *Bastion schists*, pre-Beltian, B. C. Included in Shuswap series.

Batavia moraine.

Pleistocene (Wisconsin stage): Western New York. Named for Batavia. See U. S. G. S. Mon. 41, pp. 688–690.

Batchawana series.

Pre-Cambrian: Western Ontario.

E. S. Moore, 1926 (Ont. Dept. Mines 34th Ann. Rept., pt. 4, p. 9; and 35th Ann. Rept., pt. 2, p. 59) and 1929 (Geol. Soc. Am. Bull., vol. 40, p. 552). Occurs in upper waters of Batchawana River, in Mississagi Forest Reserve, 75± mi. N. of Sault Sainte Marie, Ont.

Bates Hole formation.

This name is listed in U. S. G. S. Bull. 191, but the reference cited (J. H. Smith, Jour. Geol., vol. 8, p. 456, 1900) does not use the term. Under heading "Eocene of Bates Hole, Wyo.," Smith stated: In valley of Bates Creek, Natron [a] Co., Wyo., fossiliferous Eocene beds occur, which have been but recently recognized, and no published account of them is known to writer.

Batesville sandstone.

Mississippian: Northern Arkansas and northeastern Oklahoma.

J. C. Branner and F. W. Simonds, 1891 (Ark. Geol. Surv. Ann. Rept. 1888, vol 4, pp. xiii, 26, 49–53). [According to p. xiii the fm. was named by Branner; the description is by Simonds.] *Batesville ss.*—In Washington Co., Ark., consists of coarse ss., gray to brown, 10 to 60 ft. thick, in some places more or less massive but usually forms beds 1 to 4 ft. thick. Either immediately underlies Archimédes [Pitkin] ls. or is separated from it by Marshall sh. Overlies Fayetteville sh. [The ss. above described in Washington Co. is now known not to be the Batesville but the Wedington ss. memb. of Fayetteville sh.]

R. A. F. Penrose, Jr., 1891 (Ark. Geol. Surv. Ann. Rept. 1890, vol. 1, pp. 113, 139–140). *Batesville ss.* at Batesville consists of brown or buff-colored, fine grained ss., generally soft, though sometimes hard; splits easily along bedding lines. Contains lenticular beds of sh. Thickness 20 to nearly 200 ft. Overlies Fayetteville [really Moorefield] sh. and underlies Genevieve or Boston group.

See under *Fayetteville sh.* for explanation of erroneous correlations in above definitions. The true Batesville ss. is of Chester age, and at Batesville it overlies Moorefield sh., or in its absence Boone ls.; and to W. it underlies true Fayetteville sh.

Named for Batesville, Independence Co., Ark.

† Batesville ash bed.

Upper Ordovician (Richmond): Northeastern Arkansas (Batesville district).

J. F. Williams, 1891 (Ark. Geol. Surv. Ann. Rept. 1890, vol. 2, pp. 373–375). *Batesville ash bed* as described by Dr. R. A. F. Penrose, Jr., consists of compact, bluish green, earthy rock, 6 to 15 inches thick, containing small siliceous nodules, ⅛ to 1 inch diam., and small crystals of iron pyrites. The material is softly calc. and weathers into a brown or buff-colored mass much softer than original rock. Overlies residual clay derived from decomposition of St. Clair ls. [not St. Clair ls. of present usage but an older fm.] and underlies Boone chert [Miss.].

H. D. Miser (personal communication August 1933) states that this unit is not an ash bed but a bed in Cason sh., and that it is not a useful geologic name. It is also preoccupied.

Named for Batesville, Independence Co.

Bath sandstone sub-member (of Pony Spring siltstone member).

Permian: Central Colorado (Park and Chaffee Counties).

D. B. Gould, 1935 (A. A. P. G. Bull., vol. 19, No. 7, pp. 973, 990, 995, 1,000). *Bath ss. sub-memb. of Pony Spring siltstone memb. of Maroon fm.*—Arkosic, greenish-gray, micaceous ss., with chloritic cement. Strata range from a few tenths of a foot to 8 ft. thick, and may alternate with thin layers of greenish gray to reddish-gray siltstone. Ripple marks common; many layers cross-laminated. Plant fossils abundant at some horizons near base. Rests conformably on Chubb siltstone memb. Assigned to Perm. Forms prominent ridge that separates the Platte and Arkansas drainage for several mi. NW. of summit of Trout Creek Pass, where is abandoned town of Bath.

Bath-Reef series.

Quaternary: West Indies.

J. W. W. Spencer, 1902 (London Geol. Soc. Quart. Jour., vol. 58, p. 361).

Bathurst formation.

Carboniferous: New Brunswick.

G. A. Young, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 220).

Battery formation.

Pleistocene: Northwestern California (Del Norte County).

J. H. Maxson, 1933 (Calif. Jour. Mines and Geol., vol. 29, Nos. 1 and 2, p. 136 and map). *Battery fm.*—A thin marine terrace capping of unconsolidated sands exposed over S. part of Crescent City platform. A fossiliferous lens contains a small fauna whose general aspect is that of upper San Pedro.

Battie quartzite.

Cambrian (?): Central southern Maine (Knox County).

G. O. Smith, E. S. Bastin, and C. W. Brown, 1907 (U. S. G. S. Penobscot Bay folio, No. 149, p. 3). *Battie qtzite.*—Massive buff qtzite and clean, buff-colored qtzite cgl. of very striking appearance. The qtzite cgl. makes up Mount Battie. Thickness 400 to 500 ft. Overlies Islesboro fm. and conformably underlies Penobscot fm. Assigned to Camb. (?). Named for development on Mount Battie, a small mtn on mainland N. of Camden, Knox Co., in Rockland quad.

On 1933 geol. map of Maine, by A. Keith, these rocks are included in the Ord. and Camb. block.

Battle Creek moraine.

Pleistocene (Wisconsin stage): Southern Michigan. Named for Battle Creek. See back of 1918 ed. of U. S. G. S. Camp Custer topog. map; also Mich. Acad. Sci. Ann. Rept., pp. 53–54, 1918.

Battleground schist.

Pre-Cambrian: Southern North Carolina and northwestern South Carolina.

A. Keith and D. B. Sterrett, 1931 (U. S. G. S. Gaffney-Kings Mtn folio, No. 222). *Battleground schist.*—Chiefly white, gray, bluish, bluish black, and mottled white and bluish sericite schists, with, at top, a manganese schist memb. nearly 300 ft. thick; several very persistent beds of cgl. are present. Thickness 1,000 to possibly 2,500 ft. Uncon. underlies Kings Mtn qtzite and uncon. overlies Archean rocks. Assigned to Algonkian.

Named for exposures on Kings Mtn Battleground, York Co., S. C.

Baucari division.

A term applied by E. T. Dumble (Am. Inst. Min. Engrs. Trans., vol. 29, 1900, and vol. 31, 1902) to a great thickness of late Tert. lake deposits in Sonora, Mexico, and Cochise Co., SE. Ariz.

Bautista beds.

Pleistocene: Southern California (San Jacinto quadrangle).

C. Frick, 1921 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 12, pp. 283–288). *Bautista beds* occur in Bautista Badlands or Bautista Creek area. They have yielded Pleist. vertebrate fossils, and were evidently accumulated in part in a playalike lake, as a series of fine, worked-over fangls. and clays derived from low highlands of immediate N. and E.

D. M. Fraser, 1931 (Min. in Calif., vol. 27, No. 4, pp. 504–516, 536–537). *Bautista beds* are 1,500 or 2,000 ft. thick, and cover area of 25 sq. mi. Contain Pleist. vertebrates.

Baxter shale.

Upper Cretaceous: Southwestern Wyoming (Sweetwater County).

A. R. Schultz, 1920 (U. S. G. S. Bull. 702). *Baxter sh.*—Black and drab shales, very soft and friable; shaly sss. and aren. sh., in places highly gypsiferous. Greater part of fm. is sh. Thickness undet.; 1,000 ft. exposed in Baxter Basin, but base not seen. Underlies Blair fm. Contains fossils of Montana age. Named for exposures in vicinity of Baxter.

J. D. Sears, 1926 (U. S. G. S. Bull. 781, pp. 16, 19, map). Between Frontier and Blair fms. in Baxter Basin is 3,350 to 3,600 ft. of homogeneous gray and drab sh., in part of Colorado and in part of Montana age. Only upper part of this sh. is exposed. Schultz gave name *Baxter sh.* to this part, but in present rept the name is extended to include the whole body. It includes numerous zones of calc. concretions and soft thin-bedded ss. Thickness in Rock Springs uplift 3,350 to 3,600 ft. A ss. 850± ft. below top of fm. is called "marker bed" and is believed to mark base of Montana part of Baxter sh.

Baxters Brook formation.

Ordovician: Nova Scotia.

M. Y. Williams, 1911 (Canada Geol. Surv. Summ. Rept. 1910, p. 241).

Bayard formation.

Pennsylvanian: Northeastern West Virginia and western Maryland.

N. H. Darton and J. A. Taff, 1896 (U. S. G. S. Piedmont folio, No. 28). *Bayard fm.*—A lower ss. 196 ft. thick; a middle div. of shaly ss., sh., coal, and thin ls. 200 ft. thick; and an upper ss., which is a beach deposit. Thickness 400 to 475 ft. Underlies Fairfax fm. and overlies Savage fm. Exposed all around Bayard, Grant Co., W. Va.

Corresponds to lower part of Conemaugh fm.

Bayard sand.

A subsurface sand, of Upper Dev. (Chemung or Catskill) age and 3 to 30 ft. thick, lying 2,388 to 2,464 ft. below Pittsburgh coal in eastern Greene Co., Pa. The name is also used by drillers in W. Va. Named for Thomas Bayard farm, Whiteley Twp, Greene Co. Also called Sixth sand. Lies lower than McDonald sand and higher than Elizabeth sand. Two lower sands are called (descending) *Bayard Stray sand* and *Bayard Stray Stray sand.*

Bay City lime.

A name originally applied by miners to a zone of ls. cgl. at or near base of Dolores fm. in LaPlata dist., SW. Colo., but now applied by them to almost any limy beds in that dist., except the so-called "La Plata ls." forming basal bed of Morrison fm. Named for Bay City mine, on La Plata Creek.

Bay City moraine.

Pleistocene (Wisconsin stage): Eastern Michigan (The Thumb). Shown on moraine map (pl. 32) in U. S. G. S. Mon. 53. Named for Bay City.

Bay de Noc member (of Stonington beds).

Upper Ordovician (Richmond): Northern Michigan (Delta County).

R. C. Hussey, 1926 (Mich. Univ. Mus. Geol. Contr., vol. 2, No. 8, pp. 113–150). *Bay de Noc memb.*—Basal memb. of Stonington beds of Upper Ord. Richmond fm. Basal part of memb. is massive-bedded, argill. ls.; upper or main part consists of argill. ls. in alternate, comparatively thin, hard and soft layers. Grayish brown to dark brown. Thickness about 38 ft. Rests discon. on Bill's Creek beds and is conformably overlain by Ogontz memb. of Stonington beds. Chief exposure along E. shore of Little Bay de Noc, from 1½ mi. N. of Stratton's farm northward, and also S. to Stonington P. O.

Bayfield group.

Pre-Cambrian (upper Keweenawan): Northwestern Wisconsin (Douglas and Bayfield Counties).

F. T. Thwaites, 1912 (Wis. Geol. Nat. Hist. Surv. Bull. 25, p. 25). *Bayfield ss. group.*—Chiefly quartz sss. Formerly called *Western Lake Superior ss.* but correlation with Lake Superior ss. of Mich. doubtful. No fossils. Largely or wholly nonmarine. Thickness 4,300 ft. Included in upper Keweenawan. Divided into (descending) Chequamegon ss., Devils Island ss., and Orienta ss. Rests conformably on Oronto group. [As mapped covers a large part of Bayfield Co.]

C. K. Leith, 1935 (U. S. G. S. P. P. 184). Recent work by G. I. Atwater and G. M. Clement in NW. Wis. and NE. Minn. has established presence of a great structural discordance and erosional uncon. btw. lowest Upper Camb. ss. and uppermost Keweenawan Bayfield group.

Bayfield gravel.

Tertiary? (Pliocene?): Southwestern Colorado.

W. W. Atwood and K. F. Mather, 1932 (U. S. G. S. P. P. 166). *Bayfield gravel.*—Pebbles and boulders scattered over the surface at high levels within San Juan Mtn range or on crests of foothills. Lie at altitude of 8,000 to 13,000+ ft., but always near the summit levels. Composed chiefly of pebbles less than 5 inches diam. Thickness 0 to 200+ ft. Contemp. with Los Pinos and Bridgetimber gravels. Named for occurrence on several hills a few mi. N. of Bayfield, La Plata Co.

Bayhorse dolomite.

Cambrian (?): Southern central Idaho (Custer County).

C. P. Ross, 1932 (Idaho correlation chart compiled by M. G. Wilmarth). *Bayhorse dol.*—Generally massive, thick-bedded dol., in part oolitic. Thickness 1,000± ft. Assigned to Camb.(?). May possibly be Algonkian. Underlies (uncon.?) Ramshorn sh. and overlies (uncon.?) Garden Creek phyllite. Named for town and creek in Custer Co.

C. P. Ross, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 941, etc.). *Bayhorse dol.*—Chiefly thick-bedded dol. Most of beds light creamy gray when fresh, but weather readily to rusty buff; many are crowded with small nearly black, oval chert masses. Exceptionally the dol. is nearly black and studded with slightly larger white bodies, each consisting of a single crystalline grain of dol., commonly with rim of fine-grained carbonate, at least in part calcite. Locally beds of chert, qtzite, and cgl. or breccia, and some lenses, especially near top, are argill. Max. thickness fully 1,000 ft. Underlies Ramshorn sl. and overlies Garden Creek phyllite. Crops out at intervals along crest and E. flank of anticline that extends diagonally across NW. part of Bayhorse quad. Best exposed near town of Bayhorse. No fossils.

Bayloran series.

A term introduced by C. [R.] Keyes (Pan-Am. Geol., vol. 57, pp. 337, 350–355, 1932) to replace *Clear Fork group* of north central Tex., because "preoccupied by Broadhead, many years previously, for a coal measures section in west-central Mo." Named for Baylor Co., Tex., "through which the Clear Fork of Brazos River flows." [The Clear Fork group of Broadhead is a part of Cherokee sh. of Kans.]

Bayne series. (In Puget group.)

Eocene: Western Washington (Puget Sound region).

G. W. Evans, 1912 (Wash. Geol. Surv. Bull. 3, pp. 42–49). *Bayne series.*—Basal div. of Puget fm. in King Co. Consists of sss. and shales, with far greater percentage of sh. than in overlying Franklin series. Some coal and bony beds. Named for town in King Co.

C. E. Weaver, 1916 (Wash. Geol. Surv. Bull. 13). *Bayne memb.* (of Eocene of Green River Canyon, western Wash.).—Predominantly shales, with subordinate amounts of ss., shaly ss., and carbonaceous beds. Thickness 3,000 ft. Underlies Franklin memb.

Bayou Chicot limestone.

Upper Cretaceous(?): Southwestern Louisiana.

G. D. Harris and A. C. Veatch, 1899 (La. Geol. Surv., pt. 5, Rept. for 1899, p. 61). *Bayou Chicot ls.*—On average is of much darker color than Winnfield ls., but some fragments show tendency to white and blue banded structure so characteristic of Winnfield layers. Assigned to Ripley stage of Upper Cret. Outcrops about 8 mi. SW. of Bayou Chicot P. O., Evangeline Co.

D. C. Barton, 1936 (letter dated Dec. 23). Bayou Chicot ls. of Harris and Veatch, 1899, is cap rock ls. of Pine Prairie salt dome.

†Bayou Pierre phase.

Miocene(?) and later(?): Southwestern Mississippi.

L. C. Johnson, 1893 (Sci., vol. 21, pp. 90–91). The qtzitic phase of Grand Gulf Miocene, being only a phase of the next or Fort Adams or Ellisville phase roughly estimated. Extends from NW. corner of the fm. on Big Black River, to a curved line drawn across from Rodney to Pelatchie. It is most largely developed on Bayou Pierre and Cole's Creek. For convenience it may be called "Bayou Pierre phase." [All localities mentioned are in SW. Miss.]

Includes Catahoula ss. and possibly in places younger rocks. (See L. W. Stephenson, U. S. G. S. W. S. P. 576, pl. 2, 1928.)

Bayport limestone.

Mississippian: Michigan (Lower Peninsula).

A. C. Lane, 1899 (U. S. G. S. W. S. P. 30, p. 81), mentioned *Bayport ls.* as having "strongest possible resemblance to *Grand Rapids ls.* in character and in fossils, and both are intimately associated with and underlain by sss."

A. C. Lane, 1900 (Mich. Geol. Surv. vol. 7, pt. 2, btw. pp. 1 and 30). *Maxville or Bayport ls.*—Sandy yellow lss., cross-bedded white ss., a little dol. Thickness 20 to 50+ ft. Top fm. of Grand Rapids group or series. Overlies Michigan series [fm.]. At bottom of Coal Measures is a ss. separated off by Winchell under name of *Parma ss.* I believe Bayport ls. in its sandy phase is Parma ss. [Later repts by Lane and others treat Parma ss. as younger than Bayport ls., and of Pottsville age. *Maxville ls.* is an Ohio fm.]

Named for outcrops at Bayport, Huron Co., where it is quarried.

Bayport chert.

F. Dustin, in a paper (entitled "A study of the Bayport chert") describing Indian artifacts of Mich., described the chert from which the implements were made, and stated that it occurs "in the ls. most prominently exposed near Bayport, Huron Co.;" which is type loc. of Bayport ls. of geologic literature.

Bays sandstone.

Ordovician: Northeastern Tennessee and southwestern Virginia.

A. Keith, 1895 (U. S. G. S. Knoxville folio, No. 16, p. 4). *Bays ss.*—Red calc. and argill. ss.; changes in composition very slight. In Knoxville area the lime becomes more important than in other areas, and the rock is often an impure ls. Near Montvale feldspathic grains appear in the rock, and not far toward SW. they are an important element. The red color, however, is marked and persistent. Thickness 300 to 1,100 ft. Overlies Sevier sh. and underlies Clinch ss. Named for Bays Mtns, Hawkins and Greene Counties, Tenn.

Foregoing is definition as originally prepared by Mr. Keith, author of name. Mr. Keith's name was accepted by M. R. Campbell, who used it on a map of SW. Va. published in 1894 (Geol. Soc. Am. Bull., vol. 5, pl. 4), where the fm. was called *Bays* (*Red Medina*) *ss.*, and was shown as overlying Sevier sh. and underlying Clinch ss. (the name Clinch being here restricted to upper light-colored ss. of Safford's Clinch Mtn ss). The name was also used by Campbell in Estillville folio (No. 12), published in 1894. As defined in latter folio (which includes extreme N. end of Bays Mtn) the fm. consists of red ss. or sandy sh. 140 to 350 ft. thick, overlying Sevier sh. and underlying Clinch ss. In type area (described by Keith in Greeneville folio, No. 118, published in 1905) the fm. is everywhere an argill and calc. ss.; shows little change in appearance from place to place; color always red or brown; layers usually massive, but in some places thin and shaly; thickness 50 to 400 ft.; usually sharply separated from overlying Clinch ss., but in SW. end of Bays Mtn is more or less interbedded with the Clinch.

The Bays ss. was named "for its exposures in the Bays Mtns of Hawkins and Greene Counties, Tenn." (Morristown and Greeneville quads.). The geographic feature known as Bays Mtn extends from NW. part of Knoxville quad., across SE. corner of Maynardville quad., thence NE. across Morristown quad., the NW. corner of Greeneville quad., and SE. corner of Estillville quad. In Bays Mtn of all these quads. a fm. described as underlying Clinch ss. and overlying Sevier sh. was mapped as *Bays ss.* in early repts of U. S. Geol. Survey. But according to E. O. Ulrich and C. Butts the fm. thus mapped is not of same age in all of these areas, the Bays ss. of Estillville quad. being Juniata fm., of Upper Ord. (Richmond) age, while the Bays ss. SE. of Knoxville and at Bull Gap, in Morristown quad., is of Lowville age, a characteristic Lowville fossil (*Tetradium cellulosum*) having been found there at *base* of the rocks mapped as Bays ss.

Bays limestone.

In some areas the Bays ss. becomes so calc. that it is called *Bays ls.*

Bayview granodiorite.

Probably Cretaceous or Jurassic: Pend Oreille district, northern Idaho.

J. L. Gillson, 1927 (Jour. Geol., vol. 35, No. 1). Light-gray even-grained rock, speckled with very abundant biotite and hornblende crystals.

Named for exposures around Bayview, Kootenai Co.

Bay View Avenue sand.

Upper Cretaceous: Southeastern New Jersey.

J. K. Prather, 1905 (Am. Geol., vol. 36, pp. 171, 172, 175). *Bay View Ave. sand.*—Is a sand, although at first sight appears to be compact clay. Sometimes found as one bed, or may be made up of a number of small beds or lenses of local extent and 2 to 8 ft. thick. Color white to yellow, salmon, brown, orange, and red. Thickness 0 to 35 ft. Is probably upper part of Hazlet sand of Clark. Part of it may correspond to Wenonah sand of N. J. Survey, although on account of local variation it does not seem to fit this so well, and is therefore given a local name. Extends from Bay View Ave. Station near Atlantic Highlands some 800 ft. in direction of Hiltons.

Bay View Avenue lenses.

Upper Cretaceous: Southeastern New Jersey.

J. K. Prather, 1905 (Am. Geol., vol. 36, pp. 171, 172). *Bay View Ave. lenses*, Nos. 1, 3, 4, and 5. Lenses 4 and 5 are included as part of Bay View Ave. sand, and Nos.

1 and 3 as part of Mount Laurel sand. Lens No. 1 is 4 ft. thick and 120 ft. long; No. 3 is 4'5" thick and 120 ft. long; No. 4 is 2 ft. thick and 130 ft. long; No. 5 is 2 ft. thick and 70 ft. long.

†Bazoo porphyry.

A name applied locally, in Leadville dist., Colo., to Lincoln porphyry (Eocene). So called from its occurrence in Bazoo claim.

B. C. member.

Pre-Cambrian: British Columbia.

G. Hanson, 1935 (Canada Dept. Mines, Geol. Surv., Bur. Econ. Geol. Mem. 181, p. 4). *B. C. member of Richfield fm.* (lower fm. of Cariboo series), of Barkerville gold belt, Cariboo dist., B. C. [Apparently named for B. C. vein, on Cariboo claim.]

Beach formation.

Lower Ordovician: Newfoundland.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4). *Beach fm.*—Sss. and shales, underlying Eastern Head fm. and overlying McGraw bed. Included in Bell Island series. [Derivation of name not stated.]

Beach Mountain paramphibolite.

Pre-Cambrian: New York (eastern Adirondacks).

H. L. Alling, 1927 (Geol. Soc. Am. Bull., vol. 38, pp. 798–799).

Beacon Hill gravel.

Tertiary (Pliocene?): New Jersey.

R. D. Salisbury, 1894 (N. J. Geol. Surv. Ann. Rept. 1893, pp. 47–57, 67–72). *Beacon Hill sand and gravel* (also *Beacon Hill fm.*).—Oldest phase of the yellow gravel. Consists of coarse gravel, also fine-grained, and sand. Thickness 0 to 100 ft. Uncon. underlies Pensauken fm. and uncon. overlies Cret. Well developed and exposed on summit of Beacon Hill, 3 mi. S. of Matawan.

R. D. Salisbury, 1898 (N. J. Geol. Surv. Ann. Rept. State Geol. 1897, pp. 13–15), restricted Pensauken fm. to upper part of Pensauken fm. as defined by him in 1894, and introduced *Bridgeton fm.* for lower part. The fm. overlying Beacon Hill gravel is therefore now known as *Bridgeton fm.*

H. B. Kümmel and G. N. Knapp, 1904 (N. J. Geol. Surv. vol. 6, p. 137), *restricted Beacon Hill* to upper or gravel memb. (coarse gravel, chiefly quartz and chert) of the Beacon Hill of Salisbury, and applied *Cohansey sand* to lower memb. This is present accepted definition of *Beacon Hill gravel.*

Beadle Green granite.

Age (?): Northeastern Vermont (Orange County).

C. H. Richardson and C. K. Cabeen, 1923 (Vt. State Geol. Rept. 1921–22), stated that an intrusive *syenite* that occurs on Crompton Hill in SW. corner of Randolph Twp, Randolph quad., is locally known as *Beadle Green granite.*

Bead Mountain limestone member (of Belle Plains formation).

Permian: Central Texas (Colorado River region).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 421, 426). *Bead Mtn. bed.*—Largely dark-colored, hard, brittle, slightly shaly ls., alternating with softer light-gray ls. Thickness 6 to 50 ft. Memb. of Albany div. Underlies bed No. 12 (12 to 75 ft. of clay) and overlies Valera bed, which rests on Jagger Bend bed.

J. W. Beede and V. V. Waite, 1918 (Univ. Tex. Bull. 1816, map and section, pp. 12–13, 18, 21). [Cross section on map shows following downward succession: Grape Creek ls., *Bead Mtn. fm.*, Valera sh., Jagger Bend ls. They also gave detailed section of Wichita fm. in SW. Coleman Co. and stated:] It seems that No. 5 of this section was regarded as base of Drake's Bead Mtn. beds, but there are at least 2 lss. and 2 sh. beds below it which might be included in the section. Beginning with top of Jagger Bend beds, which is second fm. below this section, the worm tubes and reefs set in along Colorado River. It seems probable that beds Nos. 5 to 36, inclusive, constitute Drake's Bead Mtn beds. They have a thickness of 55 ft. 6 in., which is practically the thickness he ascribed to the fm. The rocks from top of Jagger Bend beds to top of Bead Mtn beds form a striking paleontological unit along Colorado River in SW. Coleman Co. and SW. Runnels Co., and probably should be included in a single fm. Through entire thickness of these rocks the dominating fossils are worm remains. Worm tubes are characteristic fossils of Bead Mtn fm, the oldest beds exposed in Runnels Co. The Bead Mtn fm. is overlain by Grape Creek fm. [This would include bed No. 12 in Bead Mtn fm.]

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, pp. 195, 198). *Bead Mtn ls.* is top memb. of Belle Plains fm. (middle fm. of Wichita group). Overlies Valera sh. memb. of Belle Plains and underlies Grape Creek sh. and ls. bed, the basal memb. of overlying Clyde fm.

Named for Bead Mtn, Coleman Co.

Beady formation.

Cretaceous (?): British Columbia.

F. A. Kerr, 1926 (Canada Geol. Surv. Summ. Rept. 1925, pt. A, p. 94).

Beale diorite.

Jurassic (?): Vancouver Island.

C. H. Clapp and J. A. Allan, 1911 (Canada Geol. Surv. map 17A).

V. Dolmage, 1920 (Canada Geol. Surv. Summ. Rept. 1919, pt. B, p. 15).

Bean Canyon formation.

Bean Canyon series.

Probably Triassic and Jurassic: Southern California (Los Angeles and Kern Counties).

E. C. Simpson, 1934 (Calif. Jour. Mines and Geol., vol. 30, No. 4, map and pp. 371–401). [*Bean Canyon series* on map; *Bean Canyon fm.* in table.] Schists, slates, qtzites, marble, crystalline ls., mica schist, amphibole schist, and andalusite-cordierite schist, meta-andesite and meta-dacite. Thickness 5,000 ft. [*Crystalline ls. of Bean Canyon series* mapped separately.] Named for excellent section in Bean Canyon, in NW. corner of Elizabeth Lake quad. Though a wider belt of schists is exposed in Bean Canyon than in the much larger roof pendants in the granitic rocks to W. (Tehachapi Mtns), the latter contain some 1,500 ft. of ls. compared with 200 ft. of it in Bean Canyon. No fossils. Probably in part Triassic and possibly in part early Jurassic.

Bear Branch limestone member (of Olive Hill formation).

Lower Devonian (Helderbergian): Western Tennessee.

C. O. Dunbar, 1918 (Am. Jour. Sci., 4th, vol. 46, p. 738). *Bear Branch memb.*—Massive ls. and oolitic hematite to N.; impure cherty ls. to S. Is more impure than overlying Flat Gap memb., and is cross bedded. Thickness 0 to 45 ft. Is middle memb. of Olive Hill fm., of Helderberg age. Overlies Ross ls. memb. Named for exposure on Bear Branch, about 2 mi. SE. of Olive Hill, Hardin Co., where it forms low bluff showing 20 ft. of low-grade ore resembling Clinton ore. Probably more or less = Pyburn ls. memb. of Olive Hill fm. at Pyburns Bluff, on Tenn. River.

C. O. Dunbar, 1919. (See 1919 entry under *Pyburn ls. memb.*)

Bear Creek shale. (In Clinton formation.)

Silurian: Central New York.

G. H. Chadwick, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 327–368). *Bear Creek sh.*—Fossiliferous sh. just beneath Furnaceville ore at old "Wolcott ore bed" on Bear Creek (Black Creek of topographic map) [Wayne Co.]. If distinct from the Martville[ss.], the Bear Creek sh. will lie above rather than below it. [Belongs in lower part of Clinton fm.]

E. O. Ulrich, 1923 (Md. Geol. Surv. Sil. vol., p. 191), placed *Bear Creek sh.* above Reynales ls. and below Sterling ore, and included Furnaceville sh. in Reynales ls.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 317, 324, 326), placed *Bear Creek sh.* below Sterling Station ore and above Reynales ls., and included *Furnaceville ore* in the Reynales. She described *Bear Creek sh.* in Rochester section as consisting of 18 ft. of purple and olive shales with thin plates of fossiliferous ls.

J. T. Sanford, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 194). The former *Bear Creek* of Genesee Gorge is designated *Brewer Dock memb. of the Reynales*, as the fm. at Bear Creek is younger.

Bearian series.

A term applied by C. R. Keyes to the deposits underlying his Bentonian series and overlying his Dakotan series.

Bear Mountain granite.

Pre-Cambrian(?): Central northern Colorado (Summit County).

H. B. Patton, 1909 (Colo. Geol. Surv. 1st Rept., p. 128, map). *Bear Mtn granite.*—Gray medium-grained biotite granite. Closely resembles Santa Fe granite, but is a biotite granite and not a biotite-muscovite granite. Occurs in more or less isolated patches and dikes. Forms summit of Bear Mtn, Summit Co. Is in contact with hornblende-gneiss series (pre-Camb.).

Bear Mountain formation.

Silurian: Mackenzie.

E. M. Kindle, 1921 (Canada Geol. Surv. Summ. Rept. 1920, pt. B, p. 45).

Bear Mountain erosion surface.

Tertiary: Northeastern Utah and southwestern Wyoming (Uinta Mountains).

W. H. Bradley, 1936 (U. S. G. S. P. P. 185). Older than Browns Park fm. and probably late Mio. or early Plio. Named for fact one of its more conspicuous remnants is the nearly level top of Bear Mtn, Utah.

Bear Passage granite.

Age(?): Ontario (Rainy Lake district).

A. C. Lawson, 1913 (Canada Geol. Surv. Mem. 40, p. 99).

Bearpaw shale. (Of Montana group.)

Upper Cretaceous: Northern, eastern, and southern Montana and Elk Basin region of central northern Wyoming; also southern Alberta.

J. B. Hatcher and T. W. Stanton, 1903 (Sci., n. s., vol. 18, pp. 211–212) and 1905 (U. S. G. S. Bull. 257). *Bearpaw shales.*—Dark clay sh., with many calc. concretions. Of marine origin. Thickness 600 to 700 ft. Conformably overlies Judith River beds. Well developed around N., E., and S. borders of Bearpaw Mtns. Not yet determined whether Bearpaw includes equivalents of Fox Hills ss. or is wholly of Pierre age.

T. W. Stanton, 1919 (U. S. G. S. P. P. 120, p. 187), correlated Bearpaw sh. with upper part of Pierre sh. and lower part of Fox Hills ss.

In central Mont. the Bearpaw is overlain by Lennep ss. (of Fox Hills age) and in NW. Mont. it is overlain by Horsethief ss. (also of Fox Hills age).

Bear Pond schist.

Pre-Cambrian: Northern New York (Adirondacks).

H. L. Alling, 1918 (N. Y. State Mus. Bull. 199). *Bear Pond schist.*—A feldspar quartz-graphite schist, included in Grenville series. Is older than Beech Mtn amphibolite and younger than Catamount schist. Thickness 30± ft. Type loc. is Bear Pond, Ticonderoga Twp, Essex Co.

Bear River formation.

Upper Cretaceous: Southern Wyoming.

F. V. Hayden, 1869 (U. S. Geol. Surv. Colo. and N. Mex., 3d Ann. Rept. Hayden Surv., pp. 91, 92). I have named the group of coal strata that is exposed beneath the middle tert. beds by upheaval at Bear River City [Wyo.], Evanston [Wyo.], and Coalville [Utah], the *Bear River group.* In cut just W. of Bear River City the beds contain the greatest profusion of molluscan life I have ever seen in tert. beds of West. There seems to be mingling of fresh and brackish water fossils. Flora and fauna are distinct from those of any other fm.

inclined to regard the beds of lower tert. age. [Relations to Wasatch and other fms. not explained.]

F. V. Hayden, 1870 (Am. Phil. Soc. Proc., vol. 11, pp. 420–425). *Bear River group* is composed of clay, ls., ss., marl, gypseous earth, bituminous and fossiliferous sh. Is exposed in R. R. cuts about 1 mi. W. of Bear River. [Gives detailed section.]

F. B. Meek, 1873 (U. S. Geol. and Geog. Surv. Terr. 6th Ann. Rept., p. 462). Brackish-water beds of Bear River have always been regarded by me as Lower Eo., but I am not wholly without suspicion they may prove to be Cret.

E. D. Cope, 1874 (U. S. Geol. and Geog. Surv. Terr. 7th Ann. Rept., pp. 435–444, and Bull. No. 2, pp. 8–15), and F. V. Hayden, 1874 (U. S. Geol. and Geog. Surv. Terr. Bull. 1, No. 2, pp. 1–2), assigned *Bear River group* to Cret.

C. A. White, 1883 (U. S. Geol. and Geog. Surv. Terr. of Wyo. and Idaho for 1878, pt. 1, pp. 52–53). I formerly included *Bear River series* in Laramie group, but lower part, which is of brackish water origin, contains a molluscan fauna, every known sp. of which is distinct from other fms. and different from any found in any other parts of regional divisions of Laramie group. It is serious question whether we ought not to regard Bear River series as separate div. of Laramie group, if not a separate group. Continuity of Bear River series with great body of Laramie group elsewhere is not known to exist.

C. A. White, 1888 (Am. Geol., vol. 2, footnote in Cope's paper on pp. 265–267). Fauna of *Bear River Laramie* is entirely different from that of Laramie proper, but I do not know which is older.

C. A. White, 1891 (U. S. G. S. Bull. 82, p. 153). The so-called *Bear River Laramie* I have long believed to be considerably older than Laramie fm. proper.

C. A. White, 1892 (Am. Jour. Sci., 3d, vol. 43, p. 97). *Bear River fm.* is not=Laramie, but underlies equiv. of the Fort Benton.

T. W. Stanton, 1893 (U. S. G. S. Bull. 106, pp. 15–16, 45–46). *Bear River fm.*—Brackish-water deposits, 650 to 2,500 ft. thick. Has recently been shown to occupy much lower horizon than Laramie fm., or probably about that of the Dakota.

T. W. Stanton, 1903 (Am. Phil. Soc. Proc., vol. 42, p. 192). *Bear River fm.*—Cgls., sss., and shales, 4,000 ft. thick, containing a large and peculiar fresh-water fauna. Principal known area extends from neighborhood of Evanston northward near W. bdy of Wyo. for more than 100 mi. Is known to lie btw. the Fort Benton [Benton] and the marine Jurassic. Indications are that the Bear River and the Dakota are of nearly same age. [See also T. W. Stanton, 1913 (Wash. Acad. Sci. Jour., vol. 3, p. 63).]

Later field work showed thickness of *Bear River fm.* to range from 500 to 5,000± ft., and it is now believed to include considerably more than the equiv. of Dakota ss.

Bear River beds.

Upper Paleozoic: Northwestern British Columbia (Portland Canal region).

A. Bowman, 1889 (Canada Geol. Surv., vol. 3, pt. 1, pp. 20C to 22C). *Bear River beds, Upper Paleozoic,* include Bear River ls. and Cherty series.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d series, vol. 6, sec. 4, p. 207), assigned *Bear River fm.*, B. C., to Dev.; W. L. Uglow, 1923 (Canada Geol. Surv. Summ. Rept. 1922, pt. A, p. 84), assigned *Bear River series* of B. C. to Carbf.; R. G. McConnell's repts have also described this fm. or a younger (?) Mesozoic *Bear River fm.*

Bear River series.

Miocene: Northern California (Humboldt County).

W. Stalder, 1915 (Calif. State Min. Bur. Bull. 69, pp. 447–449). *Bear River series.*—Conglomeratic sss. and cgl., resting on aren. bands and yellowish sss. of medium texture, poorly cemented, underlain by 300 ft. of shales of nodular character containing a little interbedded ls. and some glauconitic sand. Very fossiliferous at south fork of Bear River. Thickness 750 ft. Assigned to upper Mio. Underlies Wild Cat series and overlies Rainbow series (post-Franciscan).

†Bear River formation.

Jurassic or Triassic: Northwestern British Columbia.

S. J. Schofield and G. Hanson, 1921 (Canada Geol. Surv. Summ. Rept. 1920, pt. A, p. 8). *Bear River fm.*, Jurassic, B. C. [Hanson in 1929 (Canada Geol. Surv.

Mem. 159, p. 7, assigned *Bear River fm.* of B. C. to Jurassic or Triassic. Canada Geol. Surv. Summ. Rept. 1923, pt. A, p. 34, stated this name should be abandoned, and *Hazelton group* used instead.]

Bear River greenstones.

Age (?): British Columbia.

W. V. Smitheringale, 1928 (Econ. Geol., vol. 23, pp. 193, 194). *Bear River greenstones,* B. C.

Bear Run member (of Pottsville formation).

Pennsylvanian: Southern Ohio.

H. Morningstar, 1922 (Ohio Geol. Surv. Bull. 25, pp. 13, 25–28, 299–300). *Bear Run memb. of Pottsville fm.*—Sh., blue, locally fossiliferous, 2± ft. thick, underlain by Bear Run coal, 1½± ft. thick. Lies 17 ft. below Vandusen coal and 27 ft. above Quakertown or No. 2 coal. [Derivation of name not stated. *Bear Run coal* had been in use many years in Ohio, but this appears to be the first time that the coal and overlying blue sh. were combined into a memb. called *Bear Run memb.*]

Bears Brook formation.

Cambrian: Nova Scotia.

M. Y. Williams, 1911 (Canada Geol. Surv. Summ. Rept. 1910, p. 241).

Beartooth quartzite.

Cretaceous (Upper?): Southwestern New Mexico (Silver City region).

S. Paige, 1916 (U. S. G. S. Silver City folio, No. 199). *Beartooth qtzite.*—Qtzite with a little interbedded sh.; at base in many places is a thin cgl. containing black and white quartz pebbles an inch or more in diam. in matrix of clearly washed, fine, glassy quartz grains. Thickness 90 to 125 ft. Lies uncon. on rocks ranging from pre-Camb. to Penn. (Fierro ls.). Overlain, apparently conformably, by Colorado sh., from which it is easily distinguished, the separation being at top of uppermost qtzite bed. No fossils. Age in doubt. Tentatively classified as Upper (?) Cret. Named for Beartooth Creek, near Fort Bayard.

Beartooth Butte formation.

Lower Devonian: Northwestern Wyoming (Park County).

E. Dorf, 1934 (Jour. Geol., vol. 42, pp. 723–737). *Beartooth Butte fm.*—Thin-bedded red and buff impure shales, ls. cgl., and massive gray ls.; coarse basal cgl. Thickness 0 to 150 ft. Underlies Jefferson ls. with slight, uncon. and overlies Bighorn dol. with marked discon. Is a channel deposit. Occurs only on Beartooth Butte, in SW. corner of T. 58 N., R. 105 W., Park Co., Wyo., 3 mi. S. of Mont. line, just NW. of Beartooth Lake; and in Crandall quad. of Absaroka folio. Lower Dev. fauna and flora. [Gave a detailed section of the 4 unnamed members of which t is composed.]

Bearwallow conglomerate. (In Pottsville group.)

Pennsylvanian: Southern West Virginia and southwestern Virginia.

M. R. Campbell, 1897 (U. S. G. S. Tazewell folio, No. 44). *Bearwallow cgl.*—Coarse cgl. in most places, but in some places the pebbles are absent and the rock is coarse ss. Thickness about 60 ft. Underlies Dotson ss. and overlies Dismal fm. Named for Bearwallow Ridge, W. of Dry Fork, McDowell Co., W. Va.

According to H. Hinds, 1918 (Va. Geol. Surv. Bull. 18), the typical Dotson ss. is same as typical Bearwallow cgl.

Bearwallow facies.

Name applied by P. B. Stockdale (Ind. Dept. Cons., Div. Geol. Pub. 98, pp. 76, 288, etc., 1931) to a lithologic development of his Edwardsville fm. in a part of southern Ind.

Beattie formation. (In Council Grove group.)

Permian: Northeastern Kansas and southeastern Nebraska.

G. E. Condra and C. E. Busby, 1933 (Nebr. Geol. Surv. Paper No. 1, p. 13). *Beattie fm.*—In section on West Branch Creek, NW. ¼ of sec. 10, T. 1 N., R. 10 E., 3½ mi. S. and 7 mi. W. of Pawnee City, Pawnee Co., Nebr., it consists of (descending): Morrill ls., 1 ft.; Florena sh., 8 ft.; and Cottonwood ls., 11½ ft. The Kans. Geol. Surv. is to group the Morrill, Florena, and Cottonwood as *Beattie fm.;* type loc., Beattie, Marshall Co., Kans. The Nebr. Surv. concurs.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 7), followed above classification, as did R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22).

Beatty sand.

A subsurface sand, 25 ft. thick, in Bradys Bend well, about 85 mi. SW. of Bradford, Pa., which is considered approx. same as Tiona sand.

Beattyville shale. (In Pottsville group.)

Pennsylvanian: Southeastern Kentucky.

A. M. Miller, 1917 (Table of geological formations of Ky., p. 2), and 1919 (Dept. Geol. and Forestry Ky., ser. 5, Bull. 2, pp. 10, 147—tables only). *Beattyville substage* (also *Beattyville shales*).—Mainly shales; ss.; coal from 2 seams 3 to 4 ft. thick—Beaver Creek (Beattyville and Hudson). Bituminous ss. of Carter Co., and some of that of W. Ky. Is lower part of Lee fm., beneath Rockcastle ss. [Apparently named for Beattyville, Lee Co. In 1919 rept Miller gave thickness as 40 to 150 ft.]

Beauceville series.

Ordovician: Quebec.

B. R. MacKay, 1921 (Canada Geol. Surv. Mem. 127, pp. 12, 24).

Beauharnois formation.

Ordovician: Ontario and Quebec.

E. J. Chapman, 1863 (Can. Inst., n. s., vol. 8, pp. 186–190). [Assigned to Camb., but all later repts assign these rocks to Ord.]

Beaumont clay.

Pleistocene: Eastern Texas.

W. Kennedy, 1903 (U. S. G. S. Bull. 212, pls. 1, 2, pp. 20, 27). *Beaumont clays.*—Brown, blue, yellow, gray, and black clays, in places carrying nodules of ls. irregularly distributed through the clays; interstratified with gray, grayish white, brown and blue sands. Thickness 25 to 400 ft. Overlies Columbia sands [Lissie fm.] and underlies Recent coastal marsh deposits in eastern div. of Tex.-La. Gulf Coastal Plain.

A. Deussen, 1924 (U. S. G. S. P. P. 126), gave thickness of 300 to 900 ft.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, p. 789). Beaumont clay is uncon. on Lissie fm.

Named for Beaumont, Jefferson Co.

Beauport sands and gravels.

Quaternary: Canada.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 224).

Beauvais sandstone.

Middle Devonian: Eastern Missouri (Ste. Genevieve County).

C. L. Dake, 1918 (Mo. Bur. Geol. and Mines vol. 15, 2d ser., pp. 88, 174–175). *Beauvais ss.*—Name taken from unpublished ms. of S. Weller. Consists of very pure quartz sand of medium grain, well rounded. Chiefly very white and moderately friable, but at places becomes stained and indurated. Underlies St. Lorens [St. Laurent] ls. and overlies Grand Tower ls. Lithologically closely resembles St. Peter ss. Max. exposed thickness 50 ft.

S. Weller and S. St. Clair, 1928 (Mo. Bur. Geol. and Mines vol. 22, 2d ser., pp. 148–150). *Beauvais fm.*—[Same definition as above.] In some places the ss. becomes harder, finer grained, and somewhat qtzitic. Type exposures along Little Saline Creek, in Beauvais Twp, Ste. Genevieve Co. Occurs only within Little Saline faulted zone in Ste. Genevieve Co. The sand of fm. was clearly derived from St. Peter ss. No evidence of uncon. with overlying St. Laurent ls. but there may be uncon. btw. Beauvais and underlying Grand Tower ls. Fossils rare. Probably of early Hamilton age, but possibly of latest Onondaga age.

Beaver division.

Upper Cambrian or Lower Ordovician: Central Texas.

T. B. Comstock and E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. 259–306). *Beaver div.*—Lower 200 ft. chiefly sandy buff dolomites with some dark dol. in upper third, called *Cavern subdivision,* from caves and grottoes in it; lower 60 to 80 ft. nonfossiliferous, blue mag. dolomites, in beds 5 to 20 ft. thick, called *Bluff subdivision,* from exposures in bluffs. Basal div. of Leon series. Underlies Wyo div. and overlies Potsdam.

Named for Beaver Creek, Burnet Co.

†Beaver limestone.

Lower Cambrian: Eastern Tennessee.

A. Keith, 1895 (U. S. G. S. Knoxville folio No. 16, p. 3). *Beaver ls.*—Massive blue ls. about 300 ft. thick. Overlies Apison sh. and underlies Rome fm.

Foregoing is original definition of fm. in type region. The name, however, was incidentally referred to by C. W. Hayes in 1894 (Geol. Soc. Am. Bull., vol. 5, p. 467), in description of gray siliceous ls. underlying Rome fm. in vicinity of Rome, Ga., which was "provisionally correlated with the Beaver ls., which occupies a similar position in the stratigraphy of east Tennessee, and has been there determined as lower Cambrian." The name was also used in Ala. Later work, however, proved that the ls. of Beaver Ridge, N. of Knoxville, Tenn., for which the ls. beneath Rome fm. and above Apison sh. was named, is Rutledge ls. faulted over, and that so-called "Beaver ls." of Ga. and Ala. is Shady dol., which is older than the Apison. *Beaver* has therefore been discarded and a new name has not yet been adopted for the ls. btw. Rome fm. and Apison sh. of Tenn. (See L. LaForge, Ga. Geol. Surv. Bull. 35, 1919, pp. 43–45.) C. E. Resser (personal communication, May 1936) considers the Apison sh. as a part of Rome fm., and the so-called Beaver ls. of Knoxville folio as a ls. lentil in Rome fm.

Beaver gypsum.

Permian: Panhandle of Oklahoma.

F. W. Cragin, 1897 (Am. Geol., vol. 19, pp. 359, 363). *Beaver gyp.*, of Beaver Co., is well up in Kiger div. Seems to belong to lower horizon than One Horse gyp. or Old Crow gyp. Named for occurrence near Beaver City and in Beaver Co. and river basin of Beaver, Okla.

†Beaver sandstone. (In Pottsville group.)

Pennsylvanian: Eastern Kentucky (Magoffin County).

I. B. Browning and P. G. Russell, 1919 (Ky. Geol. Surv., 4th ser., vol. 5, pt. 2, btw. pp. 11 and 18). *"Beaver" ss.*—Massive, white, coarse-grained, cliff-forming ss., containing small white quartz pebbles. Thickness 160 ft. The lowest rock exposed in Magoffin Co. Probably = Nuttall ss. of W. Va. Is "Beaver" sand of oil drillers. Overlies Mine Fork coal and lies 60 to 90 ft. below Wheelersburg coal.

Beaver "sand."

A subsurface *ls.* in base of New Providence fm. (Miss.) of southern Ky. and in Highland Rim section of Tenn. Has also been called *Beaver Creek "sand."* *Beaver* has also been applied to a sand of Penn. age in eastern Ky. (See under †*Beaver ss.*)

Beaver granite.

Trade name of granite quarried at Beaver, Utah.

†Beaver group.

Pennsylvanian: Pennsylvania.

Same as *Beaver River fm.*

†Beaver Bay diabase.

Pre-Cambrian (Keweenawan): Northeastern Minnesota.

R. D. Irving, 1883 (U. S. G. S. 3d Ann. Rept., pl. 14, pp. 143–146). *Beaver Bay group.*—Characterized by predominance of black, coarse-grained, olivine-bearing gabbro in very heavy layers without amygdaloids, and by great abundance and prominence of included red felsitic porphyries and granite-like rocks, also considerable thickness of fine-grained ashbed diabases, with and without amygdaloids, and some ordinary fine-grained diabases with amygdaloids. Thickness 4,000 to 6,000 ft. Underlies Temperance River group and overlies Agate Bay group, all included in Keweenaw series. Exposed on Beaver Bay, Minn.

A. H. Elftman, 1898 (Am. Geol., vol. 21, pp. 90–109, 175–188, and map). *Beaver Bay diabase.*—Chiefly massive flows of coarse diabase. Includes part of Duluth, Lester River, Agate Bay, and Beaver Bay groups of Irving. Forms greater part of Irving's Beaver Bay group. Named because all essential characters appear in region of which Beaver Bay forms central point.

The U. S. Geol. Survey uses *diabase of Beaver Bay* in a geographic sense.

†Beaver Bay group.

See under *†Beaver Bay diabase.*

Beaver Bend limestone. (In Chester group.)

Mississippian: Southwestern Indiana and central northern Kentucky.

C. A. Malott, 1919 (Ind. Univ. Studies, vol. 6, No. 40, pp. 7–20). *Beaver Bend ls.*—Bedded ls., often having massive beds, and highly oolitic; conspicuously jointed. Thickness 0 to 14 ft. Is upper ledge of Mitchell ls. Underlies Brandy Run ss. and overlies Sample ss. Named for conspicuous bend in Beaver Creek just E. of Huron, Lawrence Co., Ind.

Later repts give thicknesses up to 118 ft.

Beaverburk limestone. (In Wichita group.)

Permian: Central northern Texas (Wichita, Baylor, and Archer Counties).

J. A. Udden and D. M. Phillips, 1912 (Univ. Tex. Bull. 246, pp. 31–36, 42–43). *Beaverburk ls.*—Ls., capping upland bluffs on N. side of Wichita River in SW. corner of Wichita Co. Mostly tough dark-gray rock, 0 to 3 ft. thick. Traced from basin of Beaver Creek NE. to Burk. Memb. of Wichita fm., 125 ft. above base. Separated from overlying Bluff bone bed by 65 ft. of sh. Lies 102 ft. below top of Wichita fm., and the Wichita rests on the Cisco. Fossils listed. Named for development in basin of Beaver Creek and exposures at and around Burk, Wichita Co.

W. E. Hubbard and W. C. Thompson, 1926 (A. A. P. G. Bull., vol. 10, No. 5). *Beaverburk ls.*, or, more properly, *dol.*, is important key horizon and can be traced SW. to S. line of Baylor Co.

A. S. Romer, 1928 (Univ. Tex. Bull. 2801, pp. 69–76). *Beaverburk (?) ls.* is top bed of Belle Plains fm. in Baylor and Archer Counties.

M. G. Cheney, 1929 (Univ. Tex. Bull. 2913), placed *Beaverburk ls.* in interval btw. Bead Mtn ls. above and Elm Creek ls. below.

M. M. Garrett, A. M. Lloyd, and G. E. Laskey, 1930 (Tex. Bur. Econ. Geol. map of Baylor Co.), assigned *Beaverburk ls.* to top of Belle Plains fm., as did J. Hornberger, Jr., 1932 (Tex. Bur. Econ. Geol. map of Throckmorton Co.).

F. B. Plummer, 1932 (Tex. Bur. Econ. Geol. geol. map of Callahan Co.), assigned *Beaverburk ls.* to top of Belle Plains fm. and 20± ft. above Bead Mtn ls.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 169, 173), included in top of Belle Plains fm. the Bluff bone bed of Udden and Beaverburk ls. of Udden, both of which he assigned to higher horizon than Bead Mtn ls. The Bead Mtn ls. is top memb. of Belle Plains fm. according to original definition and usage, and Clyde fm. overlies Belle Plains.

Beaver Creek coal group.

A term applied to a group of Eocene strata, of Fort Union (?) age, in SW. N. Dak., which includes coals N, O, and P. (See A. G. Leonard, 1908. N. Dak. Geol. Surv. 5th Bien. Rept.)

Beaver Creek "sand."

Mississippian: South-central Kentucky (Wayne, Pulaski, and Russell Counties).

D. C. MacLachlan, 1928 (Papers Mich. Acad. Sci., Arts, and Lett, vol. 8, pp. 298, 302). The massive, uneven-bedded, very hard, siliceous, pinkish gray ls. containing irregular masses of chert, and 5 to 10 ft. thick, occurring 40 to 45 ft. above base of New Providence sh. is so-called Beaver Creek "sand."

Beaver Creek chalky member (of Niobrara formation).

Upper Cretaceous: Northeastern Wyoming and southeastern Montana.

W. W. Rubey, 1930 (U. S. G. S. P. P. 165A). *Beaver Creek chalky memb.*—Chalk marl and calc. siltstone, gray where fresh; weathers to light yellow. Marine fossils. Thickness 125 to 200 ft. Upper memb. of Niobrara fm. Overlies Sage Breaks sh. memb. of Niobrara. Named for exposures along Beaver Creek, in T. 46 N., R. 64 W., Weston Co., Wyo.

Beaverdell quartz monzonite.

Eocene (?): British Columbia.

L. Reinecke, 1915 (Canada Geol. Surv. Mem. 79, pp. 48, 51).

Beaver Falls moraine.

Pleistocene: Northwestern New York (Lowville quadrangle).

A. F. Buddington, 1934 (N. Y. State Mus. Bull. 296, p. 42). "Not well defined. Extends S. from Beaver Falls 2 mi., and N. extension is indicated btw. 2 and 3 mi. N.-NW. of Beaver Falls."

Beaverfoot formation.

Upper Ordovician (Richmond): British Columbia and Alberta.

L. D. Burling, 1922 (Geol. Mag., vol. 59, pp. 453, 454).

C. D. Walcott, 1923 (Smithsonian Misc. Coll., vol. 67, No. 8, p. 463), gave a rather complete definition of the fm., and it has also been described in several repts by other geologists. Its Upper Ord. (Richmond) age seems to be generally accepted.

Beaver Mountain group.

Tertiary or Mesozoic: Southern British Columbia and northeastern Washington.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, maps 7, 8, 117° to 118°). [Maps show following blocks: *Beaver Mtn sediments* (gray and brown shales and sss.) and *Beaver Mtn volcanics* (flows and pyroclastic deposits of augite andesite and basalt), both assigned to Tert.]

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, pp. 317, 352). *Beaver Mtn group.*—It is proposed that *Beaver Mtn volcanic group* be extended to all lavas and pyroclastics of the complex which are contemp. with those shown typically on and in vicinity of Beaver Mtn [B. C.?]. In this area 2 patches of waterlaid clastics contemp. with the volcanics are mapped. A small outcrop of them also occurs on railway near the water tank at Beaver [B. C.?]. These sediments may be called *Beaver Mtn sediments*. They consist of black to dark-gray and brown thin-bedded shales and gray and greenish thin-bedded to massive sss. A massive cgl. crops out just W. of Champion Station. Plants, but no diagnostic fossils. More than 1,000 ft. of the sediments are exposed in section running from Champion Station eastward into Beaver Mtn. There is some ground for referring the *Beaver Mtn sediments and volcanics* to Mesozoic [but they are tentatively classified as Tert.].

Beaver River formation. (In Pottsville group.)

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia(?).

J. P. Lesley and I. C. White, 1876 (2d Pa. Geol. Surv. map of Beaver Co.), used *Beaver River group* for rocks beneath "Clarion group," which probably correspond in whole or in part to Pottsville fm.

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q, pp. 65–71). *Beaver River group.*—Underlies fire clay beneath Brookville coal. Typical section is along Big Beaver River and Connoquenessing Creek in Beaver Co., Pa., the only place it is exposed in Beaver Co., and where it consists of (descending): Upper Homewood [Homewood] ss., 155 ft.; shales, 20 to 80 ft.; Connoquenessing (Lower Homewood) ss., 115 ft.; and Sharon shales, 7+ ft.

J. P. Lesley, 1878 (2d Pa. Geol. Surv. Rept. Q, pp. 65–66). For local use in western Pa. there is no objection to term *Beaver River group*, provided it be clearly understood that the term has the same systematic value as those of the Freeport, Kittanning, and Clarion groups, and that the group is the lowest part of the well-established Allegheny River series, being synonymous with the so-called Sharon coal series.

J. P. Lesley, 1879 (2d. Pa. Geol. Surv. Rept. V). *Beaver River cgl. series* includes Homewood ss. at top and Sharon Lower ss. at base.

H. M. Chance, 1879 (2d Pa. Geol. Surv. Rept. V, pp. 6–34 and map). *Beaver River or Congl. series (No. XII, Pottsville cgl.).*—Includes Homewood ss. (at top), Mercer group, Connoquenessing sss., Sharon group, and Sharon cgl.

H. M. Chance, 1881 (The Virginias, vol. 2, p. 153). The term "Beaver River series" was proposed as a substitute for the conglomerate measures by Prof. White and myself in 1876. I think the name *New River series* may now appropriately replace it.

I. C. White, 1908 (W. Va. Geol. Surv., vol. 2A, pp. 14–16). *Beaver group (Upper Pottsville)* of W. Va., includes (descending) Homewood ss. stage, Mercer stage, and Connoquenessing ss. stage. The underlying Sharon ss. (basal bed of Pottsville series in western Pa. and Ohio) is included in New River group and correlated with Nuttall ss.

J. J. Stevenson, 1908 (Am. Phil. Soc. Proc., vol. 51), excluded Sharon cgl. from *Beaver River fm.*

The W. Va. Geol. Surv. now applies *Kanawha fm.* to upper Pottsville deposits down to top of Nuttall ss. lentil, and does not use *Beaver* or *Beaver River*. The Pa. Geol. Surv. also seems to have abandoned these names. The 1923 classification of State Geologist Geo. H. Ashley uses Kanawha for the upper Pottsville rocks.

Beavertail limestone.

Devonian: Mackenzie.

E. M. Kindle, 1921 (Canada Geol. Surv. Summ. Rept. 1920, pt. B, p. 46).

Beavertown marl. (In Brassfield limestone.)

Silurian: Southwestern Ohio.

A. F. Foerste, 1885 (Denison Univ. Sci. Lab. Bull. 1, p. 65). *Beavertown marl.*—Fine clayey or marly bed, 9 inches thick; in some places becomes quite hard and in others is replaced by soft blue clay. For present included in [so-called] Clinton group [Brassfield ls.], at top.

A. F. Foerste, 1909 (Cincinnati Soc. Nat. Hist. Jour., vol. 21, pp. 1–8). Dayton ls. includes at base fine-grained ls. 9 inches thick for which name *Beavertown marl* has been used.

A. F. Foerste, 1923 (Denison Univ. Sci. Lab. Jour., vol. 20, p. 40). In SW. Ohio the *Beavertown marl* is regarded as upper part of Brassfield ls. The name was not intended to designate the richly fossiliferous clay forming upper part of the Brassfield, but was used to designate a soft, very fine-grained deposit, an argill. ls., and not a marl in any sense of the term. The large crinoid beads it contains are of same type as those in upper part of Brassfield ls.

A. F. Foerste, 1935 (Denison Univ. Sci. Lab. Jour., vol. 30, p. 149). *Beavertown marl* was applied by Foerste in 1885 to indurated fine-grained argill. rock resting on top of typical Brassfield fm. at various localities in vicinity of Dayton, the more fossiliferous phases being located near Beavertown, SE. of city and

SE. of Soldiers Home, W. of city. [Lists fossils.] The occurrence of ***Aspidopora parmula*** in this marl and in underlying typical Brassfield suggests the Beavertown is essentially of same age as the Brassfield, differing chiefly in its depauperate fauna.

Beccaguimic formation.

Ordovician: New Brunswick.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 199). Exposed along Beccaguimic River.

Bechler conglomerate. (In Gannett group.)

Cretaceous (?): Southeastern Idaho.

G. R. Mansfield and P. V. Roundy, 1916 (U. S. G. S. P. P. 98, pp. 76, 82). *Bechler cgl.*—Gray, reddish, and "salt and pepper" sss. with interbedded cgls. Pebbles of cgl. are small, few having diam. of more than 1 inch. Thickness 1,775 ft. Underlies Draney ls. and overlies Peterson ls.; all in Gannett group. Named for Bechler Creek, which enters Stump Creek from N. about ¼ mi. N. of mouth of Boulder Creek, T. 6 S., R. 45 E., Boise meridian, Bannock Co. May be Jurassic.

Becket granite gneiss.

Pre-Cambrian: Western Massachusetts, western Connecticut, and southwestern Vermont.

B. K. Emerson, 1892 (U. S. G. S. Hawley sheet, i. e., proof sheets of geol. maps and text intended for a geol. folio, but never completed and published in that form, although cited in U. S. G. S. Bull. 191, 1902). *Becket gneiss*, a light-gray biotite gneiss, underlies Cheshire qtzite.

B. K. Emerson, 1898 (U. S. G. S. Holyoke folio, No. 50; also U. S. G. S. Mon. 29, pp. 18, 31–38, pl. 34). *Becket gneiss* (also *Becket white cgl. gneiss*).—Light gray biotite gneiss, at times a cgl. Thickness 2,000 (?) ft. Uncon. underlies Hoosac schist and uncon. overlies Washington gneiss. [Shown on p. 18 as underlying Cheshire qtzite.]

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 150–155), called the fm. *Becket granite gneiss*. "Named for fact it is quarried at Becket, Mass."

W. M. Agar, 1929 (Am. Jour. Sci., 5th, vol. 17, pp. 197+). *Becket quartz monzonite gneiss (intrusive)*.—B. K. Emerson chose the even-grained slightly gneissic rock of the quarry of Ball Mtn, N. of Norfolk, Conn., as one of type localities of Becket gneiss. Present study confirms existence of this rock as a separate type and Emerson's name is retained for it where present in Conn. But Becket as mapped in prel. geol. map of Conn. included much more. The Becket of Emerson intrudes Sharon Mtn quartz diorite, Barrack Mtn granite gneiss, and Grenville. [In 1934 (Am. Jour. Sci., 5th, vol. 27, p. 356) Agar adopted *Becket granite gneiss* as appropriate name of the fm.]

Becket moraine.

Pleistocene (Wisconsin stage): Western Massachusetts (Berkshire County). See F. B. Taylor, 1903 (Jour. Geol., vol. 11).

Beckett sand.

A subsurface sand, 10 to 20± ft. thick, in Milton field, Cabell Co., W. Va., that is believed to lie in top of Pocono fm. and to correspond to Keener sand. Named for E. W. Beckett well.

Beckwith formation.

Upper Jurassic and Cretaceous (?): Southwestern Wyoming.

A. C. Veatch, 1907 (U. S. G. S. P. P. 56). *Beckwith fm.*—Red, yellow, and reddish yellow shales and sss., at many places containing thick reddish cgl. beds. Thickness 3,800 to 5,500 ft. Underlies Bear River fm., and overlies Twin Creek ls. Extensively developed on leased State lands now forming part of Beckwith ranch, situated just E. of Beckwith Station, on Oregon Short Line.

This name has been used in Idaho, in some old repts, but its use there is now discontinued, the rocks having been divided into several fms.

Becraft limestone.

Lower Devonian: Eastern New York and Pennsylvania, western Maryland and Virginia, and northern West Virginia.

J. Hall, 1893 (N. Y. State Geol. 12th Ann. Rept., pp. 9–13). *Upper Pentamerus ls. or Scutella (Becraft) ls.* underlies Oriskany ss. and overlies Shaly ls. in Schoharie and Albany Counties. Top fm. of Lower Helderberg.

N. H. Darton, 1894 (N. Y. State Mus. 47th Ann. Rept., pp. 393–505). *Becraft ls.*—Pure, semicrystalline, massive, very fossiliferous ls., 0 to 60 or more ft. thick. Formerly called *Scutella or upper Pentamerus beds.* Underlies Upper Shaly [Port Ewen] ls. and overlies Lower Shaly [New Scotland] beds. The geographic name, suggested by Dr. Hall, is from Becraft's Mtn, Columbia Co.

Was for many years considered top fm. of Helderberg group, but in eastern N. Y. two younger fms. (Port Ewen ls. (restricted) and Alsen ls.) are now included in the Helderberg. (See W. Goldring, 1931, N. Y. State Mus. Hdb. 10, pp. 370, 376–379.)

Becsie formation.

Silurian: Quebec (Anticosti Island).

C. Schuchert, 1924 (Textbook geol., 2d ed., vol. 2).

Becsie River formation.

Silurian: Quebec (Anticosti Island).

C. Schuchert and W. H. Twenhofel, 1910 (Geol. Soc. Am. Bull., vol. 21, pp. 695, 705).

Bedford shale.

Devonian or Mississippian: Eastern Ohio, southwestern Pennsylvania, and northeastern Kentucky.

J. S. Newberry, 1870 (Ohio Geol. Surv. Rept. Prog. 1869, p. 21). *Bedford sh.*—Red and blue clay sh., 60 ft. thick, overlying Cleveland sh. and underlying Berea grit in northern Ohio. Included in Waverly group.

Named for Bedford, Cuyahoga Co., Ohio.

For many years this fm. was classified as Carbf. In 1912 (N. Y. Acad. Sci. Annals, vol. 22, p. 295) G. H. Girty placed it in Dev. The same year C. S. Prosser (also E. M. Kindle) assigned it to Dev., and repeated this classification in 1913, as did VerWiebe in 1917; but most geologists continue to classify it as Carbf. In 1914 the U. S. Geol. Survey adopted *Dev. or Carbf.* as age designation of Bedford sh., and still classifies it thus.

†Bedford limestone.

Mississippian: Indiana.

C. E. Siebenthal and T. C. Hopkins, 1897 (Ind. Dept. Geol. and Nat. Res. 21st Ann. Rept., p. 291). *Bedford oolitic ls.*—Has been called Warsaw ls., Indiana oolite stone, Spergen Hill ls., White River stone, and St. Louis ls. Underlies Mitchell ls. and overlies Harrodsburg ls. in Lawrence, Monroe, and Owen Counties.

Same as Spergen ls. The quarried rock is still known commercially as *Bedford ls.*

Named for Bedford, Lawrence Co., where it is extensively quarried.

Bedford formation.

Ordovician: Canada.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 200).

Bedford "augen" gneiss.

Age (?): Southeastern New York (Westchester County).

C. R. Fettke, 1914 (N. Y. Acad. Sci. Annals, vol. 23, p. 239). *Bedford "augen" gneiss.*—"Augen" gneiss associated with Manhattan schist SE. and S. of Bedford village [Westchester Co.]. The "augen" structure is developed in two types of rock, a mica schist and a hornblende schist, but entire area does not have the "augen" structure. It appears in bands usually parallel to the foliation. The bands grade into the ordinary schist by gradual disappearance of the "augen," which sometimes stops suddenly and at other times drops out gradually.

Bedford clay. (In Pottsville formation.)

A term applied to the clay, 4 ft. thick, underlying Bedford coal in eastern Ohio.

Bedias sandstone member.

Eocene (upper): Southeastern Texas (Grimes, Brazos, Burleson, Fayette, Lee, and Gonzales Counties).

B. C. Renick, 1936 (Univ. Tex. Bull. 3619, table opp. p. 17, and pp. 26–28). *Bedias ss. memb.*—Basal memb. of Wellborn fm. of Jackson group, in Grimes, Brazos, Lee, Fayette, Burleson, and Gonzales Counties, in all of which it is exposed. [Exposures listed.] Consists of massive gray ss., locally qtzitic, containing marine beds near top at some localities. Thickness 0 to 30 ft. Conformably overlies Caddell fm., into which, at some localities, it interfingers at base. Fossils identified by Miss Gardner as upper Jackson. Named for town of Bedias, Grimes Co., in vicinity of which it is well exposed.

† Bedrock complex.

See under *basement complex.*

† Bedrock series.

A descriptive term used in folios and other early repts on Gold Belt region of northern Calif., to include the Jurassic, Triassic, and Carbf. fms., in contradistinction to "Superjacent series," which included the Cret., Tert., and Quat. deposits. The term has also been applied to the basement rocks of any region.

Bedson limestone.

Mississippian: Alberta (Jasper Park).

P. E. Raymond, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 299–300). *Bedson ls.*—Thick-bedded gray ls., 1,085 ft. thick, exposed in backward folds on S. end of Bedson Ridge.

Bee rock.

A term that has been applied locally to Yellow Creek and Cawood ss. members of Hance fm. (of Pottsville group) of SE. Ky., "because of their tendency to weather out large cavities resembling a magnified honey comb." (G. H. Ashley and L. C. Glenn, U. S. G. S. P. P. 49, p. 38.) The term has also been applied to top ss. of the Pottsville of SW. Va., "because the laurel blossoms which cover it in early summer are the resort of immense numbers of bees." (J. J. Stevenson, Am. Phil. Soc. Proc., vol. 19, p. 96.) The top ss. of Lee fm. in Bigstone Gap coal field of SW. Va. has also been called "Bee rock" (M. R. Campbell, U. S. G. S. Bull. 111, p. 17), "probably because it weathers into a pitted surface in which bees probably found refuge at times." (M. R. Campbell, personal communication.)

Beebe limestone.

Lower Cambrian: Southwestern Vermont (Rutland County).

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 402). *Beebe ls.*—This ls. (only 5 to 20 ft. thick) would in most other regions be called a memb. of the sl. fm. But here it is such an exceptional change from usual character of the sediments, and so fossiliferous, that it is most important fm. of entire Taconic sequence. Named for exposures near Beebe Pond, in Hubbardton, Vt. Is everywhere present at proper horizon so far as known. Underlies Hooker sl. and overlies Bull sl., all of Lower Camb. age.

Beebe limestone.

Upper Devonian: Central New York (Ithaca region).

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 202). [See under *Triphammer sh. memb.*]

Beech granite.

Pre-Cambrian: Western North Carolina and eastern Tennessee.

A. Keith, 1903 (U. S. G. S. Cranberry folio, No. 90, p. 3). *Beech granite.*—Huge masses of coarse granite, usually porphyritic and seldom fine-grained. In the porphyritic varieties, constituting bulk of fm., the feldspars make greatest part of rock, giving it a dull whitish or light-gray color. Biotite is more prominent in massive portions, and causes a distinct spotted appearance. A third variety, of considerable extent, is a coarse red granite found near border of the area Cuts Cranberry granite and Blowing Rock gneiss. Youngest massive plutonic rock in region.

Named for Beech Mtn, Cranberry quad., Watauga Co., N. C.,

Beech Bottom sand.

An oil-bearing sand 1,350 to 1,385 ft. below Chattanooga sh. in Beech Bottom section of SE. part of Clinton Co., Ky. Referred by W. Nelson to Knox dol.

Beech Creek limestone. (In Chester group.)

Mississippian: Southwestern Indiana and central northern Kentucky.

C. A. Malott, 1919 (Ind. Univ. Studies, vol. 6, No. 40, pp. 7–20). *Beech Creek ls.*—Two or more massive to thin-bedded ledges with total thickness of 8 to 24 ft. Is gray, compact to suboolitic, and often crystalline ls., frequently completely oolitic. Is "middle" or "second" ls. of Chester series of Ind. Underlies Cypress ss. and overlies Elwren ss. and sh. Named for exposures along Beech Creek, Green Co., Ind. [Later repts give thicknesses up to 75 ft.]

W. N. Logan, 1926. See under *Beech Creek sh.*

Beech Creek shale. (In Chester group.)

Mississippian: Southwestern Indiana.

W. N. Logan, 1926 (Ind. Dept. Cons., Div. Geol. Pub. 55). *Beech Creek sh.*—Sh., 12 ft. thick, separating lower Beech Creek ls. (21 ft. thick) from upper Beech Creek ls. (10 ft. thick).

Beecher Island shale member (of Pierre shale).

Upper Cretaceous: Northwestern Kansas (Cheyenne County) and northeastern Colorado (Yuma County).

M. K. Elias, 1931 (Univ. Kans. Bull., vol. 32, No. 7). *Beecher Island sh. member of Pierre sh.*—Chiefly light gray sh. with distinct greenish tint on many outcrops; thin streaks of white and brownish bentonite occur in lower part of the sh., where also ls. concretions (the largest 1 ft. thick) are common; irregular-shaped and comparatively small ls. bodies with *Lucina* constitute uppermost concretionary zone, above which occur 5 to 10 ft. more of sh. with rusty limonite streaks. Thickness of memb. 100± ft. Is top memb. of Pierre sh. in Yuma Co., Colo. Lies 500 to 600 ft. higher than Salt Grass sh. memb. of Pierre. Named for exposures at Beecher Island, Yuma Co., NE. Colo.

Beechhill formation.

Silurian: Nova Scotia.

F. H. McLearn, 1918 (Am. Jour. Sci., 4th, vol. 45, p. 128).

Beechhill Cove formation.

Silurian: Nova Scotia.

M. Y. Williams, 1911 (Canada Geol. Surv. Summ. Rept. 1910, p. 243).

Beech Mountain amphibolite.

Pre-Cambrian: Northern New York (Adirondacks).

H. L. Alling, 1918 (N. Y. State Mus. Bull. 199). A para-amphibolite, included in Grenville series. Thickness 150 ft. Younger than Bear Pond schist. Named for occurrence on Beech Mtn, SE. of Graphite, Warren Co.

Beech River shaly limestone member (of Brownsport formation).

Silurian (Niagaran): Western Tennessee.

W. F. Pate and R. S. Bassler, 1908 (U. S. Nat. Mus. Proc., vol. 34, pp. 410–432). *Beech River fm.*—Almost exclusively fine shales; highly fossiliferous; gray, yellow, and bluish; weathering into white clay; some beds of ls. Thickness 74 to 106 ft. Divided into (descending): *Eucalyptocrinus* zone, *Troostocrinus* zone, and *Coccocrinus* zone. Basal fm. of Brownsport group. Underlies Bob fm. and overlies Dixon fm.

Now treated as basal memb. of Brownsport fm.

Named for Beech River, Decatur Co.

Beechwood limestone member (of Sellersburg limestone).

Middle Devonian: Central northern Kentucky and southern Indiana.

C. Butts, 1915 (Ky. Geol. Surv., 4th ser., vol. 3, pt. 2, pp. 118, 120). *Beechwood ls. memb.*—Coarse crinoidal ls., 2 to 8 ft. thick. The "Encrinal" ls. of early repts, also the Sellersburg ls. of Siebenthal, but is top memb. of Sellersburg ls. as originally defined (by Kindle) and as used in this rept. It overlies Silver Creek ls. memb. of the Sellersburg and underlies New Albany sh.

Named for Beechwood Station, Jefferson Co., Ky. Is exposed in stream a few rods N. of Shelbyville turnpike, ½ mi. S. of Beechwood, and it probably underlies Beechwood.

Beehive formation.

Pre-Cambrian: Southern British Columbia and northeastern Washington.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, map 7, 117° to 117°30′). *Beehive fm.*—Banded qtzite with thin interbeds of metargillite. Underlies Lone Star fm. and overlies Ripple fm.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, pp. 156, 178, 194). *Beehive fm.*—Chiefly qtzites and metargillites; some phyllite, ls., and quartz schist. Thickness 7,000 ft. Underlies Lone Star fm., with apparent conformity, and rests conformably on Ripple fm., all of which belong to Summit series of Selkirk Mtns at 49th par. Typical occurrence of Beehive fm. on Beehive Mtn, N. of Lost Creek, B. C.

Beekmantown group (also limestone).

Lower Ordovician: New York, western Vermont, Pennsylvania, western Maryland and Virginia, and Tennessee.

J. M. Clarke and C. Schuchert, 1899 (Sci., n. s., vol. 10, pp. 874–878). *Beekmantown ls. (new).*—The Calciferous sand rock of Eaton and authors generally. [C. A. Hartnagel (N. Y. State Mus. Hdb. 19, p. 33, 1912) stated that Calciferous sand rock of Eaton included the Little Falls dol.] At Beekmantown, N. Y., the normal fauna is finely developed and the rock section essentially complete. Underlies Chazy ls. and overlies Potsdam ss. and ls.

In 1890 (Geol. Soc. Am. Bull., vol. 1, pp. 501–516) E. Brainerd and H. M. Seely divided the †Calciferous of Champlain Valley, Vt., into (descending): E, fine-grained mag. ls. in beds 2 ft. thick, weathering drab, yellowish, or brown, 450 to 500 ft.; D, blue ls., mag. ls., sandy ls., drab and brown mag. ls., some tough ss., some cgl., 375 ft.; C, alternating ss. and mag. ls. 350 ft.; B, masses of nearly pure reticulated ls. weathering white, intermingled with light-colored dol., 295 ft.; A, drab mag. ls., 310 ft. Overlain by Chazy ls. (div. A) and underlain by Potsdam ss. In 1891 (Am. Mus. Nat. Hist. Bull., vol. 3, pp. 1–3) Brainerd and Seely published the following subdivisions of div. D (descending): No. 4, 100 ft. of blue ls. in thin beds separated by very thin, tough, slaty layers, which protrude on weathered edges in undulating lines, the ls. often appearing to be a cgl., the small enclosed pebbles being somewhat angular and aren.; No. 3, 120 ft. of sandy ls. in thin beds, weathering on edges in horizontal ridges 1 or 2 inches apart, giving to escarpments a peculiar banded appearance, interstratified with a few thin beds of pure ls.; No. 2, 75 ft. of drab and brown mag. ls. containing toward middle several beds of tough ss.; No. 1, 80 ft. of blue ls. in beds 1 or 2 ft. thick, breaking with flinty fracture; considerable dolomitic matter often intermixed.

R. P. Whitfield, 1890 (Am. Mus. Nat. Hist. Bull., vol. 3, pp. 25-28), stated that Brainerd and Seely included "Fort Cassin layers" in div. D, 375 ft. thick, which contains *Ophileta* at base "and the Fort Cassin fauna in a very few ft. at the very top, the intervening layers being essentially unfossiliferous." In his opinion the line btw. div. C and div. D should have been made above the *Ophileta* bed; and "there is certainly a much greater affinity btw. Fort Cassin fossils and those of the rocks above them than with those of the Calciferous, and as latter name applies to beds having peculiar lithological characters, and containing a very limited fauna, it appears to me much more natural to associate the later fauna with that of the rocks above, and place the lss. there also, or else consider them as distinct from those below or above, and use a distinct name, as *Fort Cassin, or Philipsburg fm.*, or any other appropriate one."

In 1903 (N. Y. State Mus. Hdb. 19, p. 16 and chart) J. M. Clarke introduced *Little Falls dol.* for "the highly mag. sparsely fossiliferous phase of 'Calciferous sandrock' in Mohawk valley."

In 1905 (N. Y. State Mus. Bull. 77) H. P. Cushing mapped *Beekmantown fm. and Little Falls dol.* in Little Falls quad., and the same year (N. Y. State Mus. Bull. 95) he proposed *Cassin fm.* (from Fort Cassin, Vt.) for Brainerd and Seely's divisions E, D_4, and D_3 of the Beekmantown, and stated that these beds "are confined to Champlain Valley so far as the immediate region is concerned, and have therefore the same restricted distribution as the following Chazy;" also that he agreed with Whitfield that these beds have more natural affinity with Chazy than with Beekmantown, and that they should either be placed with that fm. or considered distinct from either and given a separate name. He also stated that at Beekmantown type section these rocks are not exposed; that to S. and around into Mohawk Valley they are absent; and that the question as to whether the rocks involved are to be classed with Chazy or Beekmantown, or with neither, is not at issue in the giving of the name; but he assigned his *Cassin ls.* to upper Beekmantown.

In 1906 (N. Y. State Mus. Bull. 90) R. Ruedemann included *Fort Cassin beds*, as he called them, in the Beekmantown, but stated (p. 525) that "all evidence goes to show that the *Philipsburg beds*, like the typical beds at Beekmantown, are older than Fort Cassin beds."

In 1907 (N. Y. State Mus. Bull. 114) C. A. Hartnagel stated *Beekmantown dol.* (*Little Falls dol.*) is not exposed in Rochester and Ontario Beach quads.

In 1908 (Geol. Soc. Am. Bull., vol. 19, p. 171) H. P. Cushing excluded div. A from Beekmantown, stating that it is uncon. with div. B and of Camb. age, and he named these beds in Jefferson Co. the *Theresa fm.*, and doubtfully correlated them with Little Falls dol. of Mohawk Valley.

In 1909 (Jour. Geol., vol. 17, p. 251) A. W. Grabau included div. A, also Little Falls dol. and Theresa fm., in the Beekmantown.

In 1910 (N. Y. State Mus. Bull. 138) R. Ruedemann included div. A in Beekmantown, but stated that "it will probably in time be separated from the rest of the Beekmantown by Dr. Ulrich, who considers it the eastern representative of a separate fm. having possibly even the value of a system fully developed in the Mississippi Basin," and that there is a strong uncon. btw. divisions A and B. He also included in Beekmantown the *Cassin fm.*, as he called it, "although its recognition as a distinct unit is urged by Prof. Cushing, apparently on good grounds. This *Cassin fm.* is to comprise upper part of D and all of E."

In 1910 (Geol. Soc. Am. Bull., vol. 21, pp. 780-781) E. O. Ulrich and H. P. Cushing divided *Little Falls dol. of Mohawk Valley* [type region] into (descending): (1) *Tribes Hill ls.* (new name); heretofore described as "fucoidal beds" of Calciferous; contains Beekmantown fossils and represents lowest known div. of Beekmantown of N. Y.; fauna not yet recognized in Champlain Valley, and if present there the fm. is represented in upper part of div. B; (2) *Little Falls dol. restricted;* uncon. underlies Tribes Hill ls., and traced to Champlain Valley constitutes div. A and lower half of div. B of Beekmantown of Brainerd and Seely; is not Beekmantown but late Camb. (Saratogan or Ozarkian); rests on passage beds [Theresa dol.] to Potsdam ss. [This classification (which restricted Beekmantown to Brainerd and Seely's divisions E, D, C, and upper part of div. B, assigned Tribes Hill ls. to the Beekmantown, and excluded Little Falls dol.) was continued for many years. by geologists generally, although A. W. Grabau in 1916 (Geol. Soc. Am. Bull., vol. 27, p. 589) still considered the Little Falls dol. as lowest Beekmantown.]

In 1914 (N. Y. State Mus. Bull. 169, btw. pp. 66-99) R. Ruedemann stated *Fort Cassin beds* correspond to unknown parts of Brainerd and Seely's divisions D and E of the Beekmantown. In 1915 C. Schuchert (Textbook of geology, p. 629 and index) excluded *Fort Cassin fm.* from Beekmantown. Ulrich's later charts show *Fort Cassin zone*, as he called it, btw. div. D and div. E, and that it is properly a part of the Beekmantown.

E. J. Foyles, 1923 (Rept. Vt. State Geol. 1921-22, pp. 71-86) and 1924 (Rept. Vt. State Geol. 1923-24), reported that *Fort Cassin rocks* are not Beekmantown but belong to 2 fms., one of Chazy and the other of Trenton age; but A. Keith, C. Schuchert, and other geologists still consider the beds at Fort Cassin to be of Beekmantown age.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 263, 268), stated that *Beekmantown* submergence in N. Y. in general begins with Tribes Hill ls., which overlies Little Falls dol. nearly everywhere in Mohawk Valley, and includes Beekmantown E, D, C, and part of B.

In Jan. 1936 the U. S. Geol. Survey decided to adopt Ulrich's classification, which correlated, by faunas and lithology, Chepultepec dol. of Ala. and Tenn., Gasconade and Van Buren dolomites of Mo., and Oneota dol. of upper Miss. Valley with the 30± ft. of cherty beds forming top part of Little Falls dol. in Champlain Valley, N. Y., but locally absent in Mohawk Valley, the type region of Little Falls dol. This classification restricted *Little Falls dol.* to lower (major) part of the beds included in it since 1910, or to the typical Little Falls, which is said by Ulrich to be uncon.

with the overlying cherty beds. These upper cherty beds (for which no N. Y. name has been adopted) correspond to part of Beekmantown B of Brainerd and Seely, are older than Tribes Hill ls., and contain a fauna that is not Camb. and which, although differing slightly from that of the Tribes Hill, shows many relationships to the latter fauna. These beds are, therefore, restored to the Beekmantown, although they are said by Ulrich to be uncon. with overlying Beekmantown beds. The Chepultepec, Gasconade, Van Buren, Oneota and equiv. fms. are now classified by U. S. Geol. Survey as of *Lower Ord.* (*Beekmantown*) *age.*

See also under *Little Falls dol.*

The U. S. Geol. Survey treats the beds at Fort Cassin as of Beekmantown age, but has not adopted either *Cassin fm.* or *Fort Cassin fm.*

In central Pa. the *Beekmantown group* is divided into (descending) Bellefonte dol., Axemann ls., Nittany dol., and Stonehenge ls. In western Md. and Va. the rocks are not subdivided and are called *Beekmantown ls.*

Named for exposures at Beekmantown, Clinton Co., NE. corner of N. Y.

Beekmantownian.

Time term proposed by A. W. Grabau (Jour. Geol., vol. 17, pp. 209–252, 1909) "for the North American equivalent of Lower Ordovicic [exclusive of Chazy ls., which is included in Lower Ord. by most writers], while the term Canadian becomes obsolete." Underlies, uncon., Chazy ls. Includes Theresa fm. at base. "Accepted base of Ordovicic is top of Saratoga fm. of N. Y."

Bee Spring sandstone.

Pennsylvanian (Pottsville): Western central Kentucky.

C. J. Norwood, 1876 (Ky. Geol. Surv. vol. 1, n. ser., pt. 6, pp. 16, 42, 52–55). *Bee Spring ss.*, 15 to 45 ft. thick, in Upper Coal Measures of region adjacent to Louisville, Paducah & Southwestern R. R., Ky. Lies 20 ft. above coal K. Is=5th ss. of Lyon.

P. N. Moore, 1884 (Ky. Geol. Surv. Western coal field, btw. pp. 8 and 38). The 4th ss. above St. Louis ls. is here named *Bee Spring ss.*, from Bee Spring, Edmonson Co. It is 50 to 60 ft. thick. As underlying heavy cgl. thickens this ss. thins and disappears in about 2 mi. Is usually coarse and contains small pebbles; in some areas it is thin bedded and shaly. Included in Coal Measures. Overlies Nolin coal in Nolin River dist.

Beidell latite-andesite.

Miocene (?): Southwestern Colorado (south of Saguache River).

E. S. Larsen, 1935 (U. S. G. S. Bull. 843). Flows and tuffs. Lowest beds are rhyolites of no great thickness; they are overlain by several hundred ft. of hornblende andesites near quartz latites with some quartz latite and some pyroxene andesite. Over this are several hundred ft. of quartz latites near the andesites in composition, which in drainage of San Juan and Red Rock Creeks reach a thickness of nearly 1,000 ft. Probably accumulated about several centers. Largest body (rudely circular in outline and 7± mi. across) is just W. of San Luis Valley, about old mining camp of Beidell, in extreme N. part of Del Norte quad. and adjoining part of Saguache quad. The rock of this body is gray andesite porphyry. Underlies Tracy Creek andesite. Is of pre-Potosi age. Assigned to Mio. (?).

Bell limestone. (In Lecompton limestone.)

Pennsylvanian: Southeastern Nebraska.

G. E. Condra, 1930 (Nebr. Geol. Surv., 2d ser., Bull. 3, p. 48). *Bell ls.* (not the Cullom), underlies King Hill sh. and overlies Queen Hill sh. in Jones Point to Sand Point section. Is in 2 beds separated by sh. with fossils typical of the unit. Thickness 4 ft. 8 in. to 5 ft. [Derivation of name not stated.]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 176). Type loc. of *Bell ls.* is Bell farm, on Missouri River bluffs, mouth of Kenosha Creek, S. of Rock Bluff, Nebr.

Bejucal formation.

Eocene: Cuba.

E. L. De Golyer, 1918 (A. A. P. G. Bull., vol. 2, p. 142).

Belcher series.

Pre-Cambrian: Belcher Islands, Canada.

E. S. Moore, 1918 (Jour. Geol., vol. 26, p. 415).

Belcher sandstone. (In Bluestone formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 294, 318–320). *Upper Belcher ss.*—Greenish-gray, massive, medium coarse ledge, 15 to 40 ft. thick, underlying Bratton sh. and overlying Upper Belcher sh. *Upper Belcher sh.*—Red sh., with lenticular streak of carbonaceous fire clay near middle and with marine fossils; thickness 15 to 30 ft. Rests on *Lower Belcher ss.*, which consists of greenish-gray massive or flaggy micaceous ss., 15 to 45 ft. thick, which rests on *Lower Belcher sh.*, a red sandy sh. 20 to 30 ft. thick, carrying marine fossils. All are members of Bluestone group [fm.] and all are exposed just N. of Belcher School, in Mercer Co.

Belcher shale. (In Bluestone formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Tazewell County).

D. B. Reger, 1926. [See under *Belcher ss.*]

Belchertown tonalite.

Late Carboniferous or post-Carboniferous: Central Massachusetts and northern Connecticut.

B. K. Emerson, 1898 (U. S. G. S. Holyoke folio, No. 50; also U. S. G. S. Mon. 29, pp. 243–248, pl. 34). *Belchertown tonalite.*—A granitoid quartz-plagioclase-hornblende rock.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 208–217 and map). *Belchertown tonalite*, a stock of tonalite 8 mi. square and other small patches. Named for occurrence at Belchertown, Mass.

†Belemnites beds.

A paleontologic name introduced by O. C. Marsh and used in some early repts for the marine Sundance fm. (Upper Jurassic), according to J. B. Reeside, Jr.

Belfast bed.

Upper Ordovician (?): Southwestern Ohio (Highland and Adams Counties).

A. F. Foerste, 1896 (Cincinnati Soc. Nat. Hist. Jour., vol. 18, pp. 161, 189, 190). *Belfast bed.*—Unfossiliferous sandy and argill. ls., in places clayey sh., 3 to 6 ft. thick. Formerly called Medina, but not Medina. Underlain by Cincinnati fm. and overlain by Clinton or Montgomery fm. [Brassfield ls.]. Included in Lower Sil. [Ord.] of Ohio and SE. Ind. [Later repts state this bed is not present in Ind.]

For many years was regarded as top bed of Richmond group.

A. F. Foerste, 1931 (Ky. Geol. Surv., ser. 6, vol. 36, p. 184). The term *Belfast*, proposed for an aren. ls. in Highland and Adams Counties, Ohio, was dropped when it was learned that it could be traced laterally into ls. strata containing a typical Brassfield fauna. The Belfast is merely a local phase of the base of the Brassfield [early Sil.].

A. F. Foerste, 1935 (Denison Univ. Bull., Sci. Lab. Jour., vol. 30, p. 147). East of Cincinnati anticline base of typical Brassfield ls. is underlain by argill., bluish, usually massive ls., 3 to 6 ft. thick, which contains annelid teeth at Todd Fork (N. of Wilmington, O.), at Sharpsville (in NW. margin of Highland Co.), and at Belfast (in SE. corner of Highland Co.). Presence of *Halysites* in this ls. suggests Sil. age, though a distinguishable sp. is known also from Richmond beds in other areas. Writer in 1896 named this argill. ls. *Belfast bed or fm.*

Named for Belfast, Highland Co.

†Belfast beds.

Mississippian: Southeastern Iowa.

F. M. Van Tuyl, 1925 (Iowa Geol. Surv. vol. 30, pp. 43, 47, and 214). The Spergen is represented in SE. Iowa by an attenuated, near-shore facies, to which name *Belfast beds* is given, because of excellent exposures of fm. near town of Belfast, Lee Co.

The name is preoccupied, and throughout rept cited the beds are called *Spergen fm.*

Belgium member.

Devonian: Southeastern Wisconsin (Ozaukee County).

G. O. Raasch, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 260, 262, 263). *Belgium memb. novum.*—Basal memb. of Lake Church fm. Above the basal clastic zone this memb. consists of thin-bedded chocolate-brown dol., weathering readily and having a bituminous odor. Very fossiliferous. Greatest observed thickness 6 ft. Is present only to north. [Page 262 gives thickness as 8 ft.] Fauna and lithology are duplicated in basal Dev. at Spring Valley, Minn. Underlies Ozaukee memb. of Lake Church fm. and overlies Racine fm. (Sil.).

Probably named for town in Ozaukee Co.

Belknap limestone member (of Harpersville formation).

Pennsylvanian: Central northern Texas (Young County, Brazos River region).

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31, 39). *Belknap ls. memb. of Harpersville fm.*—Lies 30 to 50 ft. below top of fm. Is traceable a long distance.

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, pp. 161–166). *Belknap ls. lentil of Harpersville fm.*—Yellow to buff ls., nodular, 2 to 4 ft. thick, locally very fossiliferous. Lies 60 to 80 ft. above Crystal Falls ls. lentil of Harpersville fm. and 30 to 50 ft. below top of fm. Named for old Fort Belknap, Young Co.; typical exposures in vicinity of Newcastle, Young Co., where it lies above the workable coal bed.

Belknap syenite.

Devonian or Carboniferous: New Hampshire (Belknap Mountains). See 1936 entry (D. Modell) under *White Mtn magma series.* Type on Belknap and Gunstock Mtns.

Bell shale.

Middle Devonian: Michigan (northern part of Lower Peninsula).

A. W. Grabau, 1902 (Mich. Geol. Surv. Rept. 1901, pp. 191, 210). *Bell shales.*—Descending order: (1) Sh., 24 ft.; (2) hard white ls., 5 ft.; (3) mostly blue sh., 52 ft. Underlie Long Lake series and form basal div. of Traverse group in Alpena region. [On p. 210, in describing the rocks of Little Traverse Bay, Mich., he says that Bell sh., from its constant thickness, gives a very clear and sharply defined base for Traverse group wherever it occurs in this portion of Lower Peninsula, and shows it separated from the younger Petoskey ls. by 110 ft. of *Acervularia* and *Stropheodonta nacrea beds.*]

R. A. Smith, 1914 (Mich. Geol. and Biol. Surv. Pub. 14, geol. ser. 11, btw. pp. 22 and 32). *Bell sh.*—Heavy blue or black sh. occurs everywhere at base of Traverse fm.

W. A. VerWiebe, 1927 (Papers Mich. Acad. Sci., Arts, and Lett., vol. 7, p. 181). At time of writer's visit in 1925 the Bell sh. was to be seen at only one place in Alpena Co., and that in quarry of Great Lakes Stone and Lime Co., at Rockport. At N. side of quarry it shows 12 ft. of soft, blackish or blue, rather massive clay sh., underlying 40 ft. of Rockport ls. At E. end of quarry only a few ft. of sh. are exposed under the ls.

E. R. Pohl, 1930 (U. S. Nat. Mus. Proc., vol. 76, art. 14, p. 25), reporting from unpublished ms. of A. W. Grabau, showed *Long Lake beds* (top memb. of Presque Isle series) as separated from *Bell shales* (basal memb. of Presque Isle series) by Grand Lake ls. memb. of Presque Isle series.

A. S. Warthin, Jr., and G. A. Cooper, 1935 (Wash. Acad Sci. Jour., vol. 25, No. 12, pp. 524–526), redefined *Long Lake stage* by including in its top the lower part of

Alpena ls. of VerWiebe (which they named *Killians ls.*) and by treating Rockport ls. as a distinct fm. underlying Long Lake stage and overlying Bell sh. (See 1935 entry under *Traverse fm.*)

Named for Bell, Presque Isle Co., NE. Mich.

Bell oil zone (also *Bell sand*).

An oil-bearing zone, about 370 ft. thick, in Santa Fe Springs field, Los Angeles Co., Calif. Is capped by Foix oil zone and in turn caps Meyer zone. Top lies at depth of 3,650 to 3,850 ft. Basal bed consists of 30 to 50 ft. of sticky brown sh.

Bella shale.

Upper Devonian: Southwestern New Mexico (Sierra County).

C. R. Keyes, 1908 (Am. Inst. Min. Engrs. Bi-Mon. Bull. No. 19, pp. 7-21). *Bella shales.*—Green shales, 60 ft. thick, underlying Berenda ls. and overlying Silver shales. Named for Bella mine, near Lake Valley. No recognizable fossils. Assigned to Dev.

Appears to be upper part of Percha sh.

Bellabella formation.

Post-Pleistocene (?): British Columbia.

V. Dolmage, 1922 (Canada Geol. Surv. Summ. Rept. 1921, pt. A, p. 27).

Bellair sands.

Subsurface sands in Carbondale fm. (Penn.) and Chester group (Miss.) of Clark Co., Ill. (See Ill. Geol. Surv. Bull. 54, index.)

Bellaire sandstone. (*In Conemaugh formation.*)

Pennsylvanian: Eastern Ohio.

D. D. Condit, 1912 (Ohio Geol. Surv., 4th ser., Bull. 17, pp. 20, 22). *Bellaire ss.*—Massive ss., 8 to 20 ft. thick, immediately underlying Pittsburgh ls. and overlying Summerfield ls. Included in Conemaugh fm. Correlated with Lower Pittsburgh ss.

Named for Bellaire, Belmont Co.

Belle City limestone.

Pennsylvanian: Central Oklahoma (Seminole County).

G. D. Morgan, 1924 (Bur. Geol. [Okla.] Bull. 2, pp. 123-125, pls. 3, 27, and map). *Belle City ls.*—Name used by Boone Jones in unpublished ms. prepared for Okla. Geol. Surv. in 1922. The name was published, but not defined, by Morgan in Okla. Geol. Surv. Circ. No. 12, pl. and p. 15, 1923. The fm. consists of two lss. and an intervening sh., all fossiliferous. Average thickness 30 ft. The upper ls. is white or light gray, often characterized by well-developed stylolites; is more massive than lower ls. and from 1 ft. (near Byng) to 15 ft. (near Canadian River) thick. The lower ls. is of buff color, 1 ft. (near Byng) to 5 ft. (near Canadian River) thick, and relatively thin bedded. The intervening sh. averages 12 ft. in thickness and is of green, blue, and black colors. Underlies Vamoosa fm. and overlies Francis fm. Greatest thickness and probably best exposure on S. bluff of Canadian River in sec. 15, T. 5 N., R. 6 E.

A. I. Levorsen, 1928 (Okla. Geol. Surv. Bull. 40BB). *Belle City ls.*, 0 to 30 ft. thick, underlies Vamoosa fm. and overlies Francis fm. in Seminole Co., central Okla.

R. C. Moore, 1929 (A. A. P. G. Bull., vol. 13, p. 888). *Belle City ls.* lies at horizon of Dewey ls. and may be more or less exactly equivalent.

D. A. Green, 1936 (A. A. P. G. Bull., vol. 20, No. 11, pp. 1454, 1458, 1459), reported that N. of Stonewall quad. 225 ft. of "unclassified nonconglomeratic shales and sss." separate Vamoosa fm. from Belle City ls.

Named for exposures around Belle City, Seminole Co.

Belledune group.

Silurian: New Brunswick.

G. A. Young, 1911 (Canada Geol. Surv. Mem. 18, p. 38).

Bellefonte dolomite. (In Beekmantown group.)

Lower Ordovician: Central Pennsylvania (Center and Blair Counties).

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pp. 552, 553, 652–660, pl. 27). *Bellefonte dol.*—At Bellefonte, Center Co., it is 2,145 ft. thick. Upper 400 ft. consists of mostly argill., highly mag. ls., compact, often laminar, easily weathered, of light-gray color, and unfossiliferous. Lower 1,745 ft. consist of yellowish-gray or drab, generally fine-grained and occasionally laminated dol., alternating with fewer ledges of comparatively dark, finely crystalline dol., both generally in rather even layers and of medium thickness, with cherty beds 800 to 900 ft. below top. Is uncon. overlain by Upper Stones River ls. [Carlim ls.] and underlain by Axeman [n] ls.

The Bellefonte dol. is top fm. of Beekmantown group in central Pa.

Belle Fourche shale member (of Graneros shale).

Upper Cretaceous: Northeastern Wyoming.

A. J. Collier, 1920 (U.S.G.S. Press Bull. 9065). *Belle Fourche sh.*, Upper Cret., underlies Greenhorn ls. and overlies Mowry sh.

A. J. Collier, 1922 (U.S.G.S. Bull, 736, table opp. p. 76, p. 88, etc.). *Belle Fourche sh. memb.*—Top memb. of Graneros sh. Consists of dark-gray sh., which varies in hardness but is all softer than underlying Mowry sh. Thickness 560± ft. Contains calc. concretions near top and zone of Mowry-like sh. 100± ft. below top. Many ironstone concretions occur in lower part, and thick bed of bentonite near base. Few fossils. Named for exposure along Belle Fourche River in neighborhood of Wind Creek, Crook Co.

Belle Isle shale.

Cambrian: Newfoundland.

J. B. Jukes, 1839 (Rept. Geol. Newfoundland, p. 1). *Belle Island sh. and gritstone fm.*, Newfoundland.

J. B. Jukes, 1840 (Edinburgh New Phil. Jour., vol. 29, p. 104), and 1843 (Gen. rept. geol. Newfoundland, pp. 51+). *Belle Isle sh.*, Camb.(?), Newfoundland.

C. D. Walcott, 1889 (Am. Jour. Sci., 3d, vol. 37, p. 383), and 1890 (U. S. G. S. 10th Ann. Rept., p. 548). *Belle Isle.*—Shales and sss. of Great and Little Bell and Kelley's Islands, Conception Bay, Newfoundland, are Upper Camb.

Belle Plains formation. (In Wichita group.)

Permian: Central and central northern Texas.

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, pp. 192–198 and charts). *Belle Plains fm.*—Middle fm. of Wichita group. Includes all strata btw. top of Elm Creek ls. below and top of next higher persistent escarpment-forming stratum, named by Drake *Bead Mtn bed*, which forms top of high escarpment W. of Baird. These beds form a strikingly characteristic unit. Underlie Clyde fm. and overlie Admiral fm. Thickness 300 ft. in Callahan Co. and 200 to 250 ft. in Coleman Co. Includes (descending) following beds described by Drake: Bead Mtn ls. [includes more than Drake's Bead Mtn ls.], Valera sh., Jagger Bend ls., and "bed No. 8" sh. Named for town of Belle Plains, Callahan Co. [which is in midst of the fm. as mapped].

In central northern Tex. the Beaverburk ls. and overlying Bluff bone bed of Udden are now included in Belle Plains fm. by Tex. Geol. Survey. See under *Beaverburk ls.*

Bellepoint member (of Columbus limestone).

Middle Devonian: Central Ohio.

C. K. Swartz, 1907 (Johns Hopkins Univ. Circ. No. 7, p. 62). *Bellepoint memb.*—Fossiliferous brown ls. with coral bed; 4 to 24 ft. thick. Basal memb. of Columbus fm. Overlain by Marblehead memb. of Columbus.

Named for Bellepoint, Delaware Co.

Bellepoint limestone. (In Hinton formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 298, 365). *Middle Bellepoint ls.*—Yellow, shaly, calc. stratum, 0 to 3 ft.

thick, with marine fossils. Lies 0 to 7 ft. below Middle Bellepoint ss. and overlies Middle Bellepoint sh. All members of Hinton group [fm.]. Type loc. in vicinity of Bellepoint, Summers Co., and well exposed on Keeney Mtn road E. of Hinton.

Bellepoint sandstone. (In Hinton formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 297–298, 360–368), applied *Bellepoint* to 3 distinct sss., 3 distinct shales, and 1 ls. The sss. are defined as follows: *Upper Bellepoint ss.*—Reddish brown or greenish gray, medium coarse, sometimes massive but often shaly; 30 to 40 ft. thick; underlies Lower Goodwyn sh. and overlies Upper Bellepoint sh.; type loc. in bluffs of New and Greenbrier Rivers near Bellepoint, Summers Co.; also seen in Mercer Co. *Middle Bellepoint ss.*—Greenish gray or reddish brown, usually shaly, but often forms cliffs; 5 to 30 ft. thick; underlies Upper Bellepoint sh. and lies 0 to 7 ft. above Middle Bellepoint ls.; type loc. on lower slope of Keeney Mtn, 0.2 mi. N. of Bellepoint. *Lower Bellepoint ss.*—Greenish gray or reddish brown, usually shaly but often forms cliffs; 10 to 25 ft. thick; underlies Middle Bellepoint sh. and overlies Lower Bellepoint sh.; type loc. same as Middle Bellepoint ss. All members of Hinton group [fm.].

Bellepoint shale. (In Hinton formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 297–298, 362–371), applied *Bellepoint* to 3 distinct shales, 3 distinct sss., and 1 ls. The shales are defined as follows: *Upper Bellepoint sh.*—Red and variegated and argill., or green and sandy with occasional streaks of impure ls., and carrying marine fossils; 30 to 35 ft. thick; underlies Upper Bellepoint ss. and overlies Middle Bellepoint ss.; type loc. on lower slope of Keeney Mtn, 0.2 mi. N. of Bellepoint, Summers Co. *Middle Bellepoint sh.*—Often red and variegated but sometimes greenish gray and sandy; marine fossils, also plants; 25 to 40 ft. thick; underlies Middle Bellepoint ls. and overlies Lower Bellepoint ss.; type loc. same as Upper Bellepoint sh. *Lower Bellepoint sh.*—Red, argill., and variegated, or greenish gray and sandy; 30 to 40 ft. thick; plant and marine fossils; underlies Lower Bellepoint ss. and overlies Stony Gap ss.; type loc. in road which ascends Wolf Creek Mtn just SE. of Bellepoint; also observed in Giles and Tazewell Counties, Va. All are members of Hinton group [fm.].

Belleville formation.

Tertiary (late) or Pleistocene: Central northern Kansas (Cloud and Republic Counties).

M. E. Wing, 1930 (Kans. Geol. Surv. Bull 15, pp. 12, 19). *Belleville fm.*—Thick deposits of gravel, sand, and clay occurring in N. half of Republic Co. Primarily clay or sandy clay in upper half and sand or gravel in lower part. Most prominent feature is that it occupies a broad but well-defined channel, approx. 200 ft. deep, extending from near White Rock, Republic Co., to Chester, Nebr. Also extends beyond the old channel onto the uplands, where it is 40 to 80 ft. thick. North of Belleville the base of fm. rests on an almost flat surface of Carlile sh. Farther E. the deposit is slightly lower and in contact in places with "fence-post" ls., in upper part of Greenhorn ls. The stream in which the fm. was deposited flowed from W., and was comparable in size to Republican River. As far as can be determined only one fm. fills the channel, but this can not be determined with certainty. Is clearly Tert. and probably=part of Ogalalla fm. of western Kans. Few fossils.

A. L. Lugn, 1934 (Nebr. State Mus. vol. 1, Bull. 41, p. 355). *"Belleville fm."* (Wing) of northern Republic Co., Kans., is extension of fluviatile Pleist. sand and gravel fms. of Nebr. It is continuous with Pleist. deposits in Nuckolls and Thayer Counties, Nebr. *Equus* and other Pleist. mammalian remains have been gotten from these deposits at same localities described by Wing. Name "Belleville fm." should be discarded.

Bellevue limestone member (of McMillan formation).

Upper Ordovician: Southwestern Ohio, central northern Kentucky, and southeastern Indiana.

J. M. Nickles, 1902 (Cincinnati Soc. Nat. Hist. Jour., vol. 20, p. 82). *Bellevue or Monticulipora molesta beds.*—Lower 15 ft. rather shelly ls.; upper 5 ft. considerably different lithologically and somewhat faunally. Overlain by Corryville or *Chiloporella nicholsoni* beds and underlain by Fairmount or *Dekayia aspera* beds.

Basal memb. of McMillan fm., of Maysville group.

Named for old Bellevue House, a landmark, now disappeared, at bend in Clifton Ave., Cincinnati.

Bellingham conglomerate.

Carboniferous: Southeastern Massachusetts and northeastern Rhode Island.

G. R. Mansfield, 1906 (Harvard Coll. Mus. Comp. Zool. Bull., vol 49, geol. ser. vol. 8, No. 4, p. 99). *Bellingham cgl.* occupies only small area a few mi. NW. of Narragansett Basin.

C. H. Warren and S. Powers, 1914 (Geol. Soc. Am. Bull., vol. 25, p. 448). *Bellingham series.*—Dark-green schists and sheared cgls. intensely metamorphosed. Supposed to be of same age as Narragansett series. [Probably refers to Bellingham cgl.]

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, p. 56, and map). *Bellingham cgl.*—A coarse basal cgl. composed of pebbles of granite, qtzite, and green schist in a matrix of sericite schist. Is regarded as = Pondville cgl. Extends southward in a sinuous belt from near North Bellingham, Mass., past Woonsocket into Rhode Island. The rock has presumably been isolated by erosion from Narragansett Basin.

Bellingham beds.

Eocene: Northwestern Washington (Bellingham Bay region).

L. G. Hertlein and C. H. Crickmay, 1925 (Am. Phil. Soc. Proc., vol. 64, No. 2, pp. 225–226). *Bellingham beds.*—Continental deposits at Bellingham and Bellingham Bay, containing flora that appears to be later than Cret. and earlier than known middle Eo. flora. The Chuckanutz flora appears to be later than the leaves from Bellingham, and it is possible that there are different beds exposed near Bellingham which represent different periods. It is quite possible that Bellingham flora may represent a lower Eo. age, which might possibly belong to same epoch as Martinez fm. of Calif.

Bell Island series.

Lower Ordovician: Newfoundland.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4). *Bell Island series.*—Middle part of Lower Ord. of Newfoundland. Discon. overlain by Wabana series and discon. underlain by Clarenville series. Divided into (descending): Dominion ore bed, unnamed ss. and sh., Redmond fm., unnamed grits and shales, Eastern Head fm., Beach fm., McGraw bed, Lance Cove, Little Bell Island, and Kelly Island fms. Correlated with Lower Arenig and overlying Armorican of western Europe. [Derivation of name not stated.]

Bell Mountain sandstone member (of Miguel formation).

Upper Cretaceous: Southwestern New Mexico (Alamosa Creek Valley, Socorro County).

D. E. Winchester, 1920 (U. S. G. S. Bull. 716A). *Bell Mtn ss. memb.*—Top memb. of Miguel fm. Consists of thick-bedded, yellow to gray, coarse ss., containing *Halymenites* at top and *Inoceramus* at base. Thickness 79 ft. Well exposed near foot of Bell Mtn, T. 3 N., R. 9 W., Socorro Co. Lies about 983 ft. above Gallego ss. memb.

Bellows Falls granite gneiss.

Post-Ordovician: Southeastern Vermont (Windham County) and southwestern New Hampshire (Walpole).

E. Hitchcock, 1823 (Am. Jour. Sci., 1st, vol. 6, pp. 11–12 and map dated 1822), in description of Conn. River area from New Haven, Conn., to Bellows Falls, Vt., introduced *Bellows Falls granite* for a "sienitic granite."

C. H. Richardson and E. J. Foyles, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), assigned *Bellows Falls granite gneiss* to Camb., but without description or discussion.

C. H. Richardson, 1931 (17th Rept. Vt. State Geol., p. 229). *Bellows Falls gneiss.*—Underlies village of Bellows Falls, Vt., extends S. into Westminster, and E. across Conn. River into Walpole, N. H. Is also found in extreme SE. corner of Charlestown, N. H. Varies from medium to coarse, and in places becomes porphyritic. Color varies from light or medium gray to very dark gray. Is an acid intrusive. Age is definitely post-Ord., for the gneiss cuts Brattleboro phyllite, which is Ord.

Bellowspipe limestone.

Ordovician: Northwestern Massachusetts.

T. N. Dale, 1891 (Am. Geol., vol. 8, pp. 1–7). *Bellows Pipe ls.*—More or less crystalline ls., generally micaceous or pyritiferous, passing into calc. mica schist, feldspathic qtzite, or fine-grained gneiss. Thickness 600 to 700 ft. Underlies Greylock schists and overlies Berkshire schists on Mount Greylock. Named for occurrence at the "Bellows Pipe," in notch btw. Ragged Mtn and Greylock.

†Bellowspipe formation.

Ordovician: Northwestern Massachusetts.

T. N. Dale, 1894 (U. S. G. S. 14th Ann. Rept., pt. 2, pp. 559, 562). On Mount Greylock the Berkshire schist, 1,000 ft. or more thick, is overlain by a mass, 600 ft. thick, of more or less impure ls., qtzite, calc. sericite schist and muscovite-biotite schist, constituting *Bellowspipe fm.* [As thus defined includes Greylock schist (muscovite (sericite), chlorite, and quartz schist) and Bellowspipe ls.]

†Bellowspipe quartzite.

Ordovician: Southwestern Massachusetts.

T. N. Dale, 1894 (U. S. G. S. 14th Ann. Rept., pt. 2, p. 559, pl. 71). [The geol. map (pl. 71) of Monument Mtn, in SW. part of Berkshire Co., applies name *Bellows Pipe qtzite* to the rocks overlying the Berkshire schist. Page 559 states that the qtzite shown on the map is a vitreous qtzite, petrographically identical with that which underlies Stockbridge ls., as well as that which overlies it in places, and also with that which occurs on Mount Greylock [in NW. part of Berkshire Co.] in the Bellowspipe fm., above the Berkshire schist; also that it is 500 to 600 ft. thick.]

B. K. Emerson, 1917 (U. S. G. S. Bull. 597), mapped the qtzite of Monument Mtn as Cheshire qtzite, of Lower Camb. age. The qtzite in the Bellowspipe ls. of Mount Greylock is a much younger bed, of Ord. age.

Bells Landing marl member (of Tuscahoma sand).

Eocene (lower): Southwestern Alabama.

E. A. Smith, 1883 (Ala. Geol. Surv. Prog. Rept. for 1881–82, pp. 256, 321). *Bell's Landing marl.*—Greensand shell marl with indurated bed in its midst or at top; thickness 10–15 feet. Separated from younger Wood's Bluff marl by 50–80 ft. of lignitic clays and sands. Included in Lagrange or Lignitic.

E. A. Smith, 1886 (Ala. Geol. Surv. Bull. 1, p. 12). *Bell's Landing marl.*—Fossiliferous marine marl, 10 ft. thick, distinguished from all marls in Ala. by great size of shells it contains. Overlain by 40 ft. of sandy strata, forming top of Bell's Landing section, and separated from the older Gregg's Landing marl by 20–25 ft. of dark-gray sandy clays.

Is a memb. in upper part of Tuscahoma sand.

Named for exposures at Bells Landing, on Alabama River, in Monroe Co.

†Bells Landing series.

Eocene (lower): Southwestern Alabama.

E. A. Smith and L. C. Johnson, 1887 (U. S. G. S. Bull. 43, pp. 46–51). *Bell's Landing series.*—Consists of (descending): (1) 40 ft. of reddish sands and laminated gray, sandy clays; (2) Bell's Landing marl bed proper (fossiliferous marl, 10 ft. thick, containing some greensand); (3) gray sandy clays, 20–25 ft.; (4) Gregg's Landing marl, 4–5 ft.; and (5) 60 ft. of sandy clays of prevailingly gray color, with 1-foot marl bed about 10 ft. above base. Underlies Wood's Bluff or Bashi series and uncon. overlies Nanafalia series.

Replaced by Tuscahoma sand, better established name. Has also been called "Bells Landing fm."

Named for exposures at Bells Landing, on Alabama River, in Monroe Co.

Bellton coal group. (In Greene and Washington formations.)

Permian: Southwestern Pennsylvania and northern West Virginia.

I. C. White, 1891 (U. S. G. S. Bull. 65, pp. 32, 34). *Bellton coal group.*—Shales, sss., coals, and 2 important lss., 200 to 300 ft. thick. Top lies 275 to 300 [?] ft. below Nineveh ss. Includes Nineveh coal at top and Jollytown coal at base. Included in Dunkard Creek series [Dunkard group]. Named for Bellton, Marshall Co., W. Va., where all of the beds are present.

Has also been called "Bellton stage."

Bellvale flags.

Bellvale sandstone.

Devonian (Middle): Northern New Jersey and southeastern New York (Orange County).

N. H. Darton, 1894 (Geol. Soc. Am. Bull., vol. 5, pp. 367, 373). *Bellvale flags.*—Hard thin-bedded sss. merging into dark-colored below. Chiefly dark gray. Bellvale Mtn [Orange Co., N. Y.] consists largely of these flags. Overlain by Skunnemunk cgl. and underlain by Monroe [Cornwall] shales. Thickness 1,300 to 2,000 ft.

H. Ries, 1897 (N. Y. State Geol. 15th Ann. Rept., vol. 1). The *Bellvale flags* extend from N. J. State line to N. end of Skunnemunk Mtn, where they terminate somewhat abruptly. Assigned to Hamilton epoch.

E. C. Eckel, 1902 (N. Y. State Geol. 20th Ann. Rept., pp. r144 to r150). The *Bellvale flags* contain Middle Dev. plants.

H. B. Kümmel and S. Weller, 1902 (N. J. Geol. Surv. Ann. Rept. State Geol. 1901). The lower beds of *Bellvale flags* contain Hamilton fossils [listed].

C. A. Hartnagel, 1912 (N. Y. Geol. Surv. Hdb. 19, p. 69). The plant remains from *Bellvale flags* indicate Middle Dev. age, and it seems probable the higher beds are as late as Portage.

J. V. Lewis and H. B. Kümmel, 1915 (N. J. Geol. Surv. Bull. 14, p. 56, and geol. map of N. J.). *Bellvale ss.*—Gray ss. and sandy sh. A few Hamilton fossils.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 396). *Bellvale sh.* contains Mid. Dev. plants.

Bellyan series.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 42, p. 288). Sss., 2,000 ft. thick, lying uncon. below Pierrian series and uncon. above Coloradan series in Alberta. Of Mid Cretacic age. Includes Allison fm. [only fm. mentioned].

Derivation of name not stated.

Belly River formation.

Upper Cretaceous (of Montana age): Alberta and Saskatchewan, Canada.

G. M. Dawson, 1883 (Canada Geol. Surv. Rept. 1880–82, p. 4B) and 1885 (Canada Geol. Surv. Rept. 1882–3–4, pp. 37C–126C). *Belly River series, Cretaceous, Canada.*

R. G. McConnell, 1886 (Canada Geol. Surv., n. s., vol. 1, pp. 63C–65C). *Belly River series, Cretaceous, Canada.*

The Belly River fm. of Canada has been considered to be=Two Medicine fm. and Virgelle ss. of Blackfoot Indian Res., northern Mont., and Judith River fm., Claggett fm., and Eagle ss. of central Montana.

W. S. Yarwood, 1931 (A. A. P. G. Bull., vol. 15, No. 10, pp. 1269–70). *Belly River group* as here used includes (descending) Pale, Foremost, Pakowki, and Milk River fms. Belly River as used by Canadian Geol. Survey is restricted to Pale beds and Foremost fm. and is=Judith River of Mont.

M. Y. Williams, 1932 (Jour. Geol., vol. 40, No. 6, p. 561). *Belly River* of Alberta and Saskatchewan is=Judith River fm. of Mont.

Belmont porphyry.

Tertiary (late?): Central western Montana (Marysville district).

J. Barrell, 1907 (U. S. G. S. P. P. 57). *Belmont diorite porphyry dikes and sheets.*—Later than Marysville batholith. [Mapped on and around Mount Belmont, 1 mi. W. of Marysville. The Marysville batholith is probably late Cret. or Tert., and may be as young as Mio. Personal communication of J. T. Pardee.]

Belmont amygdaloidal basalt and tuff.

Pre-Cambrian: Southeastern Ontario (Belmont Lake area).

W. G. Miller and C. W. Knight, 1914 (Ontario Bur. Mines Rept., vol. 22, pt. 2, p. 19). Younger than Belmont gabbro diabase.

Belmont gabbro diabase.

See under *Belmont amygdaloidal basalt and tuff.*

Belmont facies.

Name applied by P. B. Stockdale (Ind. Dept. Cons., Div. Geol. Pub. 98, pp. 77, 143, etc., 1931) to a lithologic development of his Locust Point fm. in a part of southern Ind.

Belmont limestone.

Pleistocene: Bermuda.

C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 740).

Beloit dolomite.

Middle Ordovician: Eastern Wisconsin and northeastern Illinois (in wells).

F. W. Sardeson, 1896 (Am. Geol., vol. 18, pp. 356–368). *Beloit fm.*—Name proposed for the beds beneath Galena ls., which in previous repts have been called *Trenton ls.* but which are now considered to probably be older than Trenton ls. of N. Y., the Galena probably being=N. Y. Trenton. The Beloit includes beds which in previous repts have been called *Blue ls.* and *Buff ls.*

The Beloit dol. overlies St. Peter ss., and includes equivalents of Decorah sh. (of Trenton age) and Platteville ls. (of Black River age).

Named for exposures at Beloit, Wis.

Belt series.

A provincial series of pre-Camb. metamorphosed sed. rocks widely developed in Mont., Idaho, eastern Washington, and British Columbia. In early repts called "Belt fm.," "Belt terrane," "Belt beds," and "Belt group." For definition see U. S. G. S. Bull. 769, pp. 108–112.

Beltian system.

A term introduced by R. A. Daly in 1913 (12th Int. Geol. Cong. Guidebook 8, p. 132) for rocks in B. C. that correspond to Belt series of Mont. and Idaho.

Belva shale.

Pennsylvanian: Western Arkansas coal field.

A. Winslow, 1896 (N. Y. Acad. Sci. Trans., vol. 15, p. 51). *Belva sh.*—Sh., 0 to 500 ft. thick, overlying Ozark ss. and underlying Hartwell ss.; all included in Sebastian stage. [Is a part of Fort Smith fm.]

Probably named for Belva, Scott Co.

Belveal sand.

A subsurface sand, of Penn. age and 25± ft. thick, in central northern Okla., probably correlating with part of Sand Creek fm. In Garber pool, Garfield Co., it lies at 1,600 ft. depth, the Walker sand lying at 1,500 ft. and the Campbell at 1,700 ft.

†Belvidere shale.

Lower Cretaceous (Comanche series): Central southern Kansas.

R. T. Hill, 1895 (Am. Jour. Sci., 3d, vol. 50, pp. 208–234). [On pp. 208 to 210 *Belvidere sh.* is defined as consisting of blue sh., with indurated fossil layers, 106 ft. thick, overlying Cheyenne ss. and underlying "Dakota" ss., both including and excluding oyster bed (Champion shell bed) at base. On p. 211 *Belvidere* is defined as including *Belvidere shales* ("for which Cragin has proposed *Kiowa* since this paper was written") and Cheyenne ss., or all beds btw. "Dakota" ss. [the quotation marks are Hill's] above and Red Beds below.] Contains Comanche fossils. Named for Belvidere, Kiowa Co.

F. W. Cragin, 1895 (Am. Geol., vol. 16, pp. 357–385). *Belvidere beds* (or *Walker beds*) is proposed to include Kiowa sh. (=Belvidere sh. of Hill), Champion shell bed, and underlying Cheyenne ss., *Walker* being suggested in case objection is made to use of *Belvidere* to include more than Belvidere shales of Hill, but *Belvidere* is preferable name for this larger unit.

C. S. Prosser, 1897 (Univ. Geol. Surv. Kans., vol. 2, pp. 111+), divided the Comanche of southern Kans. into Kiowa sh. (including *Champion sh. bed*) and Cheyenne ss., and suggested that, if a name is needed for the 2 fms. combined, some other name than *Belvidere* be adopted.

Subsequent repts simply used *Kiowa* and *Cheyenne* for the subdivisions of the Comanche in southern Kans., and *Belvidere* and *Walker* dropped out of the literature until 1924. The *Mentor fm.* of central Kans. was assigned to a higher position in the Comanche than the Kiowa, and the 3 names were used for many years for the subdivisions of the Comanche in Kans.

W. H. Twenhofel, 1924 (Kans. Geol. Surv. Bull. 9). *Belvidere fm.* as here defined includes (descending): Greenleaf ss. memb., 25 to 50 ft.; Spring Creek sh. memb., 25 to 50 ft.; and Kiowa sh. memb., the latter including "Champion shell bed" at base. Overlies, apparently conformably, Cheyenne ss., but R. C. Moore says there is evidence, at least locally, of uncon. Underlies Kirby clay memb. of "Dakota" fm., apparently conformably. [Twenhofel divided Belvidere fm. of McPherson Co. into 4 members, listed in 1924 entry under *Mentor fm.*]

F. M. Bullard, 1928 (Okla. Geol. Surv. Bull. 47, p. 49). It seems unadvisable to retain Hill's term *Belvidere* and place the various beds as members of this fm. They certainly do not contain enough characteristics to justify placing them in a single fm. The term *Belvidere* is therefore discarded and the members (Greenleaf ss., Spring Creek clay, and Kiowa sh.) are described as fms.

Belvidere Mountain amphibolite.

Paleozoic: Northwestern Vermont (Jay Peak quadrangle).

S. B. Keith and G. W. Bain, 1932 (Econ. Geol., vol. 27, No. 2, pp. 173–174). *Belvidere Mtn amphibolite.* Paleozoic, extends from Belvidere Mtn [SE. corner of Jay Peak quad.] as far N. as Hazen's Notch road. Is a typical metamorphosed diabase or pyroxene diorite.

Bemis moraine.

Pleistocene (Wisconsin stage): South Dakota, southern Minnesota, and northern Iowa.

F. Leverett, 1922 (Geol. Soc. Am. Bull., vol. 33, pp. 102–103 and map). Name introduced for outermost moraine of Wisconsin drift in S. Dak., southern Minn., and northern Iowa, which was previously mapped as part of Altamont moraine, but which is now known to be older than the moraine at Altamont, S. Dak., the type loc. of Altamont moraine. Named for occurrence at Bemis, Deuel Co., S. Dak.

Is of late Wisconsin age, according to W. C. Alden.

Bend group (Pennsylvanian).

†Bend series (Pennsylvanian and Mississippian).

Central Texas.

E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, p. lxv). *Bend series.*—Lss. and shales forming basal Carbf. deposits in central Tex. [Llano, Burnet, and Mason Counties]. Probably includes Subcarbf. and coal measures. Contains one or more coal beds. In places seems to show uncon. with overlying Richland ss. (undoubted Carbf.). Well exposed at McAnnelly's Bend [of Colorado River], San Saba Co., for which it is named.

W. F. Cummins, 1891 (Tex. Geol. Surv. 2d Ann. Rept.). *Bend div.* is present in only central area of northern Tex. Consists of 140 ft. of shales underlain by 220 ft. of lss. Is basal div. of Coal Measures [Penn.].

G. H. Girty, 1912 (U. S. G. S. Llano-Burnet folio, No. 183, p. 8). Typical *Bend series of Tex. Surv.* is divisible into 3 portions—an upper and lower sh. separated by a series of lss. The lower div. [Barnett sh.] I am referring to Miss. According to canons at present used for determining the Penn. by paleontologic evidence the middle [called Marble Falls ls. in folio] and upper [called Smithwick sh. in folio] divisions would be called Penn. I feel no hesitation in recognizing Marble Falls ls. as middle div. of typical Bend of Tex. Surv., and although I did not see or collect fossils from the sh. at Marble Falls, it seems a fairly safe inference that this [Smithwick sh.] is upper div. It seems somewhat doubtful whether the lowest div. is represented in Burnet and Llano quads.

C. Schuchert, 1915 (Textbook geol., pt. 2, p. 732), included *Bend* in Penn., without specifying subdivisions.

J. A. Udden, C. L. Baker, and E. Böse, 1916 (Univ. Tex. Bull. 44, pp. 41–43), divided *Bend series* into (descending) Smithwick sh., Marble Falls ls., and Lower Bend sh., and stated: The age of the Bend may be Upper Miss. (St. Louis–Chester stage), as thought by J. P. Smith, but it will here be described under Penn. heading. It is uncon. overlain by Strawn fm. *Lower Bend sh.* is 0 to 50 ft. thick, and contains some layers of dark ls. [The 1919 ed. of this bull. stated: "The age of the Bend is probably early Penn."]

L. S. Kempher, 1918 (Remarks on geol. of north-central Tex. oil and gas region), assigned *Bend fm.*, as he called it, to Miss., and divided it into (descending): (1) Smithwick sh. (fauna possibly extremely early Penn., but more probably extremely late Miss.); (2) Marble Falls ls. (fauna not more recent than St. Louis–Chester and not older than Kinderhook); (3) *Bend fm.* (200 to 300 ft. of black sh., black lss. and sss., carrying fauna not more recent than early or middle Miss. and not older than extremely late Dev.).

J. A. Udden, 1919 (A. A. P. G. Bull., vol. 3, pp. 34–38), divided *Bend series*, as he called it, into (descending): Smithwick sh. (few ft. to 700± ft.); Marble Falls ls. (200 to 400± ft.); and Lower Bend sh. (few ft. to 150 ft.); age uncertain—whether all Penn., or all Miss., or part Penn. and part Miss. F. B. Plummer (pp. 132–145 of same bull.) assigned *Bend fm. or Bend series*, as he called it, to lower Penn., and included in it Smithwick sh., Marble Falls ls., and Lower Bend sh. W. G. Matteson (pp. 169–211 of same bull.) assigned *Bend series* (including the same 3 fms.) to Miss. R. C. Moore (on pp. 217+ of same bull.) assigned *Bend series* to early Penn., and stated that all fossils of basal black sh. are common to overlying beds in *lower part* of Marble Falls ls. G. H. Girty (pp. 71 to 81, 418–420 of same bull.) expressed opinion *basal Bend sh.* is Miss. and Marble Falls ls. and Smithwick sh. are Penn. Also that a thin ls. of Miss. age had been included in base of Marble Falls ls. of some authors; that lower part of this Miss. ls. is absent at Marble Falls, but that upper part of it may or may not be represented at Marble Falls. He included this thin Miss. ls. in his basal Bend sh. He also stated that important uncon. and faunal change exists btw. Marble Falls ls. and underlying sh. of Miss. age. M. I. Goldman, 1921 (U. S. G. S. P. P. 129A), assigned *true Marble Falls ls.* to Penn. and called the 20 to 50 ft. of black Miss. ls. "*Lower Bend*" *ls.* and underlying black sh. "*Lower Bend*" *sh.*, and reported an uncon. at base of Marble Falls ls. and at base of "Lower Bend ls." The *Bend series* being thus subdivided into Penn. and Miss. fms. the name was in 1920 discarded by U. S. Geol. Survey.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 25–26), replaced "Lower Bend sh." with *Barnett sh.*, which they tentatively referred to Miss. In Univ. Tex. Bull. 2132, 1922, they continued to use *Bend group* (as it is "one of most widely known geological units of the SW."), classified it as Penn., and included in it Barnett sh. They also stated that Barnett sh. included at top a thin ls. that contains fossils of "Miss. aspect," and that the Barnett appears to writers to belong to Penn. but that it may prove to be upper Miss.

C. Schuchert, 1924 (Textbook geol., pt. 2, pp. 353, 357, 358, 368), stated: *Bendian series* includes Smithwick shales, 0 to 1,000 ft.; Marble Falls ls., 200 to 700 ft.; and Lower shales. Assigned to Penn., although considered older than usual type of Penn. fms.

W. E. Hubbard and W. C. Thompson, 1926 (A. A. P. G. Bull., vol. 10, No. 5, pp. 461–462), *restricted Bend group* to Penn. (Smithwick sh. and Marble Falls ls.) and assigned Barnett sh. to Miss., as did M. G. Cheney, 1929 (Univ. Tex. Bull. 2913). R. C. Moore, 1929 (A. A. P. G. Bull., vol. 13, p. 894), however, continued to include Barnett in *Bend.* But J. P. Bowen and J. F. Gibbs, 1932 (A. A. P. G. Bull., vol. 16, No. 2, p. 181), restricted *Bend group* to Penn.

R. C. Moore, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, p. 279), divided the Penn. "system" of Mid-Continent field into 4 "series," to which he applied following names (descending): Virgil, Pottawatomie, Des Moines, and Bend. He defined latter as follows: "The *Bend series*, at base of the system, consists predominantly of marine beds containing a distinctive fauna that shows strong relationship with uppermost Miss. faunas. A distinct and widespread uncon. marks top of the series."

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 99–100), included in *Bend group* only Smithwick sh. and Marble Falls ls., and assigned both to Penn.

C. Schuchert and C. O. Dunbar, 1933 (Textbook geol., pt. 2, p. 248), included in *Bend* the Smithwick sh., Marble Falls ls., and Barnett sh., and assigned its upper part to Pottsville time and its lower part to a period of pre-Pottsville *Penn.* time "not represented by deposits in Appalachian region, Kans., Nebr., or Ill., but corresponding to lower part of Namurian of Europe."

R. H. Dott, 1934 (A. A. P. G. Bull., vol. 18, No. 5, p. 579), used *Bendian* as a time term for Penn. rocks underlying *Pottsville* of "standard" classification; but this constitutes a restriction of Pottsville, which, according to established classification, includes the oldest Penn. sediments in America. The Marble Falls ls. was in 1924 pronounced by G. H. Girty to be of Pottsville age.

B. H. Harlton, 1934 (A. A. P. G. Bull., vol. 18, No. 8, pp. 1018–1049), used *Bendian period* as a time term separating Penn. (restricted) "period" from Miss. "period," and showed unconformities at top and base of the rocks assigned to his Bendian period. He divided his Bendian period into paleontologic subdivisions called *Upper Bendian, Middle Bendian,* and *Lower Bendian,* and assigned to it various named fms. of western Tex., central Tex. (the typical Bend region), Arbuckle Mtn and Ouachita Mtn regions of Okla., and also NE. Okla and NE. Ark. In Bend region he assigned to his Bendian period the Smithwick sh., Marble Falls ls., and what appears to be upper part of Barnett sh., which he showed (p. 1020) as separated from Marble Falls ls. by a great hiatus, and as separated from what appears to be Barnett sh. restricted by another hiatus.

The U. S. Geol. Survey in 1935 adopted *Bend group* as defined by Tex. Geol. Survey in 1933, i. e., to include the two fms. of Penn. age (Smithwick sh. above and Marble Falls ls. below) that are present in Bend region. F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Surv. Bull. 3534, p. 65), also included in Bend group (Penn.) the Smithwick and Marble Falls fms. and assigned the Barnett to Miss.

†Bend formation.

Middle and Lower Jurassic: Northern California (Gold Belt region).

J. S. Diller, 1892 (prel. proof-sheet edition of U. S. G. S. Lassen Peak folio, No. 15) and 1895 (published Lassen Peak folio, No. 15). The *Bend fm.* contains some ls., but is composed chiefly of slates, sss., and cgls., and crops out along western arm of Great Bend of Pit River. Isolated areas of the ls. are exposed near stage road 1 mi. W. of Montgomery Creek, and the slates and sss. form upper part of N. slope of Cedar Creek 4 mi. W. of Round Mtn. Jurassic fossils. Rests on Cedar fm. and is overlain by Chico fm.

H. W. Fairbanks, July 1894 (Am. Geol., vol. 14, p. 27). *Bend fm.*, consisting of slates and argill. ls., embraces, as far as is known, the Lower and Middle Jura.

J. P. Smith, October 1894 (Jour. Geol., vol. 2, p. 611). *Bend fm.* was named by J. S. Diller (U. S. G. S. Lassen Peak Sheet, 1892) to include all Jurassic deposits of region of Big Bend of Pitt River. In a later publication Mr. Diller (Bull. Geol. Soc. Am., vol. 4, 1893, p. 221) stated that Pitt River Jura corresponds to Mormon ss. (Middle Jura) of Taylorsville region. About 6 mi. W. of Big Bend, in Big Canyon, H. W. Fairbanks discovered fossils, in shaly lss., which, on examination by writer, proved to be Jurassic and probably = Hardgrave ss. (Lower Jura) of Indian Valley.

Includes Potem and Modin fms.

Bend sand.

A subsurface sand, of Penn. age, in Brown, Eastland, Stephens, and Young Counties, north-central Tex. Lies at 2,700 to 4,200 ft. depth.

†Bendian series.

See under *Bend group*, C. Schuchert 1924 and R. H. Dott 1934.

Benezette limestone member (of Pocono formation).

Mississippian: Central northern Pennsylvania (Elk County).

C. A. Ashburner, 1885 (2d Pa. Geol. Surv. Rept. R_2, pp. 104–105). Ls., in Pocono fm. along main branch of Straight Creek, lying 200 ft. below Olean cgl. is probably same as *Benezette ls.*, found along road SW. of Benezette village.

F. G. Clapp, 1905 (U. S. G. S. Bull. 249, p. 21). *Benezette ls.*—At a few points in Elk Co. a triple bed of ls., supposed to be of Pocono age, has been found about 200 ft. below Olean cgl. The upper bed is reported as having probable max. thickness of not over 7 ft., the others being considerably thinner. Outcrops 1 mi. W. of village of Benezette.

Ben Harrison limestone.

Miners' local name for an ore-bearing ls., 40± ft. thick, in middle part of Oquirrh fm. (Penn.) of northern Utah. Lies 120 to 250 ft. below Black Bear ls. (miners' name) and 500± ft. above Larsen ls. (miners' name). Is worked in Ben Harrison mine, Stockton dist. (See U. S. G. S. P. P. 173, 1932.)

Ben Lomond formation.

Oligocene (?): Trinidad.

V. C. Illing, 1928 (Geol. Soc. London Quart. Jour., vol. 84, p. 15).

Bennett quartzite.

Pre-Cambrian: Quebec.

J. K. Knox, 1917 (Canada Geol. Surv. Summ. Rept. 1916, p. 233).

Bennett shale.

Pennsylvanian: Southeastern Nebraska and northeastern Kansas.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 84, 86, 88, 185). *Bennett sh.*—Bluish-gray and nearly black argill. sh. with one carbonaceous streak resembling coal and a thin yellowish to brownish ls. Thickness 8 to 10 ft. in Nebr. and 12 ft. in NE. Kans. Underlies Howe ls. and overlies Glenrock ls.; all included in Elmdale sh. memb.

G. E. Condra, 1935. (See under *Howe ls.*)

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), transferred this unit to Perm. This change in Perm.-Penn. bdy has not been considered by U. S. Geol. Survey for its publications.

E. C. Reed (Asst. State Geol. Nebr.), 1936 (letter dated Oct. 16). Type loc. of Bennett sh. is along the Little Nemaha and its branches S. of Bennett, Lancaster Co., Nebr.

Bennett oil sand.

Subsurface sand in lower part of Penn. section of Graham field, in NW. part of Carter Co., Okla., from 80 to 135 ft. below Graham oil sand and about 165 ft. above Sutherland oil sand. Thickness 10 to 45 ft.

Bennett Bridge beds.

Upper Ordovician: Northern New York (Black River Valley).

R. Ruedemann, 1925 (N. Y. State Mus. Bull. 258, pp. 87–89, 138, 141, 149, 154). *Bennett Bridge beds, zone of Pholadomorpha nasuta.*—Uppermost part of Pulaski fm. Overlie Sandy Creek beds and underlie Oswego ss. Exposed along upper Sandy Creek and at Bennett bridge, below Salmon River Falls [Oswego Co.].

Bennettsville facies.

Name applied by P. B. Stockdale (Ind. Dept. Cons., Div. Geol. Pub. 98, pp. 77, 149, etc., 1931) to a lithologic development ("that of the type locality of the fm.") of his Carwood fm. in a part of southern Ind.

Benning granite.

Trade name for a white, coarse, granular, imperfectly schistose granite exposed at Benning mine, NE. of Dahlonega, Ga., where it is associated with a dark-colored mica schist. (See U. S. G. S. Bull. 293, p. 122, 1906.)

Bennington quartzite.

Lower Cambrian: Southwestern Vermont (Bennington County).

C. D. Walcott, 1896 (U. S. G. S. Bull. 134, p. 33), in discussion of the correlation of the Lower Camb. qtzite in Eastern States, called this qtzite in N. Y. and Vt. *Bennington qtzite,* but did not otherwise define the name.

G. W. Bain, 1927 (15th Rept. Vt. State Geol., pp. 222–226). *Bennington qtzite.*—In N. part of Vt. coarse bouldery deposits were left on the ancient piedmont plain. In central Vt., btw. Brandon and Rutland, the beds are thinner and only in rare instances do constituent grains exceed ¼ inch diam. At Bennington the beds are composed of small sand grains. Unweathered feldspar pebbles are common in the deposits btw. Brandon and Rutland, which indicates rapid erosion and deposition.

F. A. Burt, 1929 (16th Rept. Vt. State Geol., pp. 68–84, in description of Bennington area). Vermont fm. consists locally of 1,600± ft. of Lower Camb. qtzites called by Bain the *Bennington qtzite.*

Bennington limestone.

Lower Cretaceous: Southeastern and central southern Oklahoma.

J. A. Taff, 1902 (U. S. G. S. Atoka folio, No. 79, p. 6). *Bennington ls.*—Massive dull-blue shell ls., 10 to 15 ft. thick, underlying Silo ss. and overlying Bokchito fm. In Tex. is represented by 80 to 100 ft. of calc. fossiliferous clays.

Named for Bennington, Bryan Co.

Benoist sand.

A subsurface sand in Chester group (Miss.) of Marion Co., Ill. (See Ill. Geol. Surv. Bull. 54, index.)

Bens Creek sandstone. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and D. B. Reger, 1914 (W. Va. Geol. Surv. Rept. Logan and Mingo Counties, p. 204). *Bens Creek ss.*—Massive, medium-grained, micaceous, grayish brown. Thickness 0 to 30 ft. Lies 0 to 5 ft. below Eagle coal and 5 to 10 ft. above Bens Creek coal. Named for association with Bens Creek coal, which was named for Bens Creek, Mingo Co.

Benson formation.

Upper Cretaceous: British Columbia.

C. H. Clapp, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 96, and Canadian Min. Inst. Trans., vol. 15, p. 338).

Benson limestone.

Middle Ordovician (Trenton): Central Kentucky.

A. F. Foerste, 1913 (Ky. Geol. Surv., 4th ser., vol. 1, pt. 1, imprint on title page July 1913, pp. 380, 389, 429, 430). *Benson or Bigby bed.*—Fossiliferous granular ls., occasionally phosphatic at top; 35 ft. thick. Underlies Brannon bed and overlies Wilmore bed. Has been regarded same as Bigby fm. of Tenn., but Bigby should either include all strata btw. Wilmore and Perryville fms. or be restricted to Woodburn horizon.

Named for Benson, Franklin Co.

Benson limestone.

Mississippian (lower and upper?): Central northern Utah (central Wasatch Mountains).

F. F. Hintze, Jr., Dec. 12, 1913 (N. Y. Acad. Sci. Annals, vol. 23, pp. 109, 113). *Benson ls.*—Descending: (1) Hard, dark-blue, cherty, coralline ls., 100 ft.; (2) massive dark-blue ls., 300 ft.; (3) fossiliferous blue ls., 3 ft.; (4) thick-bedded blue ls., 100 ft.; (5) dark-blue cherty and brecciated ls., 200 ft.; (6) hard blue ls., 100 ft.; (7) dark porous ls., very fossiliferous, 21 ft.; (8) thick-bedded blue ls., extensively bored, 120 ft.; (9) thick-bedded light-blue ls., 43 ft.; (10) thin-bedded blue ls., 45 ft.; (11) ls. cgl. at base, thin. Total thickness 1,032 ft. Underlies Reade fm. without observed discon. Uncon. overlies Maxfield fm. (Ord.). Named for occurrence in Reade [Reed] and Benson Ridge, just above old mine workings of same name [in Salt Lake Co.].

Fossils collected from lower 500 ft. of these rocks (by B. S. Butler in 1916 and 1917) have been identified by G. H. Girty as clearly of Madison (lower Miss.) age. Whether upper 900 ft. contains evidence indicating that any part of fm. is post-Madison, and of Brazer age, remains to be determined, but probably some of it is of Brazer (upper Miss.) age.

Benson sand.

A subsurface sand, of Upper Dev. (Chemung or Portage) age, in W. Va. that lies lower than Cooper sand and higher than Elk sand. The name has also been carried into SW. Pa., where it appears to have been applied to a lower sand, 70 ft. thick in boring near McDonald, Pa., where its top lies 2,129 ft. below Gordon Stray sands. Named for J. C. Benson well in W. part of Barbour Co., W. Va.

Bent sandstone. (In Bluestone formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 293, 315). *Bent ss.*—Greenish brown, micaceous, flaggy or shaly ledge, usually 40 to 60 ft. thick. Lies 50 to 200 ft. below top of Bluestone group [Bluestone fm.]. Rests on Upper Bent sh. Type loc. is on Bent Mtn (Mercer Co., 1.2 mi. SE. of Pride), where it is 55 ft. thick.

Bent shale. (In Bluestone formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Tazewell County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 293, 315–316). *Upper Bent sh.* immediately underlies Bent ss. memb. of Bluestone group and is separated from *Lower Bent sh.* by Bent ls., 0 to 1 foot thick. All belong in Bluestone group [Bluestone fm.]. *Upper Bent sh.* is sometimes red and variegated, and sometimes black and fissile, 20 to 40 ft. thick, and contains marine fossils. Its type loc. is on Bent Mtn (Mercer Co., W. Va., 1.2 mi. SE. of Pride), where it is red and green and 55 ft. thick. The *Lower Bent sh.* is green, argill., and fissile, and carries marine fossils. It was not seen in Mercer, Monroe, and Summers Counties, W. Va., but is visible in Tazewell Co., Va., about 1 mi. NW. of Bailey Station; thickness 6 to 18 ft. [See also under *Bent ls.*]

Bent limestone. (In Bluestone formation.)

Mississippian: Southwestern Virginia (Tazewell County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 293, 316). *Bent ls.*—A thin lenticular horizon, 0 to 1 foot thick, named for its association with Upper Bent sh. Contains ostracods. Is a memb. of Bluestone group [Bluestone fm.]. Presence not noted in Mercer, Monroe, and Summers Counties, but is exposed in Tazewell Co., Va., on a cross road that passes Bailey Station NW. to Mud Fork of Bluestone River, the outcrop being on the Mud Fork side of the ridge and about 1 mi. from the station, where it lies btw. Upper Bent sh. and Lower Bent sh.

Benton shale. (In Colorado group.)

Upper Cretaceous: Southeastern Montana, South Dakota, eastern Wyoming, Nebraska, southern Minnesota, eastern Colorado, Kansas, northeastern New Mexico.

F. B. Meek and F. V. Hayden, 1862 (Phila. Acad. Nat. Sci. Proc., vol. 13, pp. 419, 421). *Fort Benton group (Formation No. 2 of Cret.).*—Dark-gray laminated clays, sometimes alternating near upper part with seams and layers of soft gray and light-colored ls. Fossiliferous. Thickness 800 ft. in vicinity of Fort Benton, on Upper Missouri River. Also occurs along Missouri River from 10 mi. above James River to Big Sioux River; along eastern slope of Rocky Mtns; and at Black Hills. Overlies Dakota group and underlies Niobrara div. [This paper by Meek and Hayden described the rocks of Nebr., which at that time included Wyo., Mont., and Dak.]

Is lower fm. of Colorado group. For many years the "Fort" has been dropped from the name, and *Benton sh.* has been used.

Named for Fort Benton, on Missouri River, about 40 mi. below Great Falls, Mont., but the strat. limits of the fm. are based largely on sections along Missouri River in northern Nebr., where Benton sh. rests on Dakota ss. and is overlain by Niobrara ls. The early Cret. rocks of central Mont. region, including Fort Benton, are now classified as Colorado sh. (= undivided Niobrara and Benton) and Kootenai fm. (Lower Cret.). In parts of Wyo. and eastern Colo. the rocks formerly called Benton are now divided into (descending) Carlile sh., Greenhorn ls., and Graneros sh. In central southern Wyo. and Bighorn Mtns they are divided into (descending) Carlile sh., Frontier fm., Mowry sh., and Thermopolis sh.

Benton sand.

Tertiary: Southeastern Missouri.

C. F. Marbut, 1902 (Mo. Univ. Studies vol. 1, No. 3, pp. 18, 23, 32). *Benton sands.*—Gray, reddish, or brownish sands in lower part, white sands and whitish clays in upper part; thickness 0 to 200 ft. Underlie whole area of Crowley and Benton ridges and apparently Sikeston ridge also. Of late Tert. age, probably Lafayette [also calls them *Lafayette sands*]. Rest uncon. on Idalia sh. or clay, and underlie, probably uncon., Piketon or Lafayette gravels or the loess.

Appears to belong to Wilcox fm.

Named for exposures at Benton Ridge, Scott Co.

Bentonian series.

A term applied by C. R. Keyes to deposits underlying his Pierran series and overlying his Bearian series. Includes Niobrara ls. and Benton sh. (See Pan-Am. Geol., vol. 63, No. 4, 1935, p. 281, and vol. 64, No. 1, 1935, p. 11.)

Benwood limestone member (of Monongahela formation).

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

M. R. Campbell, 1903 (U. S. G. S. Brownsville-Connellsville folio, No. 94, p. 10). *Benwood ls.*—Geographic name (to replace inappropriate name "Great ls.") for the thick ls. which occupies interval btw. Sewickley coal and Uniontown coal. Is generally composed of 2 members having total thickness of about 140 ft. Lower memb. is entirely ls. and 70 or 80 ft. thick. Upper memb. is considerably broken by ss. and sh. beds. Name *Benwood* suggested, in correspondence, by Dr. I. C. White, from town of Benwood, Marshall Co., W. Va. According to Dr. White the ls. is well exposed in river bluffs in that vicinity.

In 1907 the W. Va. Geol. Surv. (Repts. on Ohio, Brooke, Hancock, Marshall, Wetzel, and Tyler Counties) restricted *Benwood ls.* to lower div. of "Great ls.," and applied *Fulton green sh.* to the thin sh. (0 to 5 ft.) in places separating it from overlying Uniontown ls., or upper div. of "Great ls." This is present established definition of Benwood ls.

Berea sandstone.

Mississippian: Ohio, southern Michigan, western Pennsylvania, northeastern Kentucky, and northern West Virginia.

J. S. Newberry, 1870 (Ohio Geol. Surv. Rept. Prog. 1869, pp. 21, 29). *Berea grit.*—Drab ss., 50 ft. thick, underlying Cuyahoga sh. [Cuyahoga as here used included Sunbury sh.] and overlying Bedford sh. Included in Waverly group.

Named for Berea, Cuyahoga Co., Ohio.

†Berea shale.

A name applied in some early repts to Sunbury sh. of Ohio. Abandoned because of conflict with Berea ss.

Berenda limestone.

Mississippian: New Mexico.

C. R. Keyes, 1906 (Jour. Geol., vol. 14, pp. 147–154), applied *Berenda lss.* to lss. said to underlie Lake Valley ls. in N. Mex. Derivation of name not given.

C. R. Keyes, 1908 (Am. Inst. Min. Engrs. Bi-Mon. Bull. No. 19, pp. 7–21). *Berenda ls.*—Nodular lss., 50 ft. thick, consisting of (descending): (1) 10 ft. of bluish thinly bedded cherty ls.; (2) 30 ft. of gray thinly bedded ls.; (3) 10 ft. of massive compact ls. Underlies Grande ls. and overlies Bella sh.

Probably (?) named for Berenda Valley.

In several subsequent repts Keyes assigned his Berenda ls. to Dev. and correlated it with Martin ls. of Ariz.

Beresford phase.

Pre-Cambrian: Manitoba.

J. F. Wright, 1930 (Canada Geol. Surv. Summ. Rept. 1929, pt. B, p. 160).

Beresford Lake phase.

Pre-Cambrian: Manitoba.

J. F. Wright, 1932 (Canada Geol. Surv. Mem. 169, p. 17).

Bergman group.

Cretaceous (Upper?): Northwestern Alaska (Koyukuk River region).

F. C. Schrader, 1902 (Geol. Soc. Am. Bull., vol. 13, p. 246). *Bergman series.*—Essentially thin-bedded or medium-bedded impure gray or brownish sss. and dark slates, with some dark sh. and occasional cgls., but on N. it is bordered by belt of cgl. several to 10 mi. wide, which apparently is basal memb. of series. Thickness 2,000 ft. Probably Cret. Conformably overlies Koyukuk series, also Totsen series.

W. C. Mendenhall, 1902 (U. S. G. S. P. P. 10, pp. 31–48). *Bergman series.*—Folded ss., fine cgls., and dark sandy shales, the sss. and shales usually alternating in thin bands, but occasionally the sss. disappear and broad belts of sh. many hundred ft. thick occur. To N. the sss. are replaced by cgls., and cgl. forms base of series. No fossils. Tentatively assigned to Mesozoic.

Named for trading post (Bergman) on Koyukuk River.

Berkeley group.

Pliocene: Western California (San Francisco region).

A. C. Lawson and C. Palache, 1902 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 2, p. 375 and map). The entire series of rocks, volcanic and sedimentary, from base of Orindan fm. to crest of Frowning Ridge, is here named *Berkeleyan series,* and the interval is regarded as having a break in its accumulation dividing it into Upper and Lower Berkeleyan. The Upper Berkeleyan includes Bald Peak basalt, Siestan fm., Grizzly Peak andesite, and several other unnamed fms. The Lower Berkeleyan includes Trampan and Orindan fms. and a great thickness of unnamed igneous and sed. fms. The Berkeleyan series is uncon. overlain by Campan series and uncon. underlain by Monterey series.

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). *Berkeley group* includes rocks btw. *top* of Orinda fm. and base of Campus fm. Divided into (descending) Bald Peak basalt, Siesta fm., and Moraga fm. Rests, with probable uncon., on Orinda fm., and is uncon. overlain by Campus fm.

Named for occurrence E. of Berkeley.

†Berkeleyan series.

See *Berkeley group.*

†Berkshire limestone.

Lower Ordovician to Lower Cambrian: Western Connecticut, Massachusetts, and Vermont.

E. Hitchcock, 1833 (Rept. on Geol., Min., Bot., and Zool. of Mass., pp. 297–305). *Berkshire ls.*—Constitutes part of the extensive ls. fm. which occupies western part of Conn., Mass., and Vt. It passes through numerous gradations of texture and color, from the snow-white coarsely granular and crystalline variety *in Adams [Mass.] to the dark-gray almost compact variety in* Williamstown, and to the even darker variety in West Stockbridge.

Replaced by *Stockbridge ls.*, the name *Berkshire* having for many years been restricted to the schist.

Berkshire schist.

Ordovician, Cambrian, and pre-Cambrian(?): Western Massachusetts, Connecticut, southwestern Vermont, and eastern New York.

T. N. Dale, 1891 (Am. Geol., vol. 8, pp. 1–7). *Berkshire schists.*—In character like Greylock schists, but more frequently calc., especially toward underlying Stockbridge ls. Overlain by Bellows Pipe ls. in western Mass. Thickness 1,000 to 2,000 ft. Named for prevalence in Berkshire Co., Mass.

T. N. Dale, 1893 (U. S. G. S. 13th Ann. Rept., pt. 2, pp. 303–306 and map). *Berkshire schist.*—Phyllite and muscovite chlorite schist, generally greenish or grayish, of fine micaceous aspect, saponaceous to touch; in some places contains cubes of pyrite; often interbedded with purplish schist of similar character; both often traversed by veins of milky quartz and chlorite. Thickness 200 to 2,000 ft. Is contemp. with Hudson River sh., of Lower Sil. [Ord.] age. Rests conformably on Stockbridge ls. [Now known to be, in places at least, overthrust on Stockbridge ls. See 1932 paper by Prindle and Knopf cited beyond.] Is overlain, without evidence of uncon., by Rensselaer grit in Rensselaer grit plateau of eastern N. Y.

In 1899 (U. S. G. S. Bull. 159) B. K. Emerson described *Berkshire schist* of western Mass. as a chloritic hydromica or sericite schist. In 1912 (U. S. G. S. Bull. 521) T. N. Dale assigned the Berkshire to Middle Ord.

(Trenton) and Upper Ord. In 1917 (U. S. G. S. Bull. 597, p. 39) B. K. Emerson described (and mapped) *Berkshire schist* as an extensive slaty fm., which in its western parts in N. Y. is characterized by presence of Upper Ord. fossils and in its eastern parts becomes a complete mica schist, with garnet, staurolite, and tourmaline, and so much feldspar that it may be called in places a schistose gneiss. "It makes up nearly all mtn ridges that rise from the ls. valleys in western Mass." [Mapped as Ord.]

In 1927 the U. S. Geol. Survey discarded *Hudson schist*, upon recommendation of E. B. Knopf, who stated it is same as Berkshire schist, the preferred name. For many years the Berkshire was classified as Ord., but additional work proved that in some areas the rocks mapped under that name included Camb. and pre-Camb. rocks. (See E. B. Knopf, Am. Jour. Sci., 5th, vol. 14, Dec. 1927, pp. 429–458, and references therein; also L. M. Prindle and E. B. Knopf, Am. Jour. Sci., 5th, vol. 24, Oct. 1932, pp. 257–302.) The latter rept divided the rocks in N. half of Berkshire Co., Mass., that had previously been mapped as *Berkshire schist* into several named fms. of Ord., Camb., and pre-Camb. age; and subsequent work has shown that Berkshire schist in S. half of Berkshire Co. is also susceptible of subdivision into several fms. of different ages. The name, however, is still considered a useful blanket term, in other areas in which it has been used, and its retention is recommended by Mrs. Knopf "to cover certain predominantly argill. rocks of variable metamorphic rank whose age is still undet. except that the existing evidence indicates that they are not younger than Ord. and that they may include rocks as old as pre-Camb." This recommendation has been adopted by U. S. Geol. Survey, with the expectation that as rapidly as accumulated evidence justifies, this composite unit in other areas will be separated into rocks of different ages, bearing different names.

Berkshire sand.

A commercial term applied to the friable beds of Cheshire qtzite excavated E. of the station at Berkshire, Berkshire Co., Mass.

Berkshire County series.

Pre-Cambrian: Western Massachusetts.

W. O. Crosby, 1876 (Rept. on geol. map of Mass., p. 40), applied *Berkshire County series* to pre-Paleozoic rocks of Berkshire Co., including Eolian ls., qtzite, Taconic sl., and clay sl., gneiss, and mica schist.

Berland River shales.

Cretaceous: Alberta.

J. MacVicar, 1924 (Canada Geol. Surv. Summ. Rept. 1923, pt. B, p. 34).

†Berlin gneiss.

Late Paleozoic (?): Northern New Hampshire (White Mountains).

C. H. Hitchcock, 1873 (Rept. Geol. Surv. N. H. 1872, p. 7), used, but did not define, *Berlin gneiss*, and showed it as older than gneiss of Winnipesogee Lake and younger than the porphyritic gneiss and granite of N. H. In same year (Proc. Boston Soc. Nat. Hist., vol. 15, pp. 304–309) he stated that Bethlehem gneiss "may possibly be same as the gneiss at Berlin." In 1874 (Geol. N. H., pt. 1, btw. pp. 508 and 545) he stated: I think the Lake gneiss (Lake Winnipiseogee gneiss) includes the Berlin and Manchester ranges.

C. H. Hitchcock, 1877 (Geol. N. H., pt. 2, p. 111), used *Berlin or Lake gneiss* for fine-grained gneiss underlying Montalban group and overlying Bethlehem gneiss in White Mtns, in N. part of which is Berlin Twp and village of Berlin.

On 1932 geol. map of U. S. the rocks of Berlin region are mapped as pre-Camb., upon basis of information supplied by M. Billings. But Billings later (Sci., Jan. 19, 1934) stated: "It is very probable that there are no pre-Camb. rocks in central N. H., and perhaps in whole State;" also that "most of the intrusive rocks, originally assigned to pre-Camb., are actually younger than lower Dev.;" also that "even the high-grade metamorphic rocks are Paleozoic."

M. Billings, 1935 (letter dated Aug. 27). *Berlin gneiss* belongs to New Hampshire magma series [which he classifies as late Dev. or late Carbf.].

Berlin rhyolite gneiss.

Pre-Cambrian (pre-Huronian?): Central southern Wisconsin (Green Lake County).

R. D. Irving, 1877 (Geol. Wis., vol. 2, p. 520). *Berlin quartz porphyry* occurs at city of Berlin, Green Lake Co. [See also T. C. Chamberlin, p. 149, of same vol., where he called the rock *Berlin porphyry.*]

S. Weidman, 1898 (Wis. Geol. Nat. Hist. Surv. Bull. 3, Sci. ser. 2, pp. 32–47). *Berlin rhyolite gneiss* (pre-Camb.) outcrops at Berlin, Green Lake Co. Is the Berlin porphyry of Chamberlin.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, p. 365). The pre-Camb. crystalline rocks at Berlin "may be supposed to be pre-Huronian."

†Berlin limestone. (In Conemaugh formation.)

Pennsylvanian: Southwestern Pennsylvania.

F. and W. G. Platt, 1877 (2d Pa. Geol. Surv. Rept. H_3, pp. 223, 286, 292). *Berlin ls.*—At Forwardstown, Somerset Co., it consists of an upper ls. 2 ft. thick, which rests on 1 ft. 6 in. of yellow clay underlain by 2 in. of coal, and a lower ls. 1 ft. 6 in. thick; and its top lies 90 ft. below Elk Lick ls. and its base lies 8 ft. 6 in. above Harshberger ls. [A section on p. 292 shows Berlin coal 65 to 70 ft. below Elk Lick ls. and 10 ft. above Berlin ls., which here is 8 ft. thick and occurs 5 ft. above Platt coal.]

Same as Ames ls. memb. of Conemaugh fm.

Berlin group. (In Conemaugh formation.)

Pennsylvanian: Southwestern Pennsylvania.

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q). *Berlin group* underlies Morgantown ss. and extends to base of Platt (?) coal, which underlies Green Crinoidal (Berlin) ls. in Allegheny Co.

Berlin clay.

Name applied by R. F. Flint (Geol. Soc. Am. Bull., vol. 44, No. 5, pp. 965–987, 1933) to a late Pleist. clay that underlies parts of eastern Berlin Twp, Conn.

Bermuda earth.

Miocene: Eastern Virginia.

W. B. Clark, 1897 (Md. Geol. Surv., vol. 1, p. 197). The nearly pure diatomaceous earth of Chesapeake fm. is sometimes known as "Richmond earth," from its wide occurrence in vicinity of Richmond. It was long referred to in literature as *"Bermuda earth,"* from its supposed occurrence on Island of Bermuda, but the specimen upon which the reference was based was ultimately shown to have come from Bermuda Hundred, on James River [in Chesterfield Co., Va.].

Bernadotte sandstone. (In Pottsville formation.)

Pennsylvanian: Central western Illinois (Fulton County).

T. E. Savage, 1927 (Am. Jour. Sci., 5th, vol. 14, pp. 307–316). *Bernadotte ss.*—Coarse-grained, massive ss. at base of Carbondale fm. [as he proposed restricting

Carbondale] in Fulton Co. Fills erosion channel in Pottsville fm. [Derivation of name not stated, but probably town of Bernadotte, Fulton Co.]

H. R. Wanless, 1931 (Ill. State Geol. Surv. Bull. 60, pp. 179–193). *Bernadotte ss.* in places cuts out underlying beds down to coal No. 1.

H. R. Wanless, 1931 (Geol. Soc. Am. Bull., vol. 42, p. 804), showed top of Bernadotte ss. lying 50± ft. below coal No. 2 and as cutting out beds down to and into coal No. 1.

Bernadotte cyclical formation.

A name applied by H. R. Wanless (Ill. Geol. Surv. Bull. 60, 1931, pp. 179–193) to a middle portion of Pottsville fm. (Penn.) of central western Ill., based upon the rhythmic-cycle theory of deposition. Derivation of name not stated.

†Bernalillan series.

A time term introduced by C. R. Keyes to cover part of the Perm. deposits of N. Mex.

Bernalillo shale.

Permian: Central northern New Mexico.

C. R. Keyes, 1903 (Ores and Metals, vol. 12, p. 48). The Permo-Carbf. of N. Mex. consists of series of red shales and sss. called *Bernalillo shales* in Sandia Mtns. Younger than Coyote ss. [Derivation of name not given.]

C. R. Keyes, 1903 (Rept. Gov. N. Mex. to U. S. Secy Interior, pp. 337–341), gave thickness of *Bernalillo terrane* as 1,000 ft.

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 37, p. 426). The so-called Bernalillo shales comprise Abo red beds and Yeso pink beds.

†Bernallian series (Keyes).

Same as †Bernalillan series.

Bernardston formation.

Devonian: Western and central Massachusetts, southeastern Vermont, and southwestern New Hampshire.

J. D. Dana, 1873 (Am. Jour. Sci., 3d, vol. 6, pp. 339–352), in describing the Helderberg rocks of Connecticut River Valley, referred frequently to *Bernardston garnetiferous mica sl., Bernardston sl.,* and *Bernardston qtzite,* as being of Helderberg age.

B. K. Emerson, 1890 (Am. Jour. Sci., 3d, vol. 40, pp. 263–275, 362–374). *Bernardston series.*—Upper Dev. metamorphic rocks, containing Chemung fossils, with a few Hamilton forms. Includes amphibolite, mica schist, hornblende schist, qtzite, ls., cgl., argillite, and gneiss. Occurs at Bernardston, Mass.

B. K. Emerson, 1898 (U. S. G. S. Holyoke folio, No. 50; also U. S. G. S. Mon. 29, pp. 253–300 and map). *Bernardston fm.*—Mica schists and hornblende schist; underlain by qtzite in thick beds, with lss. containing Upper Dev. corals; at base cgl. of pebbles derived from Leyden argillite, which is locally changed to gneiss. Thickness 1,650 ft. Uncon. overlies Leyden argillite and uncon. underlies Juratrias [Newark group]. [See also B. K. E., U. S. G. S. Bull. 597, 1917.]

Named for occurrence at Bernardston, Mass.

†Bernardston limestone.

Devonian: Western and central Massachusetts.

J. D. Dana, 1877 (Am. Jour. Sci., 3d, vol. 14, pp. 379–387), applied *Bernardston ls.* to crinoidal ls. in midst of Helderberg fm. at Bernardston, Mass., which is a bed in Bernardston fm. The U. S. Geol. Survey does not apply the same name to a geologic unit and to a part thereof.

Berne member.

Mississippian: South-central Ohio.

J. E. Hyde, 1915 (Jour. Geol., vol. 23, pp. 656, 657, 659, 660, 667, 669, 674–682). *Berne memb.*—Largely pebbles, but sss. of moderate coarseness and shales are found in it at some localities. Thickness 0 to 20 ft. Always present (in Licking, Fairfield, and Hocking Counties) and readily recognized resting on Black Hand memb. [restricted use of Black Hand]. Lithologically very like underlying cgls. and heretofore included in Black Hand fm. but here separated out as distinct top memb. of Cuyahoga fm. Whether it be regarded as closing the Cuyahoga or opening the Logan it separates two groups of sediments essentially different from each other in many ways. Underlies Byer memb. of Logan fm. [the beds called Byer were previously included in Black Hand fm.]. Equivalent to cgl. 1 of C. S. Prosser.

J. E. Hyde, 1927 (Ohio Geol. Surv., 4th ser., Bull. 31, pp. 43–64). *Berne cgl. memb.*—Coarse conglomeratic ss. Can be traced from Vinton Co. to Wayne Co., a distance of 120 mi. Its history belongs to Logan fm. [In detailed sections in this rept the Berne is included in Cuyahoga fm., but in description it is included in Logan fm.]

These beds belong to Black Hand fm. of Prosser and others.

Named for exposures in Berne Twp, Fairfield Co.

Berne member (of Marcellus shale).

Middle Devonian: Eastern New York (Berne-Durham quadrangle).

G. A. Cooper, 1933 (Am. Jour. Sci., 5th, vol. 26, pp. 544, 548). *Berne memb.* is proposed for interval btw. Onondaga ls. and Otsego memb. of Marcellus in region E. of Schoharie. Dark gray sh., with a white or gray streak, and usually crumbles into small lumps; conchoidal fracture when fresh. Type section is in hill S. of Berne, where memb. is 280 ft. thick. It is = Union Springs, Cherry Valley, and Chittenango members of the Marcellus of Unadilla and Chenango Valleys and other areas.

†Berners formation.

Jurassic, Triassic, and probably Paleozoic: Southeastern Alaska (Berners Bay region).

A. Knopf, 1911 (U. S. G. S. Bull. 446, pp. 14–19, map). *Berners fm.* (*Jurassic-Cret.*).—A sed. fm., dominantly slates and graywackes. Some basaltic greenstones and quartz porphyry schists, of small importance, are associated with it. Splendidly displayed along W. shore of Berners Bay and along Lynn Canal from Point St. Mary to mouth of Independence Creek; also on E. shore of Berners Bay.

G. C. Martin, 1926 (U. S. G. S. Bull. 776, pp. 256–260). "Berners fm." includes rocks of Jurassic, Triassic, and probably Paleozoic age, and name is discarded.

Beroun moraine.

Pleistocene (Wisconsin stage): Northeastern Minnesota.

F. Leverett, 1928 (U. S. G. S. P. P. 154). Named for Beroun, Pine Co.

Bertha limestone. (In Bluefield formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 299, 393). *Bertha ls.*—Yellow, impure, siliceous; 2 to 15 ft. thick; marine fossils. Underlies Upper Bertha sh. and overlies Lower Bertha sh., all members of Bluefield group [fm.]. Named for association with Bertha ss. and Upper Bertha sh., but not exposed at type loc. of Bertha ss. Observed, however, at other localities in Summers Co., and in Monroe and Mercer Counties, also in Tazewell and Giles Counties, Va.

Bertha sandstone. (In Bluefield formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Tazewell County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 299, 391). *Bertha ss.*—Usually greenish gray, shaly, and 30 to 50 ft. thick, but in some localities is massive and gray. Underlies Lower Graham sh. and overlies Upper Bertha sh., all members of Bluefield group [fm.]. Type loc. along mtn road which ascends from Bertha toward Low Gap School, Summers Co. Also exposed in Monroe Co., W. Va., and in Tazewell Co., Va.

Bertha shale. (In Bluefield formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe and Summers Counties, pp. 299, 392–394). *Upper Bertha sh.*—Usually sandy, but sometimes red and variegated; 45 to 75 ft. thick; occasional plant and marine fossils; underlies Bertha ss. and overlies Bertha ls., all members of Bluefield group [fm.]; named for association with Bertha ss., but is concealed at type loc. of that ss.; occurs in Mercer, Monroe, and Summers Counties. *Lower Bertha sh.*—Usually greenish yellow, but occasionally a red and variegated or sandy deposit, 50 to 90 ft. thick; underlies Bertha ls. and overlies Bradshaw ss.; type loc. same as Upper Bertha sh.; occurs in Mercer, Monroe, and Summers Counties.

Berthelet member.

Middle Devonian: Southeastern Wisconsin (Milwaukee region).

G. O. Raasch, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 262, 265). *Berthelet memb.* (*novum*).—Basal memb. of Milwaukee fm. Consists of dol. and waterlime, dull gray, shaly in lower part, upper few ft. a hard vitreous single layer of dol. with many cavities containing calcite, marcasite, sphalerite, and millerite crystals, and asphaltum. Faunules change considerably vertically. Highest beds contain many cephalopods; below this pelecypods and small brachiopods are abundant; lower beds have yielded most of fish remains for which Milwaukee locality has long been famous. Thickness of memb., 21 ft. at type loc., which is Milwaukee cement quarry. Underlies Lindwurm memb. of Milwaukee fm. and overlies Thiensville fm.

Probably named for village of Berthelet, Milwaukee Co.

Bertie limestone member (of Salina formation).

Silurian: New York (western to east-central) and southeastern Ontario.

E. J. Chapman, 1864 (A popular and practical exposition of the minerals of Canada, p. 190). Lower Helderberg group occupies a comparatively narrow strip of slight thickness in Western Canada, btw. E. end of Lake Erie and township of Cayuga [Ontario]. It in no place exceeds 50 ft. in thickness and consists of lowest div. of the group as subdivided by N. Y. geologists, or of equivalents of their "Waterlime group or Tentaculite ls." With us, in Western Canada, it might be called *Bertie or Cayuga dol.*, as its only known exposures are in those townships; or a still better term would be *Eurypterus fm.*, so named from its principal and characteristic fossil, *Eurypterus remipes*. In above townships it consists of thin-bedded grayish dolomites, interstratified toward base with a few brownish shales and with a brecciated bed composed chiefly of dol. fragments.

C. Schuchert, 1903 (Am. Geol., vol. 31, pp. 160–175). *Bertie fm.*—Name proposed by Chapman in 1864. The Lower Waterlime *Eurypterus*-bearing mag. lss. and shales, 50 ft. thick. Underlies Cobleskill ls. (called "Bullhead rock" in western N. Y.), and overlies *Salina proper* or Onondaga salt group. In southern half of Appalachian region the Bertie fm. is not lithologically distinguishable from the Salina, and here the latter term [Salina] is extended to embrace entire interval btw. Niagara and Manlius. [He at that time treated Cobleskill ls. as basal part of his "Manlius fm. redefined."]

In 1903 (N. Y. State Mus. Hdb. 19) J. M. Clarke introduced *Camillus sh.* for the beds underlying *Bertie waterlime*, and applied *Cobleskill* to fm. overlying the Bertie. For many years this was definition of the Bertie of N. Y. In 1909, however, W. H. Sherzer and A. W. Grabau (Geol. Soc. Am. Bull., vol. 19, pp. 544, 550) introduced *Akron dol.* for †Bullhead dol. of western N. Y., which they stated is approx.=Cobleskill of eastern N. Y. But the beds above the Bertie in western N. Y. continued to be called *Cobleskill ls.*

In 1917 (Geol. Soc. Am. Bull., vol. 28, pp. 173–174) G. H. Chadwick revived *Akron dol.* (stating that "the correlation eastward of the Akron with the Cobleskill remains to be worked out anew, but it is now believed to be substantially correct"), and divided the beds which for 14 years had been called *Bertie ls.* or *Bertie fm.*, as follows (descending):

Buffalo cement bed [later renamed *Williamsville* by Chadwick], carrying eurypterids, 0 to 6 ft.; *Scajaquada dark shales and blocky waterlimes,* 0 to 8 ft., with at base the *Bridgeburg horizon,* with eurypterids; *Falkirk dol.,* 30 ft.; *O-atka beds* (dark gray and shaly, with blocky waterlime at base carrying eurypterids), 20 ft. Chadwick also stated "the name Bertie should either be retained in the primitive sense, covering the entire series inclusive of the Akron, or else be restricted to the cement bed here called the Buffalo, a name said to be preoccupied." On p. 174 of same publication M. Y. Williams stated: I wish to make a plea for the continued use of the term Bertie. At type loc. it was clearly used to include the beds below the Akron dol. and above the Camillus sh., although the sh. is not exposed.

In 1919 (Canada Dept. Mines, Geol. Surv. Mem. 111) M. Y. Williams classified the rocks of Niagara River as follows: Akron dol., Bertie waterlime, Camillus sh. In 1925 (N. Y. State Mus. Bull. 265, pp. 5–14) R. Ruedemann divided the late Sil. deposits of western N. Y. as follows: (1) "*Bull Head*" (*Akron dol.*), "the western continuation of the Cobleskill ls.;" (2) Bertie waterlime; (3) Camillus sh.

G. H. Chadwick, 1930 (Geol. Soc. Am. Bull., vol. 41, pp. 80–82), stated: It is possible the entire succession in eastern N. Y. (Binnewater, Wilbur, Rosendale, Cobleskill, Rondout, and "Manlius") all belongs to Manlius group (Keyser) rather than any of it to the Bertie (Tonoloway) or Salina.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 343), stated: Wilbur ls. and Rosendale waterlime probably together represent Bertie waterlime farther W.

Adopted by U. S. Geol. Survey as top memb. of Salina fm. in N. Y.

Named for exposures at Bertie (and in Bertie Twp), Ontario, about 6 mi. W. of Buffalo, N. Y.

Bertram dolomite.

Silurian? (Niagaran?): Eastern Iowa (Linn County).

W. H. Norton, 1895 (Iowa Geol. Surv. vol. 4, pp. 135–138). ***Bertram beds.***—Light to medium drab mag. ls., hard and brittle, 0 to 24 ft. thick, near top of Sil. Underlie Coggon beds and overlie Anamosa or Mount Vernon beds. Assigned to Sil. See also under *Gower dol.*

W. H. Norton, 1921 (Iowa Geol. Surv. vol. 27, Ann. Rept. 1916, p. 372). While true place of *Bertram beds* must be uncertain until fossils are found in it or a distinct uncon. is seen above or below, it is related to Wapsipinicon (Dev.) in texture and brecciation, *and may now be provisionally classed with that fm.* Occurs, so far as known, in Linn Co. only, and outcrops along zone of contact btw. Sil. and Dev. Extends from Bertram up valley of Big Creek, and appears at various points in valley of Indian Creek to W. Sections on Big Creek show thickness of 50± ft. Occurs btw. the fossiliferous beds of *Coggon phase of the Otis* and uppermost Niagaran, and shows well-defined contacts with each.

M. A. Stainbrook, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 249–251), included *Bertram beds* in Otis, placed Otis above Coggon, and included all in Wapsipinicon ls. (Dev.). But A. H. Sutton (p. 277 of same rept.) stated Bertram is Niagaran, and belongs in the Gower.

See also under *Anamosa dol.*

Named for Bertram, Linn Co.

Berville moraine.

Pleistocene (Wisconsin stage): Southeastern Michigan. Shown on moraine map (pl. 32) in U. S. G. S. Mon. 53. Named for Berville, Macomb Co.

Berwick gneiss.

Pre-Cambrian(?): Southwestern Maine (Berwick and North Berwick Townships) and southeastern New Hampshire.

F. J. Katz, 1917 (Wash. Acad. Sci. Jour., vol. 7, p. 198). *Berwick gneiss.*—Highly metamorphosed and recrystallized graywacke, qtzite, and thin micaceous beds, developed in belt, 1 to 10 or more mi. wide, extending SW. from Falmouth and Gorham, Maine, to and beyond Lee, N. H. Probably Pre-Camb.

F. J. Katz, 1917 (U. S. G. S. P. P. 108, pp. 166-167). *Berwick gneiss.*—Chiefly graywacke gneiss, but contains clean qtzites, micaceous qtzites, mica schist, and argillite schist and sl. Beds range in thickness from an inch to few ft. Almost all rocks are moderately fine-grained and delicately banded. Colors dark gray, bluish gray, and brown. Thickness undeterminable. Age unknown, but pre-Carbf. Relations to Algonkian(?) complex undet. Included in Merrimack slates and Rockingham schist of Hitchcock. Named for development at Berwick, York Co., Maine.

On 1933 geol. map of Maine, by A. Keith, these rocks are mapped as pre-Camb.

Berwick quartz diorite.

Devonian(?): Southwestern Maine.

A. Wandke, 1922 (Am. Jour. Sci., 5th, vol. 4, p. 153). *Berwick quartz diorite.*—Small stock of quartz diorite about 2 mi. E. of Berwick, York Co. The contact phase is essentially a gabbro, but central mass is a typical quartz diorite. Included in Agamenticus complex, but may possibly correlate with Cape Neddick gabbro. Assigned to Dev.(?).

Berwyn conglomerate.

Pennsylvanian: Central southern Oklahoma (Arbuckle Mountains).

J. T. Richards and R. A. Birk, 1925 (A. A. P. G. Bull., vol. 9, No. 6, pp. 983, 987-988). *Berwyn cgl.*—A series of ls. cgls., arkosic sss., dark shales, and thin lss. Banded pebbles form part of the ls. cgls. at several horizons. The pebbles vary in size from a fraction of an inch to 3 inches in length. Their most common material is ls. derived from the older lss. of Arbuckle Mtns, but granite, chert, and other fragmentary materials are not uncommon. South of Arbuckle Mtns the series rests uncon. on Glenn fm. (Penn.) and is overlapped by Trinity sand (Comanchean). North of the mtns the relation of the series to underlying fm. was not determined and areal extent in this region was left for future determination. Eastern and western limits not determined definitely. Formerly called *Franks cgl.* Probably belongs to Vanoss fm. of Morgan.

Named for occurrence S. of town of Berwyn, Carter Co.

Berwyn member. (In Skaneateles shale.)

Middle Devonian: Central New York.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 219, 221, etc.). *Berwyn memb. of Skaneateles fm.*—Dark, aren. sh. overlying Pompey memb. of Skaneateles. Well exposed in Conklin's Falls (The Cascades) ravine in Butternut Valley, SE. of Syracuse. At type section the fauna has a "Marcellus or *Leiorhynchus* facies." Traced westward it becomes argill. and fissile. Well exposed at Rose Hill below the Centerfield and in Clintonville Ravine, Skaneateles quad. At both places it grades into Centerfield. Thickness at type section is 200± ft. Thins to W. to 90± ft. at Rose Hill. Is 235 ft. thick at Hamilton village. To E. of type section the "*Leiorhynchus* facies" becomes less prominent by influx of typical Hamilton fossils as the shales become more aren. At Gould's quarry, in Unadilla Valley, the characteristic *Leiorhynchus laura* is lacking and Hamilton fossils are abundant at top of section; also the basal 65 to 90 ft. of Berwyn has become aren. and similar to upper Pompey. [Derivation of name not stated, but probably is village in Tully quad.]

Bessemer granite.

Pre-Cambrian: Southern North Carolina and northwestern South Carolina.

A. Keith and D. B. Sterrett, 1917 (U. S. G. S. Bull. 660D, p. 129). *Bessemer granite.*—Medium- to fine-grained muscovite-biotite granite near quartz monzonite in composition. Locally porphyritic. In all outcrops it has a strong schistose structure, and in many places it has been metamorphosed into white and gray quartz-sericite schists that bear no resemblance to the original granite. Only in certain favorable outcrops can the gradation from the schistose granite to sericite schist be seen. The porphyritic varieties have in some places been metamorphosed into quartz-augen sericite schist or "bird's-eye" schists.

Named for fact that one of minor bodies of the granite underlies Bessemer City, Gaston Co., N. C.

Bessie member (of Quartermaster formation).

Permian: Western Oklahoma.

H. L. Griley, 1933 (Pan-Am. Geol., vol. 59, No. 3, p. 284). Subdivision of Quartermaster fm. of western Okla. has been made by field geologists to facilitate description and correlation. Names for these divisions have been in use several years without definition in geol. literature. The fm. is divided into 3 members (descending) *Elk City, Doxey,* and *Bessie.* The basal memb. (Bessie) was named by Schweer and Buckstaff. The Elk City ss., Triassic age being unproved, is left as a memb. of the Quartermaster. [All there is about these new members.]

D. A. Green, 1936 (A. A. P. G. Bull., vol. 20, No. 11, pp. 1473, 1474), divided Quartermaster fm. of Custer, Washita, Beckham, Caddo, and Grady Counties into (descending): *Elk City ss., Doxey sh.,* and Cloud Chief memb. (ss., gyp., and dol. facies). The Doxey is 160 to 200 ft. thick in Washita and Beckham Counties. Contact with Elk City ss. is irregular. Near middle of the Doxey there are several bench-forming beds of siltstone. The Elk City memb. is almost solid ss. It is well exposed in SE¼ of T. 11 N., R. 19 W. Its max. observed thickness is approx. 170 ft., but cover of windblown sands has made it impossible to locate its top.

†Bethany limestone.

An abbreviated form of Bethany Falls ls. that has been used by some geologists. According to R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 87), the Bethany ls. of C. R. Keyes, 1896 (Am. Jour. Sci., 4th, vol. 2, pp. 221–225) is synonymous with †Erie ls. of Haworth.

Bethany gas sand.

A subsurface sand occurring at depth of 2,800± ft. in Waskom gas field, Caddo Parish, NW. La.

Bethany Falls limestone. (In Kansas City group.)

Pennsylvanian: Southwestern Iowa, northwestern Missouri, southeastern Nebraska, and eastern Kansas.

G. C. Broadhead, 1868 (St. Louis Acad. Sci. Trans., vol. 2, p. 320). *Bethany Falls ls.*—Upper 7 inches fine-grained, buff-colored, brittle, shelly, fucoidal ls., with very few fossils; lower part irregularly and evenly bedded light-grayish or drab crystalline ls. weathering buff. Thickness 18 to 22 ft. Is bed 166 of detailed section of Coal Measures from NW. corner of Mo. to Glasgow, Howard Co. Mo.

H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines vol. 13), defined *Bethany Falls ls. memb. of Kansas City fm.* as consisting, in NW. Mo., of 15 to 25 ft. of ls. (locally called "cotton rock") underlying Galesburg sh. memb. and overlying Ladore sh. memb.

Until 1932 Bethany Falls ls. was included in the Kansas City (which U. S. Geol. Survey treated as a *fm.* in Mo. and Iowa and as a *group* in Kans.), and was defined as underlying Galesburg sh. and overlying Ladore sh. In Jan. or Feb., 1932 (Nebr. Geol. Surv. Bull. 5, 2d ser., pp. 17–18), C. O. Dunbar, R. C. Moore, and G. E. Condra divided Bethany Falls ls. into (descending) Swope ls., Sugar Creek sh., and Middle Creek ls. Later in 1932 (Aug. 28 to Sept. 3) R. C. Moore (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook) used *Swope ls.* to include (descending) Bethany Falls ls., Hushpuckney sh., Middle Creek ls., Elm Branch sh., Sniabar ls., Mound City sh., Critizer ls., Tennison Creek sh., and Schubert Creek ls.; and this definition was repeated by Moore and Condra in their Oct. 1932 chart, and by Moore in his classification of May 1, 1935. N. D. Newell in his May 15, 1935, classification (Kans. Geol.

Surv. Bull. 21) restricted Swope ls. to beds btw. top of Bethany Falls ls. memb. and base of Middle Creek ls. memb. Also in 1932 Moore and Condra greatly restricted both Kansas City group and Ladore sh., and treated Swope ls. as basal fm. of their Bronson group.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 86–88). *Bethany Falls ls.* (Broadhead 1868, Hinds and Greene, 1915, etc.) is traced from south-central Iowa (†Earlham ls. of Iowa Geol. Surv.) to southern Kans., near Okla. bdy. It was called †Mound Valley by early Kans. Geol. Surv., but Bethany Falls has priority. Lower part consists of 1 to 20 ft. of light-gray, dense, thin-bedded ls., in uneven, somewhat wavy layers with sh. partings and fairly abundant fossils. Upper part consists of up to 7 ft. of bluish-gray, massive, mottled or nodular ls. that is believed to be of algal origin, and locally of 13±ft. of gray-white oolitic ls. Total thickness of Bethany Falls ls. 12 to 27 ft.; av. in E. Kans., 18±ft.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

The name *Bethany Falls* has also been used in a broader sense, to include beds from top of Westerville ls. of Iowa repts to base of Hertha ls., but this usage was long ago discarded.

Bethel sandstone. (Of Chester group.)

Mississippian: Western Kentucky, southeastern Illinois, northeastern Mississippi, and northwestern Alabama.

C. Butts, 1917 (Ky. Geol. Surv. Mississippian series in western Ky., p. 63). *Bethel ss.*—The ss. overlying, probably with slight uncon., Ohara ls. memb. of Ste. Genevieve ls. in western Ky. Is thick-bedded, rather coarse-grained ss.; with some pebbles but not conglomeratic. Thickness 10 to 40 ft. Is Cypress ss. [so-called] of Ulrich in U. S. G. S. P. P. 36. Is overlain by Ridenhower sh. in some places and by Gasper oolite in other places. Is especially thick and well displayed in vicinity of Bethel School, 3½ mi. W. of Marion, Crittenden Co., Ky.

S. Weller, 1920 (Ill. Geol. Surv. Bull. 41). *Bethel ss.* underlies Paint Creek fm. and overlies Renault fm.

S. Weller, 1923 (Ky. Geol. Surv., ser. 6, vol. 10). *Bethel ss.* of Butts is same as his Sample ss.

S. Weller, 1927 (Ky. Geol. Surv., ser. 6, vol. 26). *Bethel ss.* underlies Paint Creek fm. and uncon. overlies Renault ls.

C. Butts, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14, p. 184), extended the use of *Bethel ss.* into northern Ala., for the ss. overlying Ste. Genevieve ls. in that area.

C. Butts, 1929 (Jour. Geol., vol. 37, p. 46). *Bethel ss.* underlies Renault fm. and overlies Ohara ls. memb. of Ste. Genevieve ls. Although I [originally] included in my conception of the *Bethel* the overlying Cypress ss. shown only by rock waste on the top of the hill just NE. of Bethel School, it is nevertheless true that the conspicuous ledge at the base is really a fair representation of the unit to which the name was intended to apply.

A. H. Sutton and J. M. Weller, 1932 (Jour. Geol., vol. 40, No. 5, pp. 430–442). *Bethel ss.* is same as Sample ss.

See also under *Ste. Genevieve ls.*

Bethel schist.

Upper Cambrian: Southeastern Vermont (Windsor County).

C. H. Richardson, 1924 (14th Rept. Vt. State Geol., pp. 82–83, on Bethel Twp). *Bethel schist.*—Hydro-mica schists, fine-grained greenish, schistose, highly metamorphosed sedimentary rocks, more or less intimately associated with chlorite, and characterized by numerous lenses, or eyes, and stringers of granular quartz. Underlies [igneous] chlorite schist (Lower Camb.) which underlies, with apparent discon., the various members of Missisquoi group. Of Lower Camb. age. [C. H. Richardson in 1927 assigned his Bethel schist to Upper Camb., and stated that it traverses entire W. part of Bethel Twp, from which it derived its name. See also *Bethel group*, of which he treated this schist as a part.]

C. H. Richardson, 1929 (16th Rept. Vt. State Geol., pp. 208–246, on Reading, Cavendish, Baltimore, and Chester Twps). *Bethel schist* is present in Chester Twp and to S., but is absent in Reading, Cavendish and Baltimore. Believed to form base of Upper Camb. in Vt. [In table opp. p. 288 *Bethel chlorite schist* is used, and is assigned to base of Upper Camb.]

Bethel group.

Upper Cambrian: Southeastern Vermont (Windsor County).

C. H. Richardson, 1927 (15th Rept. Vt. State Geol., pp. 127–158, describing Barnard, Pomfret, and Woodstock Twps). *Bethel group* (mapped) includes the hydromica schist (*Bethel schist*) of earlier repts and the chlorite schist. Latter schists occasionally conform in dip and strike with the *Bethel schists*, with which they are often intimately associated. In such instances they may be regarded as of sed. origin and as a part of Bethel group. In Roxbury, to N., they are not of sed. origin but are igneous. Narrow beds of chlorite schist may occur in overlying Missisquoi group. [Presumably named for Bethel, Windsor Co.]

C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), used *Bethel chlorite schist*, and assigned it to Upper Camb.

Bethel granite.

Devonian: Southeastern Vermont (Windsor County).

See under *Knox Mtn granite.* Presumably named for Bethel, which is in NW. part of Windsor Co., SE. Vt.

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), assigned this granite to Dev.

Bethel sand.

A subsurface sand, of Miss. age, in western Ky. that has been identified as Aux Vases (?) ss., of Chester group. (See A. A. P. G. Bull., vol. 16, No. 3, p. 244, 1932.)

Bethel lime.

A subsurface oil zone, of Miss. age, in western Ky. that has been identified as Renault ls., of Chester group. (See A. A. P. G. Bull., vol. 16, No. 3, p. 244, 1932.)

Bethel pyroxene diorite.

Age(?): Eastern New York (Dutchess County).

R. Balk, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 5, pl. 1, etc.).

Bethlehem gneiss.

Late Devonian or late Carboniferous: Northwestern New Hampshire (Ammonoosuc River region).

C. H. Hitchcock, 1872 (Rept. Geol. Surv. N. H. 1871). *Bethlehem gneiss.*—Gneiss abounding in talcoid mineral, perhaps pinite. Underlies whole of Bethlehem.

C. H. Hitchcock, 1873 (Am. Ass. Adv. Sci. Proc., vol. 21, pp. 135–151). *Bethlehem gneiss.*—Characterized by either chlorite or green pinite. Rests uncon. on the porphyritic gneiss. Believed to be younger than White Mtn gneiss.

C. H. Hitchcock, 1873 (Proc. Boston Soc. Nat. Hist., vol. 15, pp. 304–309). *Bethlehem gneiss* believed to be older than White Mtn gneiss.

C. H. Hitchcock, 1877 (Geol. N. H., pt. 2, pp. 104, 348–355, 428, and btw. pp. 658 and 675). *Bethlehem gneiss* assigned to Laurentian. The fine-grained is 5,000 ft. thick and the ordinary gneiss 6,300 ft. thick. Overlies the porphyritic gneiss (Laurentian).

C. H. Hitchcock, 1896 (Jour. Geol., vol. 4, pp. 44–62). *Bethlehem gneiss or protogene.*—Chloritic gneiss. Occurs only on E. slope of Conn. Valley. It does not follow that all of these protogene areas are of same character. Each one must be studied by itself. They are batholiths. Assigned to Archean.

C. H. Hitchcock, 1904 (Geol. Soc. Am. Bull., vol. 15, pp. 461–482, map). The porphyritic granite and *Bethlehem granite* are eruptive igneous rocks, of evidently middle or late Paleozoic age.

C. H. Hitchcock, 1905 (Geol. of Littleton, N. H., Univ. Press, Cambridge). *Bethlehem protogene.*—Characterized by chlorite, talc, rotten mica, or other decomposition products. Named for town of Bethlehem.

C. R. Williams, 1934 (Appalachia, vol. 20, No. 4, pp. 69–78, map), assigned Bethlehem gneiss to Carbf.(?).

M. P. Billings and C. R. Williams, 1935 (Geology of Franconia quad. N. H., p. 9 and map) assigned *Bethlehem granodiorite gneiss* to late Dev. or late Carbf., and to New Hampshire magma series; and in 1935 Billings mapped it in Littleton and Moosilauke quads. (in Geology of Littleton and Moosilauke quads., N. H.), and continued that age designation.

Bethlehem granite.

See under *Bethlehem gneiss.*

Bethlehem moraine.

Pleistocene (Wisconsin stage): Northwestern New Hampshire (Ammonoosuc River region).

J. W. Goldthwait, 1916 (Geol. Soc. Am. Bull., vol. 27, pp. 263–284). *Bethlehem moraine* is probably not older than *Carroll moraine.*

I. B. Crosby, 1934 (Jour. Geol., vol. 42, pp. 411–421), also described this moraine.

The Carroll moraine was probably named for town or Twp of Carroll, which adjoins Bethlehem Twp.

Bethpage gravel.

Name applied by late W. O. Crosby, in unpublished rept on western Long Island, to the gravel in the pits at Bethpage, in middle of the island, and believed to be of Mio. age. The name was introduced into print by C. P. Berkey and J. F. Sanborn (Am. Soc. Civil Engrs. Trans., vol. 86, Paper No. 1509, 1923, pl. 3, p. 75), who called the overlying beds *Bethpage clay beds.* According to D. G. Thompson (personal communication) Crosby called these clay beds *Kirkwood clay,* correlating them with the Mio. Kirkwood fm. of N. J. D. G. Thompson, F. G. Wells, and H. R. Blank (Econ. Geol., vol. 32, p. 460, 1937) are inclined to belief the gravel in these pits is Jameco gravel, of Pleist. age, but that, if the gravel is really Mio., it can be only an outlier of comparatively small extent. If the gravel is Pleist., the overlying clay is also Pleist.

Bethpage clay beds.

See under *Bethpage gravel.*

†Bettles group.

†Bettles series.

Silurian: Northern Alaska (Bettles River region).

F. C. Schrader, 1900 (U. S. G. S. 21st Ann. Rept., pt. 2, p. 475). *Bettles series.*—Heavy-bedded ls. or marble, usually banded and schistose, but sometimes massive; more or less mica schist is interbedded. Younger than Lake qtzite schist. Is principal capping rock over 2,000 sq. mi. of upper waters of Chandlar and Koyukuk Rivers. Excellent exposures on lower part of Bettles River, where the mtns which these rocks compose rise 2,000 ft. or more above river.

Now regarded same as Skajit ls.

†Beulah shale.

†Beulah clays.

Upper Jurassic: Northeastern Wyoming and western South Dakota (Black Hills).

W. P. Jenney, 1899 (U. S. G. S. 19th Ann. Rept., pt. 2, p. 593, fig. 122, map). *Beulah clays.*—Upper Jurassic fresh or brackish water deposits. In Hay Creek coal field, Crook Co., Wyo., consist of: (1) *Atlantosaurus* beds, 25 to 35 ft. of whitish and light-gray clays with some sandy shales and concretions of white calc. clay, the upper layers in many localities carrying fossil wood and the bones of saurians; (2) light-gray, thin-bedded ss., 5 to 10 ft. Underlie Hay Creek coal fm. with greatest uncon. in section, and uncon. overlie Lower Jurassic marine beds. Long outcrops of these clays occur 3 or 4 mi. N. of Beulah, in Red Water Valley [Creek Co., Wyo.].

Same as *Morrison fm.,* which has priority.

†Beulah limestone.

Devonian (?): Eastern Colorado (east side of Front Range).

A. E. Brainerd, H. L. Baldwin, Jr., and I. A. Keyte, 1930 (Kans. Geol. Soc. 4th Ann. Field Conf., Sept. 1930, mimeograph, pp. 84, 86, 88, 90, 94, and 2 tables). *Beulah ls.*—At Beulah, Pueblo Co., and in Priest Canyon, Fremont Co., consists of 20 ft.

of shaly, thin-bedded, light-gray to pink, fine-grained, nonfossiliferous ls., uncon. overlain by Fountain fm. and uncon. underlain by Fremont ls. (Upper and Middle Ord.). On E. side of Williams Canyon, N. of Manitou, El Paso Co., it is 25 ft. thick, contains a few thin beds of ss. and sh., is uncon. overlain by 100 ft. of Madison ls. (Miss.) and uncon. underlain by Manitou ls. (Lower Ord.). In Missouri Gulch section, Manitou Park, Douglas Co., it is 65 ft. thick, underlies 30 ft. of Madison ls. and uncon. overlies Manitou ls. No fossils found. Assigned to Miss. or Dev.

In 1932 (A. A. P. G. Bull., vol. 17, No. 4) Brainerd, Baldwin, and Keyte replaced this name with *Williams Canyon ls.*

Beverly syenite.

Early Carboniferous: Northeastern Massachusetts (Essex County).

C. H. Clapp, 1910 (Igneous rocks of Essex Co., Mass.); B. K. Emerson, 1917 (U. S. G. S. Bull. 597 and map); and C. H. Clapp, 1921 (U. S. G. S. Bull. 704, pp. 85–89).

Named for occurrence at Beverly.

Bevier fire clay.

A fire clay, 1½ to 3 ft. thick, underlying Bevier coal, in Cherokee sh. of northern Mo. (Macon Co.).

†Bexar.

Upper Cretaceous (Gulf series): Southern Texas.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, p. 114). [*Bexar* used, in table only, for Navarro fm. in Guadalupe River section of Tex.]

Probably named for Bexar Co.

Bibb dolomite.

Upper Cambrian: Northern central Alabama.

E. O. Ulrich, 1915 (U. S. Nat. Mus. Bull. 92, vol. 1, p. vii, and vol 2, pl. 2). [Fm. not defined, but name used in chart for the rocks in Ala. btw. †Lower Knox above and Ketona dol. below, the succession of fms. being, descending order: Chepultepec ls. (Upper Knox), Copper Ridge chert, †Lower Knox, Bibb dol., Brierfield dol.]

C. Butts, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14, p. 83). *Bibb dol.*—Thick-bedded, dark, coarsely crystalline, highly siliceous dol., which yields boulders deeply encrusted with cavernous drusy silica. Weathered layers are deeply pitted. So closely resembles Brierfield dol. that the two would not be separated were it not for fact that the pure Ketona dol. intervenes btw. the two. Thickness 250 to 500 ft. Overlies Ketona dol. (conformably so far as known) and underlies Copper Ridge dol. No fossils found. Named for exposures at old Bibb Furnace, 2± mi. W. of Brierfield, Bibb Co., which is located upon outcrop of fm.

Bickett shale. (In Bluefield formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Giles County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 301, 430). *Bickett sh.*—Usually red and argill., but occasionally sandy, 5 to 30 ft. thick. Underlies Reynolds ls. and overlies Webster Springs ss., all members of Bluefield group [fm.]. Type loc. on NW. angle of Bickett Knob, Monroe Co. Also observed in Mercer and Summers Counties, W. Va., and in Giles Co., Va.

Bickford granite.

Late Devonian or late Carboniferous: Northwestern New Hampshire (Ammonoosuc River region, Franconia quadrangle).

C. R. Williams, 1934 (Appalachia, vol. 20, No. 4, pp. 69–78). *Bickford granite (Carbf.?)*.—Fine-grained, even-textured. Forms small bodies in Kinsman granodiorite.

M. P. Billings and C. R. Williams, 1935 (Geology of Franconia quad., N. H., pp. 10, etc.). *Bickford granite* is scattered through Kinsman quartz monzonite and Talford schist, and is typically exposed on Bickford Mtn, Franconia quad. Is late Dev. or late Carbf. Assigned to New Hampshire magma series.

Bicknell sandstone.

Upper Jurassic: Northern California (Taylorsville region).

J. S. Diller, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 370–394). *Bicknell ss.*—Light-gray or bluish gray ss., sometimes tufaceous above. Thickness 500 ft. Is older than Hinchman tuff and younger than Mormon ss.

J. S. Diller, 1908 (U. S. G. S. Bull. 353). *Bicknell ss.*—Chiefly red and gray ss. associated with some dark shales and tuffaceous beds. Brownish-red ss. forms earliest part of fm. Middle part is compact, fine, dark-gray ss. interbedded with black shaly beds. Upper part consists of tuffaceous gray ss. Thickness 500 to 1,300 ft. Overlies, probably conformably, Mormon ss. and grades into overlying Hinchman ss. Greatest development on SE. slope of Mount Jura, Plumas Co.

C. H. Crickmay, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 81, and No. 5, pp. 895–903), included Bicknell ss. in Hinchman ss.

Named for Bicknell's ravine, Mount Jura, near Taylorsville.

† Bicknell tuff.

Name applied by A. Hyatt (Geol. Soc. Am. Bull., vol. 3, p. 407, 1892) to the tuffaceous ss. forming upper memb. of Bicknell ss. of Diller.

Bidahochi formation.

Pleistocene and Tertiary: Northeastern Arizona.

A. B. Reagan, 1924 (Pan-Am. Geol., vol. 41, p. 366 and map on p. 357). For most part the surface of Hopi Buttes volcanic field, on both sides of middle, inner, valley of Pueblo Colorado Wash from Steamboat on N. nearly to Santa Fe Railroad to S., is a sandy, rolling bad-land country. The same fm. also skirts S. edge of Black Mesa, and extends W. to Hopi Buttes, where it has not been removed by erosion. In this paper this deposit will be termed *Bidahochi fm.* [Type loc. not stated, but fm. is mapped 15 to 20 mi. to E. and N. of settlement of Bidahochi (p. 355), near Twin Buttes, NE. Ariz.]

A. B. Reagan, 1932 (Kans. Acad. Sci. Trans., vol. 35, pp. 253–258), gives further information regarding his Bidahochi fm.—lithology, thickness, and geographic distribution. "For convenience the fm. will be considered under 4 subheads, the Ganado, White Cone, Cornfield and Sunrise Springs deposits, the latter 2 being divisions of the same 'conformable' series in the Cornfields-Sunrise Springs dist." He assigned the deposits to Tert. and Pleist., and described them under following headings: *Cornfields-Sunrise Springs series; Ganado (Mesa) series* (capping an irregularly shaped mesa N. of Ganado); and *White Cone series.* The latter "series" is "found in Hopi Volcanic Buttes field and along edge of Black Mesa W. and NW. of that field," and is composed of lava and clastic igneous materials associated with and often interbedded with shales and ss., a typical (detailed) section being at White Cone.

Biddeford granite.

Post-Carboniferous (?): Southwestern Maine.

C. H. Hitchcock, 1861 (Maine Bd. Agr. 6th Ann. Rept., p. 193), mentioned *Biddeford granite.*

F. J. Katz, 1917 (U. S. G. S. P. P. 108, p. 177). *Biddeford granite.*—Generally even or slightly porphyritic medium-grained biotite granite of light-gray or pinkish buff color. A few very small dikes of pegmatite and aplite are associated with it. Intrudes Kittery qtzite (Penn. ?). Occurs in Biddeford, Kennebunkport, Kennebunk, and Dayton Twps, York Co. Assigned to post-Carbf.

On 1933 geol. map of Maine, by A. Keith, this rock is included in block labeled "mainly Carbf."

Biehl sand.

A subsurface sand in Chester group (Miss.) of Wabash Co., Ill. (See Ill. Geol. Survey Bull. 54, index.)

Big trap.

Pre-Cambrian (Keweenawan): Northern Michigan.

Descriptive term locally in use many years. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. Usually immediately overlies † St. Louis cgl. and forms basal part of Central Mine group.

Big lime.

Subsurface term. In western Pa. applied to Greenbrier ls. memb. of Mauch Chunk fm.; also to basal part of Greenbrier ls. The name has also been applied to Benwood ls. memb. of Monongahela fm. and to Loyalhanna ls. In eastern Ky. it has been applied to 800 ft. or more of oolitic and granular oil-bearing lss. of Chester and St. Louis ages. In Ohio it has been applied to Maxville ls., also to rocks extending probably from top of Delaware ls. to Brassfield ls. (basal Sil.). In Texas Panhandle it has been applied to rocks correlated with lower part of Clear Fork group and upper part of Wichita group (both Perm.). In NE. and central eastern Okla. it has been applied to post-Cherokee Penn. rocks lying at different horizons above Oswego lime (Fort Scott ls.).

Big Baldy Mountain type.

Name applied by L. V. Pirsson (U. S. G. S. 20th Ann. Rept., pt. 3, pp. 547–550, 1900) to dikes of analcite basalt on Big Baldy Mtn, Little Belt Mtns, Mont.

Big Basin sandstone. (In Cimarron group.)

Permian: Central southern Kansas and northwestern Oklahoma (Harper County).

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, pp. 3, 46–48). *Big Basin ss.*—Rather massive, blocky, red and grayish white ss., 0 to 12 ft. thick, forming top fm. of Kiger div. Overlies Hackberry shales and uncon. underlies a remnant of Belvidere beds (Cret.).

F. W. Cragin, 1897 (Am. Geol., vol. 19, pp. 362–363). *Taloga fm.* is proposed to include Big Basin ss. and Hackberry sh. [See under *Taloga fm.*]

R. L. Clifton, 1930 (A. A. P. G. Bull., vol. 14, pp. 161–172). *Big Basin ss.* is well exposed in Harper Co., Okla., where it is overlain by beds perhaps referable to Cloud Chief gyp.

N. Evans, 1931. (See under *Quartermaster fm.*)

Named for Big Basin, a depression in Clark Co., Kans.

Big Bend gravel.

Pleistocene: Northwestern Pennsylvania (Warren County).

E. H. Williams, Jr., 1917 (Pennsylvania glaciation, First phase) and 1920 (Am. Phil. Soc. Proc., vol. 59, pp. 68–75), used *Early, Middle, and Late Big Bend gravels.*

Named for Big Bend, Warren Co.

Big Bend facies (also Big Bend magnafacies).

Terms applied by K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71) to facies of Chadakoin fm. of Chadwick (late Upper Dev.) in NW. Pa. and SW. N. Y. Named for exposures of the facies along Allegheny River from Kinzua, through Big Bend, Warren Co., Pa., and on to Warren, Pa.

Big Blue series.

Big Blue group.

Permian: Eastern Kansas and southeastern Nebraska.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, pp. 3, 5). *Big Blue series.*—Ls.-bearing series, 900 to 1,100 ft. thick, known by its fossils to belong to Perm. Underlies, probably uncon., Cimarron series. Divided into Sumner div. above and Flint Hills div. below. Includes (descending) Wellington shales, Geuda salt measures, Chase lss., and Neosho shales.

This name was not adopted by Kans. Geol. Surv. until 1917 (R. C. Moore and W. P. Haynes, Kans. Geol. Surv. Bull. 3), when it was called *Big Blue group* and defined as extending from top of Wellington sh. to base of Cottonwood ls. This definition of *Big Blue group* was also followed by Moore in his 1920 classification (Kans. Geol. Surv. Bull. 6). R. C. Moore and G. E. Condra in their Oct. 1932 revised classification of Perm. and Penn. rocks of Kans. still further expanded *Big Blue series*, as they called it, by including all beds down to base of Americus ls. G. E. Condra in 1935 (Nebr. Geol. Surv. Paper No. 8) and R. C. Moore in 1936 (Kans. Geol. Surv. Bull. 22) still further expanded their *Big Blue series* by including in it all beds down to uncon. at top of Brownville ls. The U. S. Geol. Survey has never adopted this name, and has not yet given consideration to change in Perm.-Penn. bdy.

Named for Big Blue River, which in northern Kans. cuts deeply into these rocks.

Big Blue serpentinous member (of Temblor formation).

Miocene (middle): Southern California (Diablo Range and Coalinga district).

R. Anderson and R. W. Pack, 1915 (U. S. G. S. Bull. 603). Upper memb. of Vaqueros fm., locally known as *Big Blue*, but in this rept called *Big Blue serpentinous memb.*, is formed largely of small flakes of serpentine, which make up a fine-grained, compact, tough sh., slightly bluish when fresh but weathering to various shades of red, yellow, and brown, owing to oxidation of the iron. Locally this sh. becomes sandy, but through most of its extent it is remarkable for being little else than a compacted mass of serpentine dust, flakes, and pebbles. With the sh. are cgls. formed almost entirely of serpentine boulders, the largest of which are huge blocks many ft. in diam. Thickness 40 to 1,000 ft. In rept on Coalinga dist. (U. S. G. S. Bull. 398, 1910) the Big Blue was tentatively included in Santa Margarita fm. Named for exposures in Big Blue Hills.

The Vaqueros ss. being now restricted to lower part, or *Turritella inezana* zone, of Vaqueros of earlier repts, the Big Blue becomes a memb. of overlying *Turritella ocoyana* zone, or Temblor fm., and is so treated by B. L. Clark, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 7, map, pl. 89).

Big Branch formation.

Pennsylvanian: Southern Oklahoma (Carter County).

F. W. Floyd and D. C. Nufer, 1935 (Tulsa Geol. Soc. Digest, 1934, pp. 10–11), divided the Penn. of Ardmore Basin into (descending) Pontotoc, Hoxbar, Deese, *Big Branch* ("to replace Goldston's Cup Coral"), and Otterville fms.; and correlated the Big Branch with lower part of Cherokee and the Otterville with Morrow. This is all there is about the Big Branch fm. On p. 10 C. W. Tomlinson stated: The proposed "Big Branch" fm. does not occupy strat. position assigned to it by Floyd and Nufer, relative to previously named members of Dornick Hills fm.

Big Buffalo series.

Lower Ordovician: Northern Arkansas.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27), in his general time scale grouped together (descending) the Joachim of Mo., the St. Peter of Minn., and the Everton of Ark. as belonging to an "unnamed epoch" preceding the Chazyan and succeeding the Beekmantown. According to his chart these beds are represented by hiatus in N. Y., the typical Chazy and Beekmantown region. This chart showed this unnamed epoch as antedating Mosheim ls. of Tenn.

R. S. Bassler, 1915 (U. S. Nat. Mus. Bull. 92, vol. 2, pls. 1, 2) and 1919 (Md. Geol. Surv. Camb. and Ord. vol., p. 51). *Big Buffalo series* of general time scale is older than Chazyan, younger than Beekmantown, and older than Mosheim ls. of Tenn. It includes (descending) Jasper of Ark., St. Peter of Minn., and Everton and Sneeds of Ark.

H. A. Buehler, 1922 (Mo. Bur. Geol. and Mines geol. map of Mo.), used *Buffalo* as a *group* term to include Joachim ls., St. Peter ss., and Everton ls.

G. H. Ashley, 1923 (Eng. and Min. Jour.-Press, vol. 115, No. 25, p. 1107), included *Big Buffalo group* of Ark. in Chazy epoch.

E. O. Ulrich, 1924 (Tenn. Dept. Ed., Div. Geol. Bull. 28, pp. 16–17, 34), used *Big Buffalo series* in his general time scale to include beds btw. Chazyan and his Upper Canadian [upper Beekmantown], and included in it the Mosheim ls. of Tenn.

E. O. Ulrich, 1926 (Geol. Soc. Am. Bull., vol. 37, p. 329) and 1930 (U. S. Nat. Mus. Proc., vol. 76, art. 21, p. 73), used *Buffalo River series* as a general time term for rocks said to occur btw. Chazyan and Beekmantown.

E. O. Ulrich, 1927 (Okla. Geol. Surv. Bull. 45, pp. 30–31), used *Big Buffalo* as a time term to include (descending) Joachim, St. Peter, Everton, Kings River, and Sneeds. (The latter 2 are treated as members of Everton by U. S. Geol. Survey.)

G. C. Branner, 1929 (Ark. Geol. Surv. geol. map of Ark.), bracketed *Buffalo River* opposite (descending) Jasper ls., Joachim ls., St. Peter ss., and Everton ls.

Named for exposures on Buffalo River (formerly called Buffalo Fork of White River) in Newton Co., Ark. The river was also formerly called Big Buffalo. U. S. Geographic Board has adopted Buffalo River.

Bigby limestone.

Middle Ordovician (Trenton): West-central Tennessee.

C. W. Hayes and E. O. Ulrich, 1903 (U. S. G. S. Columbia folio, No. 95, p. 2). *Bigby ls.*—Generally nearly uniform, semi-oolitic or granular crystalline, laminated, phosphatic ls, of gray or bluish color; upper part often shaly or aren.; lower part frequently having beds of sh. but never sandy. Thickness 30 to 100 ft. Of Trenton age. Uncon. underlies Catheys fm, and overlies [uncon., according to Ulrich] Hermitage fm., both of Trenton age.

E. O. Ulrich, 1924 (Tenn. Dept. Ed., Div. Geol. Bull. 28, p. 34), and C. Butts, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14, chart opp. p. 80), show Cannon ls. of Tenn. as underlying Catheys ls. and overlying Bigby ls. This is present accepted definition of Bigby ls, which lies uncon. on Hermitage fm.

Named for exposures on Big Bigby Creek, Maury Co.

Big Cave.

A term applied by drillers in western Pa. to the part of Conemaugh fm. that is known as "Pittsburgh Reds."

†Big Clifty sandstone. (In Chester group.)

Mississippian: Western Kentucky.

C. J. Norwood, 1876 (Ky. Geol. Surv., n. s., vol. 1, pt. 6, pp. 10, 13, 15, 16, 51, 73, 369). *Big Clifty ss.*—Heavy-bedded ss. 60 to 130 ft. thick, constituting basal fm. of Chester group in region adjacent to Louisville, Paducah, and Southwestern R. R., Ky. Toward S. and W. borders of coal fields loses its character as a ss. and passes into shales. Equiv. of "ferruginous" ss. of Ill. Underlain by St. Louis group.

C. Butts, 1917 (Ky. Geol. Surv., Miss. fms. of western Ky., pp. 86–90). "Big Clifty" ss. of Norwood is same as true Cypress ss.

Named for exposures on Big Clifty Creek, Grayson Co.

Big Cottonwood quartzite series.

A term applied by S. F. Emmons (U. S. G. S. 16th Ann. Rept., pt. 2, p. 362, 1895) to the basal quartzite series of Wasatch Mtns, consisting of 12,000 ft. of Camb. [and pre-Camb. (?)] qtzites with clay slates at top, underlying Ute ls. [broad sense of King].

Big Cottonwood formation.

Upper Cretaceous: Southwestern Minnesota.

F. W. Sardeson, 1908 (Geol. Soc. Am. Bull., vol. 19, pp. 221–242). *Big Cottonwood fm.*—Shales, sss., and cgls., red, green, white, yellow, blue, and brown. Outcrops on Big Cottonwood River and in neighboring parts of Minn. Valley. All strata are fresh-water deposits and are referable to Dakota fm., although they possibly are contemp. with marine Colorado fm. or Niobrara. Represents a river delta or filled valley of a stream which originally descended from E. to W.

Big Creek shale. (In Carbondale formation.)

Pennsylvanian: Central western Illinois (Fulton County).

T. E. Savage, 1927 (Am. Jour. Sci., 5th, vol. 14, pp. 307–316), applied *Big Creek sh.* to that part of Carbondale fm. of Fulton Co. beneath Herrin (No. 6) coal and above his Cuba ss. Thickness and derivation of name not stated. Probably named for Big Creek, in Canton region, Fulton Co.

†Big Deciper calcareous sands.

Upper Cretaceous (Gulf series): Southern Arkansas (Clark County).

R. T. Hill, 1888 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 2, pp. 72, 77, 79, 188). *Big Deciper calc. sands.*—White unstratified rock, consisting of grains of sand like those of High Bluff blue sands, and containing occasional grains of greensands, full of casts of shells, especially the large *Exogyra costata*, all cemented by a calc. matrix. Has lithologic appearance and weathering of soft, white, chalky marl sometimes found near it and known toward south as "Rotten ls." Thickness 100 ft. Underlies and grades into High Bluff blue sands. Overlies Marlbrook-Columbus marl.

Part of Saratoga chalk. (See C. H. Dane, 1929, Ark. Geol. Surv. Bull. 1, p. 103.)

Named for exposures in bluffs of Big Deciper Creek, 6 mi. S. of Arkadelphia, Clark Co.

†Big De Gray horizon.

Upper Cretaceous (Gulf series): Southwestern Arkansas (Clark County).

R. T. Hill, 1888 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 2, pp. 79, 81, 188). *Big De Gray horizon.*—Blue marls, similar in color to those above Koster "joint clays," but having much finer structure, less sand, and more lime, mica, and perhaps glauconite. Littoral fm. locally present in Clark Co.; older than Koster joint clays and overlying Paleozoic. Do not extend beyond Clear Springs, Clark Co.

Probably a part of Brownstown marl (restricted).

Named for occurrence in bed of Big De Gray Creek, near McCaulley's, Clark Co.

Big Dunkard sand.

A subsurface sand in SW. Pa. and W. Va. that is believed to lie at horizon of Mahoning ss., the basal memb. of Conemaugh fm. (Penn.). Named for Dunkard Creek, Greene Co., SW. Pa.

Big Elk sandstone member (of Colorado shale).

Upper Cretaceous: Central southern Montana (Musselshell Valley region).

C. F. Bowen, 1918 (U. S. G. S. Bull. 691F, pp. 189, 195–198). In W. part of Musselshell Valley the lower 500 ft. of Colorado sh. consists of black fissile shales, for most part sandy, in which are numerous thin qtzitic sss. This is followed upward by a thin but prominent conglomeratic ss.; above which are 300 ft. of shales and thin qtzitic sss. Next comes a sandy div., 200 ± ft. thick, in which there is a coarse ss. at least 100 ft. thick, and at top a conglomeratic bed 4 or 5 ft. thick. This div. is here named *Big Elk ss. memb. of Colorado sh.*, from its exposures in Big Elk dome. It is 1,200± ft. below top of Colorado fm. and in approx. position of Frontier fm., but the two can not be directly correlated. Remainder of Colorado fm. consists chiefly of sh. with a sandy transition zone near top. [Detailed section of Big Elk memb. gives (descending):

1. ss., coarse, slightly conglomeratic; bone fragments, fish teeth, and *Halymenites major*, 5 ft.
2. concealed, probably sh. or sandy sh., 45 ft.
3. ss., qtzitic, in thin beds alternating with sh., 41 ft.
4. ss., coarse, somewhat massive; bone fragments, 157 ft.]

Bigelow formation. (In Council Grove group.)

Permian: Southeastern Nebraska and northeastern Kansas.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, pp. 4, 6). *Bigelow ls. fm.*, about 41 ft. thick, includes (descending): Funston ls., Blue Rapids sh., and Crouse ls. of Council Grove group. [Derivation of name not stated.]

Bigford member (of Mount Selman formation).

Eocene (middle): Southern Texas.

A. C. Trowbridge, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 75; U. S. G. S. P. P. 131D, p. 92). *Bigford fm.*—Chiefly clay of many colors with subordinate quantities of gray, green, and brown ss. which at most places is not cross bedded. Contains many beds of lignite, the heaviest 20 inches thick, and some lens-shaped concretionary masses. Contains no paper shales and sands, such as occur in Indio fm., and no thick, cross-bedded, and commonly qtzitic sands, such as occur in Carrizo ss. Thickness 0 to 470± ft. Top fm. of Wilcox group. In part contemp. with Carrizo ss. and in part younger. Underlies Mount Selman fm. Named for Bigford ranch, Webb Co.

The Bigford was formerly treated as a fm. of Wilcox group, based on its fossil plants, but its invertebrate fossils are now generally considered to be of Claiborne age. It is therefore now treated by U. S. Geol. Survey as basal memb. of Mount Selman fm., of Claiborne group, as far N. as Atascosa Co.; and to N. of that Co. the contemp. Claiborne deposits, which differ lithologically, are called *Reklaw memb. of Mount Selman fm.*

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 619–620). Trowbridge's map and description indicate clearly he intended Bigford to be a facies of Carrizo sand—simply a change from sand to clay along the strike. Miss Gardner (prel. ed. geol. map of Tex., 1932) has amended and expanded Bigford fm. of Trowbridge in order to make it a valid fm. and has separated it from Carrizo. Since Reklaw has priority over the amendation of Miss Gardner, and since it is in established usage by geologists of the State, it is preferable to adopt it exclusively, if possible.

Bigfork chert.

Middle Ordovician: Southwestern Arkansas and southeastern Oklahoma.

A. H. Purdue, 1909 (Geol. Soc. Am. Bull., vol. 19, p. 557; also Slates of Ark., Ark. Geol. Surv., pp. 30, 35). *Bigfork chert.*—Close-textured, even-bedded, siliceous rock in layers 1 to 18 inches thick; of slate to dark-gray color; very friable. In places thickly set with network of fine quartz veins. Weathered portions have appearance of fine-grained, gray weathered ss. Usually layers are crumpled to astonishing degree. Thickness 700 ft. Overlies [uncon.] Stringtown sh. and underlies Polk Creek sh. [Stringtown sh. now abandoned, for Womble sh.]

Named for development over large area around Bigfork P. O., Montgomery Co., Ark.

Big Glass Mountain complex.

Recent: Northern California (Modoc Lava Bed quadrangle).

H. A. Powers, 1932 (Am. Min., vol. 17, No. 7, pp. 280–282). *Big Glass Mtn complex.*—Big Glass Mtn, whose flows cover an area of about 9 sq. mi., is largest accumulation of Recent siliceous lava in Modoc Lava Bed quad. The lava ranges from rhyolite to dacite.

Bigheart sandstone member (of Nelagoney formation).

Pennsylvanian: Central northern Oklahoma (Osage County).

L. C. Snider, 1911 (Okla. Geol. Surv. Bull. 7, p. 221). Ss., 175 ft. thick, called *Bigheart ss.* by [L. L.] Hutchison in unpublished thesis (Univ. Okla. Lib., 1907). Overlies Stanton ls. Is separated from the higher Elgin ss. by 85 ft. of sandy and clay shales overlain by Nelagoney ss. (40 ft. thick).

C. F. Bowen, 1918 (U. S. G. S. Bull. 686D, pp. 18, 19). *Bigheart ss. (restricted.)*—The name *Bigheart ss.* was used by L. C. Snider (Okla. Geol. Surv. Bull. 7, p. 221, 1911) for 175 ft. of sss. and shales supposedly exposed at and near Bigheart, but term is here restricted to basal massive ss. of that series of beds, which is useful horizon marker over consideable area, and which is well exposed at Bigheart, forming main ledge in bluffs W. of road btw. Bigheart and Quawpaw. It is a massive, cross-bedded, ledge-making ss., 25 to 50 ft. thick [70 ft. in later repts]. In some places it consists of a single bed; in other places it is separated into two members by a bed of red sh. 4 ft. or more thick. At its base it is slightly conglomeratic, and for several ft. above this basal part it is very coarse grained or gritty. It lies from 70 to 115 ft. above Birch Creek ls.

Is now treated as basal memb. of Nelagoney fm.

Named for exposures W. of Barndall (formerly called Bigheart), Osage Co.

Big Hill beds.

Upper Ordovician (Richmond): Northern Michigan (Delta County).

R. C. Hussey, 1926 (Mich. Univ. Mus., Geol. Contr., vol. 2, No. 8, pp. 115–150). *Big Hill beds.*—Vary from light gray ls., moderately hard, noncrystalline, to dark gray, argill. ls., hard, coarsely crystalline. Thickness 27± ft. Overlie Ogontz memb. of Stonington beds and form top div. of Upper Ord. Richmond fm. of Mich. Belong to late Richmond Arctic submergence. Exposed from crest of Hinkin's Hill (also known as Big Hill) north to E. end of Maywood road. Fauna differs from that of Stonington beds.

Bighorn dolomite.

Upper Ordovician: Wyoming and southern Montana.

N. H. Darton, 1904 (Geol. Soc. Am. Bull., vol. 15, pp. 394–401). ***Bighorn ls.***—On E. side of Bighorn Mtns, Wyo., consists of 250–300 ft. of ls., in greater part hard and massive. Top memb. is thin-bedded impure ls. which NW. of Buffalo, Wyo., contains large Richmond fauna. Middle memb. is less massive than basal memb. and in places consists of fine-grained, light-colored lss. containing numerous corals, including *Halysites catenulatus*. Lower memb. is hard, massive, impure ls., light gray or faint buff, with reticulating network of silica, which on weathering gives it a very coarse honey-combed appearance; contains a few late Ord. fossils. [On p. 434 he says the fossils in lower massive memb. are Trenton.] Underlies Little Horn [Madison] ls. [lower Miss.] and overlies Deadwood fm. [Upper Camb.].

See *Leigh memb. of Bighorn dol.*

A. K. Miller, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 196–213). [Long discussion of faunas of Bighorn dol., from which he concludes whole fm. is of Richmond age. See under *Lander ss. memb.*]

E. Kirk, 1933 (Am. Jour. Sci., 5th, vol. 26, p. 42). I consider lower part of Bighorn dol. to be pre-Maysville and post-Trenton, and it probably represents a strat. unit not present in eastern United States.

Bighorn formation.

Cretaceous: Alberta.

G. S. Malloch, 1911 (Canada Geol. Surv. Mem. 9, p. 36), applied *Bighorn fm.* to a Cret. fm. in Bighorn coal basin, Alberta.

†Bighorn glacial epoch.

A name applied by W. W. Atwood and K. F. Mather (Sci., n. s., vol. 35, p. 315, 1912; Jour. Geol., vol. 20, p. 388, 1912; and Geol. Soc. Am. Bull., vol. 23, p. 732, 1912) to the time during which a till sheet of pre-Wisconsin age was deposited in San Juan Mtns of SW. Colo. It was expected that the name would be used by E. Blackwelder for a till of corresponding age in Bighorn Basin of Wyo. Atwood and Mather later replaced the name with *Durango glacial stage* (and *Durango drift*), a Colo. name.

†Bighorn moraine.

Pleistocene: Southwestern Colorado.

W. W. Atwood and K. F. Mather, 1912 (Jour. Geol., vol. 20, pp. 392–409), mapped and described *Bighorn moraine* and *Bighorn outwash* in San Juan Mtn region, SW. Colo., the deposits being correlated with glacial deposits of supposedly the same age in Bighorn Mtns of Wyo. Later (U. S. G. S. P. P. 95, p. 14, pl. 1, 1915, and P. P. 166, 1932) they replaced the name with the local Colo. name *Durango till.*

Big Injun group.

Big Injun sand.

Drillers' terms for beds that have been correlated with Burgoon ss. memb. of Pocono fm. (Miss.) of western Pa. and equiv. beds in eastern Ohio and northern W. Va. So called because of their hardness and thickness. In eastern Greene Co., Pa., the top is 1,225 ft. below Pittsburgh coal and thickness 250 to 300 ft. At Mount Morris, Greene Co., the sand is called *Mount Morris sand*, and is 101 ft. thick. In southern Ky. and Tenn. the name is applied to an oil-bearing calc. ss. of Miss. age. According to W. Stout et al (Geol. of nat. gas, A. A. P. G., 1935, p. 903), the Big Injun sand of SE. Ohio and northern W. Va. is Black Hand cgl.

Big Lake lime.

A subsurface gas-bearing ls., 10 ft. thick, in Clear Fork fm. of Big Lake oil pool, Reagan Co., Tex.

Big Lake Big lime.

A subsurface Perm. ls. series, 2,000–3,500+ ft. thick, in western Tex. (Pecos River region), extending from Big Lake to Yates on W. and S. and to N. Mex. line on N. Appears to lie 1,500 to 1,700 ft. higher than Amarillo Big lime.

Big Mountain shale member (of Keyser limestone).

Lower Devonian (Helderberg): Northern West Virginia and western Virginia.

F. M. Swartz, 1929 (U. S. G. S. P. P. 158, p. 29). *Big Mtn sh. memb.*—Greenish to yellowish calc. sh. with some impure lss.; separates upper ls. memb. of Keyser ls. from lower ls. memb. in parts of W. Va. and western Va. as far S. as Bolar Springs, where it wedges out and is replaced by part of the massive Clifton Forge ss. memb. of Keyser ls., with which it intertongues to N. Is 61 ft. thick at Big Mtn, about 1½ mi. W. of village of Upper Tract, Pendleton Co., W. Va., but thins to N. and S., being 45 ft. thick near Franklin and Wardensville, W. Va., and 10 ft. at Strait Creek, Highland Co., Va.

Big Red.

A term that has been applied by drillers in western Pa. to the part of Conemaugh fm. that is known as "Pittsburgh Reds." Also to younger beds of the Conemaugh that are known as "Washington Reds;" also to the still younger Birmingham sh. memb. of the Conemaugh.

Big Red Cave.

Drillers' name for 30 to 125± ft. of beds in Conemaugh fm. (Penn.) of W. Va., that lie in interval btw. Moundsville and Murphy sands and are believed to correspond to the beds known as "Pittsburgh Reds."

Big Shell.

A term applied by drillers of western Pa. to Patton sh. memb. of Pocono fm.

Big Sheep volcanics.

Age (?): British Columbia.

C. W. Drysdale, 1916 (Canada Geol. Surv. Summ. Rept. 1915, p. 78).

Big Snowy group.

Mississippian: Central Montana.

H. W. Scott, 1935 (Geol. Soc. Am. Proc. 1934, p. 367). *Big Snowy group* is made up of Kibbey, Otter, and *Heath* fms. Is mainly variegated shales with intercalated lss. and sss. Overlies Madison ls.

H. W. Scott, 1935 (Jour. Geol., vol. 43, No. 8, pt. 2, pp. 1011–1032). *Big Snowy group.*—New name for lower part of beds heretofore assigned to Quadrant fm. in central Mont. True Quadrant fm. is absent in central Mont., where the rocks heretofore assigned to it are all of Miss. age, are all older than typical Quadrant fm., of Quadrant Mtn, Yellowstone Nat. Park (which is of basal Penn. age and unquestionably a westward extension of Tensleep ss., into which it grades), and are also older than Amsden fm., which is Miss. and underlies the Quadrant of Quadrant Mtn as well as the Quadrant of southern Mont. and overlies Big Snowy group in central Mont. This group has max. thickness of 1,200 ft. and rests on Madison ls. It is named for its extensive distribution and excellent exposures in Big Snowy Mtns. It is also exposed in Little Belt Mtns, Castle Mtns, and Lombard Hills. It is divided into 3 conformable fms., in descending order, Heath fm. (new name), Weed's Otter fm., and Weed's Kibbey fm. It is absent in Yellowstone Park, also in north-central Wyo. and southern Mont. In 1931 (U. S. G. S. P. P. 165, pp. 135–149) F. Reeves, although calling these rocks *Quadrant fm.*, suggested that the upper ls. of the unit is Amsden fm., a suggestion that has been verified by writer's work. In most areas there is uncon. (not angular) btw. Amsden and Quadrant and btw. Amsden and Tensleep, but in Three Forks region there is evidence that would support theory of continuous deposition.

Big Springs limestone. (In Lecompton limestone.)

Pennsylvanian: Southeastern Nebraska, northwestern Missouri, southwestern Iowa, and northeastern Kansas.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 44, 47). *Big Springs ls.*—Bluish gray to light gray, massive, jointed, and quite fossiliferous. Thickness 1 to 3 ft. Overlies Doniphan sh. and underlies Queen Hill sh., all included in Lecompton ls. Recognized in Nebr., Iowa, Mo., and Kans. Exposed near Big Springs, Kans. [N. of Big Springs, Douglas Co., Kans.: Condra, 1937.]

Big Spruce Knob sandstone.

Mississippian: Southern West Virginia.

D. B. Reger, 1920 (W. Va. Geol. Surv. Rept. Webster Co., pp. 214, 221–223). *Big Spruce Knob ss.*—Greenish gray flaggy stratum, 0 to 30 ft. thick, lying 370 to 648 ft. below Pluto coal and resting on Big Spruce Knob sh. or on underlying Big Spruce Knob coal. Named for exposure at base of Big Spruce Knob, Pocahontas Co. Lies 750 ft. below Princeton cgl. and 837 ft. above Greenbrier ls. Included in Mauch Chunk.

Big Spruce Knob shale.

Mississippian: Southern West Virginia.

D. B. Reger, 1920 (W. Va. Geol. Surv. Rept. Webster Co., pp. 214, 223–224). *Big Spruce Knob sh.*—Gray sh., 0 to 2 ft. thick, containing plant fossils. Underlies Big Spruce Knob ss. and overlies Big Spruce Knob coal. Exposed on Big Spruce Knob, Pocahontas Co. Included in Mauch Chunk.

Bigstone morainic system.

Pleistocene (Wisconsin stage): South Dakota and western Minnesota.

F. Leverett, 1932 (U. S. G. S. P. P. 161, pp. 105–111). [Members not named, except that Fergus Falls moraine belongs to it. Southernmost part is in Big Stone and Swift Counties, Minn., and along SW. side of Big Stone Lake, S. Dak.]

Big Stone Gap shale.

Upper Devonian and lower Mississippian: Southwestern Virginia.

G. W. Stose, 1923 (Va. Geol. Surv. Bull. 24). *Big Stone Gap sh.*—Black sh., generally soft, but contains some beds of harder, platy, dry, dull-black argillite. Thickness 320± ft. Has same lithologic character as Chattanooga sh. at Chattanooga. Ulrich identifies fossils from upper 100 ft. as of Sunbury age and those from lower part as of Cleveland and Huron age. Was not found in any section where Chemung rocks are recognized and relation to Chemung is therefore not positively established. Rests on Portage sh. and underlies Price ss. Named for Big Stone Gap, SW. Va.

J. H. Swartz, 1926 (Sci., n. s., vol. 64, p. 226). *Big Stone Gap sh.* contains typical Chemung fossils and is definitely Dev.

J. H. Swartz, 1927 (Am. Jour. Sci., 5th, vol. 14, p. 498). The evidence to be presented later indicates a Miss. age for upper part and a Dev. age for lower part of Big Stone Gap sh. of Stose and Ulrich. The name *Big Stone Gap* is here restricted to uppermost part. (See *Big Stone Gap memb.*)

The U. S. Geological Survey at present adheres to original definition of Big Stone Gap sh.

Big Stone Gap member (of Chattanooga shale).

Devonian or Carboniferous: Southern Tennessee and southwestern Virginia.

J. H. Swartz, 1927 (Am. Jour. Sci., 5th, vol. 14, pp. 485–499). The Big Stone Gap sh. of Ulrich and Stose has been shown by direct and continuous tracing to be northward continuation of Chattanooga sh. of type area. Such being the case, the term *Big Stone Gap sh.* must be abandoned for prior term *Chattanooga sh.* Throughout whole area [Chattanooga, Tenn., to SW. Va.] the Chattanooga sh. [restricted] is divisible into 3 members: (1) An upper black sh. memb., to which the term *Big Stone Gap* is here restricted; (2) a middle gray sh. memb., here called *Olinger memb.*; and (3) a lower black sh. memb. here designated *Cumberland Gap memb.* The Big Stone Gap memb. is separated from underlying Olinger memb. by an uncon., which is most marked in SE. Tenn. and which may be absent in NE. Tenn. and SW. Va. The Big Stone Gap memb. extends continuously from Chattanooga area to Big Stone Gap and beyond. At Cameron Hill, Chattanooga, it is ⅝ inch thick; at Apison, 16 mi. away, it is 2 ft. 10½ in. thick; from here to Lafollette it remains approx. 2 ft. thick; btw. Lafollette and Cumberland Gap, on Va.-Tenn. border, it jumps suddenly to 81 ft. in thickness; at Big Stone Gap it is at least 96 ft. 5 in. thick. Is overlain, with sharp contact, by the gray Glendale sh.

J. H. Swartz, 1929 (Am. Jour. Sci., 5th, vol. 17, pp. 431–448), assigned his restricted Chattanooga sh., as defined above, to Miss., but U. S. Geol. Survey tentatively classifies these beds as Dev. or Carbf.

Big Thompson schist.

Pre-Cambrian: Central northern Colorado (Larimer County).

M. B. Fuller, 1924 (Jour. Geol., vol. 32, pp. 51–63). *Big Thompson schist.*—A series of metamorphosed sss., shales, and lss. with a small amount of cgl. The strata are a series of interbedded metamorphosed crystalline rocks derived by regional and contact metamorphism against granites which cut through the schists in stocks, bathyliths, and numerous dikes. There is a definite regular gradation of Big Thompson schists from the highly metamorphosed, dense black biotite-sillimanite schists of the Continental Divide and Estes Park region eastward through quartz-biotite and chlorite schists to pure quartz schists in Loveland Canyon. All the diverse phases are interbedded, show transition varieties, and, although clearly graded from W. to E., are undoubtedly parts of same formation. In general the schistosity is parallel to original bedding of the sediments.

Named for Big Thompson River, which, in traversing E. slope of Front Range, has exposed a complete section of the schist.

Big Valley bed. (In Strawn group.)

Pennsylvanian: Central Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 374, 380). *Big Valley bed.*—In descending order: 150 ft. of bluish and sandy or black and shaly clay; 150 ft. of ss., mostly massive but in part flaggy and a little shaly; and 200 ft. of clay, generally blue, with considerable blackish sh. and a little ss. Is memb. of Strawn div. Underlies Brown Creek bed and overlies Bull Creek ss.

Named for Big Valley, Mills Co.

Bijiki iron-formation member (of Michigamme slate).

Pre-Cambrian (upper Huronian): Northwestern Michigan (Marquette district).

C. R. Van Hise and W. S. Bayley, 1895 (U. S. G. S. 15th Ann. Rept., p. 596). *Bijiki schist.*—Peculiar schist with some qtzites. Thickness 520 ft. Equivalent in age to Goodrich qtzite of W. part of Marquette dist. Named for exposures near mouth of Bijiki River.

Later repts by C. R. Van Hise and others stated that Bijiki schist overlies Goodrich qtzite, and assigned it to upper Huronian. (See U. S. G. S. Bull. 360, 1909, and U. S. G. S. Mon. 52, 1911.)

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), changed name to *Bijiki iron-fm. memb.* and included it in Michigamme sl.

Billhook formation.

Upper Jurassic: Southwestern British Columbia (Harrison Lake region).

C. H. Crickmay, 1930 (Geol. Mag., vol. 67, p. 487 and map). *Billhook fm.*—Tuff, 1,800 ft. thick, carrying "Cadoceras" sp. Uncon. underlies Kent fm. (Upper J.) and overlies Mysterious Creek fm. (Upper J.). [Derivation of name not stated and no geographic feature of that name shown on map.]

Billings sand.

A subsurface sand, of Penn. age and 12 ft. thick, in central northern Okla., reported to correlate with basal part of Pawhuska fm.

Bill's Creek beds.

Upper Ordovician (Richmond): Northern Michigan (Delta County).

R. C. Hussey, 1926 (Mich. Univ. Mus., Geol. Contr., vol. 2, No. 8, pp. 113–150). *Bill's Creek beds.*—Largely thin-bedded sh., with a few thin layers of interbedded argill. ls., highly fossiliferous. Chief exposures on Bill's Creek and along E. shore of Little Bay de Noc. Total thickness about 88 ft. The lowest beds of Upper Ord. Richmond fm. of Stonington region of Mich. Discon. overlain by Bay de Noc memb. of Stonington beds. Lower part of the beds may not belong to the Richmond.

Biloxi sand.

Pleistocene: Southeastern Louisiana and southern Mississippi.

L. C. Johnson, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 24–25). The coastal sands, or *Biloxi sands*, as the deposits of the strip immediately adjoining the salt water of Mississippi Sound are called, represent now, by reason of modern subsidence, a remnant only of their former extent. The strip varies from zero to a width of several mi., stretching, as usually understood, from the Rigolets (or mouth of Pearl River) to Mobile Bay. Consist essentially of thin alternating layers of sand and yellowish brown or blue clay, similar to deposits now in process of accumulation upon floor of the sound. Thickness from borings at Biloxi, Pass Christian, and other places, 80 or 100 ft. Wanting at Ocean Spring. Younger than Pontchartrain clays.

See further explanation under *Pontchartrain clay* and *Port Hudson fm.*

Named for Biloxi, Harrison Co., Miss.

Bimber Run conglomerate member.

Devonian or Carboniferous: Northwestern Pennsylvania (Warren County).

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 86, table opp. p. 61). *Salamanca cgl. suite* is usually initiated by a basal cgl. which merits differentiation. Is well developed S. of Warren along Allegheny River. *Bimber Run cgl. memb.* is suggested for it, from its occurrence on this run and S. of its mouth, in Watson Twp, Warren Co., Pa. Max. thickness in type section 100+ ft. In Pa. repts has been called "Venango second B ss.," also "Tanners Hill quarry rock," in contradistinction to overlying upper Salamanca cgl. Is lenticular and not present much E. of Kinzua or Great Bend of Allegheny River; does not extend, so far as known from well logs, W. of Titusville meridian. [See also 1934 entry under *Salamanca cgl.*]

†Bingen formation.

†Bingen sand.

Upper Cretaceous (Gulf series): Southwestern Arkansas, southeastern Oklahoma, and northwestern Louisiana.

R. T. Hill, 1888 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 2, pp. 56–58). *Bingen sands.*—Extensive aren. fm., consisting of fine white quartz sand with occasional thin beds of lignite. Can only be classified as isolated outcrops of concealed westward continuation of upper and lower beds of typical Camden series. Includes many nodular concretions of iron ore and often extensive layers of ferruginous ss. Constitutes most of sandy uplands of eastern Howard, western Hempstead, southern Sevier, Little River, Nevada, and Clark Counties, Ark. Occupies same relative position above Arkadelphia shales as does Camden series. Included in Eocene.

A. C. Veatch, 1906 (U. S. G. S. P. P. 46, table opp. p. 16, pp. 23–25). *Bingen sand.*—Near-shore deposits, of white or brown sands and clays containing some greensand and considerable lignite or lignitiferous matter. Max. thickness over 500 ft. Basal fm. of Upper Cret. Time equiv. of Woodbine sand, Eagle Ford clay, and Sub-Clarksville sand [Blossom sand]. Underlies Brownstown fm. and overlies Washita group.

Is now divided into Tokio fm. above and Woodbine sand below. See under *Tokio fm.*

Named for exposures near Bingen, Hempstead Co., Ark.

Bingham quartzite.

Pennsylvanian: Central northern Utah (Bingham district).

A. Keith, 1905 (U. S. G. S. P. P. 38, pp. 33–37, map, sections). *Bingham qtzite.*—Chiefly fine-grained qtzites and sss., more or less silicified. Mostly white and frequently vitreous. In lower portions of the qtzite, especially below the Jordan ls., a slight banding is seen in many places, also cross bedding. In upper part of fm., particularly above Highland Boy ls., are many layers of ripple-marked argill. and slightly calc. sss. In places very thin layers of fine-grained quartz cgl. occur. Thickness exposed in Bingham dist. probably 8,000 or 10,000 ft., but neither top nor bottom of fm. appears in this dist. Is interbedded with many ls. masses, the most prominent of which are here named *Phoenix ls. lentil*, 0 to 300 ft. thick; *Tilden ls. lentil*, 100 ft.; *Yampa ls. lentil*, 0 to 400 ft.; *Highland Boy ls. memb.*, 0 to 400 ft.; *Commercial ls. memb.*, 0 to 200 ft.; *Jordan ls. memb.*, 20 to 300 ft.; *Lenox ls. memb.*, 200 ft.; *Butterfield ls. memb.*, 300 ft.

B. S. Butler, 1920 (U. S. G. S. P. P. 111, p. 348). The important Jordan and Commercial lss. occur in lower part of Bingham qtzite, and the Highland Boy, Yampa, and other lss. possibly considerably higher.

Binnewater sandstone. (In Salina formation.)

Silurian: Southeastern New York.

C. A. Hartnagel, 1905 (N. Y. State Mus. Bull. 80, pp. 342–357), divided *Salina beds* of High Falls region of eastern N. Y. into (descending): Rosendale cement; Wilbur ls.; *Binnewater qtzites* (the so-called Clinton qtzites); and High Falls sh. (red sh.). Of the Binnewater he says: South from High Falls the qtzite below the Wilbur ls. becomes more calc. and of a shaly nature.

In 1906 A. W. Grabau (N. Y. State Mus. Bull. 92) designated these beds as *Binnewater ss.*, by which name they have since been known. C. Schuchert in 1916 (Geol. Soc. Am. Bull., vol. 27, pp 540–542) assigned to them a thickness of 32 to 35 ft. in Binnewater-High Falls region.

Named for occurrence at Binnewater, 7 mi. SW. of Kingston, Ulster Co. See also under *Bertie ls. memb.*

Binney sand.

A subsurface sand, of Penn. age, in Binney–Hohertz field, Stephens and Palo Pinto Counties, north-central Tex., lying at 1,700 ft. depth.

Birch Creek schist.

Pre-Cambrian: Eastern Alaska.

J. E. Spurr, 1898 (U. S. G. S. 18th Ann. Rept., pt. 3, pp. 140–145, 224). *Birch Creek series*.—Chiefly qtzite schists, generally of light gray color, but locally they pass into darker, finer grained, and even graphitic schists. The typical rock is a qtzite, hard and white in the less-sheared portions. There are also found, although rather sparingly, schists of igneous origin, being dikes which have intruded into the sed. series previous to the shearing. In some places the contact btw. this igneous schist and the sed. qtzite schist was seen, proving its dikelike nature. So far as noted, these intrusions were of granite in its various phases. Thickness of Birch Creek series about 25,000 ft. The Birch Creek series forms the oldest sed. series known. It underlies Fortymile series and rests on the basal granite. Named for exposures in Birch Creek dist.

In subsequent repts the associated igneous rocks, which range in composition from basic greenstones and hornblende schists to acidic intrusives, have been both included in and excluded from Birch Creek schist. The present approved definition restricts the name *Birch Creek schist* to the sed. rocks, although the associated igneous rocks may for convenience be mapped with the Birch Creek. The assemblage is susceptible of subdivision as more detailed work is done. The rocks designated by Spurr as "Fortymile series" are in part Birch Creek schist and in part of Paleozoic age, and that term has been discarded.

Birch Creek limestone bed. (In Ochelata formation.)

Pennsylvanian: Central northern Oklahoma (Osage County).

C. F. Bowen, 1918 (U. S. G. S. Bull. 686D, pp. 17–19). *Birch Creek ls.*—Hard, light-gray, crystalline, somewhat dolomitic ls., sparingly fossiliferous. Thickness

4± ft. Laterally it grades into limy ss. Is overlain and underlain by thick sss. Lies 70–115 ft. below Bigheart ss. in T. 24 N., R. 10 E. Named for exposure in bluffs on N. side of Birch Creek, near E. edge of SE. ¼ sec. 25, T. 24 N., R. 10 E.

O. B. Hopkins and S. Powers, 1919 (U. S. G. S. Bull. 686S, p. 239, pl. 38). Above the 55 to 70 ft. of sh. which overlies Clem Creek ss. is another series of sss. which is substantially = Okesa and Torpedo sss. of twps to N. At base, or at some places 12 to 15 ft. above base, of this series of sss. is a sandy ls., 0 to 11 ft. thick, named *Birch Creek ls.* by Bowen. In NE. corner of T. 24 N., R. 11 E. this ls. is replaced by ss.

Is a bed at or near base of Torpedo ss. memb. of Ochelata fm.

Birch Lake sandstone.

Upper Cretaceous: Alberta and Saskatchewan.

S. E. Slipper, 1918 (*Canada Geol. Surv. Summ. Rept. 1917, pt. C, p. 8*).

Birch Lake series.

Pre-Cambrian: Ontario.

E. M. J. Burwash, 1922 (Jour. Geol., vol. 30, p. 396).

Bird Creek limestone member (of Buck Creek formation).

Pennsylvanian: Central northern Oklahoma (Osage County).

C. F. Bowen, 1918 (U. S. G. S. Bull. 686L, p. 137, pl. XXI). *Bird Creek ls.*—Lowest ls. exposed over any considerable part of area (Tps 24, 25, and 26 N., Rs. 6 and 7 E.; Tps 25 and 26 N., R. 5 E.; T. 26 N., R. 4 E.). Is a dense, fine-grained noncrystalline rock 4± ft. thick. On fresh surface is commonly lead-gray to black and weathers to a dirty buff or yellow. When struck with hammer it breaks along bedding planes with comparatively smooth surfaces. Few fossils. Is hard and fairly resistant to erosion but does not produce a marked topog. effect. Is older than Stonebreaker ls. Named by K. C. Heald (rept in preparation) from exposures in T. 27 N., R. 8 E.

K. C. Heald, 1919 (U. S. G. S. Bull. 686Q, pp. 214, 216). *Bird Creek ls.*—In most places where seen there is but a single bed, 2± ft. thick, but at a few localities there are two beds separated by 6± ft. of sh. The rock is hard and very brittle. Both weathered and fresh surfaces are dark bluish gray, so dark that many samples might be called black. Is characterized by a distinct brachiopod fauna. Lies 50± ft. below *Cryptozoon*-bearing ls., about 70 ft. above Turkey Run ls., and a little more than 100 ft. above "red lime" at top of Pawhuska ls. Named for exposure on valley sides of Bird Creek and tributaries.

Birdhead sandstone member (of Thermopolis shale).

Upper Cretaceous: Central southern Montana (Bighorn and Yellowstone Counties).

W. T. Thom, Jr., G. M. Hall, C. H. Wegemann, and G. F. Moulton, 1935 (U. S. G. S. Bull. 856). *Birdhead ss. memb.*—Rim-forming ss. 0 to 15 ft. thick, lying about 130 ft. above base of Thermopolis sh. in Bighorn Co. and Crow Ind. Res., Mont. Birdhead Coulee cuts across the ss. in T. 3 S., R. 27 E., Yellowstone Co.

Bird Mountain grit.

Upper Ordovician (?): Southwestern Vermont (Rutland County).

T. N. Dale, 1893 (U. S. G. S. 13th Ann. Rept., pt. 2, pp. 337–340). There is little doubt that *Bird Mtn grit and cgl.* occupies same strat. relations to schists of Taconic Range E. of it as the upper Sil. Rensselaer grit [Lower Camb. ? now] does to those of same range in Mass. and N. Y. [Bird Mtn is in Castleton quad., W. of West Rutland.]

T. N. Dale, 1900 (U. S. G. S. 20th Ann. Rept., pt. 2, pp. 15–23). *Bird Mtn grit.*—Grit and cgl. interbedded with muscovite (sericite) schist; pebbles of pre-Camb. granite and gneiss and either Camb. or Ord. crystalline ls., and calc. and micaceous qtzite. Is petrographically different from Rensselaer grit. Probably belongs in upper part of Ord. and later than Calciferous. Overlies Berkshire schist [which is now classified as Upper and Middle (Trenton) Ord.]

†Birdseye limestone.

A descriptive term applied in a titular sense in early N. Y. repts to Lowville ls. It is said to have first been used by Amos Eaton in 1824, the name being suggested by the "eyes" or light-colored specks due in part to a characteristic fossil supposed to be a form of coral and now known as *Tetradium cellulosum*. As defined by L. Vanuxem in 1838 (N. Y. Geol. Surv. 2d Rept., pp. 255, 257, 283) it included all rocks btw. Trenton ls. and "Calciferous sandrock" [Beekmantown], and thus included Black River and Chazy lss. In 1842 (Geol. N. Y., pt. 3) Vanuxem defined it as lower part of Black River ls., as overlain by grey ls. forming upper part of the Black River, and as underlain by Chazy ls. In 1899 Clarke and Schuchert replaced the descriptive term "Birdseye" with *Lowville ls.*, by which name it is known today.

birdseye porphyry.

A descriptive term that has been applied to a local mass of porphyry of pre-Camb. age in Socorro Co., N. Mex., and also to a local mass of porphyry of Tert. age in Stockton and Fairfield region, Utah.

Birdsong shale.

Lower Devonian (Helderbergian): Western Tennessee (Tennessee River Valley region).

C. O. Dunbar, 1918 (Am. Jour. Sci., 4th, vol. 46, p. 741). *Birdsong sh.*—Bluish shaly ls. and sh., 35 to 65 ft. thick. Uncon. underlies Decaturville chert and uncon. overlies Olive Hill fm. Typically developed along valley of Birdsong Creek, Benton Co., where it is about 45 ft. thick. Very fossiliferous. Correlated with New Scotland. Included in Helderbergian or Linden group.

Bird Spring formation.

Pennsylvanian: Southeastern Nevada (Goodsprings region).

D. F. Hewett, 1931 (U. S. G. S. P. P. 162, pp. 9, 21, etc.). *Bird Spring fm.*—Gray ls. and dol., in beds ranging in thickness from thinnest laminae to 60 ft., separated by sh. and ss.; from Goodsprings northward a conglomeratic ss. at base; many beds in upper 1,000 ft. were doubtless originally dol., but it appears probable the remaining lower part was made up wholly of ls., sh., and ss. Thickness 2,500± ft. Rests uncon. on Monte Cristo ls. (Miss.) and underlies Supai fm. (Perm.). Large Penn. fauna (listed). Underlies a large area in Bird Spring Range. [Mr. Hewett sent an advance copy of his Goodsprings section, and the names he proposed to apply to the fms., to W. S. Glock, who in 1929 (Am. Jour. Sci., 5th, vol. 17, pp. 326–339) described the *Bird Springs fm.* in east-central part of Spring Mtn Range, Goodsprings quad.]

C. R. Longwell and C. O. Dunbar, 1936 (Geol. Soc. Am. Proc. 1935, pp. 89, 375). Fusulinas collected in Las Vegas quad. indicate upper 2,900 ft. of *Bird Spring fm.* correlates with Wolfcamp and Leonard fms. of west Tex., and the Bird Spring is therefore considered to be Perm. The upper 1,500 ft. correlates with Leonard and the 1,400 ft. next below with the Wolfcamp.

†Birdsville formation (also †Birdsville group).

Mississippian: Western Kentucky and southeastern Illinois.

E. O. Ulrich, 1904 (Mo. Bur. Geol. and Mines vol. 2, 2d ser., p. 109). *Birdsville fm.*—Shales, sss., and thin lss. composing upper fm. of Chester group. Overlies Tribune ls. and underlies [uncon.] Mansfield ss. (Penn.).

E. O. Ulrich, 1916 (Geol. Soc. Am. Bull., vol. 27, p. 157). *Upper Chester or Birdsville group.*—Includes all of Chester series of western Ky. and Ill. above base of typical Cypress ss., which is uncon. on older rocks.

Now divided into several named fms. and discarded. (See Ill. chart.) Named for Birdsville, Livingston Co., Ky.

Birmingham shale member (of Conemaugh formation).

Pennsylvanian: Western Pennsylvania and northern West Virginia.

J. J. Stevenson, 1876 (2d Pa. Geol. Surv. Rept. K, p. 79). *Birmingham sh.*—A dark thinly laminated sh. nearly 50 ft. thick, which occurs below Morgantown ss. at Pittsburgh. Joints pass through the mass. Outcrops at Birmingham station [just W. of Pittsburgh].

P. E. Raymond, 1909 (Sci., n. s., vol. 29, pp. 940–941). Base of *Birmingham sh.*, of Conemaugh series of western Pa., lies 25 ft. above top of Ames ls.

E. W. Shaw and M. J. Munn, 1911 (U. S. G. S. Burgettstown-Carnegie folio, No. 177, p. 4). *Birmingham sh. memb.* of Conemaugh fm. overlies Berlin coal and extends up to Elk Lick coal (or Elk Lick clay where present). Consists of sh., sandy sh., and some ss. Thickness 50 to 60 ft.

†Birmingham breccia.

Lower Ordovician: Northern central Alabama (Birmingham quadrangle).

E. A. Smith, 1890 (Ala. Geol. Surv. Rept. Cahaba coal field, p. 152). *Birmingham breccia.*—Breccia made up of angular fragments, chiefly from Knox dol., and is of course younger than Knox dol. Occurs in greatest volume in Salem Hills, but also at other places [mentioned], including Birmingham. Has been called Birmingham breccia by Mr. Russell of U. S. Geol. Survey [unpublished] and Salem breccia by State Survey. This breccia belongs perhaps to Trenton or Pelham ls.

Preoccupied by Birmingham sh. memb. of Conemaugh fm., and replaced by Attalla chert cgl. memb. of Chickamauga ls.

Named for exposures at Birmingham.

Birmingham red bed. (In Conemaugh formation.)

Pennsylvanian: Western Maryland and Pennsylvania.

C. K. Swartz 1922 (Md. Geol. Surv. vol. 11, p. 63, pl. 6), applied *Birmingham red bed* to red beds in western Md. and Pa. that occur at strat. horizon of Birmingham sh. and Grafton ss.

Birmingham moraine.

Pleistocene (Wisconsin stage): Southeastern Michigan. Shown on moraine map (fig. 7) in U.S.G.S. Detroit folio (No. 205), p. 9, also on moraine map (pl. 32) in U.S.G.S. Mon. 53. Named for Birmingham, Oakland Co.

Bisbee group.

Lower Cretaceous (Comanche series): Southeastern Arizona.

E. T. Dumble, 1902 (Am. Inst. Min. Engrs. Trans., vol. 31, pp. 696–715). *Bisbee beds.*—Consist of (descending): (1) Interbedded sands and clays; (2) interbedded lss., clays, and sands, with oysters at base and *Caprotina* and other fossils at top; (3) lss. and clays containing *Trigonia, Exogyra,* and other fossils; and (4) interbedded sands and clays with cgl. at base. Of Cret. age. Exposed at Bisbee, Ariz. (whence the name) and in Rucker Canyon.

F. L. Ransome, 1904 (U.S.G.S.P.P. 21, p. 56). *Bisbee group.*—Same unit as Dumble's *Bisbee beds*, but in Bisbee quad. is here divided into 4 fms. (descending), Cintura fm., Mural ls., Morita fm., and Glance cgl.

Bisher formation.

Silurian (Niagaran): Southwestern Ohio (Highland and Adams Counties) and northern Kentucky (Lewis County).

A. F. Foerste, 1917 (Ohio Jour. Sci., vol. 17, pp. 189, 190). *Bisher memb.*—Lower memb. of West Union fm. in Highland and Adams Counties. [West Union as here used extended up to base of Cedarville dol.] Typically exposed NE. of Bisher Dam [about 1 mi. S. of Hillsboro]. Contains a very characteristic fossil horizon about 9 ft. above base, and several other layers, less abundantly fossiliferous, occur btw. 12 and 20 ft. farther up. Underlies Lilley memb. of West Union.

A. F. Foerste, 1919 (Ohio Jour. Sci., vol. 19, pp. 367–375). *Bisher memb. of West Union fm.*, 45 ft. thick, corresponds to Lower or West Union Cliff of Orton. Is faunally distinct from overlying Lilley memb., and is of upper Clinton age.

A. F. Foerste, 1923 (Denison Univ., Sci. Lab. Jour., vol. 20, pp. 41–43). *Bisher fm.* corresponds approx. to West Union or Lower Cliff of Prof. Orton, and this name would have been retained if Prof. Orton ever had described any section from West Union area, or had designated at Hillsboro the same boundaries btw. the West Union and Springfield beds as those adopted later btw. the Bisher and Lilley fms. The Bisher fauna can be traced from Hillsboro southward throughout Highland and Adams Counties, Ohio, and Lewis Co., Ky., as far S. as N. part of Fleming Co., Ky. Has not been identified anywhere N. of Hillsboro, Ohio, altho the strata immediately beneath Springfield ls. along creek ½ mi. W. of Port William, NE. of Wilmington, Ohio, appear to contain a somewhat similar fauna. But no trace of overlying Lilley fauna is to be found so far N.

A. F. Foerste, 1935 (Denison Univ. Bull., Sci. Lab. Jour., vol. 30, p. 128). In Lewis Co., Ky., *Bisher fm.* rests on Ribolt sh. and at most places underlies Ohio black sh., but on Ohio River at Vanceburg it is overlain by Greenfield dol., of Cayugan age. [Gives further details on pp. 140–141.]

Bishop conglomerate.

Tertiary (Miocene?): Northeastern Utah, northwestern Colorado, and southwestern Wyoming.

J. W. Powell, 1876 (Geology of eastern portion of Uinta Mtns, pp. 40, 44, 62, 169). *Bishop Mtn cgl.*—Composed of bowlders and pebbles of ss., qtzite, and crystalline schists, but sss. and quasi qtzites greatly prevail. Found only in isolated patches as remnants adventitiously preserved from general erosion to which this widely spread fm. has been subjected. Thickness 300 ft. [on p. 40, but on p. 170 he says 1,000 ft. at head of Sheep Creek]. Can be seen on summit of Bishop Mtn, where it lies uncon. on eroded beds of Bitter Creek group. A fine exposure can also be seen on summit of Quien Hornet Mtn, where it rests on Lower Green River beds. On N. side of Sage Creek it uncon. overlies beds of Lower Green River age. [In columnar section on p. 40 he shows this cgl. uncon. on Brown's Park group, but in text he does not say that it anywhere rests on Brown's Park, although on p. 62 he says: The Bishop Mtn cgl. is found at different places to lie uncon. upon every group of the table which is represented in Uinta Mtns and adjacent country.]

J. D. Sears, 1924 (Geol. Soc. Am. Bull., vol. 35, pp. 279–304) and 1926 (U. S. G. S. Bull. 781B, pp. 16, 22). Writer believes Bishop cgl. is = basal memb. of Browns Park fm. of Uinta Mtn region.

W. H. Bradley, 1932 (Wash. Acad. Sci. Jour., vol. 22, No. 11, p. 318) and 1936 (U. S. G. S. P. P. 185–I), demonstrated that Bishop cgl. is older than Browns Park fm., and J. D. Sears accepted Bradley's evidence.

Some workers believe Browns Park fm. is Plio. or includes beds of Plio. age, but U. S. Geol. Survey tentatively classifies it as late Mio. or early Plio.

Caps Bishop Mtn, Sweetwater Co., SW. Wyo., now known as Pine Mtn.

Bishop sandstone.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, pp. 36, 301). *Bishop ss.*—Sss., 500 ft. thick, underlying Junction lss., overlying Duchesne lss., and composing a middle fm. of Flaming Gorge series in Utah. [Assigned to late Jurassic, but Keyes also states that it may correspond to Unkpapa ss. (Upper Jurassic) and Lakota ss. (Lower Cret.) of Black Hills section. Derivation of name not stated.]

According to A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1936 (U. S. G. S. P. P. 183, chart opp. p. 40), the Bishop ss. and Duchesne ls. of above rept. are Entrada ss. and Carmel fm., both Upper Jurassic.

Bishop Brook limestone.

Devonian (Lower): Central New York (Onondaga County).

B. Smith, 1929 (N. Y. State Mus. Bull. 281, pp. 27, 32). *Bishop Brook ls.*—Top unit of Manlius group. [See 1929 entry under *Manlius ls.*] Is gray in color; lower portions are in places a mass of crinoid fragments; upper layers appear to be evenly bedded, but cross bedding has been noted in basal portions. Fauna appears to be Helderbergian, but is so far unstudied. Lies uncon. on Pools Brook ls., and at Manlius is uncon. overlain by basal quartz sands of the Onondaga (reworked Oriskany). In Onondaga Co. this fm. is known only from hillside E. of Manlius village. Named for Bishop Brook, NE. of Manlius.

G. H. Chadwick, 1930 (Geol. Soc. Am. Bull., vol. 41, pp. 80–82). *Bishop Brook ls.*, as I saw it in field with A. E. Brainerd, appears to be essentially topmost Becraft or Alsen, high in Helderbergian, thus emphasizing overlap nature of uncon. seen in eastern N. Y. btw. Manlius and Coeymans lss., first pointed out by writer.

†Bishop Mountain conglomerate.

Tertiary (Miocene?): Northeastern Utah, northwestern Colorado, and southwestern Wyoming.

See *Bishop cgl.*

†Bison beds.

A paleontologic term applied by O. C. Marsh to the beds in Denver Basin, Colo., which were later named *Denver fm.*, the paleontologic name being derived from presence in the beds of *Bison alticornis*, a horned dinosaur.

Bison banded member.

Permian: Central northern Oklahoma.

F. L. Aurin, H. G. Officer, and C. N. Gould, 1926 (A. A. P. G. Bull., vol. 10, pp. 786–799). *Bison banded memb.*—The upper 150 ft. of Hennessey sh., consisting largely of rusty red, blocky, non-fissile clay shales, characterized by considerable number of white or greenish bands or streaks of sh., here sandy, there calc. These bands or streaks are thicker and more numerous than in underlying Fairmont memb., being in some cases 3 to 4 ft. thick. Base is placed at lowest heavy white band of Hennessey sh. Named for fact it is exposed on all sides of Bison, Garfield Co.

Bissett conglomerate.

Triassic (?): Western Texas (Glass Mountains).

P. B. King, 1927 (Am. Jour. Sci., 5th, vol. 14, pp. 212–221). *Bissett fm.*—Chiefly calc. cgls. derived from underlying beds. In upper part red shales alternate with cgl. and in addition a few layers of ls. and dol. appear. Locally red shales appear beneath the main cgl. Thickness 0 to 500 [720] ft. Underlies Comanche series with angular uncon. and overlaps undoubted marine Permian fms. (Tessey, Gilliam, and upper part of Vidrio). On Bissett Mtn it rests on upper massive memb. of Vidrio fm. Named for exposures on NW. and NE. flanks of Bissett Mtn, SW. part of Glass Mtns. Absent in NE. part of Glass Mtns. No fossils found. May be late Perm., Triassic, Jurassic, or early Cret.; most probably Perm. or Triassic.

P. B. King, 1931 (Univ. Tex. Bull. 3038). *Bissett fm.* is probably upper Perm., but may be Triassic.

R. Roth, 1932 (Jour. Geol., vol. 40, No. 8, p. 701), from field study believes Bissett fm. at type loc. of Bissett Mtn is of Comanche age. Is uncon. on Tessey, Gilliam, and Vidrio fms.

P. B. King, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 738–739), changed name to *Bissett cgl.* (the fm. consisting chiefly of cgl.) and age to Perm. (?).

W. B. Lang, 1935 (A. A. P. G. Bull., vol. 19, No. 2, p. 270). It is believed Bissett cgl. represents an accumulation of lower Triassic sediments of possible Moenkopi time equivalence and therefore considerably older than the terrestrial Dockum and Santa Rosa deposits farther N.

P. B. King, 1935 (A. A. P. G. Bull., vol. 19, No. 10, pp. 1545–1546). Present evidence favors early Triassic, rather than Perm., as age of Bissett cgl. Writer is now inclined to support Lang's suggestion that the Bissett is of pre-Dockum Triassic age.

At present *Triassic (?)* is age classification of U. S. Geol Survey.

†Bitter Creek group.

Eocene: Southwestern Wyoming (Sweetwater County), northeastern Utah, and northwestern Colorado.

E. D. Cope, 1872 (Phila. Acad. Nat. Sci. Proc., vol. 24, p. 279; and Proc. Am. Phil. Soc. 1872, p. 481), in referring to the *coal series of Bitter Creek*, casually used *Bitter Creek coal strata*, *Bitter Creek series*, and *Bitter Creek series of coal*.

F. B. Meek, 1873 (U. S. Geol. and Geog. Surv. Terr. 6th Ann. Rept., pp. 455–462). *Bitter Creek series.*—A vast succession of rather soft, light-yellowish, lead gray and whitish sss. with seams and beds of various colored clays, sh., and good coal. Thickness reaches 4,000+feet. Fresh water, brackish water, and salt water fossils. Either Cret. or Tert., probably latter. Exposed along Bitter Creek (a small tributary of Green River in Wyo.) from Black Butte NW. to Salt Wells Station on U. P. R. R. and at some other points W. of Salt Wells. Conformably underlies Washakie group [Bridger fm.] and rests, apparently conformably, on thin layers of grayish and drab slabby sss. and shales, probably of Cret. age.

J. W. Powell, 1876 (Geology of eastern portion of Uinta Mtns, pp. 40, 45, 64, 162). *Bitter Creek group.*—Badland sss., often with much gyp.; indurated sss., ferruginous; shell marls; many beds of carbonaceous shales and lignitic coal. To S. the group consists of indurated sss. and lss. Thickness 3,000 ft. Underlies Green River group and rests on Point of Rocks group with erosion uncon. The beds called *Washiki group* are upper part of Bitter Creek series. [Powell mapped these beds in SW. Wyo., NE. Utah, and NW. Colo.]

A. R. Schultz, 1920 (U. S. G. S. Bull. 702, table opp. p. 24), showed Bitter Creek group of Powell in SW. Wyo., as including several Eo. and Upper Cret. fms., in descending order, Wasatch group, Evanston fm., so-called Laramie fm., Lewis sh., and upper part of Mesaverde fm. This reconnaissance term has lost its usefulness and is no longer employed.

†Bitter Creek series.

See under †*Bitter Creek group.*

Bitter Creek formation.

Jurassic or Triassic: Northwestern British Columbia (Portland Canal region) and southeastern Alaska.

R. G. McConnell, 1911 (Canada Geol. Surv. Summ. Rept. 1910, p. 63), 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 57), 1913 (Canada Geol. Surv. Mem. 32, p. 12).

J. B. Mertie, Jr., 1921 (U. S. G. S. Bull. 714, p. 134), assigned these rocks to Paleozoic or Mesozoic; G. Hanson, 1929 (Canada Geol. Surv. Mem. 159, p. 6), assigned them to Jurassic or Triassic.

Bitter Creek peridotite.

Cretaceous (?): Southern British Columbia.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, map 9, 118° to 118° 30'). *Bitter Creek peridotite, Cret. (?).* Occurs near 49th par.

Bitter Rock sand.

A term applied in western Pa. to a subsurface sand in Pocono fm., which some consider lies lower than Murrysville sand, and higher than Hundred-foot sand; others that it lies higher than the Murrysville and lower than Papoose sand, and others that it is=part of Squaw sand.

Bitterroot period.

Pre-Cambrian: Montana.

C. [R.] Keyes, 1926 (Pan-Am. Geol., vol. 46, p. 203). *Cherry Creek* [of Peale] is preoccupied several times over. The time represented may be termed *Bitterroot period*, after the most conspicuous geographic features on top of the continent. *Madisonic period* would be more appropriate, and perhaps more euphonious, and with a periodic ending would not likely be confused with the so-called Madison ls. of Carbonic age in same region, which also is repeatedly preoccupied for distant terranes. Even *Cherrio* might be permissible as a periodic term.

Biwabik iron-formation.

Pre-Cambrian (middle Huronian): Northeastern Minnesota (Mesabi district).

C. R. Van Hise and C. K. Leith, 1901 (U. S. G. S. 21st Ann. Rept., pt. 3, pp. 353, 358–370). *Biwabik fm.*—Fine-grained and largely non-clastic rocks (cherts, slates, silicate and carbonate rocks, more or less ferruginous), with a film of fine cgl. at base. Thickness 500 to 1,000 ft. Conformably underlies Virginia sl. and conformably overlies Pokegama fm.; all included in upper Huronian. Is called

Biwabik fm. because biwabik is Chippewa word for a piece or fragment of iron, and Biwabik mine is one of earliest and largest mines located on the fm.

C. K. Leith, 1903 (U. S. G. S. Mon. 43), gave thickness of Biwabik fm. as 200 to 2,000 ft., and stated the Virginia sl. grades both vertically and laterally into Biwabik fm.

C. R. Van Hise and C. K. Leith, 1909 (U. S. G. S. Bull. 360) and 1911 (U. S. G. S. Mon. 52) assigned this fm. to upper Huronian.

C. K. Leith, 1933 (16th Int. Geol. Cong. Guidebook 27, p. 9), assigned this fm. to middle Huronian, as did C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184).

Bixby zone.

A subsurface petroliferous zone, about 2,400 ft. thick, forming lower part of Fernando group in Long Beach field of Los Angeles Basin, Calif. Named for fact that the Shell Bixby No. 1 well has produced from this sand.

Bixler sand.

A subsurface sand, 5 to 50 ft. thick, in Ponca City field, Kay Co., Okla. Correlated with upper part of Cherokee sh. Is a higher sand than Markham sand and lies a short distance below Oswego lime.

Blach Ranch limestone member (of Thrifty formation).

Pennsylvanian: Central northern Texas (Brazos River region).

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31). *Blach Ranch ls.,* 3 to 5 ft. thick, lies 20 to 40 ft. below top of Thrifty fm. and 17 to 35 ft. below Breckenridge ls. memb. of Thrifty.

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, pp. 154–158). *Blach Ranch ls. memb. of Thrifty fm.*—Massive light-gray ls.; weathers buff or brown and in large slabs or rounded boulders. Rather unfossiliferous. Thickness 3 to 8 ft. Lies 30± ft. above Ivan ls. memb. of Thrifty and 25 to 45 ft. below Breckenridge ls., the top memb. of the Thrifty. Named for exposures in vicinity of Blach Bros. ranch, E. of Breckenridge, Stephens Co. Is thought to be = Chaffin ls. of Drake in Colorado River section.

†Black shale.

A descriptive term applied in early repts to a widespread deposit of black sh. commonly assigned to Dev. and supposed to be same fm. throughout several States. It is now known by following names in different States:

New York. For many years the upper black sh. has been called Genesee sh. (Upper Dev.) and the lower black sh. has been called Marcellus sh. (Middle Dev.).

Michigan. Antrim sh., Upper Dev.

Ohio. Ohio sh., Upper Dev. (Genesee, Portage, and Chemung).

Indiana. New Albany sh. (Upper Dev.).

Kentucky. Ohio sh. (Upper Dev.) in eastern Ky. as far S. as Somerset, Pulaski Co.; Chattanooga sh. (Dev. or Carbf.) S. of Somerset; New Albany sh. (Upper Dev.) W. of Cincinnati arch adjacent to southern Ind.; Chattanooga sh. in western Ky.

Virginia. Now divided into Big Stone Gap sh. (Dev. and Carbf.), Portage sh. (Upper Dev.), and Genesee sh. (Upper Dev.) in SW. Va. (Wise and Scott Counties).

Tennessee, Georgia, Alabama, Illinois, Missouri: Chattanooga sh., Dev. or Carbf. (Formerly classified as Dev.)

Arkansas. Chattanooga sh. (Dev. where Genesee and Portage (?) fossils are found; elsewhere Dev. (?)).

Oklahoma. Chattanooga sh. (Dev. ?).

Black flint member. (In Pottsville formation.)

Pennsylvanian: Southeastern Ohio (Jackson and Vinton Counties).

H. Morningstar, 1922 (Ohio Geol. Surv., 4th ser., Bull. 25, p. 130). *Black flint memb.*—Consists of (1) 0 to 6'' of nodular ore, sparingly fossiliferous, underlain by (2) very fossiliferous black flint or ls. 1 ft. thick. Very local. Outcrop confined to Jackson Co. and SW. part of Vinton Co. Overlain by Brookville coal and underlain by Homewood sh. and ss.

†Black Ledge. (In Powell dolomite.)

Lower Ordovician (Beekmantown): Northern Arkansas (Yellville quadrangle).

E. T. McKnight, 1935 (U. S. G. S. Bull. 853). *†Black Ledge.*—A coarse-grained, massive dol., characterized by quartz-lined druses and in places greenish or gray chert segregations, persistent over Yellville quad. Thickness 7 to 10 ft. Lies 50 to 60 ft. above base of Powell dol. Is called "Black Ledge" because it generally weathers dark. Commonly carries ores. There are other ledges of same type in the Powell but not so thick.

†Black Bear limestone.

Miners' local name for an ore-bearing ls., 80± ft. thick, in middle part of Oquirrh fm. (Penn.) of northern Utah. Exposed in Black Bear claim, Stockton dist. Lies from 120 to 250 ft. above Ben Harrison ls. (See U. S. G. S. P. P. 173, 1932.)

†Black Bluff group.
†Black Bluff clay.
†Black Bluff series.
(In Midway group.)

Eocene (lower): Southern Alabama.

E. A. Smith and L. C. Johnson, 1887 (U. S. G. S. Bull. 43, pp. 61–62). *Black Bluff series.*—Consists of (descending): (1) 20 to 25 ft. of yellowish clay, which makes the basis of the Flatwoods; (2) 40 ft. of black slaty clay carrying marine fossils; and (3) 8 to 10 ft. of brownish sh. or clay. Overlies Midway or Pine Barren beds and underlies Naheola and Matthew's Landing series.

Replaced (E. A. Smith, Sketch of geol. of Ala., Roberts & Son, Birmingham, Ala., 1892) by *Sucarnoochee clay,* which has become established name of the fm. in Ala. Is same as Porters Creek clay of Miss.

Named for exposures at Black Bluff, on Sucarnoochee Creek, at its junction with Tombigbee River, in Sumter Co.

†Black Butte quartzite.

Upper Cretaceous: Southwestern Wyoming (Sweetwater County).

J. W. Powell, 1876 (Geology of eastern portion of Uinta Mtns. p. 160). *Black Butte qtzite.*—A dark, indurated, and exceedingly tough qtzite that caps Black Butte, SW. of Black Butte Station, on Union Pacific R. R. [Sweetwater Co.]. In distance this qtzite has appearance of a bed of extravasated material. Thickness 200+ ft.

A. R. Schultz, 1920 (U. S. G. S. Bull. 702, pl. 1), mapped the rocks of Black Butte as middle part of Mesaverde fm., older than Almond coal group and younger than Rock Springs coal group. The rocks occupying this interval (which have a thickness of 800 to 1,000 ft.) have since been named *Ericson ss.* According to Schultz (unpublished memo.) the qtzite that caps Black Butte belongs to a larger mass, which grades laterally into ss., and the qtzite has no strat. value. The name has therefore been discarded.

Black Buttes coal group.

Name that has been locally applied to Lance fm. and underlying beds of Fox Hills age in Rock Springs uplift, Sweetwater Co., SW. Wyo. (See U. S. G. S. Bull. 702, 1920.)

Black Canyon schist.

Pre-Cambrian: Central western Colorado (Gunnison River region).

J. F. Hunter, 1925 (U. S. G. S. Bull. 777). *Black Canyon schist.*—Schists and gneisses of metamorphic complex of Gunnison River region, which show great diversity in composition and texture, including all gradations from biotite schist, quartz-muscovite schist, and granite gneiss to chlorite and amphibole schists and even to amphibolite. The commonest and fundamental rock is biotite schist. The rocks range from black to gray; weathering may give them brownish or yellowish tones, and abundant microcline may add a slight pinkish tint. Most of rocks are well laminated. Occurs throughout area, with many interruptions, from Cochetopa Creek down the Gunnison nearly to mouth of Smiths Fork. Save for the many bodies of igneous rocks that have invaded it and the River Portal schist, which might be regarded as a part of it and which extends from a point E. of Cimarron to N. end of Vernal Mesa, the pre-Camb. area adjacent to Gunnison River is composed almost entirely of *Black Canyon schist.* Best and most accessible exposures are in walls of Black Canyon from Sapinero to the Curecanti granite and up Lake Fork Canyon to granite mass 1 mi. above Vanguard. May be older than River Portal mica schist.

On 1935 Colo. geol. map this fm. was assigned to Gunnison River series, which includes all of oldest exposed rocks in Colo.

Black Canyon formation.

Jurassic: British Columbia.

C. H. Crickmay, 1930 (Calif. Univ., Dept. Geol. Sci. Bull., vol. 19, No. 2, p. 33).

Black Cap phase.

See 1928 entry under *Conway granite.*

Black Crater formation.

Late Tertiary: Central northern Oregon (Cascade Mountains).

E. T. Hodge, 1927 (Geol. Soc. Am. Bull., vol. 38, p. 163). The *Black Crater fm.* underlies glacial drift, covers most of the eastern surface with basalt flows or high volcanoes, and passes under the Deschutes sand, which is probably post-Pleist. [Appears to be next younger than his Mount Jefferson fm. (Plio.).]

E. T. Hodge, 1928 (Pan-Am. Geol., vol. 49, pp. 341–356). *Black Crater fm.*—The basalts of Black Crater cover a large area on E. slope of Cascade Mtns. Are of pre-Glacial, pre-Pleist., origin. Overlie Mount Jefferson fm.

Black Creek formation.

Upper Cretaceous: Eastern South Carolina and western North Carolina.

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2) and 1907 (Summary of mineral resources of S. C., pp. 12, 13, 14). *Black Creek sh.*—Soft shales and black clay, exposed along Black Creek in Darlington and Florence Counties, and along Pee Dee Valley interruptedly from near Society Hill to Jeffries Creek, where it passes under Burches Ferry marl. Its probable equivalent extends easterly through Marion Co., where it is exposed in bed of Little Pee Dee tributaries. Overlies Middendorf clays (Lower Cret.).

As defined above the Black Creek excluded the †Middendorf deposits (present in Ga. and S. C.), which were then supposed to be of Lower Cret. age. Further studies of †Middendorf deposits, however, resulted in proving the Upper Cret. age of their flora, and led to belief that they were = beds composing lower part of Black Creek fm. in some localities. In 1912 (U.S.G.S.P.P. 71, p. 659) L. W. Stephenson redefined Black Creek fm. so as to include, at base, the †*Middendorf arkose memb.* Still later work, however, led to exclusion (C. W. Cooke, U.S.G.S.P.P. 140, pp. 137–139, 1926) of †Middendorf deposits from overlying Black Creek deposits (from which they are now known to be separated by a distinct uncon. and with which they are in sharp lithologic contrast) and to their being treated as a distinct fm. (uncon. overlain by Black Creek fm. and uncon. underlain by crystalline rocks), the Black Creek fm. being restored to its original definition. The Black Creek is overlain (uncon. in S. C. but conformably in N. C., according to L. W. Stephenson) by Peedee fm., and is of Ripley and Eutaw age. Thickness 0 to 400 ft. The name "Middendorf fm." has been abandoned, the beds having proved to be same as Tuscaloosa fm., the older name. (See C. W. Cooke, U. S. G. S. Bull 867, 1936.)

Named for exposures along Black Creek in Darlington and Florence Counties, S. C. C. W. Cooke states (U.S.G.S. Bull. 867, 1936): Although no locality was specified by Sloan as the type, the outcrops of the fm. on Black Creek near the crossing of Cashua Ferry road E. of Darlington may be regarded as typical.

Black Creek coal group.

A group of coal beds in Pottsville fm. (Penn.) of Warrior coal field, north-central Ala., lying 600 to 800 ft. above Boyles ss. memb., and including Black Creek, Jefferson, and Lick Creek coals, also Bremen ss. memb.

Black Diamond coal group. (In Mesaverde group.)

Name locally applied to the group of coal-bearing strata in Iles fm. of NW. Colo., lying 200 to 400 ft. below Trout Creek ss. memb. of the Iles. The Black Diamond mine, in Meeker quad., works one of the coals.

†Black Earth dolomite member (of St. Lawrence formation).

Upper Cambrian: Southern Wisconsin and northern Illinois.

E. O. Ulrich, 1916 (Geol. Soc. Am. Bull., vol. 27, pp. 477–478). We are indebted to efforts of Dr. Samuel Weidman and Mr. F. T. Thwaites, of Univ. of Wis., for discovery of a dolomitic ledge in St. Lawrence fm. that in both its lithologic character and faunal contents closely resembles true Mendota dol. This ledge is developed to W. of Madison in hills bordering valley of Black Earth Creek, btw. Black Earth and Mazomanie, Wis. It should be mentioned, further, that the bed lies in middle of the St. Lawrence, beneath *Dikelocephalus minnesotensis* zone, and that the St. Lawrence is second fm. beneath top of Camb. as now defined in Upper Mississippi Valley. The Jordan ss. lies btw. the St. Lawrence and the overlapping and consequently varying base of the Ozarkian. Fauna consists of 13 species, 10 of which are strikingly like species found in nearly every exposure of fossiliferous part of true Mendota, but they occur associated with 3 fossils which, so far as known, have no representatives in true Mendota fauna, and which are for present the real guide fossils from Black Earth dol. zone.

F. T. Thwaites, 1923 (Jour. Geol., vol. 31, No. 7, p. 547). Trempealeau fm. is divided by E. O. Ulrich [unpublished at this time] into four members: (1) Norwalk fine-grained dolomitic ss. at top, underlain by (2) Lodi yellow and purple sandy thin-bedded dol., locally called "shale," which in turn rests on (3) the *St. Lawrence* [restricted] or *Black Earth dol.*, a rock almost exactly like the Mendota and which seems to make up bulk of the [†Trempealeau] fm. S. of Wisconsin River, under cover, and which rests on (4) sandy dolomitic shales of local distribution.

J. M. Wanenmacher, W. H. Twenhofel, and G. O. Raasch, 1934 (Am. Jour. Sci., 5th, vol. 28, p. 23). All evidence indicates Black Earth, Mendota, and St. Lawrence [restricted] are different expressions of same dol. [which they treat as a memb. of their Trempealeau fm., in which they include Jordan ss.].

F. T. Thwaites, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 118). [See this citation under *Mendota dol.*]

Replaced by *Mendota dol. memb.*, the earlier name, and now considered a synonym.

Blackface Mountain shale.

Devonian: Alberta.

J. A. Allan, P. S. Warren, and R. L. Rutherford, 1932 (Roy. Soc. Canada Trans., 3d ser., vol. 26, sec. 4, p. 234).

Blackfoot formation.

Pre-Cambrian (Belt series): Central western Montana (Mission Range).

C. D. Walcott, 1906 (Geol. Soc. Am. Bull., vol. 17, pp. 5, 9, 11). *Blackfoot series.*—Middle subdivision of Algonkian in Camp Creek and Swan Range sections of Mission Range, Mont. In Camp Creek section consists of (descending): Calcareo-aren. beds, 155 ft.; shaly lss., 1,310 ft.; calcareo-aren. shales, 155 ft.; thin-bedded ls., 815 ft.; shaly and thin-bedded ls., 520 ft.; siliceous ls., 1,850 ft. Underlies Camp Creek series and overlies Ravalli series [Ravalli group].

Named for exposures in canyon of North Fork of Blackfoot River, Mont., where entire section is exposed. Is correlated with Wallace fm.

Blackfoot cycle.

Name applied by G. R. Mansfield (Jour. Geol., vol. 32, 1924, p. 485) to an erosion cycle in SE. Idaho, which he had also called *Gibson cycle*.

Blackfootian series.

Pre-Cambrian (Belt series): Alberta and Montana.

C. [R.] Keyes, 1925 (Pan-Am. Geol., vol. 44, pp. 217, 218), applied *Blackfootian series* to the rocks underlying Striped Peak fm. of NW. Mont., overlying St. Regis ss., and corresponding to Wallace fm. In 1926 (Pan-Am. Geol., vol. 46) he applied the name to Newland ls. and Chamberlain sh., which he excluded from Belt series.

Black Girl limestone.

See entry No. 1 under †*Pony Express beds*.

Black Hand formation.

Mississippian: Central Ohio.

L. E. Hicks, 1878 (Am. Jour. Sci., 3d, vol. 16, pp. 216, 217). *Black Hand cgl.*—Generally rather fine pudding stone; in places beds many ft. thick are merely coarse ss. with pebbly partings; chiefly of light yellow or buff color; in some places nearly white, or brick red; highly ferruginous, but less so than Coal Measures cgl.; also contains more earthy matter and less pure silica than latter cgl. Thickness 85 to 90 ft. Overlain by Licking shales [Logan fm.] and underlain by Raccoon [Cuyahoga] shales. All included in Waverly group.

See also under *Black Hand memb.*

Black Hand member.

Mississippian: Central and southern Ohio.

J. E. Hyde, 1915 (Jour. Geol., vol. 23, pp. 657, 667–682, 757–779). *Black Hand memb. of Cuyahoga fm.*—Massive coarse quartz sss. with occasional shaly beds; usually yellow or buff, sometimes reddish. Thickness 50 to 150 ft. Is a local development of Cuyahoga fm. [expanded definition] and not as important a strat. unit as any one of the three members of the Logan. Underlies Berne memb. In central Ohio overlies Raccoon memb. of Cuyahoga. In Hocking Valley overlies Fairfield memb. of Cuyahoga fm.

Appears to be basal part of Black Hand fm. of Prosser and other geologists.

According to Jesse E. Hyde (Jour. Geol., vol. 23, p. 659, 1915) and C. S. Prosser (Ohio Geol. Surv., 4th ser., Bull. 7, p. 17, 1905) there is difference of opinion regarding the rocks originally included in Logan ss. by E. B. Andrews, also regarding the correct definitions of Black Hand and Cuyahoga. In paper cited Hyde included part of the Black Hand in Logan fm. and the rest of it in Cuyahoga fm., and restricted the name *Black Hand* to a memb. of latter fm., as expanded by Hyde. This memb. was described as consisting of 50 to 150 ft. of coarse pebbly ss. with occasional beds of cgl. lying btw. Berne memb. above and Fairfield memb. below, or to beds older than cgl. 1 of Prosser. This classification was also followed by W. Stout, 1927 (Ohio Geol. Surv., 4th ser., Bull. 31, p. 47), and appears to be present definition of Ohio Geol. Survey. According to Hyde (1915) the Black Hand fm. of Prosser extended from top of Hyde's Allensville memb. to base of his Black Hand memb.

Named for exposures at Black Hand, Licking Co.

Blackhawk formation. (Of Mesaverde group.)

Upper Cretaceous: Central eastern Utah (Wasatch Plateau and Book Cliffs).

E. M. Spieker and J. B. Reeside, Jr., 1925 (Geol. Soc. Am. Bull., vol. 36, p. 443). *Blackhawk fm.*—A succession of ss., sh., and coal beds of kinds common in Mesaverde group. Thickness 750 to 900 ft. in Wasatch Plateau and 450 ft. in Book Cliffs. Base is normally drawn at base of lowest coal bed. Is middle fm. of Mesaverde group. Underlies (uncon.?) Price River fm. and conformably overlies Star Point ss. Named for prominent exposures near Blackhawk, a mining community on E. front of Wasatch Plateau.

Blackhawk breccia.

Pleistocene: Southern California (San Bernardino County).

A. O. Woodford and T. F. Harriss, 1928 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 17, pp. 267, 279–283). *Blackhawk breccia.*—Chiefly made up of ls. blocks, usually only a few inches or at most a few ft. in diam., but at mouths of Blackhawk and Miles Canyons more or less brecciated ls., hundreds of ft. across, are mapped as part of the fm., because they seem to be landslide blocks inextricably involved in the breccia. Basal part of fm. consists of alternating beds of ls. breccia and ss. Greater part of material is spread out over the desert at foot of the mtns. The fm. is of landslip origin. Thickness 100 to 600 ft. Includes *Heights fangl.* of Vaughan, 1922. Assigned to Pleist. Typically developed at mouth of Blackhawk Canyon.

Blackhawkian.

Name proposed by C. [R.] Keyes (Pan-Am. Geol., vol. 54, 1930, p. 377) for the till deposits which have been called *Iowan* but which "should not be called by that name."

Black Hill shale.

Lower Cretaceous (Comanche series): Central southern Kansas.

F. W. Cragin, 1885 (Washburn Coll. Lab. Nat. Hist., vol. 1, No. 3, p. 90). *Black Hill sh.*—Unique deposit of carbonaceous and rapidly decomposing sh., which affords an easily recognized horizon for reference in any studies that may be made of neighboring fms. Assigned to Benton.

F. W. Cragin, 1895 (Am. Geol., vol. 16, p. 379). *Black Hill sh.*—Black carbonaceous clay sh., 15 or 20 ft. thick, forming basal bed of Fullington shales. Overlain by Blue Cut shales (upper bed of Fullington shales) and underlain by Champion shell bed. Is also called *Wafer sh.* Assigned to Comanche Cret.

Named for Black Hill, Comanche Co.

Black Hill rhyolite.

Tertiary: Leadville region, Colorado.

W. Cross, 1886 (U. S. G. S. Mon. 12, p. 349). Almost wholly quartz and feldspar. Forms Black Hill, about 18 mi. SE. of Leadville.

Blackhorse shales.

Upper Cretaceous: Central northern South Dakota and southwestern North Dakota.

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 37, No. 1, pp. 63–64). *Blackhorse shales*, 500 ft. thick, underlie Ludlow lignites and overlie Fox [Fox Hills] sss. Are basal shales of Lance fm. in S. Dak. and N. Dak. Blackhorse Butte is conspicuous landmark in Schanasse [?] Co., S. Dak., and overlooks Grand River Valley and the basal shales of the Lance.

Blackjack basalt.

Miocene: Southeastern Oregon.

K. Bryan, 1929 (U. S. G. S. W. S. P. 597, p. 55), and B. C. Renick, 1930 (Jour. Geol., vol. 38, p. 504). *Blackjack basalt.*—Normal augite hypersthene labradorite basalt, interbedded in middle of Payette fm. Thickness 350 to 450 ft. Named for fact it caps Blackjack Butte, Malheur Co. [Named by B. C. Renick.]

Blackjack School sandstone member (of Atoka formation).

Pennsylvanian: Eastern Oklahoma (Muskogee and McIntosh Counties).

C. W. Wilson, Jr., 1935 (A. A. P. G. Bull., vol. 19, No. 4, pp. 503–520). *Blackjack School ss. memb. of Atoka fm.*—Thin to massive bedded ss., medium to fine grained, commonly greenish brown, weathering dirty yellowish brown, but sometimes white to light brown on fresh surfaces; grades downward into sandy sh. Fossils. Thickness 25 to 40 ft. Lies 150 to 220 ft. below top of Atoka fm. and 150 to 350 ft. above Webbers Falls ss. memb. Named for exposures at and around Blackjack School, sec. 9, T. 11 N., R. 19 E.

Blacklead limestone.

Paleozoic? (pre-Permian): Northern Idaho (Orofino region).

A. L. Anderson, 1930 (Idaho Bur. Mines and Geol. Pam. 34). *Blacklead ls.*—Massive, thick-bedded ls. greatly resembling the grayish thick-bedded Paleozoic lss. in Mont. and in Idaho SE. of Salmon River Mtns. Considerably metamorphosed by intrusives, so that no fossils are preserved, but bedding is everywhere distinct. Magnetite in seams and lenses is extensively developed through the ls. along bedding planes and fractures, the result of contact metamorphism. Thickness 400+ ft.; base not exposed. Lies far back in Clearwater Mtns, at head of Cayuse Creek, a tributary of N. Fork of Clearwater River. Forms an engulfed block or pendant 2± mi. long and ½ mi. wide near N. margin of Idaho batholith, in a high glaciated valley btw. Blacklead Peak and Rhodes Creek. Assigned to Paleozoic (?). [Derivation of name not stated, but almost certainly is Blacklead mining dist., Clearwater Co.]

Blackleaf sandy member (of Colorado shale).

Upper Cretaceous: Northwestern and central northern Montana.

E. Stebinger, 1918 (U. S. G. S. Bull. 691E, pp. 154, 158–164). *Blackleaf sandy memb. of Colorado sh.*—An alternation of dark shales and gray to greenish gray sss. in beds 20 to 75 ft. thick, composing lower 600 to 700 ft. of Colorado sh. in Birch Creek-Sun River area, Mont. Is a unit clearly distinguishable from remaining shaly part of Colorado sh. The dark shales throughout Blackleaf memb. are very similar to shales higher in the Colorado, and range from hard fissile sh. to soft, not well bedded, and more nearly clay sh.; colors black, greenish black to bluish gray, and even light gray in more calc. parts. All of this memb. is marine. The sss. are medium to coarse grained, in places ripple marked, and are rather evenly distributed throughout Blackleaf memb. Rests on Kootenai fm. [Fossils listed.]

Named for Blackleaf Creek, along which the beds are well developed.

Black Mesa basalt.

Tertiary: Panhandle of Oklahoma (Cimarron County).

A. C. Shead, 1923 (Univ. Okla. Bull., n. s., No. 271, pp. 108–113). *Black Mesa basalt.*—Olivine diabasic basalt. Called *"Malpais" basaltic lava* by C. N. Gould in U.S.G.S.W.S.P. 148, p. 82. The basaltic cap of Black Mesa, in extreme NW. part of Okla. Panhandle, is easternmost occurrence of Tert. lava flow which is so conspicuous and picturesque a landscape feature in what is known as Mesa de Maya or Raton Mesa region of NE. N. Mex., SE. Colo., and western Okla. Area covered by flow in Okla. is 1.5± sq. mi. Rothrock gives average thickness of flow in Cimarron Co., Okla., as varying from 50 ft. 2 mi. N. of Kenton, Okla., to 66 ft. at Nigger Spring.

R. L. Six, 1930 (Okla. Geol. Surv. Bull. 40WW), assigned this basalt to Plio.

Black Mingo formation. (Broad sense.)

Eocene (lower): Eastern South Carolina (parts of Georgetown, Williamsburg, Berkeley, Clarendon, Summit, Lee, Richland, and Calhoun Counties).

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C.). *Black Mingo shales* (lower Eocene) underlie Congaree shales and overlie Burches Ferry marl (Upper Cret.).

E. Sloan, 1907 (Summ. Min. Res. S. C., pp. 12, 16). *Black Mingo shales.*—Laminated shales separated by thin layers of very fine micaceous sands, the whole partly silicified; also contains a thin layer of marl. Underlies Congaree shales and overlies Burches Ferry marl (Upper Cret.). Of lower Eocene age. Exposed along Black River from Brewington Lake, Clarendon Co., to mouth of Black Mingo Creek, up which it is exposed to point btw. Rhems and General Marion Bridge.

E. Sloan, 1908 (Catalogue of mineral localities of S. C., S. C. Geol. Surv., ser. 4, Bull. 2, especially p. 449). *Black Mingo phase (lower Eocene).*— Divided into (descending): (1) Lang Syne beds; (2) *Upper Black Mingo*, which includes (descending) Williamsburg pseudo-buhr and Rhems sh.; and (3) *Lower or Black Mingo sh.* Underlies Congaree phase (middle Eocene) and overlies Burches Ferry phase (Upper Cret.).

C. W. Cooke, 1936 (U.S.G.S. Bull. 867). Sloan's 1908 definition of *Black Mingo phase* included all strata of lower Eocene age E. of Santee River. In present rept *Black Mingo fm.* includes all Eocene strata in S. C. older than McBean fm., of middle Eocene (Claiborne) age. It is of Wilcox age, and correlates chiefly with Tuscahoma sand of Ala.

Black Mountain basalt flow.

Tertiary or Quaternary: Southern California (western El Paso Range, eastern Kern County).

C. L. Baker, 1912 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 7. pp. 121–142). *Black Mtn basalt flow.*—Olivine basalt, both vesicular and compact. Thickness more than 100 ft. Of post-Miocene Tert. age, and younger than Rosamond series.

C. D. Hulin, 1925 (Calif. State Min. Bur. Bull. 95, pp. 20–61). *Black Mtn basalt* is both intrusive and extrusive. Intrudes Rosamond series and Red Mtn andesite. Named for widespread basalt flows on Black Mtn, 7 mi. W. of El Paso Peaks, Kern Co., where they uncon. overlie Tert. sediments. They are probably very late Plio. or early Pleist.

Black Mountain volcanics.

Probably Upper Triassic or Jurassic: Southern California (San Diego County).

M. A. Hanna, 1926 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 16, No. 7, pp. 187–246). *Black Mtn volcanics.*—Chiefly volcanic, including aggls., although in certain places sediments are present. Contain rather massive cgls., qtzites, shales, massive andesitic aggls., trachytic and andesitic flows, and tuffs. All metamorphosed. Thickness more than 2,000 ft. Oldest rocks exposed in La Jolla quad. Rest on intrusive rocks, and nowhere is basement exposed. Uncon. overlain by Chico (Cret.). No fossils. Well developed on Black Mtn, N. part of La Jolla quad.

Black Mountain granite.

Age (?): Southeastern Vermont (Windham County).

C. H. Richardson, 1933 (18th Rept. Vt. State Geol., pp. 349–357, in description of Putney Twp). Acid intrusives are not present in this Twp, but in Dummerston Twp, first Twp to S., they include the well-known *Black Mtn granite.* [Black Mtn is in Brattleboro quad.]

†Black patch grit.

Lower Cambrian: Eastern New York and western Vermont.

T. N. Dale, 1893 (U.S.G.S. 19th Ann. Rept., chart opp. p. 178). *Black patch grit* overlies Camb. roofing slates [Mettawee sl.] and underlies Cambric black sh. [Schodack shales and lss.].

See *Eddy Hill grit* of Ruedemann, which replaces it.

Black Point basalt.

Pleistocene (late): Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Black Point basalt.*—Chiefly basalt and tuff. Composes Black Point (promontory). Included in middle part of Honolulu volcanic series [q. v.]. Overlies Diamond Head tuff.

†Black Prairie series.

Upper Cretaceous (Gulf series): Texas and Arkansas.

R. T. Hill, 1889 (Tex. Geol. Surv. Bull. 4, pp. xiii-xiv). *Upper Cretaceous or Black Prairie series*; a local name for the Upper Cret. deposits of Tex. and SW. Ark.

Same as Gulf series, older name.

Named for Black Prairie of eastern Tex. and Ark. defined by R. T. Hill in Am. Jour. Sci., 3d, vol. 33, p. 294.

Black River group.

Middle Ordovician: New York and Pennsylvania.

L. Vanuxem, 1842 (Geol. N. Y., pt. 3, pp. 38–45). *Black River ls.*—Underlies Trenton ls. and overlies Calciferous group [Beekmantown]. Includes (descending): (1) Mohawk ls. (base of Trenton ls.); (2) gray ls.; (3) birdseye ls.; and (4) Chazy ls. Named for exposures in cliffs on Black River.

E. Emmons, 1842 (geol. map of N. Y.). Birdseye, Trenton, and Chazy lss. excluded from Black River ls.

J. Hall, 1843 (N. Y. Nat. Hist., div. 4, geol. 4th dist., pp. 18, 28). *Black River ls. group* overlies Calciferous sandrock and underlies Trenton ls. Includes Chazy and Birdseye lss.

J. Hall, 1847 (Pal. N. Y., vol. 1). *Black River ls.* probably rarely or never exceeds 10 ft. in thickness and is absent in places. Is a well-defined mass of grayish blue ls., very compact, and sometimes subcrystalline in texture. Underlies Trenton ls. and overlies Birdseye [Lowville] ls. [Subsequent repts, by different authors, assigned to *Black River ls.* as defined by Hall a thickness of 0 to 75 ft. and to the †Birdseye a thickness of 0 to 85 ft.]

Hall's 1847 definition was used by geologists generally for many years. In 1902 (Bull. Am. Pal. No. 14), however, P. E. Raymond definitely included *Birdseye zone* in *Black River ls.*, but Ulrich (1902), Schuchert (1902), Clarke (1903, 1908), Cleland (1903), Cushing (1905, 1908), Hartnagel (1907), Miller (1909, 1910) followed the 1847 definition and excluded the †Birdseye. In 1910 (N. Y. State Mus. Bull. 145) R. Ruedemann divided *Black River group* into (descending): (1) *Amsterdam ls.;* (2) Watertown ls., 10 ft. (=7-foot tier or Black River ls. of Hall); and (3) Lowville ls., 60 ft., divided into *Leray ls. memb.* (10 ft. of ls. more cherty than that below) and *Lowville ls. s. str.* (22 to 55 ft. of dove and blue dove ls., both thick and thin bedded, and conglomeratic at base). He stated that Watertown and Leray lss. taken together are known in the Thousand Islands region as *Black River ls.* In table on p. 97 he called top fm. of *Black River group,* in Mohawk and Champlain Valleys and at Saratoga, the *Amsterdam ls.*, which he did not define but placed stratigraphically higher than Watertown ls. In further explanation of 1910 classification, H. P. Cushing in 1911 (Am. Jour. Sci., 4th, vol. 31, pp. 135–144) stated: It has finally been decided best to revert to Vanuxem's usage (except for inclusion of the Chazy), and to apply *Black River* to entire rock group btw. Trenton and Chazy, the usage which Geol. Survey of Canada has consistently followed. In N. Y. State Mus. Hdb. 19 (1912) C. A. Hartnagel followed the 1910 classification, which is present commonly accepted definition of *Black River group.*

See further details under *Lowville ls.*

In central Pa. the Black River group is divided into Rodman ls. (above) and Lowville ls. In SW. Va. it is divided into Lowville ls. (below) and Chambersburg ls.

G. M. Kay, 1935 (Geol. Soc. Am. Bull., vol. 46, p. 227), divided *Black River group* at *type section* into Chaumont fm. (including Watertown and Leray) and Lowville, and stated: *Pamelia fm.*, commonly classified as Chazyan, may belong in Black River group below the Lowville, according to Alice E. Wilson.

†Black River iron-bearing series (also *schists*).

†Black River Falls iron-bearing schists.

Pre-Cambrian (lower ? Huronian): Southwestern Wisconsin (Jackson County).

C. R. Van Hise, 1892 (U. S. G. S. Bull. 86, pp. 190, 195, and map, pl. 3). *Black River Falls series.*—*The Black River Falls iron-bearing schists* of Wis. have not such observable structural relations as to enable me certainly to determine their position. They are thoroughly crystalline schists, in vertical attitude, and are provisionally placed in lower Huronian. [Probably named for exposures at Black River Falls, Jackson Co.]

R. D. Irving, 1892 (U. S. G. S. Mon. 19, pl. 1), mapped *Black River iron-bearing schists.*

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, chart opp. p. 598), assigned these rocks to Huronian, but not to any specific part of the Huronian.

†Black Rock diabase.

Upper Triassic: Central Massachusetts (Mount Holyoke region).

B. K. Emerson, 1898 (U. S. G. S. Holyoke folio, No. 50, and Mon. 29, pp. 17–18, pl. 34). *Black Rock diabase,* cores and dikes intrusive into the Juratrias sediments [Newark group]. Named for Black Rock, S. of Mount Holyoke.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, p. 272). *"Black Rock" diabase* is not intrusive, as originally supposed, but a part of Hampden diabase flow, of Newark group, which is interbedded in Longmeadow ss.

Black Rock erosion cycle.

Name applied by E. Blackwelder (Jour. Geol., vol. 23, p. 312, 1915) to a pre-Kansan Pleist. erosion interval in Wind River Mtns, Wyo.

Black Rock coal group.

Name locally applied to Wasatch fm. in Rock Springs uplift of Sweetwater Co., SW. Wyo. (See U. S. G. S. Bull. 702, 1920.)

Black Rock limestone.

Lower Cambrian (?): Southeastern Idaho (Pocatello).

A. L Anderson, 1928 (Idaho Bur. Mines and Geol. Pam. 28, p. 4). *Black Rock ls.*—Thick-bedded, massive, relatively pure, gray ls., with some sandy ls. members near top of ridge and minor amounts of calc. sh. in some parts of fm. The ls. is 800+ ft. thick and is *overlain* by 150± ft. of calc. sh., sandy sh., ss., and qtzite, with the sh. near base and the qtzite near top where the fm. merges with Brigham qtzite. Some of ls. beds contain small rounded concretions and other more irregular forms that may be traces of fossils. Underlies Brigham qtzite conformably, and it is therefore believed it must be Lower Camb. Is underlain, probably conformably, by a sh. series. Named because of occurrence along Black Rock Creek, 2± mi. NE. of Portneuf Siding. Best exposed on N. side, where it can be traced up Black Rock Creek for several miles.

Black Rock formation.

Lower Ordovician (Beekmantown): Northern Arkansas (Sharp and Lawrence Counties) and southeastern Missouri (?).

G. C. Branner, 1929 (geol. map of Ark.). *Black Rock ls.*—Lss., 0 to 200± ft. thick, uncon. underlying Everton ls. and uncon. overlying Smithville ls. in Ozark region, Ark. [Mapped at and around Black Rock, Lawrence Co., Ark.] Assigned to Upper Canadian [which is Beekmantown of U. S. G. S.].

H. S. McQueen, 1930 (Insoluble residues as a guide in stratigraphic studies, published March 1930; Reprint of App. I, 56th Bien. Rept., 1931, p. 25). *Smithville-Black Rock fms.* have been shown on recent ed. of geol. map of Ark. Detailed features of each have not yet been published, nor has opportunity for detailed study of their insoluble residues been presented. They occur btw. Powell dol. and St. Peter ss. The Smithville is thought to occur in SE. Mo., for in a few wells ls. and slightly dolomitic ls. yielding a small residue have been found above Powell fm., but overlying *Black Rock ls.* has not been recognized in Mo.

E. T. McKnight, 1935 (U. S. G. S. Bull. 853, on Yellville quad., Ark.). *Black Rock fm.*—Chiefly fine-grained, gray, mag. ls. or dol. that weathers drab or whitish, with minor amounts of ss. and blue gray ls. Thickness in Sharp and Lawrence Counties, Ark., 200± ft. Absent in Yellville quad. Not studied in detail. Uncon. overlies Smithville fm. The Black Rock and Smithville fms. resemble Everton fm. in lithology, but are believed by E. O. Ulrich, on basis of fossil evidence, to occupy an interval btw. Everton fm. above and Powell dol. below, and to be uncon. with Everton and with Powell.

Blacksburg schist.

Cambrian (probably Lower): Southern North Carolina and northwestern South Carolina.

A. Keith and D. B. Sterrett, 1921 (Limestones and marls of N. C., by G. F. Loughlin et al: N. C. Geol. and Econ. Surv. Bull. 28, pp. 29, 73). *Blacksburg schist.*—A fm., 800 to 1,000 ft. thick, which varies from a fine-grained graywacke (an impure variety of ss.) to sericite schist. Overlies qtzite, cgl. and schist [Kings Mtn qtzite] and underlies Gaffney marble. [See also A. Keith, U. S. G. S. Gaffney-Kings Mountain folio, No. 222, 1931.]

Named for development in Blacksburg, Cherokee Co., S. C.

Blacks Fork member (of Bridger formation).

Eocene: Southwestern Wyoming.

H. E. Wood, 2d, 1934 (Am. Mus. Nat. Hist. Bull., vol. 67, art. 5, May 26, pp. 241–242). By the present somewhat unwieldy terminology, Bridger A+B, Bridger C+D, Uinta A+B, and Uinta C are each essentially members, each containing distinctive fossil mammals. They deserve equal rank with such commonly recognized units as the Lysite, Lost Cabin (=Wind River, sensu stricto) [of NW. Wyo.], and, almost, the Chadron, but are not at present named or fully treated as such. I accordingly propose *Black's Fork memb.* for lower half of Bridger (A+B of Matthew, 1909), the name being taken from Black's Fork of Green River, which flows past most of the best known exposures. Most famous and typical loc. is "Grizzly Buttes" on Smith's Fork, starting ½ mi. S. of town of Mountain View and ending 1½ mi. SW. of the town. I propose *Twin Buttes memb.* for upper half of the Bridger (C+D of Matthew), the name being taken from Twin Buttes, W. of the Green River and E. of Henry's Fork Table. Bridger C and D are both exposed on the slopes of Twin Buttes. Type loc. is Henry's Fork Table and Twin Buttes. I propose *Wagonhound memb.* for the lower Uinta (A+B of Peterson [included in Bridger fm. by U. S. Geol. Survey and others]), the name being taken from Wagonhound Canyon (which opens into White River, Utah), in and near which typical and fossiliferous exposures occur. I propose *Myton memb.* for Upper Uinta (C of Peterson), the "true Uinta" of various authors [and Uinta fm. of U. S. Geol. Survey and others], from town of Myton, Utah; typical exposures occur E., N., NW. of the town at mouth of Lake Fork, and at other points in almost all directions from the town. The Lower and Upper Bridger, as well as Lower and Upper Uinta are distinct from each other geographically as well as faunistically, so that they fully deserve to rank as separate units.

Blacks Fork glacial stage.

Pleistocene: Northeastern Utah and southwestern Wyoming.

W. H. Bradley, 1936 (U. S. G. S. P. P. 185). A glacial stage in Uinta Mtns, NE. Utah and SW. Wyo. Probably of Iowan or Illinoian age. Named for fact extensive moraines were left by its glaciers in valley of Blacks Fork, Utah.

Blacksmith limestone.

Middle Cambrian: Northeastern Utah and southeastern Idaho.

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804, pp. 6, 7). *Blacksmith fm.*—Gray aren. ls. in massive layers. Thickness 570 ft. in Blacksmith Fork, Cache Co., Utah, and 23 ft. W. of Liberty, Bear Lake Co., Idaho. Middle Camb. fossils. Underlies Bloomington fm. and overlies Ute fm. Type loc. in Blacksmith Fork Canyon, 8± mi. above its mouth and 15 mi. E. of Hyrum, Cache Co., Utah.

Blacksnake sandstone member (of Hance formation).

Pennsylvanian: Southeastern Kentucky (Cumberland Gap district).

G. H. Ashley and L. C. Glenn, 1906 (U. S. G. S. P. P. 49, p. 80 and pl. 16). [*Blacksnake* (*Cawood*) *ss.* on pl. 16; *Blacksnake* (*?*) *ss.* on p. 80. All of definition.]

†Blackstone series.

Pre-Cambrian: Northeastern Rhode Island.

J. B. Woodworth, 1899 (U. S. G. S. Mon. 33, pp. 8, 104–109). *Blackstone series.*—A series of lss., chloritic and hornblendic schists, slates, and qtzites, which occur in lower portion of Blackstone Valley and near Providence, R. I. On lithological grounds, which have some support in stratigraphy, the series can be divided into [ascending] Cumberland qtzites, Ashton schists, and Smithfield lss. Uncon. overlain by lowermost Camb. (Olenellus) horizon. Named for typical development in lower course of Blackstone River btw. Woonsocket and Pawtucket, R. I.

A local name for all pre-Camb. sediments of the region, which are now divided into Marlboro fm. (above) and Westboro qtzite.

Blackstone shale.

Upper Cretaceous: Alberta.

G. S. Malloch, 1911 (Canada Geol. Surv. Mem. 9, p. 35).

Blacksville limestone. (In Washington formation.)

Permian: Southwestern Pennsylvania and northern West Virginia.

I. C. White, 1891 (U. S. G. S. Bull. 65, p. 36). *Blacksville ls.*—Quite pure gray ls, 3 to 5 ft. thick. Lies 30 to 50 ft. above Washington coal and underlies Washington "A" coal. Outcrops near bed of Dunkard Creek, in village of Blacksville, Monongalia Co., W. Va. Is ls. III of Stevenson's Greene and Washington Co. (Pa.) Rept.

G. H. Ashley, 1908 (Pa. Topog. and Geol. Surv. Comm. Rept. 1906–1908, p. 145). In Washington and Greene Counties, Pa., the *Blacksville ls.* occurs persistently 30 to 50 ft. above Washington coal.

Blacktail formation.

Pre-Cambrian (Belt series): Northern Idaho (Pend Oreille district).

J. L. Gillson, 1925 (Am. Min., vol. 10, p. 189) and 1927 (Jour. Geol., vol. 35, No. 1, pp. 1–32). New name *Blacktail fm.* is proposed in unpublished rept. on Pend Oreille dist. [by E. Sampson and J. L. Gillson], to include the equivalents of Revett and St. Regis fms. of Coeur d'Alene dist., Idaho.

E. Sampson, 1928 (Idaho Bur. Mines and Geol. Pam. 31, p. 7). *Blacktail fm.*—Is here defined as including all rocks btw. Burke fm. below and Wallace fm. above. Represents undiff. equivalents of Revett and St. Regis fms. of Coeur d'Alene dist. Lower part is prevailingly qtzite; upper part is mostly argillite. Whole fm. is distinguished from all others in dist. by a pinkish or reddish purple color. Lower 5,000 ft., which is mostly qtzite, may have only a faint pink cast, but even in these beds thin partings of red sh. are common. The lowest beds closely resemble Burke fm., but faintly pink color serves to distinguish them. The upper Blacktail beds are alternating red and green argillites, with red predominating. In lower part of fm. the red argillite occurs only as partings. Argillite increases upward in fm. and in upper 3,300 ft. it greatly predominates. Uppermost beds, near transitional bdy with Wallace fm., are green, but those mapped with the Blacktail have a peculiar waxy appearance. Type loc., Blacktail Mtn, near Talache, where fm. is best exposed. The SW. shoulder shows the lower beds and the northerly spurs show the upper argillitic portion.

†Blacktail Deer Creek beds.

Oligocene? (upper?): Southwestern Montana (Beaverhead County).

E. Douglass, 1902 (Am. Phil. Soc. Trans., vol. 20, n. s., pt. 3, pp. 237–245). *Blacktail Deer Creek beds,* the beds on Blacktail Deer Creek, which are probably White River Olig.

H. F. Osborn, 1909 (U. S. G. S. Bull. 361, p. 106). Beds on Blacktail Deer Creek, Mont., doubtfully included in upper Olig. White River group. They are more probably lower Mio.

Blackwater formation.

Pennsylvanian: Northeastern West Virginia and western Maryland.

N. H. Darton and J. A. Taff, 1896 (U. S. G. S. Piedmont folio, No. 28). *Blackwater fm.* (also *Blackwater ss.*).—Three poorly defined ss. and cgl. beds, separated by two zones of softer argill. ss. and sandy sh. containing variable and impure coal beds. The upper ss. is conglomeratic and 110 to 200 ft. thick; the medial ss. is 125 ft. thick; and the lower ss. is 30 to 155 ft. thick and banded with cgl. Overlies Canaan fm. and underlies Savage fm. Thickness of fm. 290 (at Piedmont) to 645 (on Blackwater River below Davis, W. Va.).

Blackwater shale and limestone.

Pennsylvanian: Northeastern West Virginia.

D. B. Reger, 1923 (W. Va. Geol. Surv. Rept. Tucker Co., pp. 198, 209–210). *Blackwater sh. and ls.*—A marine memb. of Kanawha group (upper Pottsville), consisting of 15 ft. of dark sh. underlain by 7 inches of ferruginous ls., and containing marine fossils of familiar Kanawha types in the ls. and in lower part of the sh. Base lies 280 ft. below top of Homewood ss. and 115 ft. below Quakertown coal horizon. Probably correlates with Dingess ls. of Mingo Co., but this correlation is not decisive.

Named for exposures on N. side of Blackwater River, 2 mi. SW. of Davis and ½ mi. below Blackwater Falls, Tucker Co.

Blackwell sand.

A subsurface sand in Blackwell pool, Kay Co., central northern Okla., correlated with a part of Garrison sh. (Perm.). In that pool it lies at 750 ft. depth and Newkirk sand at 1,450 ft. According to Okla. Geol. Surv. Bull. 40Q, 1928, p. 180, this sand is of Penn. age.

†Bladen formation.

Upper Cretaceous: Coastal Plain of North Carolina and South Carolina.

L. W. Stephenson, 1907 (Johns Hopkins Univ. Circ. No. 71, pp. 93–99). *Bladen fm.*—Sands and clays, for most part thinly laminated and often highly cross bedded; everywhere more or less lignitic. Name used tentatively, since future investigations may prove equivalency with other fms. elsewhere. A few fossil plants indicate equivalency with Tuscaloosa fm. Grades into overlying Ripley fm. [Peedee] and rests uncon. on Capefear fm. [Tuscaloosa]. Thickness 500 to 700 ft.

Replaced by Black Creek fm., which has priority.

Named for exposures in Bladen Co., N. C., especially along Cape Fear River.

Blaine gypsum (also **formation**).

Permian: Western Oklahoma, Panhandle of Texas, and central northern Texas.

C. N. Gould, 1902 (Okla. Geol. Surv. 2d Bien. Rept., pp. 42, 47). *Blaine div.*—Red shales, with interbedded strata of gyp. and dol., averaging 75 ft. in thickness, divided into following members (descending): Shimer gyp.; Altona dol.; red sh. (Jenkins clay of Cragin); Medicine Lodge gyp.; Magpie dol.; red sh.; and Ferguson gyp. Overlies Norman div. (Enid group) and underlies Woodward div. (group). Where Ferguson gyp. memb. disappears the underlying Norman (Enid) div. extends up to base of Medicine Lodge gyp.

In Tex. the top memb. has been called *Acme dol.* and basal memb. *Quanah gyp.* The fm. underlying the Blaine in Okla. was named *Chickasha fm.* by Gould in 1924.

H. D. Miser, 1926 (geol. map of Okla.), modified the definition of *Blaine gyp.* so as to include beds above Shimer gyp. and below Ferguson gyp., and discarded †*Greer fm.* The Blaine as mapped included all beds from top of Chickasha fm. up to base of Dog Creek sh.

R. L. Clifton, 1930 (A. A. P. G. Bull., vol. 14, pp. 161–172). Evidences in field seem to indicate *Blaine* should be dropped and some new fm. name be adopted to include what now comprises Blaine and Dog Creek beds.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 168, 178). *Blaine fm.* as now used in Tex. includes more than does Blaine of type loc. in Okla. Not only is underlying Chickasha, or a part of it, merged with the Blaine in Tex. usage, but overlying Dog Creek of Okla. is included in part or entirely. Childress dol. and gyp. is top memb. of Blaine in Tex. and Quanah gyp. lies near base.

J. L. Muir, 1934 (A. A. P. G. Bull., vol. 18, No. 10, p. 1300), gave detailed section of Blaine fm. at type loc., in Salt Creek Canyon, Blaine Co., Okla., showing it as underlying Dog Creek shales, overlying Flowerpot shales, and including Lovedale gyp. at top, Shimer gyp. in middle, and Medicine Lodge gyp. 2 ft. above base.

Named for exposures in Blaine Co., Okla. Type loc. is in Salt Creek (Henquenet's) Canyon in northern Blaine Co.

Blair formation. (In Mesaverde group.)

Upper Cretaceous: Southwestern Wyoming (Sweetwater County).

A. R. Schultz, 1920 (U. S. G. S. Bull. 702). *Blair fm.*—Drab, yellow, and brown sss. and interbedded sh. and shaly ss. with little or no bituminous matter; massive sss. are grouped near top of fm., giving rise to the "golden wall," and are the "Golden-wall ss." of Powell. Thickness 1,000 to 1,200 ft. In previous repts. included in Mesaverde fm. May possibly belong to the Mesaverde, but seems to be older, and for present at least the base of Rock Springs coal group is regarded as base of Mesaverde. The Blair constitutes a distinct lithologic unit. Overlies Baxter sh. Named for exposures at Blair ranch, E. of Aspen Mtn.

Blairmore formation.

Upper and Lower Cretaceous: Southern Alberta, Canada.

F. H. McLearn, 1916 (Canada Geol. Surv. Summ. Rept. 1915, p. 112). Uncon. overlies Ellis fm. and underlies Colorado sh.

F. H. McLearn and G. S. Hume, 1927 (A. A. P. G. Bull., vol. 11, No. 3, p. 241). *Blairmore fm.* of Blairmore-South Fork areas consists of sss., sh., and, a little above middle, a bed of cgl., and another bed of cgl. at base. It discon. overlies Kootenay fm. and underlies Crowsnest volcanics. The upper part of fm. contains a Cenomania[n] flora, according to E. W. Berry, and is of Upper Cret. (Colorado) age. The flora of lower part is Lower Cret. (Aptian or Albian), according to Berry. The lower part of the Blairmore corresponds to upper part of Kootenai fm. of Mont. The flora of the pre-Blairmore Kootenay beds is Barremian, according to Berry.

Blairsville.

See *Sub-Blairsville red shale memb.*

Blakeley formation.

Oligocene: Western Washington (Puget Sound region) and southwestern Washington.

C. E. Weaver, 1912 (Wash. Geol. Surv. Bull. 15, pp. 10–22). *Blakeley fm.*—Alternating shales and sss. overlain by nearly 1,000 ft. of nonfossiliferous cgls. Thickness of fm. 8,000 ft. Fossils listed. Been considered Olig. or at least in part Olig., but writer now places them in Lower Mio., until definite understanding has been reached as to what is to constitute Olig. Type section is at Restoration Point, Kitsap Co., opp. Seattle.

C. E. Weaver, 1916 (Wash. Geol. Surv. Bull. 13). *Blakeley horizon* is characterized by *Acila gettysburgensis* zone, and is assigned to Olig. Fossils listed. The highest strata outcrop on N. shores of Blakeley Harbor. Type section is at entrance to Bremerton Navy Yard. Is younger than Porter horizon and older than Wahkiakum horizon (lower Mio.).

L. G. Hertlein and C. H. Crickmay, 1925 (Am. Phil. Soc. Proc., vol. 64, No. 2, pp. 245, 261–264). *Seattle* and *Twin River fms.* of Arnold and Hannibal's Astoria series seem to be = Weaver's *Blakeley fm.* While later studies may show *Blakeley beds* (*Acila gettysburgensis* zone) to be younger, they are at present considered to be Upper Olig.

Blakely sandstone.

Lower Ordovician: Southwestern Arkansas and southeastern Oklahoma.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, p. 676). *Blakely ss.*—Name proposed by A. H. Purdue (in letter) for ss. recently discovered, which is absent W. of Womble but locally developed to thickness of 500 ft. E. of that town. The discovery of this intercalated ss. tends to confirm high value of strat. hiatus btw. Ouachita and Stringtown shales, which hitherto was inferred chiefly on paleontologic evidence. Underlies Stringtown sh. [restricted sense] and overlies Ouachita sh.

H. D. Miser, 1917 (U. S. G. S. Bull. 660, p. 67). *Blakely ss.*—Sh., in alternating black and green layers, and hard gray ss. The sh. constitutes 75 per cent of whole fm., but the ridge-forming ss. is the prominent feature. Thickness 0 to 400 ft. Underlies Womble sh. and overlies Mazarn sh. Named for Blakely Mtn, Garland Co., Ark., from which it is continuously exposed as far W. as Womble, where it thins out and permits Womble sh. to rest on Mazarn sh. W. of that town. In 1909 this ss. was regarded by A. H. Purdue as upper part of Crystal Mtn ss., but it has since been determined by Purdue and writer to occur in middle of "Ouachita sh." [A broader use of "Ouachita sh." than as defined by Purdue in 1909.]

Is of Beekmantown and probably Chazy age, according to classification of U. S. Geol. Survey.

Blanca tuff.

Miocene: Southern California (Santa Cruz Island).

W. W. Rand, 1931 (Mining in Calif., vol. 27, No. 2, p. 217). ***Blanca tuff.***—Distinctly bedded, water deposited, acid to intermediate crystalvitric tuffs and cgls., with thin flow of andesite near top. Included in Monterey group, which, on Santa Cruz Island, consists of (descending) (1) siliceous sh., (2) volcanics, (3) ***Blanca tuff,*** (4) Temblor fm., and (5) Vaqueros fm. [Derivation of name not stated.]

†Blanchard moraine.

Replaced by Defiance moraine (Pleist.) in U. S. G. S. Mon. 41, p. 581. *Blanchard* has priority but *Defiance* has usage. Named for a stream in Ohio.

Blanchester division. (In Richmond group.)

Upper Ordovician: Southwestern Ohio, southeastern Indiana, and north-central Kentucky.

A. F. Foerste, 1909 (Denison Univ. Sci. Lab. Bull. 14, p. 291). ***Blanchester div.***—Includes upper part of Waynesville bed of Richmond fm., or beds btw. top of upper *Hebertella insculpta* horizon and base of lower *Hebertella insculpta* horizon. Is overlain by Liberty beds and underlain by Clarksville div.

Named for Blanchester, Clinton Co., Ohio.

Blanco formation.

Pliocene (middle): Panhandle of Texas.

E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., p. lxxi, pl. 3). ***Blanco Canyon beds.***—White clays, infusorial earth, etc., containing fossil remains of turtles and large animals. Forms upper portion of Staked Plains. Probably corresponds to upper part of Fayette beds, which it closely resembles in some lithologic features.

W. F. Cummins, 1890 (Tex. Geol. Surv. 1st Ann. Rept., p. 190). ***Blanco Canyon beds.***—Red clay, white sandy clays, white clays, and a hardened clayey ls., fronting to E. and forming bold escarpment 200 ft. high. Constitute Staked Plains. Uncon. overlie Dockum beds. Later than Cret. [Name changed by W. F. Cummins in 1892 (Tex. Geol. Surv. 3d Ann. Rept., p. 134) to *Blanco beds*.]

H. F. Osborn (1907 and 1918) assigned ***Blanco fm.*** to middle Plio.

Named for Blanco Canyon, Dickens Co., and Mount Blanco P. O., Crosby Co. Included in *Ogallala fm. (Plio.)* on 1937 geol. map of Tex.

Blanco Basin formation.

Tertiary (Oligocene ?): Southwestern Colorado (San Juan Mountains).

E. S. Larsen, 1935 (U. S. G. S. Bull. 843). In many places on S. slopes of San Juan Mtns, in San Cristobal, Pagosa Springs, Summitville, and Conejos quads, a series of arkosic sss., cgls., and other sediments, lacking in volcanic material, uncon. overlies Cret. fms. and Animas fm. (Eocene ?), and are overlain, with apparent conformity, by Conejos andesite (Mio.). The name ***Blanco Basin fm.*** is proposed for these beds, from their prominent development about Blanco Basin, in central part of Summitville quad. Is in general a thin, soft fm., overlying in many places Mancos sh. and overlain by great thickness of volcanic breccia. It is imperfectly known and only approx. mapped. East of Chama River, near S. bdy of Summitville quad., it is 575 ft. thick, is overlain by several hundred ft. of beds belonging to Conejos andesite, and rests with angular uncon. on Mancos sh.

† Blanco Canyon beds.

Pliocene: Panhandle of Texas.

See *Blanco fm.*

†Blan[d]ford limestone.

Pre-Cambrian: Western Massachusetts.

E. Hitchcock, 1833 (Rept. Geol., Min., Bot., and Zool. of Mass., p. 305). *Blanford ls.*—Coarsely granular, white, crystalline ls. exposed in NW. part of town of Blan[d]ford. [According to B. K. Emerson (unpublished communication) this is a large boulder of Coles Brook ls.]

Blandford serpentine and pyroxenite.

Age (?): Massachusetts.

B. K. Emerson, 1898 (U.S.G.S. Mon. 29, p. 85).

Blankenship sand.

See *Sallyards sand.*

Blaydes sand.

A subsurface sand, of Penn. (?) age, in Stephens Co., southern Okla., lying at 2,200 ft. depth in Empire pool, the Brown sand lying at 2,100 ft. and the Kagay at 2,300 ft.

Blaylock sandstone.

Silurian (early): Southwestern Arkansas and southeastern Oklahoma.

A. H. Purdue, 1909 (Geol. Soc. Am. Bull., vol. 19, p. 557). *Blaylock ss.*—Ss. uncon. underlying Slatington sh. [Missouri Mountain sl.] and overlying Polk Creek sh.

A. H. Purdue, 1909 (Slates of Ark., Ark Geol. Surv., pp. 30, 36). *Blaylock ss.*—Fine-grained to medium-grained ss. of dove, dark gray, or green color, interbedded with dark-colored, often black, and fissile sh. Thickness 1,500 ft. In parts, through 100 or more ft., consists almost wholly of ss.; in other parts is made up of alternating beds of ss. and sh. The ss. is usually in layers 1 to 6 inches thick and bedding is very even. Some of layers are qtzitic and contain numerous quartz veins; other thin layers closely resemble chert. Overlies Polk Creek sh. Underlies, probably uncon., Missouri Mtn sl.

Named for Blaylock Mtn, Montgomery Co., Ark.

Bledsoe limestone.

Silurian (Niagaran): Western Tennessee.

A. F. Foerste, 1901 (Geol. Soc. Am. Bull., vol. 12, pp. 397, 402). *Bledsoe ls.*—Top bed (0 to 32 ft. thick) of Clifton ls. in Tenn. Overlies Newsom (Waldron) shaly clay and uncon. underlies Pegram ls. (Dev.) or Chattanooga sh. Same as Louisville ls. of Ind.

Named for Bledsoe, Sumner Co.

Bliss sandstone.

Upper Cambrian: Western Texas and southern New Mexico.

G. B. Richardson, 1904 (Univ. Tex. Min. Surv. Bull. 9, p. 27). *Bliss ss.*—Massive, compact, fine-textured, fossiliferous gray ss., about 300 ft. thick, varying in color from almost white to brown; toward top locally cross bedded and some of beds hard. Overlies coarse red granite and uncon. underlies El Paso ls. (Ord.).

Named for Fort Bliss, El Paso Co., Tex.

Bliss basalt.

Pleistocene: Southern Idaho (Twin Falls and Gooding Counties).

H. T. Stearns, 1932 (Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932) and 1936 (Jour. Geol., vol. 44, No. 4, pp. 434–439). *Bliss basalt.*—Brecciated subaqueous flow composed chiefly of vitreous porphyritic basalt, containing pillow structures. May be subaqueous facies of McKinney basalt or, possibly, of Sand Springs basalt. Thickness 100±ft. Exposed at Bliss Cone and Bliss Bridge, sec. 11, T. 6 S., R. 12 E., Twin Falls Co., also at Bliss Spring, Gooding Co.

Block porphyry.

A descriptive term formerly applied by miners to the White porphyry of Leadville dist., Colo., because of its tendency to split into angular blocks.

Block limestone.

Pennsylvanian: Eastern Kansas, northern Missouri, and Iowa(?).

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 85, 97). *Block ls. memb. of Cherryvale sh.* overlies Fontana sh. memb. of Cherryvale and underlies Wea sh. memb. of Cherryvale.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pp. 35, 37). *Block ls.* here introduced for fine-grained, bluish gray, thin-bedded ls, with a few thin fossiliferous sh. partings. Thickness 3 to 8 ft. Underlies Wea sh. and overlies Fontana sh., all fms. in Kansas City group. Named for a hamlet in Miami Co., Kans. Has considerable persistence throughout NE. Kans. and adjoining parts of Mo.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), stated that Newell is author of this name.

Blomidon shale.

Triassic: New Brunswick and Nova Scotia.

S. Powers, 1915 (Geol. Soc. Am. Bull., vol. 26, p. 93).

Blood Reserve sandstone.

Cretaceous: Alberta.

L. S. Russell, 1932 (Canada Geol. Surv. Rept. 1931, pt. B, p. 32).

Bloody Run zone.

Upper Devonian: North-central Iowa (Floyd County).

C. L. Fenton and C. L. Webster, 1924 (Univ. Mich. Pub., Contr. Mus. Geol. vol. 1, frontispiece, map), divided Cedar Valley ls. of Floyd Co. into Nora above and Shell Rock below, and divided Shell Rock into (descending): *Pachyphyllum* zone, *Aulopora* sh., *Bloody Run zone*, Lithographic beds, and mud-crack zone, and gave no further explanation of *Bloody Run zone.*

Bloomfield sandstone. (In Cayuga group.)

Silurian: Central Pennsylvania (Perry County).

E. W. Claypole, 1885 (2d Pa. Geol. Surv. Rept. F_2, pp. 54, 401). *Bloomfield ss.*—Soft friable ss., breaking up into rectangular brick-shaped fragments. Of dull reddish and greenish colors. About 10 ft. thick. Underlies New Bloomfield, and exposed on road to Newport, ½ mi. E. of town. Overlain and underlain by variegated shales, all of which are included in Onondaga red and variegated shales. [On pp. xi–xvi of above rept. J. P. Lesley made Bloomfield ss. the top div. of Onondaga red sh.]

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 2 pp. 761–777). *Bloomfield ss.* replaced by *Landisbury ss.* [See under *Landisbury ss.*]

Bloomfield sand.

Eocene: Southeastern Missouri (Stoddard and Scott Counties).

C. R. Keyes, 1894 (Mo. Geol. Surv. vol. 4, p. 30). *Bloomfield sands.*—Sands of Eocene age, 85 ft. thick. [Name used in table on p. 30. On p. 88 the Eocene deposits of Mo. ("probably Bloomfield sands") are described as chiefly brown sands and blue clays with some iron ores, best exposed in bluffs of Mississippi River in Scott and Stoddard Counties.] Named for Bloomfield, Stoddard Co.

Is a part of Wilcox fm.

Bloomfield limestone. (In Conemaugh formation.)

Pennsylvanian: Southeastern Ohio (Muskingum County).

W. Stout, 1918 (Ohio Geol. Surv., 4th ser., Bull. 21, p. 242). *Bloomfield ls.*—Nodular, hard, dense, non-fossiliferous light-gray ls., in places stained with iron oxide. Of fresh-water origin. Thickness 0 to 2½ ft. Lies 3 ft. 9 in. below Anderson coal and 8 ft. 8 in. above Cambridge ls. in Muskingum Co. (Harrison, Bluerock, Salem, and Highland Twps). Named for exposures W. of Bloomfield.

Bloomingdale limestone member.

Upper Cambrian: Eastern Tennessee.

C. R. L. Oder, 1934 (Jour. Geol., vol. 42, No. 5, pp. 478–479, 492, 496). *Bloomingdale ls. memb.*—Upper memb. of Conococheague-Copper Ridge fm. in eastern Tenn. Overlies Morristown dol. (lower memb. of Conococheague-Copper Ridge fm.) and underlies the thin ss. at base of Chepultepec fm. Consists of 170 to 650 ft. of thin to heavy-bedded, light to dove-gray, dense to medium crystalline, fine to coarsely laminated ls. and dol.; dol. is minor in amount in E. sections, but composes practically all of western sections. Color and texture closely resemble underlying Morristown memb. Thin aren. zones occur at numerous levels, 10 sometimes occurring in thickness of 100 ft. Base is formed of 3 to 15 ft. of aren. and shaly dol. and qtzitic ss. The Bloomingdale chert is scarcely distinguishable from that in Morristown memb.; its quantity is nil to abundant. [Details.] Belongs to Ozarkian series of Camb. system. Type section is along a branch of Reedy Creek, 1½ mi. NW. of Bloomingdale, 4 mi. NE. of Kingsport.

Bloomington formation.

Middle Cambrian: Northeastern Utah and southeastern Idaho.

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804, pp. 6, 7). *Bloomington fm.*—Bluish gray, more or less thin-bedded lss. and argill. shales Small rounded nodules of calcite are scattered irregularly through many layers of ls. Thickness 1,320 ft. in Blacksmith Fork Canyon, Cache Co., Utah, and 1,162 ft. W. of Liberty, Bear Lake Co., Idaho. Overlies Blacksmith fm. and underlies Nounan fm. Abundant Middle Camb. fauna. Type loc. about 6 mi. W. of Bloomington, Bear Lake Co., Idaho. Bloomington Creek, near type loc., passes through fm.

Bloomington morainic system.

Pleistocene (Wisconsin stage): Across central Ohio, Indiana, and Illinois. Shown in part on moraine map (pl. 32) of U.S.G.S. Mon. 53, 1915, and in part on moraine map in U.S.G.S.P.P. 106. In some earlier repts called *Bloomington moraine*. Named for Bloomington, Ill.

Bloomsburg redbeds. (Of Cayuga group.)

Silurian: Central and southern Pennsylvania, western Maryland, northern West Virginia, and western Virginia.

I. C. White, 1883 (2d Pa. Geol. Surv. Rept. G_7, p. 252). *Bloomsburg red sh.*—A series of dark, deep or dull red shales, somewhat sandy and blotched with a few thin layers of bright green sh. Thickness 245 to 750 ft. About 440 ft. visible in vicinity of Bloomsburg [Columbia Co.] along E. bank of Fishing Creek at N. line of town of Bloomsburg. Represents basal memb. of Salina series as defined by N. Y. geologists. Underlies Middle Salina group, which consists of 407 ft. of green, buff, and bluish lss. and shales with some red sh. Overlies Clinton series.

C. Butts, 1918 (Am. Jour. Sci., 4th, vol. 46, pp. 523–537). In central Pa. (Blair and Huntingdon Counties) the *Bloomsburg red memb.* forms basal 50 to 150 ft. of Wills Creek sh.

C. K. and F. M. Swartz, 1931 (Geol. Soc. Am. Bull., vol. 42, No. 4, pp. 622–660), treated *Bloomsburg red beds* as a distinct fm., underlying Wills Creek fm. and overlying McKenzie fm., and on pp. 651 to 660 they extended the name into SE. N. Y. as far as Otisville, Orange Co. On p. 657 they stated: It has been shown [pp. 622–660] *Bloomsburg red beds* can be followed continuously from type loc. in NE. Pa. southward into Md. and eastward through central and eastern Pa. to Delaware Water Gap, where it was called *Clinton* by Chance and *High Falls* by Stose. It is continuous with Medina-Longwood red ss. of N. J. and High Falls red beds of Hartnagel in SE. N. Y. It is manifest it is same fm. throughout this entire area and should have one name to avoid confusion. The term Bloomsburg has priority. It is manifest the Bloomsburg is a lithological phase—not a geological age. It accumulated on the continental margin to E. while different marine deposits were formed to W. On p. 660 they show *Bloomsburg red beds* to NE. to be the time equiv. of lower part of Tonoloway ls., Wills Creek sh., and upper part of McKenzie, its basal bed to S. (called *Rabble Run red bed*) interfingering with middle part of McKenzie, while a higher heavy bed of the Bloomsburg wedges in btw. the McKenzie and the Wills Creek. This higher bed, however, they show as representing an early part of the Bloomsburg to E.

C. Butts and G. W. Stose, 1932 (16th Int. Geol. Cong. Guidebooks of Appalachian region). Wills Creek sh. restricted to beds above Bloomsburg sh., the latter to hereafter be treated as distinct fm. This is present approved definition of *Bloomsburg*.

Bloomsbury formation.

Carboniferous or Devonian: New Brunswick.

G. F. Matthew, 1895 (Roy. Soc. Canada Trans., vol. 12, sec. 4, p. 89).

Originally assigned to Dev.; later repts assign it to Carbf.

Blossburg formation. (In Chemung formation.)

Upper Devonian: Central northern Pennsylvania (Tioga County).

M. L. Fuller, 1902 (U. S. G. S. 22d Ann. Rept., pt. 3, pp. 585, 593). The term "Blossburg fm." has been applied by drillers to the source of supply of the oil of the wells of the Manhattan group, 1 mi. E. of Gaines [Tioga Co.]. It is a series of alternating sands, shales, and shaly lss., of which certain of the more sandy members have produced oil. Top, though somewhat variable, is about 200 ft. above horizon of Atwell sand. Included in Chemung fm.

Blossburg.

Upper Devonian: Central northern Pennsylvania (Tioga County).

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60, No. 2, pp. 99, 279, 282, 357). Back in 1842 T. A. Conrad (Jour. Acad. Nat. Sci. Phila., vol. 8, p. 234) applied name *Blossburg* to these red-beds ("Cattaraugus" of the folio) [U.S.G.S. Elkland-Tioga, No. 93], now found to be of pre-Cattaraugus age, and his name has precedence over drillers' use of "Blossburg fm." for an oil-producing zone down in the Chemung. I have therefore revived it (Geol. Soc. Am., Bull., vol. 43, p. 273, 1932) to cover these supposed Girard-Chadakoin beds, which overlie Wellsburg ss. [On p. 357:] "The Blossburg now appears to be older than the Girard-Chadakoin." [In book cited Conrad used *red ss. of Blossburg*. The reference to Bull. G.S.A., vol. 43, p. 273, is an error, as *Blossburg* is not mentioned in the abstract on that page. The listing of *Blossburg ss.* in U.S.G.S. Bull. 191 is also an error, as Conrad, although describing the sandstone, did not name it *Blossburg ss.*]

Blossburg Monkey ledge.

See under *Scranton ss.*

Blossom sand.

Upper Cretaceous (Gulf series): Northeastern Texas.

C. H. Gordon, 1909 (Am. Jour. Sci., 4th, vol. 27, pp. 371, 373). *Blossom sands.*—Glauconitic sands, brown and red at surface from oxidation of iron, interlaminated with and grading into clay. Thickness 80 to 100 ft. Top memb. of Eagle Ford fm. in NE. Texas. Underlies Brownstown marl. Same as Sub-Clarksville sands of Veatch.

Later work by L. W. Stephenson showed that Blossom sand is younger than Eagle Ford clay, and in 1917 it was treated by U. S. Geol. Survey as a distinct fm. overlying the Eagle Ford. The 1925 and 1926 work of L. W. Stephenson established fact that the clay underlying Blossom sand and formerly called Eagle Ford in NE. Tex. is younger than true Eagle Ford clay and = lower part of Austin chalk, and he named it Bonham clay—later changed to *Bonham marl.*

Named for Blossom, Lamar Co., which is located on an outcrop of the sand.

Blossom oil sand.

A name that has been applied in Smackover oil field of Ouachita and Union Counties, SW. Ark., to 10 ft. of subsurface sand said to lie a short distance below Brownstown fm. and at supposed horizon of Blossom sand (Upper Cret.). Locally called *2,600-foot sand.* (See H. G. Schneider, Am. Inst. Min. and Met. Engrs. Trans., vol. 70, pp. 1078-1099, 1924.)

Blount group.

Lower Ordovician (Chazy): Alabama, eastern Tennessee, western Virginia, and West Virginia.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pp. 379, 382, 413, 567, 576, 627, pl. 27). *Blount group.*—Ls., sh., and ss., with max. thickness in Grainger and Blount Counties, Tenn., of at least 3,500 ft., not less than 1,500 ft. of which is ls. Underlies Black River group and overlies Stones River group. Included in Chazyan. Includes (downward) Ottosee [Sevier], Tellico, Athens, and Holston.

Named for Blount Co., Tenn.

Blowing Rock gneiss.

Pre-Cambrian: Western North Carolina.

A. Keith, 1903 (U.S.G.S. Cranberry folio, No. 90, p. 3). *Blowing Rock gneiss.*—Wholly gneiss of two varieties, one with large porphyritic feldspar crystals, the other of very fine, even grain. In places the two varieties grade into each other; in other places they are repeatedly interbedded. Cuts Carolina gneiss and appears to cut the still younger Cranberry granite.

Named for Blowing Rock, in Cranberry quad., Watauga Co.

†Blowout Mountain sandstone. (In Double Mountain group.)

Permian: Central northern Texas (Runnels and Taylor Counties).

W. E. Wrather, 1917 (SW. Ass. Pet. Geol. Bull., vol. 1, pl., pp. 95, 96, 98). *Blowout Mtn ss.*—Massive, dark red, coarse-grained, cross-bedded ss., 40 to 105 ft. thick. Lies 0 to 25 ft. above base of Greer fm., being in places underlain by 20 to 25 ft. of red clay, but in most places forms basal memb. of Greer fm. Named for exposure in Blowout Mtn, SW. of Merkel, Taylor Co.

J. W. Beede and V. V. Waite, 1918 (Univ. Tex. Bull. 1816, pp. 7, 8). *Blowout Mtn ss.* of Wrather is same as San Angelo beds of Lerch (named in 1891), and San Angelo will replace Blowout Mtn as name of this fm. It connects with San Angelo beds.

J. W. Beede and D. D. Christner, 1926 (Univ. Tex. Bull. 2607). *Blowout Mtn ss.* is northern extension of San Angelo fm.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 168). *Blowout Mtn ss.* is discarded for *San Angelo ss.*

Bloyd shale.

Pennsylvanian (Pottsville): Northwestern Arkansas.

A. H. Purdue, 1907 (U.S.G.S. Winslow folio, No. 154). *Bloyd sh.*—Upper fm. of Morrow group. With exception of Brentwood and Kessler ls. lentils and a bed of coal consists almost entirely of thin, fissile, black, carbonaceous clay sh. of uniform character, with locally small amount of ss. in lower part. Brentwood ls. lentil lies 5 to 10 ft. above base; Kessler ls. lentil lies usually 60 to 75 ft. below top. Underlies [uncon.] Winslow fm. and overlies Hale fm. Of Pottsville age.

Named for Bloyd Mtn, Washington Co.

†Blue limestone.

A name applied in a titular sense in some early repts to the Upper Ord. rocks of SW. Ohio, northern Ky., and southern Ind.

†Blue limestone.

A descriptive term applied to the blue lss. of Miss. and Upper Dev. age in Leadville dist., Colo. Later named *Leadville ls.* The name *Leadville* is now, however, restricted to the Miss. lss., while the Dev. lss. (now called *Dyer dol. memb.*) and underlying Parting qtzite (also Upper Dev.) are now included in Chaffee fm.

†Blue chert series.

Devonian (?): Northwestern California (Klamath Mountains).

O. H. Hershey, 1906 (Am. Jour. Sci., 4th, vol. 21, pp. 58–66). *Blue chert series.*—A great series of black shales, lss., and blue cherts, 5,000 ft. thick, of which 3,000 is chert. Is presumed to be Dev., because similar rocks elsewhere in Klamath region carry Dev. fossils. Is thoroughly intruded by dioritic and diabasic materials. Uncon. overlain by volcanic rocks. Must be pre-Bragdon. Named for its most characteristic constituent, blue chert.

Blue Ball fire clay. (*In Allegheny formation.*)

Pennsylvanian: Central Pennsylvania (Clearfield County).

H. M. Chance, 1884 (2d Pa. Geol. Surv. Rept. H7). *Blue Ball fire clay,* 0 to 10 ft. thick, underlies Brookville coal and overlies Pottsville cgl. in Clearfield Co.

Bluebell dolomite.

Ordovician (Upper to Lower): Central northern Utah (Tintic district).

G. F. Loughlin, 1919 (U. S. G. S. P. P. 107). *Bluebell dolomite.*—Alternating beds of medium to dark-gray or bluish-gray dol., mostly fine-grained but some beds medium- to coarse-grained. Between 100 and 200 ft. above base of fm. throughout the dist. the beds contain a number of small nodules and thin seams of chert. Thickness 700 to 1,100 (?) ft. Conformably underlies Pinyon Peak ls. and overlies Opohonga ls. with sharp contact. Is most extensively exposed fm. in Tintic dist. Named for Bluebell mine. Fossils indicate that it ranges in age from Lower to Upper Ord., and it is possible the upper 400 ft. include Sil. or Dev. strata.

Blueberry Mountain argillite.

Devonian (Lower? Dev.): Northwestern New Hampshire (Ammonoosuc River region).

C. H. Hitchcock, 1905 (Geol. of Littleton, N. H., Univ. Press, Cambridge). *Blueberry Mtn argillites.*—Bluish and black slates of Helderberg (Upper Sil. or Dev.) age. Underlie glacial till and overlie coarse cgls.

Appears to be upper part of Blueberry Mtn series of Lahee. Blueberry Mtn is N. part of ridge 2 mi. W. of Littleton, the S. part of which is called Bald Hill. (Lahee, 1913.)

Blueberry Mountain series.

Devonian and Silurian: Northwestern New Hampshire (Ammonoosuc River region).

F. H. Lahee, 1913 (Am. Jour. Sci., 4th, vol. 36, pp. 231–250, being a description of parts of Littleton and Lyman Twps, N. H.). *Blueberry Mtn series.*—Divided into (descending):

Devonian (?):

1. dark-gray ss. with dark sh. layers. Forms top of Blueberry Mtn.
2. banded argillite, 450–500 ft. Forms part of Blueberry Mtn. Marine fossils of Dev. age (probably Lower Dev.) found in fine-grained banded argillites 3,000 ± ft. above base of Upper Sil. [On pl. 13 he assigns these rocks to Helderberg. This argillite appears to be the Blueberry Mtn argillites of Hitchcock.]

Silurian:

1. basic sill, 200 ft.
2. basal series. The lower members of this sed. series are known to be of Niagaran (Upper Sil.) age. They were formerly called Helderbergian. Consist of (descending): (a) Fitch Hill arkose, 200–300 ft.; (b) basic sill (not a part of the series); (c) nonfossiliferous ls. and sl., 150 ft.; (d) calc. sl. with Niagaran fossils, 6–10 ft.; (e) ls. with Niagaran fossils, 30–40 ft.; (f) basal arkose, which may grade locally into qtzite beds, 2–80 ft. Rests uncon. on Fitch Hill granite gneiss, which intrudes Lyman schists (pre-Sil.).

Blueberry Mtn is N. part of ridge 2 mi. W. of Littleton, the S. part of the ridge being called Bald Hill.

†Bluebird aplite.

A name that was applied by W. H. Weed to the aplite in Butte dist., Mont., in Jour. Geol., vol. 7, 1899, pp. 744–747, and U. S. G. S. Bull. 213, 1903, p. 170, but which he mapped as *aplite*, without the geographic name, in U. S. G. S. Butte Special folio, No. 38, 1897. The geographic name is not considered necessary and is not now used by U. S. Geol. Survey.

Bluebird dolomite.

Cambrian (Middle?): Central northern Utah (Tintic district).

G. F. Loughlin, 1919 (U. S. G. S. P. P. 107). *Bluebird dol.*—Dark bluish-gray fine-grained dol. spangled with short white rods averaging 10 mm. (⅖ inch) in length and 1 or 2 mm. in width. Thickness 175 to 200 ± ft. Underlies Cole Canyon dol. and overlies Herkimer ls. North of Eureka Gulch and W. of Cole Canyon is well exposed along backbone of Bluebird Spur for nearly 1,000 feet.

†Blue Bluffs division.

Upper Cretaceous (Gulf series): Central Texas.

R. T. Hill, 1889 (Tex. Geol. Surv. Bull. 4, p. xiii). *Exogyra Ponderosa marls or Blue Bluffs div.*—Underlies Glauconitic div. and overlies Austin-Dallas chalk.

Same as Taylor marl.

Named for blue bluffs of Colorado River, Travis Co.

Blue Canyon formation.

Mississippian: Northern California (Colfax quadrangle).

W. Lindgren, 1900 (U. S. G. S. Colfax folio, No. 66). *Blue Canyon fm.*—Black and fissile clay slates and dark-gray fine-grained qtzitic sss.; only one occurrence of cgl. noted in the fm.; a few ls. lenses and some chert occur in it in E. part of area, including a belt of gray or brown chert referred to as *Duncan chert*. Corresponds to lower part of Calaveras fm. Few fossils not diagnostic, but fm. assigned to Carbf. Underlies Relief qtzite. Oldest fm. exposed in Colfax quad. Named for exposures at village of Blue Canyon, Placer Co.

According to later work by H. G. Ferguson (Am. Inst. Min. and Met. Engrs. Tech. Pub. 211, p. 4, 1929) two fms. (Tightner below and Kanaka above), composed of interbedded sed. and igneous rocks, are now discriminated btw. Relief qtzite and Blue Canyon fm.

Bluecastle sandstone bed. (In Price River formation.)

Upper Cretaceous: Central eastern Utah (Book Cliffs).

D. J. Fisher, 1935 (U. S. G. S. Bull. 852). Cross-bedded ss., medium-to fine-grained, weathering buff to gray. Thickness 0 to 100±ft. Included in Nelson coal-bearing memb. of Price River fm., lying 200±ft. above base of that memb. Is younger than Thompson Canyon ss. bed, and younger than Chesterfield coal zone and Sulphur Canyon ss. bed to E. Named for Bluecastle Canyon. Caps Bluecastle Butte.

†Blue Cliff limestone.

Descriptive term which in early Ohio repts was applied in a titular sense to Springfield ls. (Sil.) of current nomenclature.

Blue Creek series.

Cambrian: Southwestern Oklahoma.

H. F. Bain, 1900 (Geol. Soc. Am. Bull., vol. 11, pp. 135, 138–140). *Blue Creek series.*—Cgls., qtzites, and sss. conformably underlying Rainy Mtn ls. and uncon. overlying older rocks in Wichita Mtns.

Probably same as Reagan ss., later but better established name.

Named for Blue Creek, Comanche Co.

Blue Cut shale.

Lower Cretaceous (Comanche series): Central southern Kansas.

F. W. Cragin, 1895 (Am. Geol., vol. 16, pp. 361, 380). *Blue Cut shales.*—Alternating blue-black and gray argill. shales, with minor beds of sandy sh., ferruginous ss., and shell ls. The zone of typical and abundant *Gryphaea roemeri*. Forms top bed of Fullington shales. Overlies Black Hill sh. (lower bed of Fullington shales) and underlies Tucumcari shales.

Named for the Blue cut, a deep railway cut a few mi. S.-SW. of Belvidere, Kiowa Co.

Blue Earth siltstone.

Lower Ordovician: Southeastern Minnesota (Lesueur County).

L. H. Powell, 1935 (St. Paul Inst. Sci. Mus., Sci. Bull. 1). From Ottawa to Mankato, along Minn. River, the Kasota ss. seems to be everywhere overlain by a thin bed of white to greenish (sometimes red) laminated argill. siltstone—the Blue Earth siltstone—, which seems to spread beyond limits of underlying Kasota ss. and to then rest, apparently conformably, on Jordan ss. The siltstone underlies Oneota dol., or fills irregular solution cavities along more or less vertical joints in Oneota dol. There is sharp break in sedimentation btw. Blue Earth siltstone bed and Oneota dol. Relations of Blue Earth siltstone bed to overlying and underlying fms. are unknown. Because of historical significance of term "Blue Earth," this siltstone is here called *Blue Earth siltstone bed.* It occurs for some distance up Blue Earth River. Thickness at Kasota and Ottawa a few inches (Stauffer found 6 inches at Kasota); Winchell found 3 ft. of the siltstone along Blue Earth River near Mankota; it probably is never much thicker. Assigned to Ord.

A. C. Trowbridge et al., 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., fig. 1), list *Blue Earth siltstone* and *Kasota ss.* as "local fms. in Minn." and place them opposite basal part of Oneota dol.

The U. S. Geol. Survey at present recognizes Oneota dol. as resting on Jordan ss.

Bluefield shale.

Mississippian: Southern West Virginia and southwestern Virginia.

M. R. Campbell, 1896 (U. S. G. S. Pocahontas folio, No. 26, p. 3). *Bluefield sh.*—Transition series from underlying Greenbrier ls. to overlying sandy Hinton fm. Varies from prevailingly calc. at base to sandy at top. Limited above by heavy bed of qtzite forming basal memb. of Hinton fm. Thickness 1,250 to 1,350 ft.

The 1928 prel. ed. of Va. Geol. Surv. geol. map. of Va. redefined Bluefield sh. and Hinton fm. by restricting Bluefield to the prevailingly calc. beds and transferring to overlying Hinton fm. about 200 ft. of shaly or sandy beds included in Bluefield as defined. This is present definition of U. S. Geol. Survey.

Named for exposures at Bluefield, Mercer Co., W. Va.

Bluefield group.

A term applied by W. Va. Geol. Surv. to *Bluefield sh.* of U. S. Geol. Survey repts.

Blue Gate sandstone member (of Mancos shale).

Upper Cretaceous: Central southern Utah (Henry Mountains region).

G. K. Gilbert, 1877 (Geology Henry Mtns, pp. 4+). *Blue Gate ss.*—Heavy-bedded yellow ss., 500 ft. thick, underlying Masuk sh. and overlying Blue Gate sh. in Blue Gate Plateau.

Is now treated by U. S. Geol. Survey as a memb. of Mancos sh. in Henry Mtns region.

†Blue Gate shale. (In Mancos shale.)

Upper Cretaceous: Central southern Utah (Henry Mountains region).

G. K. Gilbert, 1877 (Geology Henry Mtns, pp. 4+). *Blue Gate sh.*—Blue black argill. sh. weathering to a fine gray clay. Thickness 1,000 ft. Underlies Blue Gate ss. and overlies Tununk ss. in Blue Gate Plateau.

Is a part of Mancos sh., but name conflicts with *Blue Gate ss.*, the adopted name.

Blue Grass group.

Middle Ordovician: Central Kentucky.

S. S. Lyon, 1873 (Ohio Geol. Surv. vol. 1, pt. 1, pp. 119–120). *Blue grass group.*—Includes those strata which immediately underlie surface in Blue grass region about Lexington. Consists of thin-bedded lss., abundantly fossiliferous. Underlies Cincinnati group and overlies Birdseye ls. group.

W. M. Linney, 1882 (Ky. Geol. Surv. Mercer Co. Rept., pp. 14–16). *Blue Grass beds.*—Thin-bedded gray lss., with interbedded shales, and near base a layer of dark-gray hydraulic ls.; thickness 90 ft. Underlain by 30 ft. of siliceous ls. and overlain by 25 ft. of granular ls. correlated with Capitol ls. of Tenn. All included in Trenton group.

Named for part of State where the blue grass grows, as these lss. furnish the soil for that grass.

Blue Hill granite porphyry.

Devonian or Carboniferous: Eastern Massachusetts (eastern Norfolk County).

W. O. Crosby, 1880 (Boston Soc. Nat. Hist. Occ. Papers No. 3, with map), mentioned *Blue Hill granite.*

G. R. Mansfield, 1906 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 49, geol. ser. vol. 8, No. 4, p. 100), mentioned *Blue Hills porphyry.*

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 191–194 and map). *Blue Hill granite porphyry.*—Forms all of higher hills of Blue Hills range as far E. as Pine Hill, in Quincy, and their southern slopes, down to margin of Carbf. Norfolk Basin. Is regarded as peripheral zone or shell of Quincy granite stock. Overlies main mass of the granite, into which it grades in places, and from which in other places it is abruptly separated. It also underlies Pondville cgl., to the composition of which it has contributed.

L. LaForge, 1932 (U. S. G. S. Bull. 839). The Quincy granite intrudes Lynn volcanic complex, which is probably contemp. with Mattapan volcanic complex (Dev. or Carbf.).

Blue Hill shale member (of Carlile shale).

Upper Cretaceous: North-central Kansas.

W. N. Logan, 1897 (Kans. Univ. Geol. Surv. vol. 2, pp. 218, 225, 228, 229). *Blue Hill shales.*—Dark-blue, loosely coherent, nonfossiliferous shales, 100 ft. thick, overlying *Ostrea* shales and forming top div. of Victoria clays and of Benton group. Overlain by *Septaria* layer, included in Niobrara.

W. N. Logan, 1899 (Jour. Geol., vol. 7, pp. 83–91), included *Septaria* layer in Blue Hill sh., and subsequent writers, including U. S. Geol. Survey, have followed that definition.

C. H. Dane and W. G. Pierce, 1933 (U. S. G. S. Press Notice, June 8, Geol. and oil and gas prospects in part of eastern Colo.), restricted *Blue Hill sh. memb.* to beds beneath Codell ss. bed of previous repts, and elevated Codell ss. to rank of a memb. of Carlile sh. This is definition at present used by U. S. Geol. Survey and Kans. Geol. Survey.

Apparently named for the Blue Hills, in Mitchell, Russell, and Republic Counties, Kans., which Logan stated "rest upon the *Ostrea* beds and are composed of the Blue Hill shale, capped by a layer of Ft. Hays limestone," and probably also for Blue Hill Twp, Mitchell Co. *Ostrea shales* has been replaced by *Fairport chalky sh. memb.*

†Blue Hills complex.

Cambrian and later and older?: Eastern Massachusetts (Boston Basin).

W. O. Crosby, 1900 (Boston Soc. Nat. Hist. Occ. Papers, vol. 1, pt. 3). *Blue Hills complex* is an area of granitic rocks and associated Camb. strata which includes the Blue Hills proper and extends thence eastward across Quincy and N. parts of Braintree and Weymouth. Includes Middle Camb. slates or *Paradoxides* beds and Lower Camb. or *Olenellus* zone.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597), mapped the rocks of area described above as *Blue Hill granite porphyry, Quincy granite, Braintree sl.* (Middle Camb.), and *Weymouth fm.* (Lower Camb.).

Bluejacket sandstone member (of Cherokee shale north of Arkansas River and of Boggy shale south of Arkansas River).

Pennsylvanian: Northeastern and central eastern Oklahoma and southeastern Kansas. This name was first used in unpublished ms., by D. W. Ohern, on Nowata and Vinita quads.

A. W. McCoy, 1921 (A. A. P. G. Bull., vol. 5, No. 5, pp. 541–550). *Bluejacket ss.* of eastern Okla., which outcrops just W. of Pryor, has been traced S. and SE. and mapped by E. A. Trager, W. R. Berger, F. L. Aurin, and D. K. Greger as a ss. near Warner which occurs in lower part of McAlester sh. A small trilobite horizon about 70 ft. below Bluejacket ss. near Pryor was found below Warner ss. in several places.

C. N. Gould, 1925 (Okla. Geol. Surv. Bull. 35, p. 64). *Bluejacket ss. memb.*, 50 to 60 ft. thick, occurs near middle of Cherokee sh. It consists sometimes of a solid mass of ss. but is usually separated into several beds by intervening shales. *It was named by D. W. Ohern in unpublished mss.*, for exposures near Bluejacket, Craig Co. It is basal sand of Bartlesville group of oil sands. Its base is shown on Miser's geologic map of Okla.

C. W. Wilson, Jr., 1935 (A. A. P. G. Bull., vol. 19, No. 4, pp. 503–520). Uppermost ss. memb. of Savanna ss. S. of Arkansas River, Okla., is same as Bluejacket ss. memb. of Cherokee sh. N. of the river, and is here designated *Bluejacket ss. memb. of Savanna ss.*

C. H. Dane and T. A. Hendricks, 1936 (A. A. P. G. Bull., vol. 20, No. 3, pp. 312–314). Data obtained during 1934 show that *Bluejacket ss.* (the surface equiv. of Bartlesville sand) is = lowest ss. memb. of Boggy sh., instead of uppermost ss. memb. of Savanna ss.

Blue Jay oil sand.

See under *Sheffield oil sand.*

Bluelick limestone. (In Conemaugh formation.)

Pennsylvanian: Western Maryland (Castleman Basin).

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, p. 114). *Bluelick ls.*, 2 ft. thick, underlies fire clay beneath Lonaconing coal and is separated from underlying Upper Hoffman coal by 13 ft. of sh.

Blue Monday sand.

Drillers' name for an oil sand of Upper Dev. or early Carbf. age in NW. Pa. Considered same as Snee sand. Lies lower than Nineveh 30-foot sand.

Blue Mountain series.

Upper Cretaceous and Eocene: Jamaica.

R. T. Hill, 1899 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 34, pp. 41–69).

Blue Mountain formation.

Ordovician: Ontario.

W. A. Parks, 1928 (Roy. Soc. Canada Proc. and Trans., 3d ser., vol. 22, sec. 4, p. 53).

Bluepoint limestone.

Mississippian (upper): Southeastern Nevada (Muddy Mountains).

C. R. Longwell, 1921 (Am. Jour. Sci., 5th, vol. 1, p. 46) and 1928 (U. S. G. S. Bull. 798). *Bluepoint ls.*—Dark-gray to nearly black heavy-bedded ls., with finely granular or dense texture is common rock; heavy beds of lighter gray are not uncommon; gray chert in layers or nodules at some horizons, but less abundant than in underlying Rogers Spring ls., and contains larger percentage of very dark, extremely carbonaceous rock and less coarse granular ls. than the Rogers Spring. Thickness 900± ft. Neither top nor bottom accurately located. Underlies Callville ls. with probable uncon. and there must be uncon. at base but writer failed to detect it. G. H. Girty says fossils are of Brazer age. Named for town in Clark Co.

Blue Rapids shale. (In Council Grove group.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., p. 22). *Blue Rapids sh.* is new name for basal part of Speiser sh. as originally defined. It includes the beds btw. Crouse ls. below and Funston ls. above. Thickness in Nebr. 23 ft. or more, decreasing southward to about 16 ft. at Okla. line.

From Junction City, Kans., southward to Okla. the lower part of the Blue Rapids is a slabby sandy sh. Type loc. in cuts of highway 77, about 1¼ mi. N. of Blue Rapids, Kans.

G. E. Condra, 1935. (See under *Bigelow ls.*)

Blue Rapids sh. as used on p. 66 of Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, Sept. 4 to 7, 1936, is a misprint for *Blue Springs sh.*

†Blue Ridge shale.

Ordovician: Northeastern West Virginia and adjacent parts of Virginia and Maryland.

A. Keith and H. R. Geiger, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 155–164). [In one place the Martinsburg sh. is (evidently inadvertently) called *Blue Ridge sh.*]

†Blue Ridge sandstone.

Silurian and Ordovician: Northeastern West Virginia and adjacent parts of Virginia and Maryland.

A. Keith and H. R. Geiger, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 155–164). [In two places the †Massanutten ss. is (evidently inadvertently) called *Blue Ridge ss.*]

Blue Ridge conglomerates.

See under *South Mountain slates.*

Blue Springs shale. (In Chase group.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., p. 38). *Blue Springs sh.*—Top memb. of Matfield fm. Thickness in Nebr., 28 or 29 ft.; 25 ft. in section E. of Burden, Kans., where it consists of upper and lower shales and a ls. below middle. These units extend N. to beyond Florence and S. to Okla. The ls. is herein named *Bruno ls.*, from exposures on Bruno Creek, a few mi. NE. of Florence, Kans. Type loc. in foot of Blue River bluffs SE. of Blue Springs, Gage Co., Nebr. Overlies Kinney ls. and underlies Florence flint.

Bluestone formation.

Mississippian: Southern West Virginia and southwestern Virginia.

M. R. Campbell, 1896 (U. S. G. S. Pocahontas folio, No. 26, p. 3). *Bluestone fm.*—In general red sh., but contains many beds of impure ls., sometimes conglomeratic, and red ss. of varying thickness and character. At Pocahontas extends upward to coal-bearing series whose base is generally marked by a heavy bed of ss. Probably throughout area of Pocahontas quad. this heavy ss. marks upper limit of red shales, but eastward the red shales extend several hundred ft. higher. Thickness 800 ft. Overlies Princeton cgl. and underlies Pocahontas fm.

Named for Bluestone River, Tazewell Co., Va.

Bluestone group.

A term used by some geologists to include same rocks as Bluestone fm. of U. S. Geol. Survey repts.

Blue Water basalt flow.

See under *Laguna basalt flow.*

Bluff bed. (In Trinity group.)

Lower Cretaceous (Comanche series): Western Texas (El Paso County).

J. A. Taff, 1891 (Tex. Geol. Surv. 2d Ann. Rept., pp. 727, 736). *Bluff bed.*—Consists of (descending): (1) *Caprotina* ls. (third horizon) with *Monopleura;* (2) massive foraminiferal ls., 40 to 100 ft. thick; (3) alternating bands of ss. and siliceous shell brecciate ls., 65 ft. thick, with last *Exogyra texana* horizon 15 ft. above base. Underlies Quitman bed and overlies Yucca bed; all included in Washita div.

C. L. Baker, 1927 (Univ. Tex. Bull. 2745, p. 21). Mountain bed of Taff belongs to Cox ss.; his *Bluff bed* and Quitman bed belong to overlying Finlay ls.

[On p. 25 is statement that Bluff Mesa is capped by *basal* Finlay ls., 200 ft. thick.]

Named for Bluff Mesa, El Paso Co.

Bluff bone bed. (In Wichita group.)

Permian: Central northern Texas (Wichita County).

J. A. Udden and D. M. Phillips, 1912 (Univ. Tex. Bull. 246, pp. 35–42). *Bluff bone bed.*—Calc. bed, 0 to 5 ft. thick, consisting of sand, fragments of fish scales and bones, and rolled lumps of marly clay, embedded in matrix of lime and ocherous material. In some places horizon is marked by ss. containing much calc. material and many fish scales and bones, or by cgl. of rolled lumps of calc. and clayey material embedded in sandy matrix containing fragments of bones and fish scales. Memb. of Wichita fm., lying 32 ft. below top in SW. part of Wichita Co. [Fossils listed.]

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 169, 173), included this bed in Belle Plains fm.

Named for Bluff Creek, S. of Electra, Wichita Co.

Bluff limestone.

Middle Oligocene: Cayman Islands, British West Indies.

C. A. Matley, 1924 (Pan-Am. Geol., vol. 42, pp. 313–315). Massive, white, recrystallized, fossiliferous ls., closely resembling the White ls. of Jamaica, and forming an inner and more elevated platform than Ironshore fm.

Bluff sandstone member (of Morrison formation).

Upper Jurassic: Southeastern Utah (San Juan County).

A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1936 (U. S. G. S. P. P. 183, p. 21). At Bluff the lower part of Morrison fm. is composed of thin red and gray sss. and red shales with highly contorted bedding, overlain by a massive gray ss. that forms the cliffs along San Juan River and is locally known as "Bluff ss."

H. E. Gregory (U. S. G. S. P. P. 188, in press). *Bluff ss. memb.*—White to gray-brown, massive or thick-bedded, cross-bedded ss.; in places thin-bedded; includes quartz aggregates, clay balls, and mudstones. Thickness 100(?) to 350 ft. Is basal memb. of Morrison fm. Rests, with uncon. (?), on Summerville (?) fm. in the San Juan country. Is outstanding topog. feature on both sides of the San Juan at town of Bluff, San Juan Co.

†Bluff formation.

Descriptive term used in early repts on Gulf Coastal Plain and Central States to designate the Pleist. loess, which has a tendency to form bluffs.

Bluff sand.

Drillers' name for Waynesburg ss. memb. of Washington fm. in parts of W. Va. and western Pa. The term has also been applied to 9 other sands in the Greene, Washington, Monongahela, Conemaugh, Allegheny, and Pottsville fms. of western Pa.

Bluff Creek shale member (of Graham formation).

Pennsylvanian: Central Texas (Colorado River region).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 387, 400). *Bluff Creek bed.*—Bluish or yellowish sandy clay, 10 to 75 ft. thick, with 2 to 25 ft. of ss. near top. Fossiliferous. Memb. of Canyon div., near top. Underlies *Campophyllum* bed and overlies Home Creek bed.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31; Univ. Tex. Bull. 2132, pp. 127, 130–137). *Bluff Creek sh.*—Sandy clay and thin calc. sss. 74 ft. thick to N., 30 or 40 ft. thick to S. In places a thin yellow ls. has been mapped in middle portion of the sh., and this may be=Bunger ls. of Young and Stephens Counties. The Bluff Creek bed is lower memb. of Graham fm. in Colorado River valley. Upper part is in places very fossiliferous and fauna is similar to that of Wayland sh. at Gunsight. Overlies Home Creek ls. memb. of Caddo Creek fm. and underlies Gunsight ls. memb. (=Campophyllum bed of Drake).

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501, pp. 197, 221–225). *Bluff Creek* of Drake is here (McCulloch Co.) divided into (descending): (1)

Upper Bluff Creek sh., 50 to 70 ft.; (2) Bunger ls. lentil, 23± ft.; (3) sh., 15 to 20 ft.; (4) White Ranch ls. (new), 2 to 3½ ft.; and (5) Lower Bluff Creek sh., 35 to 45 ft. The latter rests on Home Creek ls.

Named for Bluff Creek, McCulloch Co.

Bluff Dale sand. (In Travis Peak formation.)

Lower Cretaceous (Comanche series): Central northern Texas.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, pp. 152, 154, 462, 463, 464, 474, 491). *Bluff Dale sands.*—Sands, 40 ft. thick. Form top memb. of Basement sands at Glen Rose and vicinity. Underlie Glen Rose fm. Northern equiv. of Hensell sands of Colorado River section.

Named for Bluff Dale, Erath Co., where the sands supply artesian wells.

Bluff Point flagstone.

Name used by P. D. Torrey on a cross section (from Tyrone gas field to Penn Yan, Schuyler, and Yates Counties, N. Y.) on p. 976 of Geol. of nat. gas, A. A. P. G., 1935, for a bed in Standish sh., lying some distance above Crosby ss. Not defined.

†Bluff Springs granite.

Post-Carboniferous: Eastern Alabama (southeastern part of Clay County).

W. F. Prouty, 1923 (Ala. Geol. Surv. County Rept. No. 1, pp. 16, 51, 52, 53, 62, 65). Biotite granite of same character as Pinckneyville granite, exposed in SE. part of Clay Co., and locally designated as *Bluff Springs granite.* Reaches max. width a little N. of Bluff Springs. [Mapped as *Pinckneyville granite* by Prouty in rept. above cited, also by G. I. Adams, Ala. Geol. Surv. geol. map of Ala., 1926. Is intrusive.]

Named for development around Bluff Springs, Clay Co.

Bluffton moraine.

A Pleist. moraine (of Wisconsin stage) in northern Ind. (See U. S. G. S. Mon. 53, 1915, table opp. p. 30.)

†Blufftown marl.

Upper Cretaceous: Western Georgia.

J. O. Veatch, 1909 (Ga. Geol. Surv. Bull. 18, pp. 86, 88–89). *Blufftown marl.*—Black lignitic clays, gray calc. and argill. sand, and thin layers of nodular calc. rock. Thickness 200 ft. Basal div. of Ripley fm. Underlies Cusseta sand. Overlies Eutaw fm. Below Florence, Stewart Co., it probably merges with the younger Renfroes marl.

According to later studies of J. O. Veatch and L. W. Stephenson, the lower part of Blufftown marl was considered to belong to Tombigbee sand memb. of Eutaw fm. and upper part to Ripley fm., and the name was discarded. (See Ga. Geol. Surv. Bull. 26, pp. 135, 152, 1911, and U. S. G. S. W. S. P. 341, p. 65, 1915. Also see under *Cusseta sand memb.*) The "Blufftown" is now considered to be = Tombigbee sand memb. only. Named for exposures at Blufftown, Stewart Co.

Bob crystalline limestone member (of Brownsport formation).

Silurian (Niagaran): Western Tennessee.

W. F. Pate and R. S. Bassler, 1908 (U. S. Nat. Mus. Proc. vol. 34, pp. 410–432). *Bob fm.*—Basal 5 to 30 ft. (*Uncinulus* zone) red ls. and shales in lower two-thirds, overlain by gray massive ls.; very similar lithologically to Dixon fm. Middle 25 to 42 ft. white, yellow, blue, and grayish shales and lss. holding abundance of brachiopods and called *Dictyonella* zone. Uppermost 15 ft. massive nodular cherty ls. or hard sh., called *Conchidium* zone, because brachiopods of genus *Conchidium* are most characteristic fossil. Is middle fm. of Brownsport group. Overlies Beech River fm. and underlies Lobelville fm.

Now treated as middle memb. of Brownsport fm.

Named for Bob Landing, Decatur Co.

Bob Wright coal group.

A group of coal beds in Blackhawk fm., of Mesaverde group (Upper Cret.), in Castlegate region, Utah.

Bodcaw sand lens.

A Lower Cret. subsurface sand, few ft. to 20 ft. thick, belonging to Davis oil and gas horizon in Webster Co., NW. La. Named for lease on which first producing well was drilled. (See under *Davis oil and gas horizon.*)

Bodega diorite.

Jurassic? (pre-Franciscan): Western California (Marin County).

V. C. Osmont, 1904 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 4, p. 43). *Bodega diorite.*—Bodega Peninsula is made up almost wholly of this rock, which is a biotite diorite. The E. shore of Bodega Bay, however, is entirely Franciscan. Point Reyes Peninsula, to S., is composed largely of this diorite and granite. There are two varieties, one biotite diorite and the other quartz diorite. Best exposures of this diorite occur on ocean side of Bodega Peninsula, at S end, where it forms steep cliffs 50 to 80 ft. high.

Bodega Bay deposits.

Quaternary: Western California (Marin County).

V. C. Osmont, 1904 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 4, p. 76). *Bodega Bay deposits.*—At Bodega Bay similar deposits [to those described as Tomales Bay deposits] occur on both sides of bay, but only in small patches, most of them having been removed by erosion. Near Bodega Point, on bay side, is a remnant resting upon a wave-cut shelf just about at high-water mark and extending up to 113 ft. above it, consisting principally of diorite sands and occasional pebbles showing very indistinct horizontal stratification and cross bedding. On ocean side of peninsula occasional still smaller patches, some 20 to 30 ft. thick, may be seen resting on a very evenly worn diorite surface, which about 3 mi. S. of mouth of Salmon Creek dips gently to N. and passes under the beach and eolian sands. On E. side of bay is a broad, flat terrace about ¼ mi. wide and some 75 to 90 ft. above sea level at its back. In most places only a thin veneer of gravel covers this terrace, but at one point on shore, at N. end of bay, a remnant of gravel some 50 ft. thick rests on worn Franciscan surface, which is here only 20 ft. above sea level. It is composed chiefly of Franciscan pebbles, and loosely coherent sands showing cross bedding. Is somewhat distorted, and dips slightly to N.

†Bodeville series.

Pre-Cambrian (Llano series): Central Texas.

T. B. Comstock and E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. lvi, 255–267). *Bodeville series.*—Mica and chloritic schists, chiefly acidic, forming top div. of Burnetan system. Probably overlies Long Mtn series. Uncon. underlies Valley Spring gneiss.

A part of either Packsaddle schist or Valley Spring gneiss of present nomenclature.

Named for Bodeville, Mason Co.

Bogachiel formation.

Cretaceous (?): Northwestern Washington.

A. B. Reagan, 1909 (Kans. Acad. Sci. Trans., vol. 22, p. 160). *Bogachiel fm.*—Several thousand ft. of soft to hard green sl. (talc) interbedded with gray ss. and some sh. Greatest development in Bogachiel Valley, near headwaters of that stream. Is pitched nearly to vertical position, with trend of dip btw. SE. and NW. and E. and W. The Bogachiel and Hoh Rivers have cut channels in it. No fossils, but believed to be Cret. Uncon. underlies Soleduck fm.

Boggs member. (In Pottsville formation.)

Pennsylvanian: Southeastern Ohio (Muskingum County).

W. Stout, 1918 (Ohio Geol. Surv., 4th ser., Bull. 21, p. 70). *Boggs memb.*—Hard, dense, bluish gray, fossiliferous, rather siliceous, marine ls.; in places represented in part or wholly by flint and iron ore. Thickness 1 to 3 ft. Lies 9 ft. 4 in. below Flint Ridge coal and 0 to 5 ft. above Lower Mercer or No. 3 coal in Muskingum Co. Is correlated with confidence with Boggs iron ore of Scioto Co., hence name.

Boggy shale.

Pennsylvanian (Allegheny): Central southern and eastern Oklahoma and western Arkansas.

J. A. Taff, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, p. 438). *Boggy sh.*—Alternating shales and sss., nearly 3,000 ft. thick, overlying Savanna ss. and underlying Thurman ss. Contains not less than 16 beds of ss., 20 to 150 ft. thick, separated by sh. beds 100 to 600 ft. thick.

Named for exposures along North Boggy Creek, Pittsburg and Atoka Counties, Okla.

The base of Boggy sh. in McAlester dist. is now drawn by U. S. Geol. Survey at base of or 20± ft. below Lower Witteville coal.

Bogue Island formation.

Pleistocene: Jamaica.

R. T. Hill, 1899 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 34, p. 103).

Bogus tongue (of Cutler formation).

Permian: Central eastern Utah (Moab region).

A. A. Baker, 1933 (U. S. G. S. Bull. 841). *Bogus tongue of Cutler fm.*—Red arkosic ss. and red mudstone forming top part of Cutler fm. in Moab region S. of Indian Creek. Max. thickness 100± ft. Overlies Cedar Mesa ss. memb. of Cutler, which consists of massive cross-bedded white to pale red ss. Uncon. underlies Moenkopi fm. (Lower Triassic). Crops out in Bogus pocket, SW. corner of T. 30 S., R. 21 E., San Juan Co. May or may not be continuous with Organ Rock tongue of Cutler fm. in Monument Valley.

Bohemia conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan.

L. L. Hubbard, 1898 (Mich. Geol. Surv. vol. 6, pt. 2, pp. 3, 30, 52, 66, 72, 83, 99, plates 4 and 7). Beginning near end of the [Keweenaw] Point, at bottom of the series as exposed, at contact with Potsdam or Eastern ss., we find in Bohemian Range a succession of both basic and acid volcanics, frequently in alternation with detrital beds of similar composition, the whole capped by an extensive and rather persistent bed of fairly coarse and rather acid cgl. This bed, which in following pages I shall provisionally call "Bohemia" cgl., skirts N. side of this range near its summit. Above it comparatively few cgls. occur until we reach the so-called Ashbed group above the Greenstone. It is a triple complex cgl. and is same as St. Louis cgl.

Is top fm. of Bohemian Range group.

Named for fact it caps Bohemian Range, in Keweenaw Co.

Exposed N. of Mount Bohemia.

Bohemia porphyrite.

Pre-Cambrian (Keweenawan): Northern Michigan.

L. L. Hubbard, 1898 (Mich. Geol. Surv. vol. 6, pt. 2, pp. 40 and 72). Mapped as older than Bohemia cgl. and younger than Lac la Belle cgl.

Belongs to Bohemian Range group.

Named for fact it occurs N. of Mount Bohemia, Keweenaw Co.

Bohemian Range group.

Pre-Cambrian (Keweenawan): Northern Michigan and probably northern Wisconsin.

R. D. Irving, 1883 (U. S. G. S. Mon. 5, pp. 179–187, pls. 17 and 18). A series of flows, consisting of diabase, diabase amygdaloid, melaphyr, diabase porphyry, and orthoclase gabbro, including cgl. beds and quartz porphyry and granite porphyry. Underlies Central Valley beds. Forms lower part of Keweenawan series of Keweenaw Point, Mich. Thickness 10,000 ft.

According to A. C. Lane (Mich. Geol. and Biol. Surv. Pub. 6, geol. ser. 4, 1911) the Bohemia (No. 8) cgl. is top fm. of the group, which is uncon. underlain by Huronian series.

Named for fact its rocks compose Bohemian Range, Keweenaw Co., Mich.

†Bohicket marl sands.

Pleistocene: Southern South Carolina (Charleston County).

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv. ser. 4. Bull. 2) and 1907 (Summary of mineral resources of S. C., pp. 12, 20, 21). *Bohicket marl sands.*—A bed of exceedingly fine grained sands about 5 ft. thick. The color is rendered gray-green and yellow-red, probably by fine glauconitic inclusions, portions of which have been more or less weathered, with effect of rendering the mass semi-plastic with residual clay; the iron has in part leached out, and cemented to "hard pan," a thin portion of the material immediately above the phosphate rock. Immediately overlies Wadmalaw marls and extends over Wadmalaw shell-marl, into which it grades. It overlaps typical Wadmalaw shell-marl and extends over a great portion of the phosphate rock area as far N. as Ten Mile Hill. Is overlain by Accabee gravels. Is a marine deposit.

C. W. Cooke, 1935 (personal communication). Is a facies of Pamlico fm.

Named for exposures in Bohicket Creek, near Rockville, Charleston Co.

Bohio limestone.

Eocene (upper): Panama.

E. Howe, 1907 (Isthmian Canal Comm. Rept., pp. 108, 139). [Contains upper Eocene fossils.]

Bohio conglomerate.

Oligocene (?): Panama Canal Zone.

D. F. MacDonald, 1913 (Geol. Soc. Am. Bull., vol. 24, p. 708).

Bois d'Arc limestone.

Lower Devonian (Oriskany and Becraft?): Central southern Oklahoma.

C. A. Reeds, 1911 (Am. Jour. Sci., 4th, vol. 32, pp. 256–268). *Bois d'Arc ls.*—Thin-bedded, crystalline and noncrystalline ls., with occasional chert lentils and thin beds of intercalated yellowish sh. Lower part has New Scotland aspect, but is more nearly Becraft than New Scotland of N. Y. It may yet be determined that upper 40 ft. is Oriskany in age. Thickness 0 to 90 ft.; average 60 ft. Originally included as top div. of Hunton fm. Overlies Haragan sh.

C. Schuchert, 1922 (Geol. Soc. Am. Bull., vol. 33, p. 667). *Bois d'Arc ls.* contains upper Oriskany fossils in upper 5 to 8 ft., and Helderberg fossils in lower part. In all probability it does not pass unbroken into the Haragan. All lower Oriskanian is absent in Arbuckle Mtns.

C. A. Reeds, 1926 (Am. Mus. Nat. Hist. Jour., vol. 26, pp. 470–474). Top fm. of Hunton group is here named *Frisco ls.*, 0 to 20 ft. thick. It rests on Bois d'Arc ls. [restricted], 0 to 90 ft. thick, which contains abundant fauna that indicates Becraft age. Fauna of Frisco ls. is Oriskany. The Frisco is best exposed in bed and bank of Bois d'Arc Creek and in vicinity of Coal Creek, 7 mi. S. of Frisco.

E. O. Ulrich, 1927 (Okla. Geol. Surv. Bull. 45, p. 32). *Bois d'Arc ls.* is evidently of early Oriskany age.

Named for exposures along Bois d'Arc Creek, Pontotoc Co.

Boise granite.

Jurassic or Cretaceous: Southwestern Idaho (Boise Mountains).

I. C. Russell, 1902 (U. S. G. S. Bull. 199, p. 39). The terrane named "Boise granite" by Lindgren, from which the rugged mtns which lie to N. and E. of Boise have been sculptured, extends eastward from this area and occupies an extensive and exceedingly rugged region lying N. of Mountain Home. As stated by Lindgren, the granite is intrusive and of ancient date (perhaps pre-Algonkian). [The compiler has been unable to find where Lindgren named this granite. In U. S. G. S. 18th Ann. Rept., pt. 3, 1898, he mapped and described the *granite of Boise Mtns.* He also mapped the granite in U. S. G. S. 20th Ann. Rept., pt. 3, pl. 8, 1900, but did not apply a geographic name to it. The granite is a part of the enormous Idaho batholith (which is now regarded as probably of Jurassic or Cret. age, but possibly younger) and a special geographic name for it does not appear to U. S. Geol. Survey to be necessary.]

Boise sandstone.

Pliocene (?): Southwestern Idaho.

V. R. D. Kirkham, 1928 (Idaho Bur. Mines and Geol. Pam. 29, p. 1). Massive grit or ss. locally known as *Boise ss.* This fm., along with a varying thickness of sandy and shaly layers, is assigned to Poison Creek fm., of probable Plio. age.

Boissevain sandstone.

Tertiary: Winnipeg region, Canada.

W. A. Johnston, 1934 (Canada Dept. Mines, Geol. Surv. Mem. 174, p. 11).

Bokchito formation.

Lower Cretaceous (Comanche series): Southeastern and central southern Oklahoma.

J. A. Taff, 1902 (U. S. G. S. Atoka folio, No. 79). *Bokchito fm.*—Chiefly clay and sandy clay, with beds of friable ss., siliceous shell ls., and iron-stone segregations and concretions. Thickness 140 ft. Underlies Bennington ls. and overlies Caddo ls.

Named for Bokchito Creek, near Bokchito, Bryan Co.

Bolin sandstone member (of Roubidoux formation).

Lower Ordovician (Beekmantown): Central Missouri (Miller and Morgan Counties).

S. H. Ball and A. F. Smith, 1903 (Mo. Bur. Geol. and Mines vol. 1, 2d ser., p. 50). *Bolin Creek ss. memb.*—Heavy deposits of ss., 1 to 50 ft. thick, occurring as massive beds and as a number of thinner beds in uninterrupted succession in St. Elizabeth [Roubidoux] fm. to S. of Osage River, in Miller Co.

E. R. Buckley, 1903 (Mo. Bur. Geol. and Mines vol. 1, 2d ser., pp. xii–xv). St. Elizabeth fm. includes all of so-called Second ss. and parts of Second (Jefferson City) and Third (Gasconade) Mag. ls. fms. Ball and Smith found that in some places the ss. has a development of 6 to 50 ft. over sufficient area to warrant distinguishing and mapping it as a memb. or lentil in St. Elizabeth fm. On map all these lenses have been called *Bolin Creek ss.*, although it is not known that they all constitute a part of same horizon. In fact, in some instances the evidence gathered by Mr. Smith indicates such is not the case. However, the name *Bolin Creek ss.* has been made to apply to any of the several ss. lenses occurring in St. Elizabeth fm. in Miller Co.

C. F. Marbut, 1908 (Mo. Bur. Geol. and Mines vol. 7, 2d ser.), described Roubidoux fm. of Morgan Co. as consisting of (descending): (1) "Cotton rock" (fine-grained ls.); (2) *Bolin ss. memb.* (persistent, consisting of 10 ft. of gray and reddish sand, 8 to 15 ft. of ls. and chert, and 10 ft. of gray and reddish sand); (3) cherty mag. ls. and chert; (4) ss. in some places, heavy-bedded brecciated chert in other places.

C. L. Dake, 1918 (Mo. Bur. Geol. and Mines vol. 15, 2d ser.), described Roubidoux fm. of Mo. as consisting of (descending): (1) dol. and sss.; (2) *Bolin Creek ss. memb.*, 0 to 50 ft., cross bedded and ripple marked; (3) dol. and sss.

C. L. Dake, 1922 (Pan-Am. Geol., vol. 37, No. 4), described Roubidoux ss. as a succession of beds in which lateral gradations from ss. into chert or ls. are the rule, and while one section may be almost wholly ss., another may be over three-fourths ls., the lss. becoming more abundant to E., W., and probably to S. The fm. is notably cross bedded and ripple marked.

Named for exposures on Bolin Creek, Miller Co.

This name as used by U. S. Geol. Survey is applied locally to a ss. memb. of Roubidoux fm. in Miller and Morgan Counties, the typical region.

Bolinas sandstone.

Jurassic (?): Western California (San Francisco region).

R. Arnold, March 1902 (Sci., n. s., vol. 15, table on p. 416). *Bolinas ss.* (volcanics), 2,000 ft. thick. A div. of the Franciscan. [Shown in table as underlying Sausalito cherts and overlying volcanics that are younger than Calera ls.]

A. C. Lawson, February 1903 (Geol. Soc. Am. Bull., vol. 13, pp. 544–545). [Same as above.]

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). [The Franciscan rocks of Bolinas Ridge, also of shore of Bolinas lagoon and shore of Bolinas Bay (all in Marin Co.), are mapped as undiff. sss. of Franciscan group, with radiolarian chert lentils of undet. horizons, but in other parts of region the rocks btw. Sausalito chert and Calera ls. are mapped as upper part of Cahil ss.]

†Bolin Creek sandstone member (of Roubidoux formation).

See under *Bolin ss. memb.*

Bolivar sandstone. (In Allegheny formation.)

Pennsylvanian: Western Pennsylvania.

J. J. Stevenson, 1878 (2d Pa. Geol. Surv. Rept. K_3). *Bolivar ss.*, 25 ft. thick in Fayette and Westmoreland Counties, lies 31 ft. below Lower Kittanning coal and 5 ft. above Clarion coal.

This ss. has been correlated with Kittanning ss. memb., but B. L. Miller, 1925 (Pa. Geol. Surv., 4th ser., Bull. M7, p. 273), places it beneath Vanport ls. memb.

Bolivar fire clay. (In Allegheny formation.)

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

I. C. White, 1891 (U. S. G. S. Bull. 65, pp. 159–160). *Bolivar fire clay.*—Where Upper Freeport ls. is absent or only slightly developed, there usually comes into the section at this horizon a bed of excellent fire clay, which from having long been mined near Bolivar, Westmoreland Co., Pa., is generally known as Bolivar clay.

E. V. d'Invilliers, 1895 (2d Pa. Geol. Surv. vol. 3, pt. 2). The Freeport upper fire clay, occurring a short distance below Freeport upper ls., is known as "Bolivar fire clay."

G. H. Ashley, 1908 (Topog. and Geol. Surveys Pa.). *Bolivar fire clay* lies short distance below Upper Freeport ls.

B. L. Miller, 1925 (Pa. Geol. Surv., 4th ser., Bull. M7, pp. 261, 316). *Bolivar fire clay* underlies Upper Freeport ls.

Bolivar sandstone.

Lower Ordovician (Beekmantown): Southwestern Missouri.

E. M. Shepard, 1904 (Bradley Geol. Field Sta. Drury Coll. Bull. 1, pt. 1, p. 42). *Bolivar ss.*—Used in table only, as = Marshfield ss., First ss., Pacific ss., and Crystal City ss.

H. F. Bain and E. O. Ulrich, 1905 (U. S. G. S. Bull. 260, p. 234, and Bull. 267, p. 12), doubtfully correlated *Bolivar ss.* with Roubidoux fm.

E. M. Shepard, 1907 (U. S. G. S. W. S. P 195). Marshfield and *Bolivar ss.* are commonly believed to represent St. Peter ss., but Ulrich regards them as lenses in Jefferson City ls. [broad sense].

The 1922 geol. map of Mo. shows Jefferson City dol., Cotter dol., and Powell dol. to be the surface rocks at and around Bolivar, Polk Co.

J. Bridge, 1930 (personal communication), stated that this ss. is either equiv. to Marshfield ss. or represents some of the basal Penn. sands.

Bolivar sand.

Name applied by drillers in some early repts. to Richburg or Allegany oil sand of Allegany Co., N. Y.

Bolsa quartzite.

Middle Cambrian: Southeastern Arizona.

F. L. Ransome, 1904 (U. S. G. S. P. P. 21, pp. 28–30). *Bolsa qtzite.*—Consists of (descending): (1) Thinner bedded [than below], more vitreous, fine-grained qtzites showing no feldspathic material; (2) hard pebbly grits in beds 10 to 20 ft. thick, cross bedded in lower part; (3) cgl. at base, ½ to 1 ft. thick. Thickness 430 ft. Rests uncon. on pre-Camb. schists and is conformably overlain by Abrigo ls. Is without much doubt = Tonto ss. of Grand Canyon. Well exposed in newly named Bolsa Canyon, on SW. side of Escabrosa Ridge, Bisbee quad. [For reason for introduction of name see entry No. 2 under *Dragoon qtzite.*]

Bolsa zone.

An oil-producing zone, 600 to 800 ft. thick, in Huntington Beach oil field of Orange Co., Calif. Consists of sands, sandy shales, and thin sands. Its top lies at depth of about 1,914 ft. H. S. Gale (A. A. P. G. Bull., vol. 18, No. 3, 1933, p. 330) assigned it to Repetto siltstone (lower Plio.).

Bolsa Chica oil sand.

A subsurface sand, lying at 7,670 ft. depth, in Kettleman Hills, King Co., Calif., sec. 24, T. 22 S., R. 17 E.

Bolton schist.

Carboniferous (?): Central northern Connecticut.

J. G. Percival, 1842 (Conn. Geol. Surv. Rept., pp. 229–233 and map). *Bolton mica sl. fm. (No. 3 of group C of Eastern Primary system).*—Appears as a narrow micaceous band btw. two parallel granitic ranges. Throughout whole extent the predominant rock is a soft dark or light bluish (lead) gray mica sl., with garnets and staurotides and, more rarely, with kyanites. Is prevailingly coarse grained, thin and uneven, but thicker and more even quartzose varieties occur in different parts of the range. Occupies W. part of town of Bolton [Tolland Co., Conn.].

The rocks in Mass. that have been called "Bolton schist" were divided by B. K. Emerson (U. S. G. S. Bull. 597, 1917) into Quabin qtzite and Amherst schist.

Bolton mica slate.

See under *Bolton schist.*

†Bolton gneiss.

Late Carboniferous or post-Carboniferous: Eastern Massachusetts (Worcester County).

B. K. Emerson and J. H. Perry, 1903 (Geol. of Worcester, with map, p. 79). *Bolton gneiss.*—Passes into Paxton schist to W., and is the Carbf. micaceous qtzite made gneissoid by abundant injection of granite btw. its laminae. Named for town of Bolton, which it extends through. Includes Millbury ls. and other lss.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 80–87, 219). *"Bolton" gneiss.*—A complex of mica gneiss, chiefly biotitic, but in places containing muscovite, with which is associated some hornblende gneiss. Has been closely folded, and greatly squeezed, and much of it is closely and intricately plicated. Is certainly in part sedimentary and almost certainly in part igneous, but the two sorts of rock are so complexly interbedded and folded that in many places they can be distinguished with difficulty, if at all, and in most places to map them separately is out of question. This complex has been called Bolton gneiss, but that name is preoccupied by a fm. in Conn., and its use in this connection is discontinued. Adoption of a new name postponed until the rocks have been studied more closely and an agreement has been reached, if possible, regarding their age and correlation. Are typically exposed in towns of Bolton and Berlin. Correlated with Brimfield schist and Paxton quartz schist. [Explains conflicting views regarding age and correlation.]

Bolton moraine.

Pleistocene (Wisconsin stage): Southern Ontario. Shown on moraine map (fig. 8) in U. S. G. S. Niagara folio (No. 190), 1913, p. 17.

Bolton igneous series.

Late Devonian or post-Devonian: Quebec.

T. H. Clark, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 1, p. 11).

Bolza quartzite.

Cambrian: Mexico (Sonora).

N. L. Taliaferro, 1933 (Jour. Geol., vol. 41, No. 1, p. 18).

Bomoseen grit.

Lower Cambrian: Eastern New York (Washington and Rensselaer Counties) and southwestern Vermont (Bennington and Rutland Counties).

R. Ruedemann, 1914 (N. Y. State Mus. Bull. 160, pp. 67–70 and map). *Bomoseen grit.*—Olive green grit, nearly a pale brick red, in places associated with a bed of qtzite 12 to 55 ft. thick. Underlies Mettawee sl. in Washington Co., N. Y.; in Rensselaer Co. it underlies Diamond Rock qtzite and overlies Nassau beds—all Lower Camb. Thickness 50 to 200 ft. Type loc. on W. side of Lake Bomoseen, Vt. [Castleton quad., Rutland Co.].

Bonair sandstone. (In Lee group.)

Pennsylvanian (lower Pottsville): Central Tennessee.

M. R. Campbell, 1899 (U. S. G. S. Standingstone folio, No. 53, p. 3). *Bonair cgl. lentil of Lee fm.*—Coarse ss. or cgl., 100 to 200 ft. thick, forming massive cliffs along W face of table-land from Bonair to Monterey, where it suddenly disappears, apparently breaking down into sandy sh., which can not be distinguished from underlying and overlying shales. At Bonair it rests on 110 ft. of sh., which overlies Bonair coal and forms basal part of Lee fm. Where this sh. is absent the cgl. rests on Bonair coal or on underlying Pennington sh. Separated from younger Rockcastle cgl. lentil of Lee fm. by about 125 ft. of sh.

Belongs to Lee group, of lower Pottsville age. Underlies Vandever sh. and overlies Whitwell sh., all fms. of Lee group. (See C. Butts and W. A. Nelson, Tenn. State Surv. Bull. 33D, 1925.)

Named for Bonair, White Co.

†Bon Air Measures.

Pennsylvanian: Southeastern Tennessee.

J. M. Safford and J. B. Killebrew, 1900 (Elements of geol. of Tenn., pp. 104, 148–151, 167, 168). *Bonair or Lower Coal Measures.*—Alternating shales and sss., with coal beds, and with Sewanee cgl. (70 ft. thick) at top. [Later studies by C. Butts show that this cgl. is Bonair ss. and that †Bon Air Measures are all above true Sewanee cgl.] Thickness 250 to 500 ft. Underlies Tracy City Measures. Overlies Mountain ls.

Preoccupied by Bonair ss. Included part of Lee group, of lower Pottsville age.

Named for important mines in White Co.

Bon Ami beds.

Devonian: Quebec.

J. M. Clarke, 1913 (12th Int. Geol. Cong. Guidebook 1, p. 89).

Bon Ami andesite.

Devonian: New Brunswick.

W. V. Howard, 1926 (Geol. Soc. Am. Bull., vol. 37, p. 477).

Bonanza latite.

Tertiary: Southern Colorado (Bonanza district, Saguache County).

H. B. Patton, 1916 (Colo. Geol. Surv. Bull. 9, pp. 21–63). *Bonanza latite.*—Usually gray, grayish black when fresh, sometimes brown, fine-grained, with phenocrysts of feldspar and often biotite. Is country rock of most of Bonanza dist.

W. S. Burbank, 1932 (U. S. G. S. P. P. 169). *Bonanza latite.*—Mostly flows; some tuff and breccia in upper part. Overlies Rawley andesite. Thickness 500 to 1,000 ft. The Bonanza latite of Patton applied to only the lower flow or series of flows of this fm. The name as here applied includes all lavas that lie stratigraphically btw. Rawley andesite and Squirrel Gulch latite.

Bonanza group.

Upper Triassic and Lower Jurassic(?): Vancouver Island, British Columbia.

H. C. Gunning, 1933 (Canada Geol. Surv. Summ. Rept., pt. A2, p. 34).

Bonanza King formation.

Middle Cambrian: Southeastern California (San Bernardino County).

J. C. Hazzard and J. F. Mason, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 2, pp. 229–240). *Bonanza King fm.*—Consists of (descending): (1) Sandy dol. and platy sh., thin; (2) light-gray, fine- to medium-grained dol., 200 to 225 ft.; (3) *Silver King dol. memb.*, 200 to 250 ft.; (4) nodular and lenticular chert underlain by light- and dark-gray dol., 900± ft.; (5) sandy, reddish, platy dol., 25 to 30 ft.; (6) light- and dark-gray dol. and partially dolomitized ls., 600 to 650 ft. Thickness of fm., 2,000± ft. Poorly preserved fossils in lower 100 ft. in Providence Mtns indicate Middle Camb. Overlies Cadiz fm. (Middle Camb.) and underlies Cornfield Springs fm., in part at least Middle Camb. Occurs in Providence and Marble Mtns. Named for Bonanza King Mine, on E. side of Providence Mtns.

Bonaparte marble.

Mississippian: Southeastern Iowa.

C. H. Gordon, 1895 (Iowa Geol. Surv. vol. 4, p. 211). A few ft. of ls. appears at Des Moines River level on S. side, about half way btw. Bentonsport and Bonaparte [Van Buren Co.], which may represent uppermost part of Upper Burlington ls. These beds have been penetrated at Bonaparte and are there called "Bonaparte marble."

Bonaventure formation.

Bonaventure conglomerate.

Bonaventure series.

Mississippian or Pennsylvanian: Quebec and New Brunswick.

E. J. Chapman, 1863 (Canada Inst., n. s., vol. 8, pp. 450–451). *Bonaventure fm.*, Carbf., Canada.

All writers appear to have classified *Bonaventure fm.* as Carbf. until R. W. Ells (Canada Geol. Surv. Rept. 1880–82, p. 3D, 1883) stated that in New Brunswick it is partly Dev. G. A. Young (Canada Geol. Surv. Summ. Rept. 1909, p. 220, 1910; and Mem. 18, p. 52, 1911) assigned it to Dev., J. M. Clarke, 1913 (12th Int. Geol. Cong. Guidebook 1, p. 91) and 1915 (N. Y. State Mus. Bull. 177, p. 152) assigned *Bonaventure cgl. to* Devono-Carbf.; H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 212) assigned *Bonaventure fm.* to Carbf.; J. M. Clarke, 1920 (N. Y. State Mus. Bull. 219, 220, p. 147) assigned *Bonaventure cgl.*, to Dev.; F. J. Alcock, 1922 (Canada Geol. Surv. Summ. Rept., 1921, pt. D, p. 82) assigned *Bonaventure series* to Devono-Carbf.; J. M. Clarke, 1924 (N. Y. State Mus. Bull. 251, pp. 123–127) assigned *Bonaventure fm.* to early Carbf. or late Dev.; C. Schuchert and J. D. Dart, 1926 (Canada Geol. Surv. Bull. 44, p. 53) assigned *Bonaventure series* to Dev.; C. Schuchert, 1930 (Am. Jour. Sci., 5th, vol. 20, p. 175) assigned it to late Lower Carbf.; W. A. Parks, 1931 (Geol. Soc. Am. Bull., vol. 42, p. 795) assigned *Bonaventure fm.* to Miss.

See also E. M. Kindle, 1930 (Canada Geol. Surv. Dept. Mines Summ. Rept. 1928, pt. C, pp. 82C–89C, pl. opp. p. 82C).

C. H. Kindle, 1936 (Eastern Geol., No. 1, April 1936, p. 5). *Bonaventure fm.* consists mainly of red sss. and ls. cgls. West of Mal Baie (where it is flat) and on S. border of it (where it is upturned and in places overthrust) the fm. is thinner than elsewhere and may be divided into a lower cgl., a middle red sh. zone, and an upper light-colored ss. In this upper ss. occur carbonized logs and tree stumps and also casts of smaller plants, such as *Calamites*, which Dr. Bell of

Canadian Geol. Surv. has examined and concluded represent lower Penn. or possibly upper Miss. time. [In heading, *Penn.* (?) is used; on maps, *Penn.*, without a query.]

Bonavista formation.

Lower Cambrian: Newfoundland.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4). *Bonavista fm.*—Red and green shales with ls. nodules. Contains *Coleoloides*, etc. Basal fm. of Etcheminian series. Underlies Brigus fm. and uncon. overlies Algonkian Random fm. (Keweenawan). [Derivation of name not stated.]

Bond sand.

A subsurface sand in Strawn fm. (Penn.) of Bryson oil field, Jack Co., Tex.

†Bone Canyon member.

†Bone Canyon limestone.

Permian: Western Texas (Guadalupe Mountains, Sierra Diablo, etc.).

P. B. and R. E. King, 1929 (A. A. P. G. Bull., vol. 13, pp. 921, 922, 925). *Bone Canyon memb.*—Black ls. containing fossils of Leonard age, uncon. underlying Delaware Mtn ss. (restriction of name) in Bone Canyon, on W. side of Guadalupe Mtns. A short distance N. of Bone Canyon a wedge of gray ls. (here named *Victorio Peak memb. of Leonard fm.*) appears beneath the uncon. at base of Delaware Mtn ss., and separates Bone Canyon memb. from that ss. Thickness 500 to 1,000 ft. Conformably overlies 500 ft. of massive ls. containing rich Hess fauna.

See *Bone Spring ls.*, the approved name.

†Bone Lake crystalline schists.

Pre-Cambrian (middle Huronian): Northwestern Michigan (Crystal Falls district).

J. M. Clements, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, pp. 60+). *Bone Lake crystalline schists.*—Certain crystalline schists which are best developed in N. part of Crystal Falls dist., in vicinity of Bone Lake. They are fine to medium grained, and vary in color from moderately light green for the more chloritic phases to very dark green or purplish black for those in which hornblende, mica, and iron ores are prominent. They are but extremely metamorphosed members of Hemlock volcanic fm. Outcrops scarce except in vicinity of Bone Lake.

Bone Spring limestone.

Permian: Western Texas (Guadalupe and Delaware Mountains).

W. G. Blanchard, Jr., and M. J. Davis, 1929 (A. A. P. G. Bull., vol. 13, p. 962, pls. 10, 11). The basal dark ls. series in Guadalupe and Delaware Mtns is here designated *Bone Springs ls.*, although its correlatives elsewhere will continue to be called *Leonard fm.* Named for Bone Springs Canyon, which opens in sec. 2, Blk 66, NW. part of Culberson Co. The series will not here be included in Delaware Mtn fm., because of faunal difference, lithologic dissimilarities, and angular uncon. that separates the two. Upper part is gray ls., lower part is black ls. Cross bedding is noticeable at many points in both black and gray phases along Guadalupe scarp. North of Bone Springs Canyon a mass of hard, gray hackly ls., which evidently has been removed at Bone Springs Canyon, comes into the series. It lies conformably on top of the black ls. The gray and black phases seem to grade into each other from point to point. Total thickness exposed in Guadalupe Mtns 1,600± ft. From Guadalupe Pt. the Bone Springs ls. has been traced southward along W. base of Delaware Mtns for approx. 25 mi. Correlated with Leonard fm. of Glass Mtns, on similarity of fossils and lithology.

P. B. and R. E. King, 1929 (A. A. P. G. Bull., vol. 13, pp. 921–922, 924, 925), treated this ls. as basal memb. of Delaware Mtn fm., and named it *Bone Canyon memb.* (See under *Delaware Mtn fm.*)

P. B. King, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 731, 755–768), redefined *Bone Springs ls.* by including, at top, Victorio Peak massive memb., and changed name to *Bone Spring ls.*, because there is only 1 spring present in Bone Canyon, although the place is locally called *Bone Springs*. This is present approved usage of U. S. Geol. Survey. He stated: The Bone Spring ls. was included by Richardson as a memb. in Delaware Mtn. fm., but the unit has a greater extent and thickness than was originally supposed, and the faunas, as first pointed out by Girty, are not entirely like those of the beds above, so that it is now generally recognized as a distinct fm. Also: The definition of King and King applied only to the black lss. of the fm.; in present paper the name is given the broader usage of Blanchard and Davis and applied to lss. of various sorts, of same general age and strat. position.

These beds were included in Delaware Mtn fm. as originally defined and subsequently used, but they are now treated as a distinct fm., underlying (in places uncon.) Delaware Mtn fm. and=Leonard fm.

See also †*Bone Canyon memb.* and W. B. Lang, 1937 (A. A. P. G. Bull. vol. 21, No. 7).

Bone Springs limestone.

See *Bone Spring ls.*, the approved name.

Bone Valley gravel.

Pliocene (lower?): Southern central Florida.

G. C. Matson and F. G. Clapp, 1909 (Fla. Geol. Surv. 2d Ann. Rept., table opp. p. 50 and pp. 138–141). *Bone Valley gravel.*—Light-colored gravel and marl, containing phosphatic pebbles. Consists of a fine-grained matrix containing pebbles of phosphate or chert, fragments of bone and other organic remains. Matrix is commonly a marly clay, though sand is not uncommon, especially in upper part of fm. The finer grained material is soft and plastic when wet, but upon exposure to the air hardens to a firm mass. The fm. comprises nearly all of the pebble phosphates now being mined in Fla. Thickness not more than 30 ft. Rests, probably uncon., on Plio. marls or older rocks. Overlain, uncon., by Pleist. sands. Is believed to be younger than "Arcadia marl" and older than upper beds of Caloosahatchee marl. Is a nonmarine deposit, probably in part contemp. with Alachua clay.

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept., p. 162). The "land-pebble" phosphate deposits make up large part of *Bone Valley gravel,* which rests uncon. on Hawthorn fm. (from which it is in part derived) and is uncon. overlain by Quat.

Named for exposures at town of Bone Valley, W. of Bartow, Polk Co.

Bonham marl.

Upper Cretaceous (Gulf series): Northeastern Texas (Fannin, Lamar, and Red River Counties).

L. W. Stephenson, 1927 (A. A. P. G. Bull., vol. 11, p. 8). *Bonham clay.*—A partly calc. and partly non-calc. clay, which toward W. in Fannin Co. merges into Austin chalk and toward E. extends through Fannin, Lamar, and Red River Counties. In Fannin Co. it conformably underlies Brownstown marl and conformably overlies Ector tongue of Austin chalk. In Lamar and Red River Counties the upper part of Bonham clay is replaced by Blossom sand, which is conformably underlain by the lithologically persistent lower part of Bonham clay, which there rests uncon. on Eagle Ford clay. In previous repts has been confused with Eagle Ford. Named for exposures a short distance N. of town of Bonham, Fannin Co., and for fact that the town, especially the part N. of the railroad, is located on the clay.

Name changed (at request of L. W. Stephenson) to *Bonham marl* April 7, 1936.

Bonilla formation.

Miocene: Costa Rica.

A. H. Redfield, 1923 (Econ. Geol., vol. 18, p. 365).

Bonita sandstone. (In Franciscan group.)

Jurassic (?): Western California (San Francisco region).

R. Arnold, March 1902 (Sci., n. s., vol. 15, table on p. 416). *Bonita ss.*, 1,400 ft. thick, top fm. of Franciscan. [Shown in table as overlying San Miguel cherts and uncon. underlying Knoxville.]

A. C. Lawson, February 1903 (Geol. Soc. Am. Bull., vol. 13, table on pp. 544–545). [Same as above.]

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). *Bonita ss.*—Massive, obscurely bedded ss. of dark greenish gray color and medium texture, with subordinate amounts of sh. and cgl. Thickness about 1,400 ft. Top fm. of Franciscan group. Conformably overlies Ingleside chert.

Named for exposures at Point Bonita, on N. shore of Golden Gate.

Bonnellian series.

Name proposed by C. [R.] Keyes (Pan-Am. Geol., vol. 64, No. 2, 1935, pp. 138–139), to include Pawpaw sss., Main Street marls, Grayson shales, and Buda ls. of central Tex. "These are usually placed in Washita div., by Tex. geologists, but they are, more properly, seemingly, to be grouped by themselves." Named for Mount Bonnell, near Austin, Tex.

Bonner Springs shale.

Pennsylvanian: Eastern Kansas and southeastern Nebraska.

R. C. Moore, 1931 (Kans. Geol. Soc. 5th Ann. Field Conf. Guidebook, correlation chart). *Bonner Springs sh.*, new name; underlies Plattsburg ls. and overlies Farley ls.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 85, 93, 97). *Bonner Springs sh.* includes the strata btw. top of Wyandotte ls. and base of Plattsburg ls. [Derivation of name not stated. On p. 46 *Bonner Springs sh.* is described as consisting of 20.2 ft. of gray aren. sh. with plant fossils.]

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pp. 18, 65, 67–69). The term *Bonner Springs* is here applied to sh. btw. underlying Plattsburg ls. and overlying Farley ls., and generally erroneously referred to as "upper Lane sh." It is much younger than true Lane sh. Consists of sh. (olive-green, argill., maroon layer near top) underlain by soft greenish buff micaceous ss. or aren. sh. In places includes at top a 5-ft. bed of ls. and shell breccia, as ½ mi. W. of Bonner Springs. One-half mi. E. of De Soto the breccia bed of the Bonner Springs lies on Farley ls., through absence of the sh. of the Bonner. Thickness of fm. 0 to 35± ft. Named for town in Wyandotte Co. Type exposure at cement plant NE. of the town.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), stated that Newell is author of this name.

Bonneterre dolomite.

Upper Cambrian: Southeastern Missouri.

F. L. Nason, 1901 (Am. Jour. Sci., 4th, vol. 12, pp. 358–361). *Bonne Terre or St. Joseph ls.*—Non-cherty lss., 300 ft. thick; some fossiliferous strata; contains upper and lower lead zones. Overlies La Motte ss. and uncon. underlies Potosi slates and cgls., the basal bed of which consists of 6½ ft. of cgl.

E. O. Ulrich and H. F. Bain, 1905 (U. S. G. S. Bull. 267, pp. 21–26). *Bonneterre ls.*—As a rule consists of more or less heavily bedded, granular, and highly mag. lss., generally compactly crystalline and often minutely vesicular, with dol. crystals lining the cavities; a few beds are fine grained; color light or dark gray; usually weathers yellowish; locally contains beds of a pink or more decidedly red color; chert and drusy quartz seem to be entirely absent; some beds, especially in lower part, contain much chlorite, in places sufficient to give them a decidedly green color; toward base much silica occurs as grains of sand in the ls. Thickness varies from 200 to 250 ft. in vicinity of Mine La Motte and Fredericktown to nearly 500 ft. in St. Francois Co., to N. It seems to wedge out on old hillsides. Appears to grade into underlying La Motte ss. Where top of Bonneterre has suffered least from widespread erosion that took place prior to deposition of Elvins fm., it grades upward from the massive lss. into a thinly bedded zone, and this finally into a bed of blue sh.; locally the thinly bedded and shaly zones appear to be absent. [See also under *Elvins fm.*]

E. R. Buckley, 1909 (Mo. Bur. Geol. and Mines vol. 9, pt. 1). *Bonneterre fm.*—Consists of (descending): (1) Argill. dol.; (2) 250 to 300 ft. of dark and light-gray dol. with thin sh. partings; (3) 50 to 100 ft. of buff or gray dol., aren. buff or yellowish dol., thin green, gray, or brownish black sh. beds, chloritic dol. Grades into underlying La Motte ss. Is overlain by Davis fm. (lower part of Elvins fm. of Ulrich), 150 to 190 ft. thick.

S. Weller and S. St. Clair, 1928 (Mo. Bur. Geol. and Mines vol. 22, 2d ser., p. 39). Nason placed upper limit of Bonneterre at edgewise cgl. horizon, which is about

6 ft. below "Central" marble boulder memb. of Davis fm. From sections given by Ulrich in 1905 it would appear that he similarly revised the Bonneterre, as defined by Nason, his Elvins fm. being above the cgl., just below the "Central" marble boulder memb. of Buckley's Davis. Therefore Davis fm. as recognized in latest repts contains probably 100 ft. or more of sh. and shaly dol. that had been included in Bonneterre in earlier repts.

Named for exposures at Bonneterre, St. Francois Co.

†Bonneville beds.
†Bonneville group.
See *Lake Bonneville beds.*

Bontour Point.
Oligocene: Trinidad.
C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 701).

Booch sand.
A subsurface sand, of early Penn. (Cherokee) age, in Okla., lying lower than Bartlesville sand, higher than Dutcher sand, and correlated with Tucker and Taneha sands. In type area (Booch field, Muskogee Co.) it lies at 1,075 ft. depth.

Boone limestone (Oklahoma and Missouri).
Boone formation (Arkansas).
Mississippian (Warsaw and Osage): Northern Arkansas, eastern Oklahoma, and southwestern Missouri.

J. C. Branner and F. W. Simonds, 1891 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 4, pp. xiii, 27-37). [According to p. xiii the fm. was named by Branner; the description is by Simonds.] *Boone chert and cherty ls.*—Characterized by layers of ls., usually hard, compact, and gray, interbedded with chert, white or gray on freshly broken surface but becoming brownish on exposure. Thickness 150 to 200 ft. in Washington Co., Ark. Underlies Wyman [Batesville] ss. and overlies Dev.(?) Eureka sh. [Chattanooga sh.].

R. A. F. Penrose, Jr., 1891 (Ark. Geol. Surv. Ann. Rept. for 1890, vol. 1). In Batesville region, Ark., *Boone chert* underlies Fayetteville sh. [Moorefield sh.] and overlies Sylamore ss.

T. C. Hopkins, 1893 (Ark. Geol. Surv. Ann. Rept. 1890, vol. 4). Basal memb. of *Boone chert* is here named St. Joe ls.

G. I. Adams and E. O. Ulrich, 1904 (U. S. G. S. P. P. 24). Correct strat. succession in northern Ark. is (descending): (1) Wedington ss.(=Batesville ss. of Simonds); (2) Fayetteville fm.; (3) Batesville ss. (=Wyman ss. of Simonds); (4) Moorefield sh. (=Fayetteville sh. in part of Branner); (5) Spring Creek ls. (local); (6) *Boone ls.*, including St. Joe ls. memb. at base. Wedington ss. may belong to Fayetteville fm. [The Wedington ss. has for many years been treated as a memb. of Fayetteville sh.]

E. T. McKnight, 1935 (U. S. G. S. Bull. 853), described *Boone fm.* of Yellville quad., Ark., where St. Joe ls. memb. (20 to 45 ft. thick) lies 0 to 18 ft. above its base.

A. W. Giles, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 12, pp. 1815-1867), made a detailed study of the chert of the Boone ls., and divided the fm. into the following members in NE. Okla. and N. Ark. (descending order): Green ls. and Short Creek oolite (both of Warsaw age); Keokuk ls.; Burlington ls.; Fern Glen ls.; and St. Joe ls. (of Fern Glen age).

Named for extensive development in Boone Co., Ark.

Boone Creek limestone member (of Palo Pinto limestone).
Pennsylvanian: Central northern Texas (Jack and Wise Counties, Brazos River region).

J. M. Armstrong, 1929 (Tex. Bur. Econ. Geol., geol. map of Jack Co.). *Boone Creek ls.*, 5± ft. thick, is in Palo Pinto fm., and *Willow Point ls.* is in Graford fm., 40± ft. above Bridgeport coal.

E. H. Sellards (September 1931, News Letter from Bur. Econ. Geol. Univ. Tex.). In Wise Co. the Palo Pinto ls. has been found to be divided into 2 thin lss. separated by sh. The lss. are named *Boone Creek* and *Willow Point*.

G. Scott and J. M. Armstrong, 1932 (Univ. Tex. Bull. 3224, p. 23). *Boone Creek ls.* included in Palo Pinto fm.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 105). *Boone Creek ls.* in Palo Pinto fm., is named for Boone Creek, Jack Co.

Booneville stage.

Pennsylvanian: Western Arkansas coal field and central eastern Oklahoma.

A. Winslow and H. M. Chance, 1896 (N. Y. Acad. Sci. Trans., vol. 15, pp. 51-52). *Booneville stage.*—Interbedded shales and sss., with coal beds, 400 to 2,500 ft. thick, underlying Norristown stage [Hartshorne ss.] and overlying Appleton stage. Includes Grady coal at base. [Not Grady (Hartshorne) coal but a lower coal.]

Represents upper part of Atoka fm.

Probably named for Booneville, Logan Co., Ark.

Booth zone.

A petroliferous zone, about 270 ft. thick, included in Alamitos zone of Fernando group. Named for San Martinez Booth No. 1 well, in Long Beach field, Los Angeles Basin, Calif.

Bopesta formation.

Miocene (upper): Southern California (northeastern part of Kern County).

J. P. Buwalda, 1934 (Pan-Am. Geol., vol. 61, No. 4, p. 310). *Bopesta fm.*—Wholly different from underlying Kinnick and Witnet fms., being continental in origin. Many hundred ft. thick in type section along Cache Creek, NE. of Monolith [NE. part of Kern Co.]. Contains the upper Mio. Cache Peak fauna. Moderately folded. Rests (probably uncon.) on Kinnick fm. [Derivation of name not stated.]

Boquilla slate.

Pre-Cretaceous: Mexico.

R. H. Burrows, 1909 (Min. and Sci. Press, vol. 99, p. 292) and 1910 (Soc. geol. mexicana, Bol., t. 7, p. 89).

Boquillas flags.

Upper Cretaceous (Gulf series): Western Texas.

J. A. Udden, 1907 (Univ. Tex. Bull. 93, pp. 17, 29-33). *Boquillas flags.*—Thin-bedded, closely jointed, fossiliferous flaggy strata, separated by delicate seams which may not appear on freshly exposed surfaces. Upper 100 ft. of chalky texture. Color variable but characteristically cream grayish white; in Boquillas region faint ferruginous red stain; in other areas some ledges are dark and almost black on fresh fractures. Thickness 585 ft. Basal fm. of Upper Cret. Western equiv. of Eagle Ford shales. Grades into overlying Terlingua beds and overlies Buda ls.

Named for Boquillas, Brewster Co., on Tornillo Creek, Chisos Mtns quad.

Borden sandstone. (In Monongahela formation.)

Pennsylvanian: Western Maryland (Georges Creek Basin).

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, pl. 7). *Upper Sewickley ss.* (*Borden ss.*).—Lies a short distance above Borden coal. [In text this ss. is called *Upper Sewickley ss.*, which is said to be 6 ft. thick in Borden shaft.]

Borden group.

Mississippian: Indiana.

E. R. Cumings, 1922 (Hdb. Ind. Geol., pt. 4, Sep. Pub. 21, pp. 408, 470 (footnote), 487-490, 492, 531, and chart). *Borden group* (also *series*).—Great group of shales and sss. of Burlington and Keokuk age well exposed about village of Borden (formerly called New Providence). Overlain by Harrodsburg (Warsaw) ls. and underlain by Rockford ls., or, where that is absent, New Albany sh. Includes Riverside ss., Rosewood sh., Kenwood ss., and New Providence sh. Replaces obsolete name "Knobstone."

P. B. Stockdale, 1929 (Ohio Jour. Sci., vol. 29, No. 4, p. 170). *Borden (Knobstone) group*, 500 ft. thick in Ohio River localities; 750 or more ft. in central Brown Co. A sharply delimited strat. unit of predominately clastic material. Underlies Harrodsburg (Warsaw) ls. and overlies Rockford (Kinderhook) ls. Work of previous investigators has been incomplete and disconnected, and attempts to subdivide the group into strat. units have been made only locally. The results are, therefore, not applicable thruout entire outcrop area. Writer's studies reveal that Borden group consists of five geol. fms., each recognizable thruout entire area. The fms. carry sharply defined members which are locally traceable. In order of superposition the names of the fms., all but lowest one of which are suggested by the writer, are as follows, *Edwardsville, Floyds Knob, Carwood, St. Joseph*, and *New Providence*. The chief source of confusion in past has been failure to fully realize that each fm. displays numerous facies. There is much lithologic dissimilarity in a given fm. btw. areas not widely separated. Perhaps outstanding case is *Carwood fm.*, which displays 7 distinct facies over the 125 mi. outcrop strip. In addition to lithologic facies, faunal facies add difficulty to recognition of the different fms. The various facies have been appropriately named.

P. B. Stockdale, 1931 (Ind. Dept. Cons., Div. Geol. Pub. 98, pp. 85, 109, 120, 310, 311, etc.). The 2 Borden fms. that generally display greatest lithologic contrast with the rocks which dominate Borden group are New Providence fm. and Floyds Knob ls. The group is here divided into (descending) Edwardsville fm., Floyds Knob ls., Carwood fm., Locust Point fm. (replaces St. Joseph, preoccupied), and New Providence fm. (redefined to include Kenwood ss.). The Edwardsville and Floyds Knob replace Warsaw fm. of Butts. The Carwood includes "Holtsclaw ss." of Butts (which is abandoned) and upper part of "Rosewood sh." of Butts (also abandoned). The Locust Point fm. corresponds to lower part of "Rosewood sh." of Butts. Borden group underlies Harrodsburg ls. and overlies Rockford ls. (where present) or New Albany sh. [See further under the several fms. On pp. 310–311 he suggests redefining top of Borden group, as explained under *Harrodsburg ls.*]

†Border conglomerate. (In Newark group.)

Upper Triassic: Eastern Virginia.

J. K. Roberts, 1923 (Pan-Am. Geol., vol. 39, pp. 185–200). *Border cgls.*—Cgls. of same age, occurring on both sides of Triassic basin of northern Va. Represent oldest Triassic sediments of basin. Are older than Manassas ss. and Bull Run shales.

J. K. Roberts, 1928 (Va. Geol. Surv. Bull. 29, pp. 24–25, 38–43). The [nongeographic] term "Border" for the cgls. is proposed because it is about the only appropriate term which could be applied. It is particularly applicable because the cgls. lie exposed along E. and W. borders, especially along the latter. The Border cgl. extends in a broken manner from Potomac River at Point of Rocks to Carolina line. Manassas ss. is for most part intercalated with Bull Run shales. Where not disturbed by faulting and not covered by Recent material or soil the Border cgls. underlie Manassas ss.

D. B. McLaughlin, 1932 (Mich. Acad. Sci. Arts and Lett., vol. 16, pp. 421–427). Writer concludes *Border cgl.* is for most part of Brunswick age, and is, therefore, among the youngest of the Triassic fms. On other hand it lies directly on pre-Triassic in places, showing that Newark series has overlapped the older rocks from SE. to NW. The same general conclusions were reached by Wherry (Proc. Acad. Nat. Sci. Phila., vol. 65, p. 114, 1913) as a result of studies near Reading and elsewhere. Stose (U. S. G. S. folio 225, 1929) finds Border cgl. the youngest Triassic fm. in Fairfield-Gettysburg area. Kummel (U. S. G. S. folio 191, 1914) finds that in Raritan area not only the Brunswick, but the Stockton and Lockatong as well, pass along the strike into Border cgl. Thus, though the cgl. is in the main of Brunswick age, local bodies of it may be of any age within Newark series.

Boscabel boulder beds.

Upper Triassic: Eastern Virginia (Richmond Basin).

N. S. Shaler and J. B. Woodworth, 1899 (U. S. G. S. 19th Ann. Rept., pt. 2, pp. 424–425). *Boscabel boulder beds.*—Local deposits, boulders of gneiss and granite. Thickness 0-50± ft. Believed to be associated with Newark rocks and included in Tuckahoe group, basal div. of the Newark. Best exposed at Boscabel Ferry.

Bosche formation.

Cambrian: Alberta (Jasper Park).

P. E. Raymond, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 290, 300). *Bosche fm.*—At Roche Miette consists of (ascending): (1) Green sh., poorly exposed, no fossils; (2) impure nodular gray ls. with fragments of trilobites suggesting Middle Camb., 300 ft.; (3) massive, dark-gray, unfossiliferous, mag. ls., forming cliff which slopes off northwestward toward the road, 200 ft., which lithologically and for purposes of mapping should be united with Nos. 1 and 2. Name taken "from across the Athabaska, for lack of a more local designation." Overlain by 150 ft. of shaly blue and gray ls. containing Upper Camb. trilobites.

†Bosque division.

Lower Cretaceous (Comanche series): Texas and Oklahoma.

J. A. Taff, 1892 (Tex. Geol. Surv. 3d Ann. Rept., pp. 272–273, 281–325). The *Bosque, or lowest div.* of Lower Cret. of Tex., has been formed to bring together three beds which have hitherto been placed in separate divisions, but which, for reasons that will appear as details are brought out, must be considered and treated as a continuous series of deposits from the Paleozoic upward to the Fredericksburg. These three beds are (descending) Paluxy sand, Glen Rose (Alternating) beds, and Trinity sands. Is succeeded by rocks more homogeneous in nature, namely the *Texana* bed [Walnut clay] of Fredericksburg div.

Same as Trinity group, older name.

Named for Bosque River.

Bossardville limestone. (In Cayuga group.)

Silurian: Northeastern Pennsylvania (Monroe, Carbon, and Schuylkill Counties) and northern New Jersey.

I. C. White, 1882 (2d Pa. Geol. Surv. Rept. G_6, pp. 77, 141–145). *Bossardville ls.*—The main quarry lime through Monroe Co., Pa. Almost nonfossiliferous. Upper 65± ft. mostly bluish black layers with thin veins of calcite intersecting in all directions. Basal 25± ft. is dark grayish slaty ls., finely laminated with gray, whitish, blue, etc., and often exhibiting columnar structure. Total thickness 75 to 100 ft. Underlies Decker's Ferry shales and overlies Poxono Island sh.

I. C. White, 1883 (2d Pa. Geol. Surv. Rept. G_7), extended this name to counties NW. of Pike and Monroe Counties and gave thickness of 50 to 120 ft.

Top fm. of Cayuga group in Monroe, Carbon, and Schuylkill Counties.

Named for Bossardville, Monroe Co., Pa., where it has been quarried.

Boss Point formation.

Pennsylvanian: Nova Scotia.

W. A. Bell, 1913 (12th Int. Geol. Cong. Guidebook 1, p. 333) and 1914 (Canada Geol. Surv. Summ. Rept. 1912, p. 366).

†Boston group.

Pennsylvanian and Mississippian: Northwestern Arkansas and northeastern Oklahoma.

J. C. Branner, 1891 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 4, p. xiii). *Boston group.*—[Name proposed, in table only, for equiv. of Genevieve group of H. S. Williams.] Approx. equiv. of H. S. Williams' "Chester," "St. Louis," and "Warsaw." Includes (descending) Kessler ls., Coal-bearing sh., Pentremital ls., Washington sh. and ss., Archimedes ls., and Marshall [Fayetteville] sh.

Named for Boston Mtns, Washington Co., Ark.

†Boston conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan.

See †*Albany and Boston cgl.* and *Allouez cgl.*

Boston Bar group.

Carboniferous or Triassic: British Columbia.

J. W. Dawson, 1872 (Canada Geol. Surv. Rept. 1871–72, pp. 62–63).

Boston Basin series.

See *Boston Bay group.*

Boston Bay group.

Carboniferous or Devonian: Eastern Massachusetts (Boston Basin).

W. E. Hobbs, 1899 (Am. Geol., vol. 23, pp. 109–113). To E. [of W. rim of Boston Basin] we have the well known *Boston Basin series,* consisting of Roxbury cgl. and Cambridge sl., with various intrusives. It rests uncon. on Algonkian metamorphic sedimentary terrane, which consists (descending) of Lincoln sl., Kendall Green sl., and Stonybrook qtzite.

L. La Forge, 1932 (U. S. G. S. Bull. 839). *Boston Bay group.*—Comprises the late Paleozoic stratified rocks, which, with the interbedded Brighton melaphyr, occupy Boston Basin, including most of Boston Lowland, a part of Southwestern Upland, and a strip along the South Shore. These rocks are not found except in Boston Basin. Includes Roxbury cgl. below, Cambridge sl. above, and Brighton melaphyr, which is intruded into and interbedded with lower part of Roxbury cgl. Is not older than Dev. and not younger than Carbf., with a slight balance of probability in favor of Carbf. Is overlain by Quat. The sed. rocks seem to be wholly nonmarine and largely terrestrial.

According to B. K. Emerson (U. S. G. S. Bull. 597, p. 50, 1917) "the Boston Basin is a roughly triangular area that occupies the coast of Boston Bay between Revere and Hull and extends westward to Sherborn."

Boston Neck granite.

Late Carboniferous or post-Carboniferous: Southern Rhode Island (north of Narragansett Pier).

F. H. Lahee, 1912 (Am. Jour. Sci., 4th, vol. 33, pp. 365, 449, 454–469). *Boston Neck granite.*—The granitic rocks of South Kingstown, which are especially prominent on Boston Neck and are probably intrusive into the Carbf. sediments. Occurs at various places along W. coast of Narragansett Bay from Watson's pier southward, and inland on Little Neck, Boston Neck, and Tower Hill. Is typically medium grained, white, pinkish or cream colored; predominantly microcline, with quartz, micropegmatite, microperthite, a coarsely twinned plagioclase, and orthoclase. Same as Sterling granite to W.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597), mapped the granite of Boston Neck as *Sterling granite gneiss.*

Bostwick member (of Dornick Hills formation).

Pennsylvanian: Central southern Oklahoma (Carter County).

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z, p. 14). The most resistant part of Dornick Hills fm. is a massive ls. cgl. with associated lss. and sss. known as *Bostwick memb.* It disappears northward from Ardmore. Above Bostwick memb. occur 3 or more very fossiliferous lss., including the coarsely crystalline and oolitic *Lester ls.* The Bostwick memb. lies higher in fm. than Otterville ls.

C. W. Tomlinson, 1929 (Okla. Geol. Surv. Bull. 46, pp. 30–32). *Bostwick memb.* forms Bostwick Ridge. Type loc. is on Bostwick dairy farm, in W½NE¼ sec. 11, T. 5 S., R. 1 E., whose buildings stand upon the ridge. It lies 750 ft. above Otterville memb. as here defined, and 400 to 500 ft. below Lester ls. memb. to N. of Ardmore, and 800 to 1,000 ft. below to S. Included in this interval are 2 or 3 other highly fossiliferous lss. from a few inches to 2 ft. thick. Max. thickness of Bostwick memb. 300 ft. It disappears within a mi. along the strike in each direction from Dornick Hills Country Club, due either to strike faulting or to uncon. within Dornick Hills fm. or to a combination of these two factors. Has not yet been identified certainly anywhere N. of that locality.

C. W. Tomlinson, 1934. (See 1934 entry under *Confederate ls. memb.*)

Bosworth formation.

Upper Cambrian: British Columbia.

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804, pp. 2, 3). *Bosworth fm.*—Aren. dolomitic lss., massive, thin bedded, and shaly, with bands of purple and gray siliceous shales. Thickness at Mount Bosworth, 1,855 ft. No fossils observed, but referred to Upper Camb. Underlies Upper Camb. Paget fm. and overlies Middle Camb. Eldon fm. Type loc. ridge extending NW. from Mount Bosworth, and SE. base of Paget Peak and Mount Daly.

†Bosworth sandstone and shale.

Devonian: Mackenzie, Canada.

E. M. Kindle, 1921 (Canada Geol. Surv. Summ. Rept. 1920, pt. B, p. 48). *Bosworth ss. and sh.*

G. S. Hume, 1923 (Canada Geol. Surv. Summ. Rept. 1922, pt. B, p. 58).

E. M. Kindle, 1936 (Sci., n. s., vol. 83, No. 2140, pp. 14–15). *Bosworth ss. and sh.* (preoccupied) replaced by *Carcajou Mtn beds.*

†Bosworthian series.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 42, p. 288). Shales, 1,200 ft. thick, underlying Sullivanian series, uncon. overlying Eldonian series, and composing basal fm. of Late Cambric section of Alberta. [Apparently same as lower part of Bosworth fm., the upper or dolomitic part being here removed and christened *Thompson dolomites.*]

Boulder drift.

Boulder clay.

Descriptive terms that have been applied to Pleist. deposits in different parts of United States and Canada.

Boulder sand.

Drillers' name for a sand of late Upper Dev. or early Carbf. age in western Pa. Is younger than Gordon Stray sand.

Boulder granite.

Jurassic: British Columbia.

C. Camsell, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 108).

Boulder Creek granite gneiss.

Pre-Cambrian: Central northern Colorado (Boulder region).

M. F. and C. M. Boos, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 2, pp. 305–306). Oldest observed intrusive pre-Camb. rock in Front Range is gray granite and gneissoid granite that crops out widely on Boulder Creek, on E. flank of Front Range, W. and SW. of Boulder, Colo., and is known as *Boulder Creek granite gneiss.* It intrudes Coal Creek qtzite, Ralston fm., and the schist. Is=Archean quartz monzonite of Georgetown region.

Boulder Pass formation.

Pre-Cambrian (Belt series): Northwestern Montana (Glacier National Park) and southern Alberta (Waterton Lakes National Park).

C. L. and M. A. Fenton, 1931 (Jour. Geol., vol. 39, No. 7, pp. 670–679). *Boulder Pass fm.*—Section made up from near Boulder Pass, S. of Ahern Pass (Glacier Nat. Park), and in Waterton Lakes Nat. Park, includes (descending): Kintla memb., 890 ft.; Sheppard memb., 520 to 650 ft.; Purcell lava, 100 to 200 ft.; Hole-in-the-Wall memb., 391 to 441 ft. Overlies Siyeh ls.

Boule limestone.

Upper Devonian: Alberta (Jasper Park).

P. E. Raymond, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 294–296, 300). *Boule dolomitic ls.,* 1,600 ft. thick; well exposed at tunnel at SE. end of Boule Range, but northern end of Miette Range should be accepted as type section. Overlies Perdrix sh. and underlies Coronach sh., all Upper Dev.

Bouleaux formation. (In Chaleur series.)

Silurian (Niagaran): Quebec (Gaspé Peninsula).

C. Schuchert and J. D. Dart, 1926 (Canada Geol. Surv. Bull. 44, p. 49).

S. A. Northrop, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, p. 271). Bouleaux, West Point, and Indian Point fms. of middle Sil. Chaleur series contain faunas of Lockport and Guelph age.

Boundary argillites.

Paleozoic (?): Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 80, map). *Boundary argillite.*—Chiefly argillites, with lss. and carbonaceous argillites interbedded. In places black carbonaceous argillites and quartz mica schists are interbedded with the true argillites; in places the latter become calc. In vicinity of Int. Bdy the schists and argillites are intruded by a complex of dikes so numerous that nearly half of area is composed of this igneous complex. Thickness of fm. 4,000± ft. Probably in part at least=Mission argillites. [Seems to be named for Int. Bdy.]

Boundary granodiorite.

Jurassic or Cretaceous: Southeastern Alaska (Hyder district).

A. F. Buddington, 1929 (U. S. G. S. Bull. 807, pp. 32–33, 55–59, maps). *Boundary granodiorite.*—Granodiorite forming upper part of Coast Range intrusives. Named for exposures along both sides and at head of Boundary Glacier from about 1 mi. above its foot.

Boundary Bay formation.

Tertiary: British Columbia.

W. A. Johnston, 1923 (Canada Geol. Surv. Mem. 135, p. 30).

Boundary Peak granite.

Age (?): Central eastern California (Inyo Range).

See under *Pellisier granite.*

Bouquet Cañon breccia.

Probably Miocene: Southern California (30 miles north of Los Angeles).

A. O. Woodford, 1925 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 15, No. 7, p. 212). *Bouquet Cañon breccia.*—These may well be correlatives of San Onofre (breccia facies of Temblor fm.) N. of San Gabriel Mtns. A suggestion of this is given by a specimen of fine schist breccia furnished by Prof. F. P. Vickery and Mr. S. W. Harris. This is from lower Bouquet Cañon, 30 mi. N. of Los Angeles and 5 mi. NE. of Saugus. It may be Mio. The rock is made up of 1–4 cm. fragments of white quartz, quartz-muscovite schist, hornblende-epidote schist (hornblende close to karinthine), etc., in a carbonate cement, almost without fine clastic grains.

Bourbon series.

A term proposed by C. [R.] Keyes (Pan-Am. Geol., vol. 55, p. 231, 1931) to replace Lexington ls. of Ky., because of prior use of Lexington for a Carbf. unit in Mo. Named for Bourbon Co., Ky.

Bourbon group.

Bourbon formation.

Pennsylvanian: Eastern Kansas and southeastern Nebraska.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 90, 97). *Bourbon group.*—Consists almost wholly of sh. and ss., that lie beneath Swope fm. and above the pre-Missouri uncon. Thus defined the group has thickness of 150± ft. Considerable field study is needed on these beds. At present they include (descending) Ladore sh., *Uniontown ls.*, and unnamed sh. and ss. The Ladore sh. corresponds to that at Ladore type loc. [Derivation of names not stated.]

J. M. Jewett, 1932 (p. 99 of book cited above). *Bourbon group* contains at least one very persistent fm.—"Uniontown ls.," which is generally less than 1 ft. thick, of dark, earthy ls. bearing bellerophontids and ammonites, and everywhere overlying black sh. containing phosphatic concretions and ranging up to several ft. in thickness. Has been traced from Linn Co., Kans., to vicinity of Delaware, Nowata Co., Okla., and is reported to be widespread in NE. Mo. Named for Bourbon Co., Kans.

R. C. Moore, May 1, 1935 (Univ. Kans. Bull. 20, table opp. p. 14). *Bourbon group* underlies Hertha ls., rests uncon. on Lenapah ls., and includes (descending): Undiff. sh. and ls., "Uniontown" ls., unnamed sh., and Warrensburg channel ss. [This definition excludes Ladore and underlying ls. of 1932 definition.]

N. D. Newell, May 15, 1935 (Kans. Geol. Surv. Bull. 21). [*Bourbon fm.* shown as basal fm. of *Bronson group* on p. 19; as distinct from Bronson group on p. 21; and as a *group* on p. 20. The ls. separating Bourbon fm. from overlying Ladore sh. is here called *Sniabar ls. memb. of Hertha ls.*]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 41). *Bourbon fm.*, at base of Missouri series, includes the deposits, chiefly sh. and ss., btw. post-Des Moines uncon. below and base of Hertha ls. above. Conformably underlies Bronson group. [On pp. 73–75 are following statements:] Most of Bourbon fm. consists of bluish gray and yellowish brown silty to sandy sh.; locally at base there is thick, irregularly bedded or massive yellow-brown ss., and in places there are extensive sss. in middle and upper parts. Prominent channel sss. belong to Bourbon throughout much of west Mo. The Warrensburg and Moberly sss. in central Mo. and several other channel sss. in that State are in part certainly and in part questionably classed as belonging to Bourbon fm. Local deposits of cgl. also belong to the Bourbon. The Critzer ls. occurs near top of fm., but for present recognition of the "Critzer" as a named memb. of the Bourbon is withheld; much additional study is needed. Thickness of fm. probably 100+ in most places; in Kansas City region appears to be 150+ ft. Because lower bdy of fm. is difficult to trace, except where fairly prominent ss. occurs at base, it may be necessary in geol. mapping to combine the Bourbon with the discon. underlying upper Des Moines sh., but this does not invalidate strat. definition of Bourbon fm. Much detailed work remains to be done on this part of section.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Bow formation or group.

Name suggested by A. C. Veatch (Jour. Geol., vol. 15, p. 548, 1907, and Am. Jour. Sci., 4th, vol. 24, pp. 18–22, 1907) as appropriate substitute for "Lower Laramie." From Medicine Bow River, Wyo. In 1918 (U. S. G. S. P. P. 108, p. 229) C. F. Bowen introduced *Medicine Bow fm.* to replace "Lower Laramie" of Hanna Basin.

Bowden formation.

Miocene: Jamaica.

W. H. Dall, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, p. 340).

Bowdoin sand.

A productive subsurface sand lying 445± ft. below top of Colorado sh. in Bowdoin dome, NE. Mont., and lower than Martin sandy zone.

Bowers sand.

A subsurface Perm. oil and gas sand in Hobbs field, Lea Co., N. Mex. Named for discovery in Humble's Bowers No. 1 well.

Bowhan sandstone member (of Nelagoney formation).

Pennsylvanian: Central northern Oklahoma (Osage County).

M. I. Goldman and H. M. Robinson, 1920 (U. S. G. S. Bull. 686Y, pp. 361–362, pl. 51). *Bowhan ss.*—Thin slabby ls., which caps Bowhan Point, in sec. 16, T. 28 N., R. 11 E., and forms top of many ridges in SW. part of the area (T. 28 N., Rs. 11 and 12 E.). Is one of lower sss. in Lawrence sh. of Kans., and may be = Jonesburg ss. of T. 29 N., R. 11 E. Lies 95 ± ft. above Iatan ls. and Cheshewalla ss. and 40 ± ft. above Labadie ls.

N. W. Bass and L. E. Kennedy, 1935 (Subsurface geol. of Osage Co., Okla.), show this ss. lies 20 ± ft. below Cochahee ss.

Bowie shale member (of Mesaverde formation).

Upper Cretaceous: Central western Colorado (Delta County region).

W. T. Lee, 1909 (U. S. G. S. Bull. 341, pp. 20, 23). *Bowie sh. memb. of Mesaverde fm.*—Dark-colored sh. and gray sh. containing marine and brackish water invertebrates; coal-bearing. Thickness 0 to 425 ± ft. (absent in central part of Grand Mesa coal field). Conformably overlain by Paonia sh. memb. of Mesaverde fm. at E. end of field; absent in central part of field; uncon. below Paonia at W. end of field. Rests on Rollins ss. memb. of Mesaverde. Typically exposed at Bowie, Delta Co.

Bowler formation.

Triassic and Permian: Central southern Montana (Carbon County).

J. P. Rowe, 1906 (Univ. Mont. Bull. 37, geol. ser. No. 2, p. 81). *Bowler fm.*—Red shales and sss., thick gyp. beds. Thickness 400 to 500 ft. Triassic (?) and Perm. "Red Beds." Underlies Ellis fm. and overlies Quadrant fm. [Type loc. not stated, but judging from list of occurrences on p. 16 it is town of Bowler, Carbon Co.]

Bowling Green limestone member (of Edgewood limestone).

Silurian (early): Northeastern Missouri and southwestern Illinois.

C. R. Keyes, 1898 (Iowa Acad. Sci. Proc., vol. 5, pp. 59, 62). *Bowling Green ls.*—Fossiliferous buff mag. ls., 4 to 30 ft. thick, forming topmost fm. of Sil. in Pike Co., Mo., and Calhoun Co., Ill. Regarded as = part of so-called Niagara of upper Miss. Basin.

Later repts by T. E. Savage and other geologists classify this ls. as top memb. of Edgewood ls., of pre-Niagara Sil. age, and state that it is uncon. on Noix oolite and uncon. below Sexton Creek ls.

Named for exposures near Bowling Green, Pike Co., Mo.

Bowling Green stone.

Trade term for a building stone (white ls.) quarried from Gasper oolite (of Chester group) near Bowling Green, Warren Co., Ky.

Bowman limestone.

Middle Cambrian: Central northern Utah (Oquirrh Mountains region).

J. Gilluly, 1932 (U. S. G. S. P. P. 173). *Bowman ls.*—Mottled shaly lss., intraformational cgl., and oolitic ls., with shaly memb., about 35 ft. thick, at base. Thickness 280 ft. Grades into overlying Lynch dol., the bdy being arbitrarily drawn at base of lowest dol. bed. Conformably overlies Hartmann ls. Named for exposures in Bowman Gulch, NW. of Ophir.

Bow River group.

Lower Cambrian and pre-Cambrian: Alberta and British Columbia.

R. G. McConnell, 1887 (Canada Geol. Surv., n. s., vol. 2, pp. 15D, 29D–30D).

According to C. D. Walcott this term covers St. Piran, Lake Louise, and Fort Mtn fms. (all Lower Camb.), but consists chiefly of pre-Camb. rocks. It underlies Castle Mtn group. (See Smithsonian Misc. Coll., vol. 53, No. 1804, p. 4, 1908.)

Box Elder limestone.

Ordovician (Lower): Northeastern Utah (northern Wasatch Mountains).

E. Blackwelder, 1910 (Geol. Soc. Am. Bull., vol. 21, p. 519), in strat. table in a paper on geol. of Wasatch Mtns, applied *Box Elder ls.* to ls. of Ord. age, but did not describe it, nor give its thickness or type loc., and no geographic feature bearing that name is shown on his maps or mentioned in his paper. In 1913 G. B. Richardson applied *Garden City ls.* to the ls. of Lower Ord. (Beekmantown) age in NE. Utah, and fully defined the fm. This is presumably the same fm. that Blackwelder intended to name *Box Elder.*

Boyd series.

Carboniferous: New Brunswick.

W. J. Wright, 1922 (Canada Geol. Surv. Mem. 129, pp. 7, 13). [Assigned to Carbf.]

G. W. H. Norman, 1932 (Canada Geol. Surv., Econ. Geol. ser., No. 9, p. 170), assigned *Boyd fm.* of N. B. to Miss.

Boyd's Creek sand.

A subsurface sand of Niagaran age in Barren Co., Ky.

Boyer "sand."

Drillers' name for a *ls.* in Weston sh. (Penn.) of Butler Co., Kans.

Boyer till.

Term introduced by C. [R.] Keyes (Pan-Am. Geol., vol. 55, p. 284, 1931) to replace *Iowan*. Named for river "in headwaters basin of which the till reaches in Sac Co.," Iowa.

Boyle limestone.

Middle Devonian: Central Kentucky.

A. F. Foerste, 1906 (Ky. Geol. Surv. Bull. 7, pp. 10, 92). *Boyle lss.*—Dev. lss., 0 to 47 ft. thick, underlying Ohio sh. and overlying Crab Orchard fm. (Sil.). Includes Duffin layer at top and Kiddville layer at base, separated by thick series of lss., in places richly fossiliferous and cherty. Equiv. of Sellersburg, Jeffersonville, and Geneva lss. of west-central Ky. and southern Ind.

T. E. Savage, 1930 (Ky. Geol. Surv., ser. 6, vol. 33, pp. 1–21), redefined Boyle ls. by excluding Duffin layer. See under *Duffin layer,* 1930 and 1931 entries.

Named for Boyle Co.

Boyles sandstone member (of Pottsville formation).

Pennsylvanian: Northern central Alabama.

C. Butts, 1910 (U. S. G. S. Birmingham folio, No. 175, p. 8). *Boyles ss. memb.*—Coarse, thick-bedded, quartzose ss., in places conglomeratic at base. Forms basal memb. of Pottsville fm. in Warrior coal field. Thickness 100 to 600 ft. Probably = Shades and Pine ss. members of Cahaba coal field, or = Pine ss. alone.

C. Butts, 1927 (U. S. G. S. Bessemer-Vandiver folio, No. 221), correlated Boyles ss. with Pine ss. only.

Named for exposure at Boyles Gap, N. of Birmingham.

Boylston schist.

Carboniferous: Massachusetts (eastern part of Worcester County).

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 61, 67–68, and map). *Boylston schist.*—In Boylston it is a ragged, coarsely micaceous rock, which commonly lacks fissility because the muscovite scales are crushed and crumpled together. In many places it is crowded full of square prisms of andalusite, about an inch long, changing to sericite, and imperfect garnets changing to chlorite. It is a coarse contact "hornfels". Grades into Worcester phyllite and is intermediate btw. the Worcester and the Brimfield schist.

Boyne beds.

Cretaceous: Manitoba.

S. R. Kirk, 1930 (Canada Geol. Surv. Summ. Rept. 1929, pt. B, p. 129).

Boynton sand.

A subsurface sand, 25±ft. thick, of early Penn. (Cherokee) age, in Muskogee Co., central eastern Okla., which in Boynton pool lies at depth of 1,500 ft., the Leidecker sand at 1,400 ft., and †Mississippi lime at 1,800 ft.

Bozeman "lake beds."

Tertiary (late): Central southern Montana (Three Forks quadrangle) and southwestern Montana.

A. C. Peale, 1893 (U. S. G. S. Bull. 110, pl. 1), mapped, but did not describe, *Bozeman lake beds* (*Neocene*), over a large area in vicinity of Threeforks, Mont.

J. P. Iddings and W. H. Weed, 1894 (U. S. G. S. Livingston folio, No. 1). *Bozeman lake beds.*—The cgls., sss., and clays deposited in waters of a lake that once occupied Gallatin Valley, receive their name from town of Bozeman. Loosely cemented. Consist of variety of materials from adjacent mtn slopes, with marls and layers of volcanic dust. Thickness exposed in this quad. 1,200±ft., but much greater in other parts of Gallatin Valley. Rest uncon. on Archean schists and all sed. strata up to and including Livingston fm. (of Cret. and Eocene age.).

A. C. Peale, 1896 (U. S. G. S. Three Forks folio, No. 24). *Bozeman lake beds.*—Sand, cgl., ls., clay, and volcanic dust, deposited in extinct Gallatin Lake. Named for good exposures in vicinity of Bozeman. Total thickness may be 2,000 to 2,500 ft.

W. P. Haynes, 1916 (Jour. Geol., vol. 24, pp. 270–290). The whole series of Tert. valley sediments [in region about Three Forks] has been grouped under heading *Bozeman fm.* for convenience in mapping. Dr. Peale's name "Bozeman lake beds" seems no longer applicable, since they have been shown to be due to subaerial and fluviatile deposition rather than to lakes. Bozeman fm. here is chiefly Mio., but in some parts of region strata of Olig. (White River) age have been identified.

Brad formation (restricted). (In Canyon group.)

Pennsylvanian: Central and central northern Texas.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24–31, 35). *Brad fm.*, 225 ft. thick to N., about 200 ft. thick to S. Underlies Hog Creek sh. memb. of Caddo Creek fm. and overlies Adams Branch ls. memb. of Graford fm. In Colorado River Valley divided into (descending): Ranger ls. memb., 10 to 50 ft.; Placid sh., 30 to 50 ft.; Clear Creek ls. 10 to 25 ft.; and Cedarton sh. and ss., 20 to 80 ft. In Brazos River Valley divided into (descending) Ranger ls. memb. and Seaman Ranch sh. memb. Named for Brad, Palo Pinto Co., Brazos River region.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 104, 112), defined Brad fm. of Colorado River Valley as consisting of Ranger ls. memb. (above) and Placid sh. memb. (below), and transferred to underlying Graford fm. the Clear Creek ls. and older members originally included in Brad fm. He stated that in Wise Co. the Adams Branch ls. is absent and that the shales and sss. from Devils Den ls. up to Ranger ls. have been named *Ventioner beds.*

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501, pp. 197+), divided *Brad fm.* of McCulloch Co., Colorado River region, into the following members (descending), Ranger ls., Placid sh., Clear Creek ls., and Cedarton sh., and stated (p. 205): Clear Creek ls. is also known as Merriman ls. They drew base of Brad fm. at top of Adams Branch ls. memb. of Graford fm.

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, pp. 47–55). *Brad fm.* was named by Plummer and Moore and made to include the strata from top of ls. capping the escarpment W. of Graford (here called Merriman ls. memb. of Graford fm., but previously misidentified as the older Adams Branch ls.) up to top of Ranger ls. Type loc. is the outcrop N. of Brad, Palo Pinto Co. The Brad of Palo Pinto Co. is divided into 2 members, Ranger ls. (45 ft. thick) above and Seaman Ranch beds (135 ft. thick) below.

The definition of Brad fm. that has recently been adopted by U. S. Geol. Survey (based upon rept of Wallace Lee soon to be published by Tex. Geol. Surv.) draws line btw. Brad fm. and underlying Graford fm. in midst of Placid sh. memb. of Plummer and Moore, the upper or shaly part of their Placid sh. being included in Brad fm. and the lower or ls.-bearing part being included in Graford fm.

†Braddyville limestone. (In Shawnee formation.)

Pennsylvanian: Southwestern Iowa and northwestern Missouri.

G. L. Smith, 1909 (Iowa Geol. Surv. vol. 19, pp. 617, 618, 623, 629, 632). *Braddyville lss.*—Lss. and shales, 50 ft. thick, forming basal part of Atchison shales. Underlies City Bluffs [Scranton] shales and overlies Forbes [Deer Creek] ls. Included in Missouri stage.

Includes Topeka ls. and Calhoun sh., according to R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 191, 195).

Named for exposures at Braddyville, Page Co., Iowa.

†Bradford schist.

Ordovician: Northeastern Vermont (Orange County).

C. H. Richardson, 1898 (Am. Ass. Adv. Sci. Proc., vol. 47, pp. 295–296). *Bradford schist.*—The noncalc. memb. of Calciferous mica schist. Named for Bradford, Vt. [Mount Cube quad.], where it predominates. The calc. memb. is here named *Washington ls.*

C. H. Richardson, 1902 (3d Rept. Vt. State Geol., 1901–02, p. 81). *Bradford schist.*—Contains lower Trenton fossils. Was originally a ss., which is now represented by terranes of granular and micaceous qtzite and a foliated mica schist. Overlies black sl. of Ord. age. The Washington ls. is intimately interstratified with Bradford schist.

C. H. Richardson, 1906 (5th Rept. Vt. State Geol., pp. 90, 115, footnote). *Bradford schist* includes all of the non-calc. members of old "Calciferous Mica Schist." It therefore embraces the qtzite, staurolitic, actinolitic, amphibolitic, ottrelitic, graphitic, and garnetiferous phases lying btw. 2 large narrow belts of sl. and sh., one on E. near Conn. River, the other on W. passing through Newport and Montpelier to Barnard. [U. S. Geol. Survey has adopted *Vershire schist* as substitute for *Bradford schist* (preoccupied). *Washington ls.* (preoccupied) is replaced by *Waits River ls.*]

C. H. Richardson, 1924 (14th Rept. Vt. State Geol.). *Bradford schists*, in Bradford Twp, overlie Waits River ls. and are therefore younger than the phyllites here named *Randolph phyllite*.

See also *Vershire schist*.

Bradford oil sand group.

Drillers' term, long in use, for a series of Upper Dev. sands, of probable Chemung age, in NW. Pa. Lies higher than Elk sand. The principal sands have been called (descending) Bradford First sand, Bradford Second sand, and Bradford Third sand. Intervening sands are Sugar Run sand, Chipmunk sand, and Harrisburg Run sand.

Bradford division.

See 1912 entry under †*Bradfordian*.

Bradford group.

A term applied by C. Schuchert and C. O. Dunbar (Textbook Geol., pt. 2, pp. 199, 203, 204, 1933) to the post-Chemung Dev. deposits in N. Y., which are stated to be "much like the Chemung, being separated only by certain differences in its faunas." The term is used by them as synonymous with *Bradfordian*, the name used on p. 197.

†Bradfordian.

Devonian or Carboniferous: Southwestern New York and northwestern Pennsylvania.

G. H. Girty, 1904 (Sci., n. s., vol. 19, p. 24). *Bradfordian*.—The series of rocks and faunas in SW. N. Y. which overlie true Chemung, inclusive of sub-Olean cgl., recently assigned by Prof. J. M. Clarke to Carbf., really lie below Carbf. system as at present recognized in this country, just as they lie above the Chemung beds, the recognized top of Dev. This series, having approx. thickness of 500 ft., represents an interval not provided for in geological time scale, and for it the term *Bradfordian* is proposed. This term, which will rank with Senecan, Chautauquan, etc., includes Cattaraugus, Oswayo, and Knapp beds of N. Y. section, which may provisionally be accepted as its subdivisions. The Bradfordian faunas are equally distinct from those of Chemung group and from those of Waverly group. Contain to some extent an intermingling of Carbf. and Dev. species, and are in fact transitional btw. those of the two eras. Whether Dev. or Carbf. is question reserved for further study.

In 1903 (N. Y. State Mus. Hdb. 19) J. M. Clarke assigned Knapp, Oswayo, and Cattaraugus fms. to Carbf. The same year L. C. Glenn (N. Y. State Mus. Bull. 69, pp. 967–989) assigned Knapp and Oswayo to Carbf. and assigned Cattaraugus to Dev. In 1910 C. Butts (U. S. G. S. Warren folio) assigned all to "Devono-Carboniferous." In 1911 E. O. Ulrich (Geol. Soc. Am. Bull., vol. 22) assigned "Bradfordian," Bedford, Cleveland, and "late Catskill" to his Waverlyan system, and stated that "Bradfordian" is of Kinderhook age.

G. H. Girty, 1912 (U. S. G. S. P. P. 71, p. 421). In NW. Pa. I have discriminated a group of rocks btw. Berea ("Corry") ss. and top of typical Chemung under name "*Bradfordian*." In Ohio I am tentatively assigning to this group Bedford sh., Cleveland sh., and Chagrin ("Erie") sh., or at least upper portion of Chagrin sh., from which our fossil faunas are obtained. Because "Bradfordian" faunas were very different from Waverly faunas (inclusive of Berea ss. but exclusive of Bedford sh.) I originally assigned "Bradfordian" without hesitation to Dev. After comparing "Bradfordian" faunas with typical Chemung, however, I find there exists a difference, almost equally marked, and feel somewhat doubtful whether the "Bradfordian" would not better be placed in Carbf. In northern Ohio the most convenient horizon at which to draw base of Carbf. would doubtless be immediately below Berea ss. If Bedford sh. is included in Carbf., so must also be the Cleveland. A more or less conspicuous change of fauna occurs in passing from the Chagrin into the Bedford.

G. H. Girty, 1912 (N. Y. Acad. Sci. Annals, vol. 22, pp. 295–319), assigned Bedford fauna to Dev.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 87 and chart). *Bradford div.* assigned to Miss. Includes Knapp, Oswayo, and Cattaraugus fms.

G. H. Girty, 1915 (Wash. Acad. Sci. Proc., vol. 8, p. 7). *Bradfordian* correlates with Pocono and part of Catskill and in western Pa. with the Riceville and considerable thickness of underlying beds.

W. A. VerWiebe, 1917 (Am. Jour. Sci., 4th, vol. 44, pp. 35–47), correlated Knapp, Oswayo, and Cattaraugus fms. with Bedford sh. and assigned all to Dev. But G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69), excluded Cleveland and Bedford from *Bradfordian* and assigned them to overlying "Waverlyan," while he assigned Bradfordian to Upper Dev.

C. Schuchert (1924 Textbook geol.) assigned *Bradfordian* to Dev., as did G. H. Chadwick in 1924 (N. Y. State Mus. Bull. 251, p. 157), and 1925 (Geol. Soc. Am. Bull., vol. 36, p. 463). In latter publication Chadwick restricted †Bradfordian to beds beneath Olmsted sh. memb. of Cleveland sh. of Ohio and base of his Le Boeuf ss. of Erie Co., Pa., and in his 1923, 1924, and 1925 repts he drew its base at base of Venango group and top of Chadakoin.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 190). Knapp, Oswayo, and Cattaraugus included in *Bradfordian series* and all assigned to Miss.

K. E. Caster, Feb. 28, 1933 (Geol. Soc. Am. Bull., vol. 44, pt. 1, pp. 202–203). *Bradfordian series* is divided into (descending) Knapp fm. (revised Cussewago group), Riceville fm. restricted (Oswayo sh. memb.), and Cattaraugus fm. Base of Miss. is drawn at top of Oswayo memb. Thus "Bradfordian series" is misleading term. Includes both Miss. and Dev.

G. H. Chadwick, Oct. 1933 (Pan-Am. Geol., vol. 60, p. 197). Considering *Bradfordian* as presumably a unit, I assigned it all to Dev., with prediction of an uncon. at top, but recently K. E. Caster's careful faunal analyses and collecting have led him to divide Riceville sh., putting Early Carbf. basal uncon. within it. Thus, by exclusion of Cussewago (Knapp), the "Bradfordian" becomes invalidated, a fortunate circumstance since it was so readily confused with Bradford oil sands of greater age, and name *Conewangan epoch* now naturally replaces it for closing division of Dev.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 54, etc.), *Bradfordian series* must go. For Dev. portion the name *Conewango series* is appropriate. The original "Conewango fm." of Butts precisely covers Dev. part of former Bradfordian system, and now, on demise of the latter, should be elevated to series rank.

G. H. Chadwick, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, p. 334). Girty's *Bradfordian* included all these disputed beds from base of the Conewango to top of the Knapp. [On p. 338 he stated:] Conewango group, which with probably the overlying Cussewago (including perhaps also the false "Berea" of Pa.), constitutes closing epoch (Bradfordian) of Upper Dev. [On p. 351 is following:] Standing out with marked faunal individuality are 3 Upper Dev. epochs: Senecan, Chautauquan, and *Bradfordian*. [On p. 352:] The *Bradfordian* embraces the Conewango, with its various component members awaiting more refined field tracing, and probably the Cussewago (Knapp and so forth).

This term was never adopted by U. S. Geol. Survey. The age of the fms. included under it is still unsettled. They are all, including Bedford, Cleveland, Conewango, and Knapp, now classified by U. S. G. S. as *Devonian or Carboniferous.*

Bradley sand.

A subsurface sand in Pennington sh. of eastern Ky., supposed to be same as Maxton sand.

Bradore formation.

Lower Cambrian: Labrador and Newfoundland.

C. Schuchert and C. O. Dunbar, 1934 (Geol. Soc. Am. Mem. 1, pp. 18, 21).

Bradshaw granite.

Pre-Cambrian: Central Arizona (Bradshaw Mountains).

T. A. Jaggar, Jr., and C. Palache, 1905 (U. S. G. S. Bradshaw Mtns folio, No. 126). A coarse plutonic rock, which in places has a gneissic structure and in places a coarse granular structure. Frequently shows zones where the rock becomes highly schistose and would more properly be called a mica gneiss. Normal type is coarse biotite granite with rare green hornblende. Intrudes Yavapai schist, Algonkian. In places merges into Crooks complex.

Named for mtns in which it is so well displayed.

Bradshaw limestone. (In Bluefield formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 299, 397). *Bradshaw ls.*—Shaly, siliceous, calc. bed, 0 to 3 ft. thick. Marine fossils. Underlies Bradshaw ss. and overlies Bradshaw sh., all members of Bluefield group [fm.]. Named for association with Bradshaw ss., although not noted at type loc. of the ss. Is well exposed in Talcott dist., Summers Co., in bluff S. of Greenbrier River, just W. of Stony Creek and 0.3 mi. SW. of Bargers Springs.

Bradshaw sandstone. (In Bluefield formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 299, 394). *Bradshaw ss.*—Greenish gray, shaly or massive, medium-grained, 15 to 50 ft. thick. Underlies Lower Bertha sh. and overlies Bradshaw ls., all members of Bluefield group [fm.]. Type loc. in vicinity of Indian Mills and along Bradshaw Creek, there being a cliff on the road which ascends the mtn immediately N. of Indian Mills and the mouth of Bradshaw Creek, Summers Co. Also observed in Mercer and Monroe Counties, W. Va., and in Tazewell Co., Va.

Bradshaw shale. (In Bluefield formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Tazewell County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 299, 398). *Bradshaw sh.*—Usually red and variegated, but sometimes green and sandy, 30 to 55 ft. thick, marine and plant fossils. Underlies Bradshaw ls., where present, or Bradshaw ss., and overlies Indian Mills ss., all members of Bluefield group [fm.]. Type loc. on mtn road immediately N. of Indian Mills, Summers Co. Also observed in Mercer and Monroe Counties and in Tazewell Co., Va.

Braeburn limestone.

Carboniferous (?): Yukon Territory and British Columbia.

D. D. Cairnes, 1910 (Canada Geol. Surv. Mem. 5, p. 28).

Bragdon formation.

Mississippian: Northwestern California (Klamath Mountains region).

O. H. Hershey, 1901 (Am. Geol., vol. 27, pp. 236, 238). *Upper slates or Bragdon fm.*—The latest of the fms. included in "Auriferous Slate series." Consists of 2,000 ft. of alternating thin-bedded slates and thick-bedded blue qtzites; no ls. Similar to Mariposa slates. Tentatively assigned to Jurassic.

According to J. S. Diller (U. S. G. S. Redding folio, No. 138, 1906) the Bragdon fm. is 2,000 to 6,000 ft. thick in Redding quad., it underlies Baird fm., uncon. overlies Kennett fm., and is of Miss. age.

Named for exposures in Bragdon Gulch and vicinity of Bragdon, Weaverville quad.

Brainard shale. (In Maquoketa group.)

Upper Ordovician: Northeastern Iowa, northwestern Illinois and western Wisconsin.

S. Calvin, 1906 (Iowa Geol. Surv. vol. 16, pp. 60, 97). *Brainard sh.*—Blue and bluish gray shales, with some intimately associated ls. beds at top and bottom. Thickness 120± ft. Forms top fm. of Maquoketa stage [group]. Overlies Fort Atkinson ls. of Maquoketa stage and is succeeded by Hopkinton ls. of Niagara age.

E. O. Ulrich, 1924 (Wis. Acad. Sci., Arts, and Lett., vol. 21, p. 71). *Brainard sh.* at Savannah, Ill., is uncon. overlain by Burroughs dol.

Named for exposures near Brainard, Fayette Co., Iowa.

Brainerd quartz monzonite.

Tertiary (Eocene): Central northern Colorado (Ward district, Boulder County).

P. G. Worcester, 1921 (Colo. Geol. Surv. Bull. 21, p. 32). *Brainerd quartz monzonite porphyry.*—There are 2 large dikes of this rock on N. side of valley near mouth of Brainerd tunnel, on Lefthand Creek about a mi. E. of Ward, and another dike occurs farther N. in Tuscarora Gulch.

T. S. Lovering, 1935 (U. S. G. S. P. P. 178, p. 26), referred to *Brainerd quartz monzonite* of Ward dist.

Braintree slate.

Middle Cambrian: Eastern Massachusetts (Boston Basin region).

N. S. Shaler, 1871 (Boston Soc. Nat. Hist. Proc., vol. 13, pp. 173–175). *Braintree series.*—Probably not far from 1,000 ft. thick. Whole is fossiliferous, but it is only in upper 100 ft. that well-preserved characteristic fossils are found. Is composed of beds which were evidently at time of their formation very uniform mud of a sea floor tolerably remote from land, and although much changed by metamorphic action it is easily perceived that the whole set of beds contain no trace of shore deposits. [Mentions *Braintree slates*, but does not say what rest of "series" consists of.]

G. R. Mansfield, 1906 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 49, geol. ser. vol. 8, No. 4, p. 100). *Braintree slates* contain Middle Camb. fossils.

L. LaForge, 1909 (Sci., n. s., vol. 29, pp. 945–946). *Braintree sl.* contains Middle Camb. fauna. Overlies Weymouth fm. and is older than Roxbury cgl.

B. K. Emerson, 1917 (U.S.G.S. Bull. 597, pp. 38–39 and map). *Braintree sl.*—Dark-gray to black carbonaceous slates and dark gray lydite with a few calc. and epidotic layers and nodules. Appears to overlie Weymouth fm. conformably. To N. is overlapped uncon. by Roxbury cgl. Thickness at least 1,000 ft. Named for occurrence in Braintree.

Braintree argillite.

A name applied in some early repts to Braintree sl.

Brallier shale. (In Portage group.)

Upper Devonian: Central Pennsylvania (Bedford, Blair, Huntingdon, and Center Counties).

C. Butts, 1918 (Am. Jour. Sci., 4th, vol. 46, pp. 523, 531, 536). *Brallier sh.*—Fine-grained, siliceous sh., in thick, even layers, revealing fissility on weathering; largely wavy or dimpled laminæ; some even and slaty; a few thin fine-grained ss. layers. Thickness 1,350 to 1,800 ft. Is upper fm. of Portage group. Underlies Chemung fm. and overlies Harrell sh.

Named for railway station 6 mi. NE. of Everett, Bedford Co., which is spelled *Brallier* in official Ry Guide.

Branch Pond gneiss.

Pre-Cambrian: Central southern Maine (Waldo County).

E. H. Perkins and E. S. C. Smith, 1925 (Am. Jour. Sci., 5th, vol. 9, pp. 204–228). *Branch Pond gneiss.*—Mixed gneisses, schists, and phyllites, the latter observed especially in more NW. portions of fm. Named for fine exposures near Branch Pond in West Palermo. In general the fm. is a dark bluish quartzitic gneiss. At lower end of China Lake an area of staurolite schist is interbedded in fm. The portion of Branch Pond fm. from Beaver Ridge E. becomes noticeably more biotitic, and hence has been mapped separately and called *Branch Pond biotite gneiss*. Probably pre-Camb. Relations to Vassalboro ss. hidden.

On 1933 geol. map of Maine, by A. Keith, these rocks are mapped as pre-Camb. sediments.

Branchtown clay.

Pliocene (?): Southeastern Pennsylvania.

H. C. Lewis, 1881 (Phila. Acad. Nat. Sci. Proc., vol. 32, pp. 258–272, 296–309). *Branchtown clay.*—Found at high elevations at a few places in gneissic region. Contains occasional boulders. Is probably nearly coeval with Bryn Mawr gravel, judging from its contained boulders. In village of Branchtown [a suburb of Philadelphia], on a plateau 250 ft. above river, there is a local deposit of this brick clay. Thickness 2 to 3 ft. It rests on decomposed gneiss.

Brandon lignite.

Brandon residual formation.

Tertiary (Eocene): Southwestern Vermont (northern part of Rutland County).

E. Hitchcock, 1861 (Rept. Geol. Vt., vol. 1). The *Brandon deposit* is the type of a tertiary fm. hitherto unrecognized as such, extending from Canada to Ala. Probably belongs to pliocene.

H. C. Lewis, 1881 (Phila. Acad. Nat. Sci. Proc., vol. 32, pp. 282–291, 297). *Brandon period* is possibly Olig. The lignite at Brandon, Vt., lies in beds of plastic clay, kaolin, and iron ore. Contains fossil plants.

W. B. Clark, 1891 (U.S.G.S. Bull 83, pp. 90–93). Under name *Brandon fm.* are included the lignitic beds of Vt., Pa., and Ga., deposits whose taxonomy has not yet been definitely determined, but which may provisionally be referred to Eocene.

G. H. Perkins, 1910 (7th Rept. Vt. State Geol., pp. 43–55). Tertiary is exposed in Brandon only, but without doubt is more widely distributed in Vt., but has been deeply covered by Pleist.

E. W. Berry, 1919 (Am. Jour. Sci., 4th, vol. 47, pp. 211–216). Evidence is sufficiently weighty to justify considering *Brandon lignite* and its contained flora as Eocene.

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), assigned *Brandon lignite* to Mio.

G. H. Perkins, 1931 (17th Rept. Vt. State Geol., pp. 7–27). Tertiary clays extend from Colchester to Bennington; include *Brandon lignite*.

F. A. Burt, 1931 (17th Rept. Vt. State Geol., pp. 115–135). *Brandon residual fm.*—Kaolin, ocher, sands, lignite, and iron ores, 0 to 175 ft. thick. Extends through W. tier of counties from Colchester on N. to Mass. line on S. Lies in Vermont Valley btw. Green Mtn Range on E. and Taconic Mtns on W. It is unfortunate that *Brandon* has been used to denote both this entire fm. and also its lignite memb. The rock materials included under Hitchcock's and Clark's term *Brandon fm.* are kaolin, ocher, quartz sand, nodular and concretionary iron ores, manganese ore, and lignite, all, with exception of the lignite and manganese ore, residual products of rock decomposition. In endeavor to find a handle to apply to the group which will not involve the error implied by calling them a *fm.*, writer proposes compound word *residual fm.*, and will hereafter refer to them as *Brandon residual fm.* The only place in State where all of members are known to be present is in old lignite mining area E. of Brandon. The fm. is Tert., and its age has been established as Mio. by Lesquereux, Knowlton, and Perkins.

The flora is Eo. according to E. W. Berry.

Brandy Run sandstone. (In Chester group.)

Mississippian: Southwestern Indiana and northern Kentucky.

C. A. Malott, 1919 (Ind. Univ. Studies, vol. 6, No. 40, pp. 7–20). *Brandy Run ss.*—Gray blue shales and sandy shales, overlain by a thin ls. This interval represents strat. position of a ss. which farther S. in Ind. becomes prominent and reaches thicknesses of 30 to 50 ft. This ss. is well developed in region of Marengo, on Brandy Run Creek, Ind. Thins S. of Ohio River and is absent beyond Breckinridge and Meade Counties, Ky.

E. R. Cumings, 1922 (Hdb. Ind. Geol., pt. 4, Sep. Pub. 21, p. 515). Later investigations, as yet unpublished, by Butts and Malott in southern Ind. and in Meade and Breckenridge Counties, Ky., have shown that Malott's Brandy Run ss. is= Sample ss.

Brandywine formation. (Of Columbia group.)

Pleistocene: Atlantic Coastal Plain from Delaware to Georgia.

W. B. Clark, 1915 (Am. Jour. Sci., 4th, vol. 40, pp. 499, 506). The recognition by U. S. Geol. Surv. and the various State Surveys in Atlantic border area of the inappropriateness of the term *Lafayette* as employed in Atlantic border region has led to proposal by author of name *Brandywine* for the oldest of the terrace fms. of that dist. This name has already been submitted to Board of Geologic Names of U. S. Geol. Survey and adopted by it. The name Brandywine is proposed for this fm. because the deposits are extensively and typically developed in vicinity of Brandywine, Prince George's Co., Md. The terms *Appomattox* and *Lafayette* as originally employed in Middle Atlantic Coastal Plain embraced much more than it is proposed to include under the name *Brandywine fm.*, the diagnosis of which is based on different physiographic conceptions from those used by McGee and Darton. The Brandywine fm. covers extensive area in southern Md. peninsula, reaching from E. bdy of D. C. to N. line of St. Marys' Co., Md., with numerous outliers to N. and to S. of these lines. It attains max. width from NW. to SE. of nearly 40 mi. It extends northward into Del. and Pa., and has been traced southward through Va. into the Carolinas. Altitude of landward bdy reaches 400 ft. in outliers in W. part of D. C.; 486 ft. at Burtonville, Montgomery Co., Md.; 508 ft. at Catonsville, 480 ft. at Loch Raven, Baltimore Co.; and 470 ft. at Woodlawn, Cecil Co. Each of these outliers is extensively eroded and isolated from main body of the fm. farther seaward. The altitude of the fm. along the seaward bdy in northern St. Mary's Co. is not over 200 ft., while farther northward in Md. elevations of 240 ft. are found at Marriott Hill, Anne Arundel Co., and 300 ft. on Elk Neck, Cecil Co. The fm. is composed of gravel, sand, and loam. Over considerable areas the gravel occurs in great abundance at the base. Thickness of fm. .10 to 30 ft., the thickness for most part increasing from the landward toward the seaward margin of the fm. Exceptional thicknesses of over 50 ft. have been found. No determinable fossils have been found in type area. The fm. uncon. overlies all older Coastal Plain fms. of Tert. and Cret. age, and at a few places rests on crystalline rocks. Throughout much of region it is separated from next younger (Sunderland) fm. by a clearly marked escarpment and uncon. Brandywine, Prince George's Co., Md., is located on the slightly eroded surface of the old Brandywine terrace not far from center of largest tract still preserved intact. Max. thickness of fm. is in general area in which Brandywine is situated. The adjacent ravines to E. and W. of Brandywine cut through the fm. Most authors have referred these deposits to Plio., but author questions whether they may not with equal propriety be referred to early Pleist.

F. Bascom, 1920 (U. S. G. S. Elkton-Wilmington folio, No. 211, p. 12), and 1921 (Jour. Geol., vol. 29, pp. 540–559). The *Brandywine fm.* includes sand and marl of two levels and of different ages. The *early Brandywine* consists of about 50 ft. of sand and gravel lying at altitudes of 200 to 400 ft., and is believed to be of Pleist. or late Tert. age. The *late Brandywine* consists of about 1 foot of sand and gravel lying at altitudes of 390 to 500 ft., and is thought to be a terrestrial deposit of Pleist. streams.

F. Bascom, 1924 (U. S. G. S. P. P. 132H, pp. 117–119). The *early Brandywine gravels* are found in Elkton-Wilmington dist. at altitude of 380 ft., capping Egg Hill and other outstanding hills on W. border of Elkton quad. The *late Brandywine gravels* lie at altitudes of 220 ft. or more. The deposit at the type loc. in Md. is the low level (200 to 300 ft.) or late Brandywine, presumably of Pleist. age. The high-level gravels (390 to 480 ft.) are presumably of Plio. age. Such a time interval btw. the early and late gravels as is now recognized has made it infeasible to treat the deposits as a unit. It is therefore proposed to *restrict the term Brandywine fm.* to the late or lower-level deposits of the type loc., and to reinstate the old term *Bryn Mawr gravel* for the early or high-level deposits of Pa., Del., and Md. (Cecil Co.).

C. W. Cooke, 1931 (Wash. Acad. Sci. Jour., vol. 21, pp. 503-513), suggested that Brandywine fm. be restricted to the 270-foot level, but there is not unanimity of opinion in regard to this matter. The terrace fms. of Columbia group (including the Brandywine) now recognized by Cooke across the Atlantic Coastal Plain from Del. to southern Ga. and probably into Fla., are enumerated herein under *Columbia group*.

Brandywine granite.

Commercial term for a quartz diorite quarried in Elkton and Wilmington quads., Md.-Del.

Branford granite gneiss.

Pre-Cambrian: Central southern Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 114, 146, and map). *Branford granite gneiss.*—Medium grained granite, with banded structure, consisting very largely of white feldspar. In the feldspars are embedded small round quartz grains having a slightly brownish tint, and biotite is present in about equal amount. Small reddish garnets commonly present. Covers large part of Branford Twp. Probably igneous and pre-Camb.

H. E. Gregory and H. H. Robinson, 1907 (Conn. Geol. and Nat. Hist. Surv. Bull. 7, p. 38). *Branford gneiss* is of igneous origin.

Branford granite.

A facies of Branford granite gneiss. See under ***Light House granite.***

Brannon cherty member (of Flanagan limestone).

Middle Ordovician: North-central Kentucky.

A. M. Miller, 1913 (Ky. Geol. Surv., 4th ser., vol. 1, pt. 1, p. 324). *Brannon bed.*—Siliceous ls., 15 ft. thick, which weathers to chert. Is weathered phase of lower part of Flanagan chert of Campbell; upper part is bouldery. Extends S. of Kentucky River. Overlies Bigby fm. and underlies Woodburn bed of Flanagan memb. of Lexington.

Adopted by U. S. Geol. Survey as ***Brannon cherty memb. of Flanagan ls.*** Named for exposures at Brannon Station, Jessamine Co.

Brannon limestone member. (In Millsap Lake formation.)

Pennsylvanian: North-central Texas (Parker County).

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 106, 107), from ms. of rept, by G. Scott and J. M. Armstrong, on geol. of Parker Co. (See 1933 entry under *Millsap Lake fm.*) Type loc. not stated.

This name appears to have been replaced by ***Brannon Bridge ls.*** in 1936.

Brannon Bridge limestone. (In Millsap Lake formation.)

Pennsylvanian: Central northern Texas (Brazos River region).

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, p. 16). *Brannon Bridge lss.*—Top beds of Lazy Bend memb. of Millsap Lake fm. as defined by G. Scott and J. M. Armstrong (unpublished ms., on Parker Co.). Consists of 3 prominent lss. separated by 10-ft. breaks of sh. and some sand. Outcrop in vicinity of Brannon Bridge on the Brazos, about 6 mi. S.-SW. of Millsap, Parker Co. The upper 2 lss. have been mapped across SE. corner of Palo Pinto Co. [This name appears to replace the preoccupied name ***Brannon ls.***, used by Scott and Armstrong in 1933, as listed by Sellards under ***Millsap Lake fm.***]

Brassfield limestone.

Silurian (early): Central Kentucky, southern Tennessee, southwestern Ohio, southern Indiana, southwestern Illinois, and central northern Arkansas.

A. F. Foerste, 1905 (Ky. Geol. Surv. Bull. 6, p. 145) and 1906 (Ky. Geol. Surv. Bull. 7, pp. 10, 27). *Brassfield ls.*—Fossiliferous ls., 13 to 19 ft. thick, usually consisting in lower part of several rather thick and massive layers, and in upper part of more numerous thinner bedded layers; toward top thin layers of clay are often interbedded. Called *Clinton ls.* in earlier repts. Overlies Ord. and underlies Indian Fields fm., basal fm. of Sil. in Ky.

Has generally been considered to be of Albion age (pre-Clinton), altho W. Stout and R. E. Lamborn (Ohio Geol. Surv., 4th ser., Bull. 28, chart opp. p. 358, 1924) correlated it with Wolcott ls. memb. of Clinton fm., and W. Stout (personal communication Feb. 7, 1930) still adhered to this correlation. See also C. Schuchert, Geol. Soc. Am. Bull., vol. 25, p. 278, 1914. In SW. Ohio it underlies Dayton ls. In Ind. it discon. underlies Osgood fm. In central northern Ark. it underlies St. Clair ls. and overlies Cason sh.

A. F. Foerste, 1931 (Ky. Geol. Surv., ser. 6, vol. 36, pp. 184–185). In Ind. and Ohio the Brassfield overlies Centerville fm. (earliest Sil. and supposed equiv. of Edgewood fm. of SW. Ill. and adjacent Mo.). [See under *Centerville ls.*, 1931 entry.]

Foerste amplified his description in Denison Univ. Bull., Sci. Lab. Jour., vol. 30, 1935, pp. 123–127, and stated that type exposure is along Louisville & Atlantic R. R. btw. Brassfield and Panola, Madison Co., Ky., where it is 21 ft. thick; is 40 to 50 ft. thick in Adams and Highland Counties, Ohio; 22 ft. at Lewisburg, Ohio; 14 ft. at Elkhorn Falls, 4 mi. S. of Richmond, Ind.; in northern Tenn. 3 ft. thick E. of Bledsoe and 33 ft. btw. Franklin and Centerville. He gave further details on pp. 145–149.

See also under *Belfast bed, Beavertown marl*, and *Dayton ls.*

Brasstown schist.

Lower Cambrian: Western North Carolina, eastern Tennessee, and central northern Georgia.

A. Keith, 1907 (U.S.G.S. Nantahala folio, No. 143, p. 4). *Brasstown schist.*—Greater part consists of banded ottrelite schist, at base of which is a variable thickness of banded sl. with little or no ottrelite. This lower memb. is most developed S. of Valley River, and relation of the two members to each other are well seen btw. Brasstown and Hayesville. A few mi. N. of Brasstown the ottrelite-bearing rocks are much less conspicuous and banded slates occupy a large area. The strata are there less folded and metamorphism is less. On N. side of Valley River Basin practically all of fm. contains ottrelite. Eastward toward Nantahala River the ottrelite diminishes, and disappears in neighborhood of Nantahala. All schists and slates of the fm. are dark colored and vary from dark blue or bluish black to dark gray. They are nearly always marked by fine banding of light-gray and dark colors. The light-gray layers are slightly siliceous and occasionally grade through sandy sl. into seams of light-gray ss. Thickness estimated at 1,200 to 1,500 ft. Underlies Valleytown fm. and overlies Tusquitee qtzite.

Named for exposures on Brasstown Creek, Clay Co., N. C.

Brattleboro phyllite.

Ordovician: Southeastern Vermont (Windham County).

C. H. Richardson, 1929 (16th Rept. Vt. State Geol., p. 232). *Brattleboro phyllite.*—Includes all phyllites that flank Cavendish schist and Reading gneiss on E. of Reading, Cavendish, Baltimore, and Chester. Its home is in Springfield, Rockingham, Putney, Brattleboro, Guilford, and Vernon, and southward into Mass. Is youngest fm. in SE. Vt. Assigned to Ord. Named because Brattleboro Twp is practically all covered with a fine-grained graphitic phyllite schist. Brattleboro phyllite and the older Randolph phyllite are interstratified with Waits River ls.

C. H. Richardson, 1931 (17th Rept. Vt. State Geol., pp. 192–211). *Brattleboro phyllite* may be time equiv. of Randolph phyllite. Belongs to Memphremagog group.

Bratton shale. (In Bluestone formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 294, 318). *Bratton sh.*—Sandy sh., red in places, greenish brown in other places; 25 to 35 ft. thick. Underlies Bratton ss. and overlies Upper Belcher ss. (all members of Bluestone group [fm.]). Type loc. same as Bratton ss.

Bratton sandstone. (In Bluestone formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 293, 317). *Bratton ss.*—Green, flaggy, or massive, fine-grained ss., 5 to 20 ft. thick. Underlies Hunt sh. and overlies Bratton sh. (all members of Bluestone group [fm.]). Type loc. near extreme head of Bratton Branch of Brush Creek, in Mercer Co.

Brave Boat Harbor biotite granite.

Carboniferous (?): Southwestern Maine (York County).

A. Wandke, 1922 (Am. Jour. Sci., 5th, vol. 4, pp. 148, 149, 154). Much more sheared than the other nearby intrusives. Doubtfully classified as Carbf. Highly cataclastic. Occurs on NE. side of Brave Boat Harbor, Kittery Twp, York Co.

Braxton formation.

Pennsylvanian: Northern West Virginia.

J. A. Taff and A. H. Brooks, 1896 (U.S.G.S. Buckhannon folio, No. 34). *Braxton fm.*—Chiefly red clay sh. with some green and yellow shales interbedded with friable brown ss.; some ss. beds are compact and 30 to 40 ft. thick. The shales locally become calc. and grade into impure ls. Max. thickness in this quad. 750 ft., but top has been eroded away. Is surface rock over greater part of Braxton Co. Overlies Upshur ss.

Corresponds to upper part of Conemaugh fm. and Monongahela fm.

Brayman shale.

Ordovician (?): Eastern New York (Schoharie and Albany Counties).

A. W. Grabau, 1906 (N. Y. State Mus. Bull. 92, p. 101). *Brayman shales.*—Pyritiferous sh., olive or grayish clay sh., often alternating with bluish beds and weathering to lighter color. Thickness 27 to probably 40 ft. Is of distinctive character and local development, and demands separate name as a local memb. of Salina series, whose exact equivalence in complete Salina series of central N. Y. is doubtful. Called Clinton shales, pyritiferous shales, Salina shales, etc., in the literature. No fossils. Probably approx. = Rosendale cement bed. Is uncon. overlain by Cobleskill ls. and rests on a ss. that may be Binnewater ss. Named for Braymanville, Cobleskill Co.

J. M. Clarke, 1911 (N. Y. State Mus. Bull. 149, p. 12). During investigation of Frankfort sh. in Cobleskill region, evidence was obtained showing that Brayman sh., which formerly was referred to the Clinton and later correlated with the Salina, is most probably of Lower Siluric [Ord.] age.

In 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27) E. O. Ulrich assigned the Brayman to Ord. and correlated it with Frankfort sh.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, pp. 52-53). Age of Brayman sh. not definitely determined. Absence of lower members of the Salina in section where it occurs, and apparent hiatus btw. the Brayman and the Cobleskill, make it imperative, if the Brayman belongs to Salina series, to correlate it with the Camillus. On other hand, since basal Brayman is intimately connected with underlying shales without any apparent break, it is highly probable the Brayman constitutes uppermost memb. of Lower Siluric [Ord.] system.

R. Ruedemann, 1912 (N. Y. State Mus. Bull. 162) and 1930 (N. Y. State Mus. Bull. 285, p. 40), assigned Brayman sh. to Ord., but in 1929 (Geol. Soc. Am. Bull., vol. 40, p. 412) he assigned it to Sil.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 318, 342). *Brayman sh.* probably represents a residual soil of the Ord., according to Ruedemann (1912 and 1930) and Ulrich. [But she placed it opposite Salina, and in N. Y. State Mus. Bull. 303, 1935, she assigned it to Sil.]

Brazean formation.

Cretaceous (?): Alberta.

G. S. Malloch, 1911 (Canada Geol. Surv. Mem. 9, p. 37). [Assigned to Triassic.]

W. Malcolm, 1913 (Canada Geol. Surv. Mem. 29, p. 45), assigned this fm. to Cret., and J. A. Allan and R. L. Rutherford, 1934 (Alberta Research Council Rept. No. 30, p. 34) assigned it to Tert.

Brazer limestone.

Mississippian (upper and middle): Northeastern Utah, eastern and south-central Idaho, and southwestern Wyoming.

G. B. Richardson, 1913 (Am. Jour. Sci., 4th, vol. 36, pp. 407, 413). *Brazer ls.*—Massive to thin-bedded light-gray siliceous ls. and ss., 800 to 1,400 ft. thick, in northern Utah. Underlies Wells fm. and overlies Madison ls.

Named for exposures in Brazer Canyon, Rich Co., NE. Utah.

Brazil formation.

Pennsylvanian: Southwestern Indiana.

M. L. Frller and G. H. Ashley, 1902 (U. S. G. S. Ditney folio, No. 84). *Brazil fm.*—Alternating shales and thin sss., with an occasional thin ls. and several coal beds; 300 ft. thick; massive ss. near top and near base. Extends from top of Mansfield ss. to base of Petersburg coal (basal memb. of Petersburg fm.). [Includes strata of Pottsville and Allegheny age.]

E. R. Cumings, 1922 (Hdb. Ind. Geol., pt. 4, Sep. Pub. 21, p. 525). Brazil fm. of Fuller and Ashley corresponds to nothing significant in Coal Measures stratigraphy, overlapping from the Pottsville into the Allegheny, and includes beds unknown in vicinity of Brazil. Either the name should be abandoned, or it should be restricted to limits consonant with strat. requirements, and in keeping with the rocks exhibited at Brazil. Writer prefers latter procedure, and has accordingly amended the name *Brazil fm.* to include only the Brazil block coal intervals and the Minshall coals up to the marked discon. above coal No. 2. The Mansfield and Brazil as emended constitute the Pottsville of Ind. Is discon. overlain by Staunton fm.

W. N. Logan, 1926 (Ind. Dept. Cons., Div. Geol. Pub. 55, pp. 477–478), divided the Penn. rocks of Putnam Co., Ind., into *Brazil (Allegheny)* and *Mansfield (Pottsville)*. On other pp. of this rept he classified the Penn. rocks as *post-Allegheny, Allegheny,* and *Pottsville.*

W. N. Logan, 1929 (Ind. Dept. Cons. 11th Ann. Rept., pp. 30–34). Pottsville div. of W. and SW. Ind. divided into (descending): (1) *Brazil group* (80 ft. thick, including coal No. 2 at top and Lower Block coal at base) and (2) *Mansfield group* (100 to 400 ft. thick, resting uncon. on Miss.). Brazil group underlies Staunton group, lowest group of Allegheny div. [This classification was followed by M. A. Harrell, 1935 (Ind. Dept. Cons. Pub. No. 133).]

Named for Brazil, Clay Co.

Brazil limestone.

Pennsylvanian: Central western Indiana.

F. C. Greene, 1911 (Ind. Acad. Sci. Proc. for 1910, pp. 169–171). *Brazil ls.*—Dark-colored bituminous stone, having irregular fracture, exposed just below surface at Brazil; 7 to 17 ft. thick. Probably to be correlated with Fort Scott ls. of Kans., since it contains similar fauna.

Preoccupied. Included in Brazil fm.

Named for Brazil, Clay Co.

Brazil Branch breccia.

Cretaceous: Central northern Arkansas (Perry County).

C. Croneis and M. Billings, 1929 (Jour. Geol., vol. 37, pp. 543, 554) and 1930 (Ark. Geol. Surv. Bull. 3, pp. 158–160). The rock here described as *Brazil Branch breccia* crops out in W½ of SE¼ of sec. 29, T. 4 N., R. 17 W., about 3 mi. S. by W. of Perryville, in valley of Brazil Branch (a perennial tributary of Fourche la Fave River), on land owned by J. R. Myers. Consists chiefly of angular fragments of black sh. set in a gray to black groundmass containing crystals of biotite. Less common fragments are ouachitite, nephelite-aegirite syenite, and shonkinite. Probably middle Cret.

†Brazos series.

Late Permian and Triassic: Texas, Oklahoma, southern Kansas, and eastern New Mexico.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, pp. 100–103). *Brazos series.*—All rocks of Tex., Okla., Kans., and eastern N. Mex. btw. top of conformable Coleman div. [now known to be approx. same as Wichita] of Permo-Carbf. beds below and base of uncon. Cret. above. Consists of red clays, sss., occasional impure ls., some cgl., and great beds of gyp. [Also called "Red Beds" and "Permo-Triassic Red Beds."] Includes Wichita [then supposed to be older than Coleman div.], Clear Fork, Double Mtn, and Dockum fms.

Named for Brazos River, central northern Tex.

†Brazos sandstone.

Pennsylvanian: Central northern Texas.

F. B. Plummer, 1919 (A. A. P. G. Bull., vol 3, p. 138). Strawn div. overlies Millsap div., and is divided into (descending) Gordon, Mineral Wells sss., *Brazos ss.*, etc. [Subdivisions not described.]

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 25, 31; Univ. Tex. Bull. 2132, p. 76 and charts). [See 1922 entry under *Brazos River cgl. memb.*]

Same as *Brazos River cgl. memb. of Garner fm.*, of Strawn group.

Brazos River conglomerate member (of Garner formation).

Pennsylvanian: Central northern Texas.

F. B. Plummer, 1919. [See *Brazos ss.*]

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 25, 31; Univ. Tex. Bull. 2132, pp. 75, 76, and charts). *Brazos River ss. and cgl. memb. of Mineral Wells fm.*—The lowest of the thick sss. which are most prominent feature of Mineral Wells fm. Occurs about 300 ft. above base of that fm. Is a very prominent ledge of massive, coarse-grained ss. that produces a striking escarpment. In places contains lenticular masses of cgl. Thickness 25 to 50 ft. Underlies East Mtn sh. memb. and overlies Mingus sh. memb.; all included in Mineral Wells fm. Named for widely distributed exposures along Brazos River, especially the high cliff at Inspiration Point, 8 mi. due S. of Mineral Wells.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 106, 108). G. Scott and J. M. Armstrong (unpublished rept on geol. of Parker Co.) restrict *Mineral Wells fm.* to beds above *Brazos ss. and cgl.* and introduce *Garner fm.* for lower part of original Mineral Wells fm., extending from top of Brazos ss. and cgl. down to base of Thurber coal.

The name *Brazos* being preoccupied, the U. S. Geol. Survey designates this memb., which is chiefly cgl., as *Brazos River cgl. memb. of Garner fm.* F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, pp. 23+), call this memb. *Brazos River ss.* They state that, as pointed out by H. X. Bay (Univ. Tex. Bull. 3201, 1933, pp. 165–166), it is in part at least of fluviatile origin and that it grades to W. into beach and marine deposits.

Breakwater quartzite.

Pre-Cambrian (upper Huronian): Northeastern Wisconsin (Florence district).

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184, p. 4). *Breakwater qtzite*, named for its location near Breakwater Falls on Pine River, Florence Co., is tentatively assigned to Goodrich epoch [being correlated with Goodrich qtzite of Marquette dist.].

Breathitt formation. (In Pottsville group.)

Pennsylvanian: Southeastern Kentucky.

M. R. Campbell, 1898 (U. S. G. S. London folio, No. 47). *Breathitt fm.*—Sandy sh. and coarse ferruginous ss. with occasional coal seams, the Pittsburg (Ky.) coal lying at base. Thickness 550 ft. Overlies Corbin cgl. lentil of Lee fm. and includes all post-Lee Penn. rocks. Named for Breathitt Co., where it is present in great force. [As defined included rocks of Pottsville age only, the Allegheny fm. not being present in this part of Ky.]

A. M. Miller, 1910 (Ky. Geol. Surv. Bull. 12). Crandall, like Mr. Campbell, made no attempt to define upper limits of any fm. which has as its base a contact with the Conglomerate Series. Crandall in his rept on Whitely Co. enumerated 9 coal seams in the Measures above the Cgl. Whether all of these will be finally included in the Breathitt is yet to be determined. [He included in the Breathitt, Lily coal or No. 4 (No. 1 of old writers), Lower Blue Gem coal (No. 5), Upper Blue Gem coal (No. 6), and Main Jellico coal (No. 7), also 200 ft. of beds above Jellico coal.]

A. M. Miller, 1919 (Dept. Geol. and Forestry Ky., ser. 5, Bull. 2, p. 10). *Breathitt fm.* overlies Corbin cgl. and includes Homewood ss. at top. Thickness 525 to 600 ft.

†Breckenridge formation. (In Cisco group.)

Pennsylvanian: Central northern Texas.

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, pp. 133–145). *Breckenridge fm.* consists of 3 persistent and lithologically similar ls. members, upper, middle, and lower, respectively, separated by thick sh. beds and lenticular sands. In places a 4th ls. memb. is present about 10 ft. below the lower ls. The 3 lss. form escarpments around E. end of Breckenridge oil-field. Underlies Waldrip fm. and overlies Gunsight ls.

F. B. Plummer and R. C. Moore in 1922 replaced this name with *Thrifty fm.* (in which, however, they included 0 to 140 ft. of sh. above Gunsight ls.), and adopted *Breckenridge ls.* for top memb. of Thrifty fm.

Breckenridge limestone member (of Thrifty formation).

Pennsylvanian: Central northern Texas (Brazos River region).

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31; Univ. Tex. Bull. 2132, pp. 152, 154, 155, 160). *Breckenridge ls. memb.*—Gray, massive, and resistant ls., 3 to 5 ft. thick, forming top memb. of Thrifty fm. Makes prominent escarpment in and about town of Breckenridge, Stephens Co., and is typically exposed S. of Main Street. Lies 25 to 45 ft. above Blach Ranch ls. memb. of Thrifty, the two lss. being separated by sh.

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501, pp. 197+), used *Breckenridge ls.* for top memb. of Thrifty fm. in Colorado River region.

The U. S. Geol. Survey at present treats Chaffin ls. as top memb. of Thrifty fm. in Colorado River region. Some geologists regard Chaffin ls. as = Breckenridge ls.

Breckenridge lime.

See under *Caddo lime.*

†Brecksville shale member (of Orangeville shale).

Mississippian: Northeastern Ohio.

C. S. Prosser, 1912 (Ohio Geol. Surv., 4th ser., Bull. 15, pp. 69, 98, 127). *Brecksville sh. memb.*—Blackish or bluish black sh., with few thin sss., 105 ft. thick; forming major part of Orangeville fm. Underlain by Aurora ss. memb. of Orangeville [0 to 10 ft. thick] and overlain by Royalton fm.

Corresponds to all of Orangeville sh. except basal 10 to 20 ft. (See U. S. G. S. Bull. 818, 1931.)

Named for Brecksville, Cuyahoga Co.

Breedon sand.

A subsurface sand in Mingo Co., W. Va., that is believed to lie at base of Pottsville group (Penn.). Occurs near Breedon, Mingo Co.

Brelsford sand.

A subsurface sand, 0 to 45 ft. thick, in Smithwick sh. (Penn.) of central northern Tex., lying 75 to 160 ft. above Black lime.

Bremen sandstone member (of Pottsville formation).

Pennsylvanian: Northern central Alabama.

C. Butts, 1910 (U.S.G.S. Birmingham folio, No. 175). *Bremen ss. memb.*—Gray, coarse-grained, thick-bedded quartz ss., 80 ft. thick, occurring in lower part of Pottsville fm. in Warrior coal field. Overlies Black Creek coal.

Named for exposures in Bremen, Cullman Co., NW. corner of Birmingham quad.

Bremen moraine.

Pleistocene (Wisconsin stage): Northern Indiana. Shown on moraine map (pl. 32) of U.S.G.S. Mon. 53. Named for Bremen, Marshall Co.

Brentwood limestone member (of Bloyd shale).

Pennsylvanian: Northwestern Arkansas.

G. I. Adams and E. O. Ulrich, 1904 (U. S. G. S. P. P. 24, pp. 28, 109). *Brentwood ls.*—Geographic name to replace non-geographic term *Pentremital ls.* Sometimes occurs in single ledge, but often separated into two ledges btw. which intervene shales and sss. Overlies Washington sh. and ss. of Ark. Geol. Survey [Hale fm.] and underlies Coal-bearing sh. of that Survey. Included in Morrow fm.

G. I. Adams and E. O. Ulrich, 1905 (U.S.G.S. Fayetteville folio, No. 119). *Brentwood ls. memb.*, 80 ft. thick, consists of thin beds of gray crystalline ls. and sh. underlain by sandy sh. [This sandy sh. appears not to be the same as the 6 to 10 ft. of calc. black sh. which in Winslow, Eureka Springs, and Harrison quads. and other areas underlies the Brentwood ls., being of same character as the black calc. shales which occur higher up in the Bloyd sh., but it appears to correspond to beds which in other areas are included in the underlying sandy Hale fm. When Morrow fm. was subdivided into Bloyd sh. above and Hale fm. below, the Brentwood was included in the Bloyd and was defined as separated from Hale fm. by the 6 to 10 ft. of calc. black sh. This is the present approved definition. (See U.S.G.S. Eureka Springs–Harrison folio, No. 202, 1916, by A. H. Purdue and H. D. Miser.)]

Named for Brentwood, Washington Co.

Brereton limestone. (In McLeansboro formation.)

Pennsylvanian: Central western Illinois (Fulton County).

T. E. Savage, 1927 (Am. Jour. Sci., 5th, vol. 14, pp. 307–316), applied *Brereton ls.* to basal beds of McLeansboro fm. of Fulton Co., and called overlying beds *Copperas Creek sh. and ss.* Thickness and derivation of name not stated, but probably named for the town in Fulton Co.

Brereton cyclical formation.

A name applied by H. R. Wanless (Ill. Geol. Surv. Bull. 60, 1931, pp. 179–193) to lower part of McLeansboro fm. (Penn.) and uppermost part of Carbondale fm. (Penn.) of central western Ill., based upon the rhythmic-cycle theory of sedimentation. Includes coal No. 6. Derivation of name not stated.

Bretonian.

Upper Cambrian: New Brunswick.

C. D. Walcott, 1891 (U.S.G.S. Bull. 81, p. 247). *Bretonian.*—This name is applied by Mr. G. F. Matthew to upper series of Camb. rocks as found in the vicinity of St. John, New Brunswick, and on island of Cape Breton, where fauna of the div. is well developed. It will be arranged as an Upper Camb. fm. (Footnote: "Illustrations of the fauna of the St. John group, No. 5. Trans. Roy. Soc. of Canada, vol. 8, 1890, p. 129.")

In 1903 (Canada Geol. Surv. Rept. Camb. rocks of Cape Breton, p. 49) G. F. Matthew assigned *Bretonian div.* to Camb. In 1909 (Sci., n. s., vol. 29, pp. 351–356) A. W. Grabau proposed that *Bretonian* be redefined and adopted as name for Upper Camb., to replace Saratogan and Potsdamian. He stated that Bretonion of Matthew included at top basal Ord. beds corresponding to post-Tremadoc beds of Europe, which should be excluded from Bretonian, and that at base Bretonian should be extended so as to include the upper part of Johannian of Matthew. Named for Cape Breton, where its thickness approaches 1,000 ft. In 1911 (Geol. Soc. Am. Bull., vol. 22, p. 624) E. O. Ulrich stated that "All of the Bretonian seems to me younger than the Ozarkian" [and therefore all of Ord. age]; and (p. 679) that he "refers most—perhaps all—of Matthew's Bretonian to the Canadian" [Lower Ord.]. In 1913 (12th

Int. Geol. Cong. Guidebook 1, p. 270) Hyde referred Bretonian to Camb., as did Matthew in 1914 (Roy. Soc. Canada Trans., ser. 3, vol. 8, sec. 4, p. 77). In 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4) G. Van Ingen referred Bretonian to Lower Ord., as did Ulrich in 1919 (Md. Geol. Surv. Camb. and Ord. vol., chart opp. p. 90).

Brevard schist.

Lower Cambrian: Western North Carolina (Transylvania, Buncombe and McDowell Counties), northwestern South Carolina, and northwestern Georgia.

A. Keith, 1905 (U.S.G.S. Mount Mitchell folio, No. 124, p. 5 and columnar section). *Brevard schist.*—Mostly schist, of dark bluish black or black color and sed. origin. Between Swannanoa Gap and Old Fort the schistose character is less pronounced and the rock is a banded mica-slate. All strata are fine grained except a few siliceous layers, which represent original sandy strata. The rocks are composed mainly of very fine quartz and muscovite, with countless minute grains of iron oxides scattered throughout. Graphite in minute grains is a common constituent and here and there occurs in layers; has been mined. Lss. are not found in Mount Mitchell quad., but a few mi. SW. of Fairview they appear at frequent intervals for more than 50 mi. Principal variation in appearance of fm. is in presence or absence of garnets (of secondary origin). Thickness 1,000+ ft. Rests uncon. on Archean gneisses and granites.

Named for exposures near Brevard, Transylvania Co., N. C.

Brewer phyllite member (of Talladega slate).

Pre-Cambrian or Paleozoic: Northern central and eastern Alabama.

C. Butts, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14, map, p. 52). *Brewer phyllite memb. of Talladega sl.*—Sericitic phyllite of deep purplish or chocolate color, occurring in Talladega sl. a few hundred ft. above Sawyer ls. memb. Max. thickness 1,000± ft.

C. Butts (U.S.G.S. Montevallo-Columbiana folio, No. 226, in press), treated *Brewer phyllite* as a distinct fm., underlain by Waxahatchee sl. and overlain by Wash Creek sl.

Named for exposures at Brewer School, in Columbiana quad., in Chilton Co.

Brewer Creek latite.

Tertiary: Southern Colorado (Bonanza district, Saguache County).

W. S. Burbank, 1932 (U.S.G.S.P.P. 169). *Brewer Creek latite.*—Flows, 500± ft. thick. Overlies Porphyry Peak rhyolite and is overlain by andesite flows. Exposed N. of and westward along Brewer Creek.

Brewer Dock member.

Silurian (Niagaran): Western central New York (Rochester region).

H. E. Alling and J. E. Hoffmeister, 1932 (16th Int. Geol. Cong. Guidebook 4, chart opp. p. 6, pp. 106, 107, 108). In the Clinton of Rochester region, above Maplewood sh. occurs about 3 ft. of interbedded ls. and sh., typically exposed in Genesee Gorge near Brewer Dock, and locally known as *Brewer Dock lss. and shales.* Characteristic fossil (chiefly in ls. layers) is a minute gastropod of genus *Cyclora.* The brachiopod *Hyattidina congesta* is also found in the fm. Overlain by Furnaceville iron ore.

J. T. Sanford, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 194). The former *Bear Creek* of Genesee Gorge is designated as *Brewer Dock memb. of the Reynales,* as the fm. at Bear Creek is younger. [All are included in Clinton.]

Brewerton shale.

Silurian: Central New York.

G. H. Chadwick, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 327–368). *Brewerton sh.*—Fossiliferous shales, 36 ft. thick, lying just under Kirkland ls. in Lakeport section, and terminating downward with a black pebble seam. Exposed at Brewerton [Onondaga Co.]. Overlies true Williamson sh. [memb. of Clinton fm.].

E. O. Ulrich, 1923 (Md. Geol. Surv. Sil. vol., pp. 191, 347, etc.). [See 1923 entry under *Phoenix or Schroeppel sh.*]

†Brewerville sandstone. (In Chester group.)

Mississippian: Southwestern Illinois and southeastern Missouri.

S. Weller, 1913 (Ill. Acad. Sci. Trans., vol. 6, pp. 120, 121). *Brewerville ss.*—Massive brown, fine or medium-grained ss., in thick beds, often more or less conspicuously cross bedded. Thickness 70 to 80 ft. Uncon. underlies Renault fm. and uncon. overlies Ste. Genevieve ls., or, where that fm. is absent, St. Louis ls. Equiv. to more massive basal memb. of Cypress ss. of Engelmann and Ulrich.

Later (1920) abandoned by Weller, for older name *Aux Vases ss.* The true Cypress is now known to be a much younger ss. (See Ill. chart.)

Named for Brewerville Twp, Randolph Co., where it is well exposed in Mississippi River bluffs.

†Brewster formation.

Middle Ordovician: Southwestern Texas (Brewster County).

J. A. Udden, C. L. Baker, and E. Böse, 1916 (Univ. Tex., Bur. Econ. Geol. and Tech. Bull. 44, pp. 35, 37). *Brewster fm.*—Interbedded dark-colored sss. and shales of Upper Camb. age, occupying small areas in the ancient eroded mtn folds in Brewster Co., 5 to 30 mi. S. of Marathon. Total thickness unknown. Underlies Marathon series (Lower and Middle Ord.)

P. B. King, 1931 (A. A. P. G. Bull., vol. 15, No. 9, pp. 1063–1064). Fossils recently collected from typical Brewster fm. show that type section is part of Woods Hollow sh., of Middle Ord. (Trenton) age, and that "Brewster" should be abandoned and a new name be given to the indigenous Upper Camb. strata. They are here named *Dagger Flat ss.*

Named for exposures in Brewster Co.

Brezee phyllite.

Lower Cambrian: Southwestern Vermont (Rutland County).

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 399). *Brezee phyllite.*—Almost wholly sl. or phyllite, dark or bluish gray, much of it banded with light gray. Weathers brownish or dull greenish gray. In upper part is a bed of calc. qtzite, 5 to 10 ft. thick, that can be followed for considerable distances. Locally this qtzite passes into sandy ls. A few ft. below the qtzite is a zone of small ls. lenses. Lowest part of fm. contains beds of cherty sl., mostly black but associated with purple sl. of kind so characteristic of the Lower Camb. in Taconic Range. Thickness doubtless exceeds 500 feet. Outcrops around N. and NW. margins of Taconic Range. Underlies Stiles phyllite. What normally lies beneath it is not known because of overthrust. Named for Brezee Mill Creek, which flows out of NE. end of Taconic Range [3 mi. S.–SW. of Brandon, according to Keith, personal communication; so must be in Brandon or Castleton quad., but name not shown on either map].

Briarfield dolomite.

See *Brierfield dol.*

Briceville shale. (In Pottsville group.)

Pennsylvanian: Eastern Tennessee.

A. Keith, 1896 (U. S. G. S. Loudon folio, No. 25, p. 4). *Briceville sh.*—Mainly bluish gray and black fine-grained sh., containing many small beds of hard ss. and workable coal seams. Thickness 300 ft. or more. Highest fm. in Loudon quad. Overlies Lee cgl. [In type area (to NE. of Loudon quad.) the fm. is overlain by Wartburg ss., according to U. S. G. S. folio No. 33; but the fm. overlying the Briceville was in 1925 named *Jellico fm.* by L. C. Glenn, and Wartburg ss. was restricted to a ss. near middle of Briceville sh., which, according to Glenn, is the ss. exposed at Wartburg. These changes of definitions have not been considered by U. S. Geol. Survey for its publications.]

L. C. Glenn, 1925 (Tenn. Dept. Ed., Div. Geol. Bull. 33B, p. 16), gave thickness of Briceville fm. as 550 to 825 ft., and stated it is now known that there are at least 200 and probably 300 or even more ft. of shales belonging to this fm. beneath drainage level in Briceville-Coal Creek region, and that 85 per cent of fm. is sh.

Named for occurrence at Briceville, Anderson Co.

Brick Yard limestone.

Pennsylvanian: Northern central Texas (Eastland County).

W. G. Wender, 1929 (Tex. Bur. Econ. Geol. geol. map of Eastland Co.). [*Brick Yard ls.* is shown in section as lying 75 ft. below Lake Pinto ss., in Mineral Wells fm. Is not defined, and is not listed by E. H. Sellards, Univ. Tex. Bull. 3232, 1933.]

Bridal Veil granite.

Probably Cretaceous: Northern California (Yosemite region).

H. W. Turner, 1899 (Jour. Geol., vol. 7, p. 154). *Bridal Veil granite.*—Fine-grained white granite, occurring in drainage of Bridal Veil Creek, on Horse Ridge, and at many other points in Yosemite Park.

Forms brink of Bridalveil Fall.

Bridgeburg horizon.

Silurian: Western New York.

G. H. Chadwick, 1917 (see 1917 entry under *Bertie ls. memb.*).

Derivation of name not stated.

Bridge Creek limestone member (of Greenhorn limestone).

Upper Cretaceous: Western Kansas.

N. W. Bass, 1926 (Kans. Geol. Surv. Bull. 11, p. 67). *Bridge Creek ls. memb.*—Alternating limy sh. and thin chalky ls. Four-fifths of memb. is limy sh., but the ls. beds are the conspicuous feature. Thickness 74 ft. Top memb. of Greenhorn ls. in Hamilton and Kearny Counties. Top 25 ft. is = Pfeifer sh. memb. of counties to E., and rest of memb. corresponds to Jetmore chalk memb. of areas to E. Rests on Hartland sh. memb. of Greenhorn ls. and is overlain by Fairport chalky sh. memb. of Carlile sh.

Named for exposures in Bridge Creek NW. of Medway, Hamilton Co.

Bridge Creek shales.

Miocene (lower) or Oligocene: Central northern Oregon (John Day Basin).

R. W. Chaney, 1927 (Carnegie Inst. Wash. Pub. 346). *Bridge Creek leaf shales*, heretofore included in upper part of Clarno fm., properly belong to John Day series (Olig.). [See 1927 entry under *Clarno fm.*]

R. W. Chaney, 1927 (Carnegie Inst. Wash. Pub. 349, pp. 1–22). *Bridge Creek shales.*—At least 40 ft. thick. On Bridge Creek consist of layers of leaf-bearing shales separated by beds of fine yellow clay up to 1 ft. thick. At Clarnos Ferry and at Grays Ranch on Crooked River the intervening clays are thicker and coarser than at Bridge Creek. Horizontally the leaf shales do not appear to extend great distances, probably not more than a few hundred ft., and are surrounded by the banded reddish and yellowish shales characteristic of lower John Day. On lithologic and strat. grounds it does not seem possible to draw line btw. the leaf shales and the lower John Day beds with which they are associated. Flora is more closely related to Mio. floras of West than to Eo. [On p. 47 he assigned Bridge Creek flora to Olig.] Bridge Creek sh. here included in John Day series, instead of Clarno fm.

See under *Clarno fm.*

R. W. Brown classifies the flora from Bridge Creek, Oreg., as lower Mio. (See recent U. S. G. S. publications.)

Bridgeport sandstone. (In Wills Creek shale.)

Silurian: Central Pennsylvania (Perry County).

E. W. Claypole, 1885 (2d Pa. Geol. Surv. Rept. F_2, pp. 57, 58). *Bridgeport ss.*—Hard flinty ss. 5 ft. thick. Overlain by 200 ft. of red sh. and underlain by

500 ft. of red sh., all included in Onondaga red and variegated shales. Best two exposures are near [S. of] Bridgeport [Perry Co.], on bank of Sherman's Creek and near Mr. Egolf's mill in Kennedy's Valley.

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 2, pp. 761–764). The *Bridgeport ss.,* in Salina Lower (Bloomsburg red) sh., is a very singular bed of hard flinty ss., about 8 ft. thick, very hard and solid in middle but more soft and shaly toward top and bottom.

Bridgeport limestone. (In Palo Pinto formation.)

Pennsylvanian: Central northern Texas (Wise County).

E. Böse, 1918 (Univ. Tex. Bull. 175, pp. 12–13). *Bridgeport ls.*—Thick-bedded gray and yellowish ls. full of crinoids. Excellent horizon marker. Is 3± ft. thick near Bridgeport [Wise Co.], 5 ft. thick near ranch house of Waggoner ranch; eroded to SW. Exposed in W. part of East Bridgeport. Lies 180± ft. below Rockhill ls. Is separated from underlying coal seam worked at Bridgeport by 30± ft. of gray marly sh. Appears to belong to Strawn fm.

Replaced by *Willow Point ls.* (see 1932 and 1933 entries under *Willow Point ls.*) and included in Palo Pinto fm. by E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 105, 110).

Bridgeport sand.

Subsurface sand in Carbondale and Pottsville fms. (Penn.) of Crawford and Lawrence Counties, Ill. (See Ill. Geol. Surv. Bull. 54, index.) The name is also applied to a sand in Mansfield ss. memb. of Pottsville fm. of southern Ind.

Bridger formation.

Eocene (middle and upper?): Southwestern Wyoming, northwestern Colorado, northeastern Utah (Uinta Mountains region).

F. V. Hayden, 1869 (U. S. Geol. Surv. Terr. 3d Ann. Rept., p. 191 of 1873 ed.). The next group commences not far W. of Bryan and is doubtless a prolongation upward of Green River shales. The sediments are composed of more or less fine sands and sss., mostly indurated, sometimes forming compact beds, but usually weathering into those castellated and domelike forms which have given such celebrity to the "Bad Lands" of White River. Church Buttes, near Fort Bridger [Uinta Co., Wyo.], is an example of this group, and shows the style of weathering to which I refer. I have called this group the *Bridger group,* from fact it is best developed in this region. Assigned to upper tertiary.

F. V. Hayden, 1871 (U. S. Geol. Surv. Terr. 4th Ann. Rept., pp. 55–58). *Bridger group.*—Leaden-gray, sombre, indurated aren. clays intercalated with beds of rusty-brown and gray sss., all tending to concretionary structure and disintegrating by exfoliation in thin concentric layers. Aren. materials predominate. Covers large area E. of Fort Bridger and composes upper part of Bridger Butte. Grades into underlying Green River group, which is lighter colored.

C. King, 1878 (U. S. Geol. Expl. 40th Par., vol. 1). *Bridger group,* upper Eocene fresh-water deposits, is 0 to 2,500 ft. thick. Upper part consists of 1,500 ft. of peculiar clay ss., olive and drab banded with olive green; lower part consists of 1,000 ft. of drab and gray ss. with some admixture of clay. Deposited in Washakie Lake. On N. side of the Uinta the beds overlap Green River group and come in contact with Vermilion Creek group (=Wahsatch group of Hayden).

According to J. D. Sears and W. H. Bradley (U. S. G. S. P. P. 132F, 1924, p. 99) the Bridger deposits are of fluviatile and fresh-water lake origin.

In Uinta Basin of NE. Utah the Bridger fm. is overlain by Uinta fm. (upper Eocene). (See under *Uinta fm.*) Farther NE. in Utah, however, and in SW. Wyo. and NW. Colo., the Uinta fm. is absent and the Bridger is uncon. overlain by the much younger Browns Park fm. or the Bishop cgl. The Bridger ranges in thickness up to 2,500 ft. For many years the Bridger fm. has been divided by vertebrate paleontologists of Am. Mus. Nat. Hist. into several named paleontologic zones, each characterized by certain vertebrate genera. These zones have also been called, for convenience, Bridger A, Bridger B, Bridger C, Bridger D, and Bridger E, in ascending order. In Uinta Basin of Utah the Bridger beds equiv. to Bridger A, Bridger B, Bridger C, and Bridger D are said not to be fossiliferous, and the beds corresponding to Bridger C and D have in the past been assigned to Uinta fm. and called *Uinta A*, while beds corresponding to Bridger E horizon of Bridger Basin have been called *Uinta B*, the overlying beds (*Diplacodon* zone) being called *Uinta C*. The latter zone (Uinta C) is present only in Uinta Basin, Utah, where it is 600± ft. thick. It is the "true Uinta" of H. F. Osborn, 1895, 1909, 1929, etc., and is Uinta fm. of U. S. Geol. Survey and other authors. Some (all?) members of Am. Mus. Nat. Hist. staff, however, continue to follow the old classification, and include in Uinta fm. the beds equiv. to Bridger C, D, and E, calling Bridger C and D the *Uinta A*, and calling Bridger E the *Uinta B*. This old classification is followed by H. E. Wood, 2d (Am. Mus. Nat. Hist. Bull., vol. 67, art. 5, May 26, 1934, pp. 241–242), who calls these zones *members* and applies to them new geographic names, as explained under *Blacks Fork memb. of Bridger fm.*

†Bridgerian series.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, pp. 36, 279, 309). *Bridgerian series.*—Sss., 500 ft. thick, uncon. underlying Brownian series [Browns Park fm.] and uncon. overlying Greenian series [Green River fm.] in Utah. In Colo. consists of 600 ft. of shales, occupying same interval. In SW. Wyo. it is 1,500 ft. thick. Widely known as the *Bridger beds* or *Bridgerian series*.

Bridge River series.

Pennsylvanian or Permian (?): British Columbia.

C. W. Drysdale, 1916 (Canada Geol. Surv. Summ. Rept. 1915, p. 79). [Assigned to "Devono-Carbf.," but later Canada Geol. Surv. repts assign it to "Penn.-Perm."]

Bridge River augite diorite.

Post-Lower Cretaceous: British Columbia.

V. Dolmage, 1934 (Canadian Min. and Met. Bull. 268, p. 422).

Bridgetimber gravel.

Tertiary? (Pliocene?): Southwestern Colorado.

W. W. Atwood and K. F. Mather, 1932 (U. S. G. S. P. P. 166). *Bridgetimber gravel.*—Ancient gravel fans of coarse gravel, composed of bowlders and pebbles. Thickness 0 to 20 ft. Contemp. with Los Pinos and Bayfield gravels. Caps Bridge Timber Mtn, SW. of Durango.

Bridgeton formation. (In Columbia group.)

Pleistocene: New Jersey.

R. D. Salisbury, 1898 (N. J. Geol. Surv. Ann. Rept. State Geol. 1897, pp. 13–15). *Bridgeton fm.*—In general gravel, but contains both sand and loam and occasionally clay. Differs somewhat from overlying Pensauken fm. [restricted] and from underlying Beacon Hill fm., though difference is not always great. Is unlike Beacon Hill in containing bits of ironstone derived from Cret. or from Beacon Hill fm. Is like Beacon Hill in containing much decayed chert. In general it may be said to contain any sort of material which Beacon Hill contains and some which it does not. In some places seems not to be clearly separable from Beacon Hill fm., while in others it is not easily distinguishable from Pensauken. In other places it is distinctly separable from the Pensauken and in still others from the Beacon Hill.

R. D. Salisbury, 1901 (N. J. Geol. Surv. Ann. Rept. State Geol. 1900, p. xxxv). *Bridgeton fm.* is uncon. with overlying Pensauken fm. restricted and with underlying Beacon Hill fm. Was included in Pensauken fm. of 1895 and earlier repts.

R. D. Salisbury and G. N. Knapp, 1917 (N. J. Geol. Surv. vol. 8, pp. 11, 62). *Bridgeton fm.*—Chiefly coarse sand and gravel. Uncon. underlies Pensauken fm. and uncón. overlies Beacon Hill gravel. It has two contemp. phases so unlike that they are best described separately. They will be called *Glassboro phase* and *Woodmansie phase*. The *Glassboro* is better known and the more distinctive. It has its distinctive development in SW. part of State. Consists primarily of gravel and sand, arkose in many places. Contains occasional boulders and, exceptionally, seams and lenses of clay. Thickness 0 to 60 ft. Its material is primarily quartzose, and is believed to have been brought in largely from N. by rivers and deposited in wide valley btw. Amboy and Salem. It may be in part glacial outwash. The *Woodmansie phase* occurs E. and N. of Glassboro phase. It is not arkose and is without crystalline rock, sh., red ss., etc., of Glassboro phase. It is more largely sand and is thinner. Its materials were derived chiefly from the Miocene and Cohansey fms.

The Bridgeton fm. is now classified as basal fm. of Columbia group in N. J. Is of nonglacial origin.

Named for exposures at Bridgeton, Cumberland Co.

Bridgewater member (in Marcellus shale).

Middle Devonian: Central eastern New York.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 133, 219, etc.). *Bridgewater memb. of Marcellus fm.*—The sh. overlying Chittenango memb. of Marcellus fm. and underlying Solsville memb. of Marcellus in Chenango and Unadilla Valleys. Lower part is soft, fissile, slightly aren. sh. especially characterized by *Leiorhynchus limitare, Conularia,* and *Styliolina fissurella.* The succeeding zone is coarser nonlaminated sh. containing *Leiorhynchus laura* associated with many typical Hamilton fossils, showing the change in faunal facies to E. No continuous sequence of this memb. is exposed in Unadilla Valley, so that a number of ravines must be visited in order to construct a complete section. The lower part, including transition with Chittenango, is shown in Wordens Gulf 1¼ mi. W. of West Winfield; the middle of section is exposed in gully behind the buildings of Rose Farm ¾ mi. N. of West Winfield; and the upper part, and its contact with Solsville memb., are exposed in Seabridge Farm 2¼ mi. W. of Bridgewater. Markham and Fork Mtns at Unadilla Forks are almost completely composed of Bridgewater sh., the Solsville being also top of these elevations. Thickness 200 to 360 ± ft.

Brier slate member (of Vulcan iron-formation).

Pre-Cambrian (middle Huronian): Northwestern Michigan (Menominee district).

C. R. Van Hise and W. S. Bayley, 1900 (U. S. G. S. Menominee folio, No. 62). *Brier sl. memb.*—Heavy, black, ferruginous quartzose sl., 100 to 360 ft. thick. Middle memb. of Vulcan fm. Underlies Curry ore-bearing memb. and overlies Traders ore-bearing memb. Named for Brier Hill.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), adopted *iron-fm.* as a lithologic term, and changed age of *Vulcan iron-fm.* from upper Huronian to middle Huronian.

†Brier Creek marl.

Oligocene and Miocene: Southeastern Georgia and western South Carolina.

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 12, 18, name only, not defined); 1908 (S. C. Geol. Surv., ser. 4, Bull. 2, pp. 435, 464, 465). *Brier Creek phase.*—A high grade marl of a pale yellow color typically exhibited along Brier Creek, near Jacksonboro, Ga In a silicified form it is probably represented on western scarp of Coosawhatchie River near Gifford Station. Overlies King's Creek phase S. of line of Cohen's Bluff near upper line of Hampton Co., S. C. Assigned to Olig.

According to studies of C. W. Cooke this bed in Ga. (type loc.) is Flint River fm. (Olig.), and at the one locality mentioned in S. C. it is Hawthorn fm. (lower Mio.).

Brierfield dolomite.

Upper Cambrian: Northern central Alabama.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pp. 628, 633, 634, pl. 27). Name suggested by Charles Butts. *Briarfield dol.*—Chiefly medium thick-bedded blue and gray siliceous dol., 1,250 ft. thick. Well exposed in Cahaba Valley along Six-Mile

Creek, 10 mi. SW. of Montevallo. Not observed elsewhere. Upper 200 ft. blue dol.; the weathered rock above the middle for 400 to 500 ft. is streaked with convoluted plates of silica and weathers with drusy incrustations; except for basal part, the lower half is without chert; the basal part on weathering is marked by abundant dense residual chert. Underlies Ketona dol. and uncon. overlies Upper Camb. blue lss. [Conasauga ls.] and Conasauga sh. [=Conasauga ls.]. Basal fm. of Ozarkian system. Named for exposures on Mahan Creek in vicinity of Brierfield [correct spelling], Bibb Co.

Brigham quartzite.

Middle and Lower (?) Cambrian: Northeastern Utah and southeastern Idaho.

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804, pp. 6, 7). *Brigham fm.*—Massive qtzitic sss. underlying Langston fm. Thickness at Brigham, Utah, 2,000+ft.; in Blacksmith Fork, Utah, 1,250 ft.; in section W. of Liberty, Bear Lake Co., Idaho, 1,000+ft. Characteristic Middle Camb. fossils in upper part. Type loc. is W. front of Wasatch Range NE. of Brigham, Box Elder Co., Utah.

C. D. Walcott, 1912 (U.S.G.S. Mon. 51, p. 153, footnote). Line of separation btw. Middle and Lower Camb. occurs somewhere in Brigham qtzite.

Bright Angel shale. (Of Tonto group.)

Middle Cambrian: Northern Arizona (Grand Canyon).

L. F. Noble, 1914 (U. S. G. S. Bull. 549). *Bright Angel sh.*—Soft, greenish, micaceous, fossiliferous, sandy sh. with two thin layers of brown crystalline ls. locally present in middle of fm. Thickness 25 to 375 ft. Consists of (descending): (1) Alternating layers of sh. and purplish brown ss. underlain by soft, greenish, micaceous sandy sh., 13 ft.; (2) snuff-colored ls., locally known as "Snuffy ls." 57 ft., including 25 ft. of soft sh.; (3) soft, green, micaceous sandy sh. and thin sss. 160 ft. Middle fm. of Tonto group. Conformably underlies Muav ls. and conformably overlies Tapeats ss. Named for Bright Angel Canyon, in walls of which the fm. is well exposed.

L. F. Noble, 1922 (U. S. G. S. P. P. 131B), transferred from Muav ls. to Bright Angel sh. 58 [68?] ft. of shaly beds containing near base a few beds of mottled ls. similar to the mottled lss. of Muav ls.

Bright Diamond limestone. (In Morrison formation.)

Upper Jurassic: Southwestern Colorado (Ouray district).

J. D. Irving, 1905 (U. S. G. S. Bull. 260, p. 56). [In geologic section of Gold Hill given on this page, upper part of *McElmo fm.* is shown as consisting of (descending): (1) Greenish altered shales and shaly sss.; (2) *Bright Diamond ls.;* (3) *Bright Diamond qtzite;* (4) reddish and greenish shales and sss. The names seem to be derived from Bright Diamond mine.]

Bright Diamond quartzite. (In Morrison formation.)

Upper Jurassic: Southwestern Colorado (Ouray district).

See under *Bright Diamond ls.*

Brighton melaphyr. (In Boston Bay group.)

Carboniferous or Devonian: Eastern Massachusetts.

W. W. Dodge, 1881 (Boston Soc. Nat. Hist. Proc., vol. 21, pp. 205–208), applied *Brighton amygdaloid* to fm. now known as Brighton melaphyr.

L. LaForge, 1932 (U. S. G. S. Bull. 839). *Brighton melaphyr.*—Greenish, brownish, or purplish amygdaloidal melaphyr of basaltic character. Composed of dikes, flows, and probably sills intruded into and interbedded with Brookline cgl. memb. and Dorchester sl. memb. of Roxbury cgl. Few ft. to several hundred ft. thick. Included in Boston Bay group. [B. K. Emerson in U. S. G. S. Bull. 597, p. 56, 1917, included these rocks in Mattapan volcanic complex.]

Named for occurrence at Brighton.

Brigus formation.

Lower Cambrian: Newfoundland.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4). *Brigus fm.*—Red shales with nodular ls. Fossils. Underlies Smith Point fm. and overlies Bonavista fm. Included in Etcheminian series. [Derivation of name not stated.]

Brill sand.

A subsurface sand in Pottsville fm. (Penn.) of SE. Ohio.

Brimfield schist.

Carboniferous: Central Massachusetts, southwestern and central southern New Hampshire, and northern Connecticut.

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, p. 17, map, pl. 34). *Brimfield schist.*—Rusty graphitic fibrolite schist. Overlies Paxton whetstone schist.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 59, 60, 68–72, 86–87, 234–235, and map). *Brimfield schist.*—Coarse, rusty muscovite-biotite schist, full of pyrite, graphite, fibrolite, and pink garnet. Includes coccolite ls. Named for occurrence at Brimfield, Mass. Overlies Paxton quartz schist. To E. becomes Worcester phyllite.

E. Callaghan, 1931 (N. Y. Acad. Sci. Annals, vol. 33, pp. 29, 63–74). *Brimfield schist* restricted and redefined. Given significance as a fm. rather than a rock type. Retained for thin layer of biotite schist that overlies Paxton feldspathic schist; the biotite schist that underlies Paxton feldspathic schist and was formerly included in Brimfield schist being here named *Ware schist.* The schist at Brimfield, the type loc., is this upper biotite schist. Occurs btw. shaft 4 and the granite and in W. end of Wachusett-Coldbrook tunnel. Thickness 900 ft. to E., 1,100+ ft. to W. May be Carbf.

W. G. Foye and A. C. Lane, 1934 (Am. Jour. Sci., 5th, vol. 28, p. 138), consider this fm. to be pre-Carbf.

Briones sandstone. (In San Pablo group.)

Miocene (upper): Western California (San Francisco region).

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). *Briones ss.*—Prevailingly light-colored to whitish, well-washed ss., in some places pebbly or conglomeratic, and in general of coarser texture than lower sss. of Monterey group, of which it is top fm. Thickness 2,300 ft. Very fossiliferous. [Fossils listed.] Includes the nonpersistent Hercules sh. memb. Overlies Rodeo sh. and uncon. underlies San Pablo fm. Named for exposures in Briones Hills, Contra Costa Co.

B. L. Clark, 1921 (Jour. Geol., vol. 29, pp. 586–614), transferred these beds to San Pablo group.

B. L. Clark, 1930 (Geol. Soc. Am. Bull., vol. 41, pp. 751–770). San Pablo group (upper Mio.) includes (descending) Neroly fm., Cierbo fm., and *Briones fm.* The latter fm. is locally known as *Astrodapsis brewerianus* zone. It was formerly included in Monterey group, but Parker Trask (1922) showed that stratigraphically and faunally it is more closely related to overlying San Pablo group. [This is present approved definition of U. S. Geol. Survey.]

Brisco formation.

Silurian: British Columbia.

C. D. Walcott, 1924 (Smithsonian Misc. Coll., vol. 75, pp. 11, 26, 47).

Bristol granite gneiss.

Ordovician (?): Central Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 104–105 and map). *Bristol granite gneiss.*—Consists of granite of varying texture and color, of gneisses and schists derived from the granite, and of hornblende gneiss and hornblende schist. The typical granite gneiss is light gray, with gneissoid structure more or less developed by presence of layers of biotite; the more schistose layers have muscovite. Quartz, orthoclase, some oligoclase, andesine, and biotite are chief components. Garnet nearly always present and in places is principal mineral. Noticeable feature is presence of rounded and lens-shaped eyes, made up of zone of white, granular quartz-feldspar aggregate, inside which is a dark spot composed largely of garnet and chlorite. Covers large part of Bristol Twp.

H. E. Gregory and H. H. Robinson, 1907 (Conn. Geol. and Nat. Hist. Surv. Bull. 7, p. 34). *Bristol granite-gneiss* was originally a mass of granite and diorite intruded into Hartland [Hoosac] schist.

W. M. Agar, 1934 (Am. Jour. Sci., 5th, vol. 27, pp. 354–374). *Bristol quartz diorite* appears to be older than Brookfield diorite.

Bristol limestone. (In Washington formation.)

Permian: Northern West Virginia.

R. V. Hennen, 1912 (W. Va. Geol. Surv. Rept. Doddridge and Harrison Counties, p. 168). *Bristol ls.*—Buff-colored ls., very often nodular and brecciated. Thickness 0 to 4 ft. Underlies Washington fire clay and overlies Washington ss. Named for Bristol, Harrison Co.

E. L. Core, 1929 (W. Va. Acad. Sci. Proc., vol. 3, pp. 204–205). Near base of Little Washington coal near Core, Monongalia Co., occurs a massive, very hard, blue-gray ss., 10 to 15 ft. thick, here named *Dolls Run ss.* Beneath this ss. comes the siliceous *Bristol ls.,* quite persistent but here commercially unimportant. Its thickness is 2 to 8 ft. The 40 to 50 ft. beneath Bristol ls. is made up mostly of shales and thin shaly sss. except in N. part of area, where occurs the massive Mannington ss., 15 to 25 ft. thick. [According to Core and other writers the Washington ss. lies much higher in the section than Bristol ls., so whether the ls. called Bristol by Core is true Bristol ls. is a question.]

†Bristol formation.

Pliocene: Northern Florida.

E. H. Sellards, 1918 (Fla. Geol. Surv. 10th and 11th Ann. Rept., p. 51). If Altamaha is retained as a fm. name, restricted if necessary to the deposits consisting chiefly of red sands and clays lying above the Miocene, it is very possible that the similar materials of this area btw. Apalachicola and Ocklocknee Rivers may be included in that fm. If not referable to Altamaha fm., possibly these materials may be referred to Citronelle fm., although this should not be done until fossils can be obtained or continuity of deposition with Citronelle fm. can be determined. If these materials can be referred to neither of these fms., they may be known as *Bristol fm.,* from their typical exposure in vicinity of Bristol, where they are known to lie stratigraphically above the Choctawhatchee Miocene.

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept.), mapped these deposits as *Citronelle fm.,* and abandoned the preoccupied name "Bristol."

Bristol series.

Pre-Cambrian: Quebec.

M. E. Wilson, 1924 (Canada Geol. Surv. Mem. 136, p. 23).

Bristol Bay silts and gravels.

Pleistocene: Southern Alaska.

J. E. Spurr, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 177–178). *Bristol Bay silts and gravels,* Pleist., extend from Togiak Bay to Bristol Bay.

Bristol Pass limestone.

Mississippian (lower): Eastern Nevada (Pioche district).

L. G. Westgate and A. Knopf, 1932 (U. S. G. S. P. P. 171, pp. 7, 20, map, etc.). *Bristol Pass ls.*—Gray, finely crystalline ls., slightly cherty. Greatest measured thickness 305 ft., but full thickness is unknown. Seems to conformably overlie West Range ls. (Upper Dev.) and occupies strat. position below Peers Spring fm. Named for occurrence at Bristol Pass, in summit of hill immediately N. of benchmark 6149. Fossils (of Madison age) listed.

Bristow shale and sandstone. (In Chester group.)

Mississippian: Southwestern Indiana and western central Kentucky.

W. N. Logan, 1924 (Ind. Dept. Cons. Pub. 42, pp. 11, 125. Taken from unpublished rept. on Perry Co., Ind., by C. A. Malott). *Bristol sh. and ss.*—Underlies Mount Pleasant shales and sss. and overlies Buffalo Wallow shales. Belongs in upper part of Chester group. Thickness 25 ft. in well log in Knox Co., Ind.

C. A. Malott, 1925 (Ind. Acad. Sci. Proc., vol. 34, pp. 110–132). *Bristow ss.*—Thin to massive ss., fine-grained and hard, often qtzitic, well jointed. Occurs in upper Chester shales, about 210 ft. above Glen Dean ls. Thickness usually 3 to 7 ft., but in places it reaches a known max. of 25 ft. Lies 20 or more ft. above Siberia ls. and 15 to 35 ft. below Mount Pleasant ss. Named for exposures at and near village of Bristow, Perry Co., Ind. Also identified at Buffalo Wallow, 1½ mi. W. of Cloverport, Breckinridge Co., Ky., where it is 0 to 4 ft. thick.

M. A. Harrell, 1935 (Ind. Dept. Cons. Pub. 133, p. 78), listed (but did not define) *Gennet Creek fm.*, 10 to 35 ft. thick, as underlying Mount Pleasant ss. and overlying Bristow ss.

Bristow formation.

Pennsylvanian: Central Oklahoma (Creek County).

A. E. Fath, 1925 (U. S. G. S. Bull. 759, pp. 13–15). *Bristow fm.*—Includes all strata btw. Elgin ss. above and base of Tiger Creek ss. memb. below. Consists of an interbedded series of ss. and sh. aggregating 600± ft. in thickness. The sss. are generally gray to yellowish brown and friable. In N. part of Bristow quad. some of shales are gray and have considerable thickness. Here and to N. beyond this quad. it would be possible to divide the fm. into strat. units, but to S. the shales become thinner, change from gray to red, and lose their identity as mappable units, making the fm. a monotonous series of interbedded ss. and sh. throughout. Named for Bristow, Creek Co.

Brito formation.

Tertiary: Nicaragua.

C. W. Hayes, 1899 (Geol. Soc. Am. Bull., vol. 10, pp. 285–308; and Nicaragua Canal Commission Rept., p. 114). Assigned to Olig.

A. H. Redfield, 1923 (Econ. Geol., vol. 18, p. 361) and 1924 (Revista económica, San Salvador, año 11, No. 4, p. 175), assigned *Brito beds* of Costa Rica to Eo.

Brittania formation.

Carboniferous (?): British Columbia.

O. E. Le Roy, 1908 (Canada Dept. Mines, Geol. Surv. Branch Pub. No. 996, p. 15). [Assigned to "Devono-Carbf." Subsequent repts of Canada Geol. Surv. assign it to Carbf., to Jurassic, and to Triassic (?).]

Britton clay.

Upper Cretaceous (Gulf series): Eastern Texas (Trinity and Brazos River regions).

W. S. Adkins, 1933 (Univ. Tex. Bull. 3232, pp. 239, 270, 425). *Britton clay (from W. L. Moreman's unpublished description).*—Type loc., Britton, NW. part of Ellis Co. Typical thickness 250 ft.; near Dallas 300 or more ft. Mostly blue clay, with a few flaggy ls. seams and calc. concretions, the latter more abundant near top. Grades up into Arcadia Park fm. and overlies Tarrant fm., all of which are= Eagle Ford.

Broadback series.

Pre-Cambrian: Quebec.

H. C. Cooke, 1914 (Canada Geol. Surv. Summ. Rept. 1912, p. 339).

Broad Branch series.

Pre-Cambrian: District of Columbia.

W J McGee, G. H. Williams, and N. H. Darton, 1893 (5th Int. Geol. Cong., p. 244). Granitic and schistose rocks assigned to Archean.

Broad Ford sandstone. (In Pocono sandstone.)

Mississippian: Southeastern West Virginia and southwestern Virginia.

D. B. Reger, 1925 (Econ. Geol., vol. 20, pp. 778–779). *Broad Ford ss.*—A very prominent red ss. with distinctive lithology and marine fossils. Occurs a few ft. below Langhorne coal in Poverty Gap and is traceable for several hundred mi. through Appalachian region. Thickness 230 ft. Named for its best exposure in Smyth Co., Va.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 505, 520). *Broad Ford ss.*—Usually reddish brown; occasionally greenish gray or rusty ledge; rarely gray; usually thick bedded; frequently hard but often shaly and weathering to concretionary or chunky blocks; marine fossils in several zones. Thickness 50 to 300 ft. Lies a few ft. below Langhorne coal and 25 to 100 ft. above Sunbury sh.; all included in Pocono series. Type loc. at line btw. Smyth and Tazewell Counties, Va., about ½ mi. N. of Broad Ford Village where Laurel Creek of Holston River cuts a gap through ridge known as Pine Mtn on W. and

Brushy Mtn on E. Also observed in Montgomery and Giles Counties, Va., and in Mercer, Monroe, Greenbrier, and Summers Counties, W. Va., and across latter State, through Pocahontas and Preston Counties, into Pa.

Broad Top series.

Carboniferous: Pennsylvania.

H. D. Rogers, 1836 (1st Ann. Rept. State Geol. Pa., pp. 16–18). Included in Coal Measures.

Broadway moraine.

Pleistocene (Wisconsin stage): Northern Ohio. Named for village in Union Co. See U. S. G. S. Mon. 41, 1902, pp. 531–537.

Brock shale.

Upper Triassic: Northern California (Redding quadrangle).

J. S. Diller, 1906 (U. S. G. S. Redding folio, No. 138). *Brock sh.* conformably overlies Hosselkus ls. in Brock Mtn, whence the name, and has a thickness of about 400 ft. In lower 300 ft. or more adjoining the ls. the shales are dark, somewhat calc., and frequently contain *Halobia*. Above these come sandy shales, gray and reddish in color, and characterized locally by *Pseudomonotis subcircularis*. Is overlain, probably uncon., by Modin fm. [Brock sh. is approx.=Swearinger sl.]

Brock series.

Pre-Cambrian: Quebec.

H. C. Cooke, 1919 (Jour. Geol., vol. 27, p. 263).

Brockenback Hill formation.

Lower Cretaceous: Southwestern British Columbia (Harrison Lake region).

C. H. Crickmay, 1930 (Geol. Mag., vol. 67, pp. 487, 488). *Brockenback Hill fm.*—Aggls., 3,600 ft. thick, yielding *Aucella crassicollis*. Assigned to Lower Cret. Overlies Peninsula fm. (Lower Cret.).

Brockville granite.

Pre-Cambrian: Ontario.

J. F. Wright, 1923 (Canada Geol. Surv. Mem. 134, p. 25).

Broken Arrow formation.

Pennsylvanian: Northeastern Oklahoma (Tulsa County) and central Oklahoma (Creek County).

R. H. Wood, 1925 (Okla. Geol. Surv. Bull. 35, p. 71). *Broken Arrow fm.*—Mostly green sh., but includes a few thin beds of ls. and some ss., notably in lower part, S. of Arkansas River. Thickness 350 to 500 ft. or more; thickest toward S. Outcrops in a belt 10 to 15 mi. wide, extending from village of Broken Arrow [Tulsa Co.] southward to Arkansas River and beyond it for several miles. Embraces all strata btw. Fort Scott ls. below and Dawson coal above. The equivalent fms. to N. are (descending) Nowata sh., Altamont ls., Bandera sh., Pawnee ls., and Labette sh.

Brokeoff andesite.

See under *Divide Peak andesite*.

Bromide formation.

Middle Ordovician: Central southern Oklahoma (Arbuckle Mountains).

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27), showed a new fm., called *Bromide*, of Black River and uppermost Chazy age, as overlying, in places uncon., Simpson fm. and uncon. underlying Viola ls., in Arbuckle Mtns, Okla., the typical region of the Simpson and the Viola. As originally defined and used up to this time the Viola rested on the Simpson.

E. O. Ulrich, 1927 (Okla. Geol. Surv. Bull. 45, pp. 21–32). Simpson fm. of Taff comprises at least 3 faunas of exceedingly diverse origin and geographic distribution. None of these faunas, nor any beds that might contain them, are found in southern Mo. or Ark. The closing stage, provisionally added to top of *Bromide div.* of Simpson, contains a good representative of Decorah and Prosser faunas of Minn. (Black River and lower Trenton). *Typical Bromide* is of late Chazy age [and is shown as constituting topmost part of Simpson fm.].

F. C. Edson, 1927 (A. A. P. G. Bull., vol. 11, No. 9, pp. 967–975). Simpson fm. divided into *Bromide group* above and "Wilcox" sand below. The Bromide is a series of mag. limes and sands, in places interbedded with small amounts of green sh. Thickness 315 to 495 ft. in Arbuckle Mtns; 0 to 600 ft. in Mid-Continent field. The descriptive term "post-Wilcox" was applied by Luther White to these beds to indicate that part of Simpson fm. which is younger than "Wilcox" sand. Ulrich (1911) classified Bromide fm. as occurring btw. Simpson fm. and Viola ls. Taff mapped type loc. of Bromide fm., near Bromide, sec. 19, T. 1 S., R. 8 E., as *lower Viola ls.* This outcrop was visited recently by a party of geologists under direction of Okla. Geol. Surv., and all present agreed that this outcrop is made up of sediments that in every way resemble the "post-Wilcox" well cuttings. It is suggested by Luther White, the writer, and others that term "post-Wilcox" be dropped and that *Bromide* be retained to designate the group of sediments that occurs btw. "Wilcox" sand and Viola lime.

E. O. Ulrich, 1928. See under *West Spring Creek fm.*

E. O. Ulrich, 1929 (Letter dated Nov. 11, 1929, published by C. E. Decker in Okla. Geol. Surv. Bull. 55, p. 40, 1931). As used by me in past 2 yrs the Bromide includes all beds of Black River and Trenton ages that were deposited in Arbuckle region.

E. O. Ulrich, Feb. 1930 (U. S. Nat. Mus. Proc., vol. 76, art. 21, p. 73). See under *West Spring Creek fm.*

F. C. Edson, July 1930 (A. A. P. G. Bull., vol. 14, No. 7, p. 947). *Bromide fm.* is overlain, with angular uncon., by Viola ls. and underlain, with angular uncon., by Tulip Creek fm.

C. E. Decker, Dec. 1930 (A. A. P. G. Bull., vol. 14, No. 12, pp. 1498–1505). *Bromide fm.*—Chiefly lss., some sh., some ss., with a ss. of variable thickness at base. Thickness of fm. 171 to 600± ft. Of Trenton and Black River age. Overlies Tulip Creek fm. and underlies Viola ls. As *Bromide* has been used more extensively in connection with the Simpson it seems best to retain it for the upper fm. and drop Criner.

C. E. Decker and C. A. Merritt, 1931 (Okla. Geol. Surv. Bull. 55, pp. 11–12, 98). The *Simpson* is here raised to a *group*, divided into 5 fms. (ascending): Joins, Oil Creek, McLish, Tulip Creek, and Bromide. Heretofore *Bromide*, in various tables, has been used to represent a number of different horizons, but its last use was to limit it to upper part of section exposed in hill just W. of the hotel at Bromide, and it was thought that the fauna represented in this section was younger than that found in upper part of Simpson elsewhere. Further studies of a section above the 3 artesian wells at NE. edge of Bromide, and sections on Robertson ranch about 3 mi. S. of Bromide, have contributed evidence to show that certain parts of fauna and the physical characteristics of upper part of the Simpson at E. end of mtns are almost identical with those of upper part of Simpson in most of its outcrops. As Bromide has been used more extensively and longer in connection with the Simpson, it is thought better to retain it as the name for upper fm. of this group and drop *Criner*, which was at first the name of a memb., but later was raised to fm. name before it was realized the fauna at Rock Crossing in Criner Hills is largely a duplication of upper Simpson fauna to N., with addition of several apparently local forms. Named for town of Bromide, Johnston Co., where type section was made on a hill NW. of Galbraith Hotel.

E. O. Ulrich, 1933 (Geol. Soc. Am. Bull., vol. 44, p. 105). *Bromide fm.* included in Simpson group. Typical Bromide correlates with Lowville.

Bromley shale. (*In Cynthiana formation.*)

Middle Ordovician (Trenton): Southwestern Ohio and northern Kentucky.

R. S. Bassler, 1906 (U. S. Nat. Mus. Proc., vol. 30, p. 9). *Bromley shales.*—Drab to dark-blue shales, 30 ft. thick, underlying Point Pleasant ls. and outcropping along Ohio River bank opposite Cincinnati. Well exposed along river just below Bromley, Kenton Co., Ky. Characterized by trilobite remains and a form of *Dalmanella.*

R. S. Bassler, 1915 (U. S. Nat. Mus. Bull. 92, vol. 2, pl. 2) and 1919 (Md. Geol. Surv. Camb. and Ord. vol., p. 51), and A. F. Foerste, 1924 (Canada Dept. Mines, Geol. Surv. Mem. 138, geol. ser. No. 121, chart opp. p. 58), divided Cynthiana fm. into (descending) Rogers Gap, Gratz, *Bromley*, and Greendale.

Broncho Mountain granite.

Pre-Cambrian: Colorado (Gold Brick district).

R. D. Crawford and P. G. Worcester, 1916 (Colo. Geol. Surv. Bull. 10). A comparatively small body of granite unlike the ordinary kind is exposed on Broncho Mtn [Gold Brick dist., Gunnison Co.], about ½ mi. SE. of top. Since this rock differs materially in composition, texture, and color from rest of granite of dist., it has been mapped separately and for purposes of reference is here called *Broncho Mtn granite*. Is commonly reddish, but facies very rich in biotite are almost black.

Bronson formation.

Bronson group.

Pennsylvanian: Eastern Kansas, Iowa, Oklahoma.

G. I. Adams, 1904 (U. S. G. S. Bull. 238, pp. 1, 17, 21). *Bronson fm.*—Heavy ls. fm., 60 to 80 ft. thick, including some ss. and sh. Overlies Dudley sh. and underlies Chanute sh. [Chanute as here used includes Cherryvale sh., Drum ls. and Chanute sh.] Includes (ascending) Hertha ls., Ladore sh., Mound Valley [Bethany Falls] ls., Galesburg sh., and Dennis [Winterset] ls.

In succeeding years this name had very limited usage in the literature, but when used it was applied to beds beneath Cherryvale sh. and above Dudley sh.

R. C. Moore, 1931 (Kans. Geol. Soc. 5th Ann. Field Conf. correlation chart), defined *Bronson group* as extending from top of Winterset ls. (above) to base of sh. and channel ss. underlying Hertha ls. and resting uncon. on Pleasanton sh.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3, pp. 90, 97). *Bronson group* [restricted].—*Bronson* was introduced by Adams in 1904 for prominent compact group of lss. in lower part of Missouri series which until recently has been designated *Hertha* (here renamed *Sniabar ls.*, as explained under *Hertha ls*), Bethany Falls, and Winterset. This group of lss. and associated shales, which are now referred to (ascending) the Swope, Galesburg, and Dennis fms., form a distinct and very persistent strat. unit traceable from Iowa to southern Kans. The distinction from associated strata is, however, mainly lithologic, and accordingly physiographic, rather than paleontologic. The div. is a convenient and natural one from strat. standpoint. [The Swope ls. of Moore rested on what he called Ladore sh. and treated as top fm. of his *Bourbon group* (new name). R. C. Moore and G. E. Condra (Oct. 1932 revised classification chart of Penn. rocks of Kans. and Nebr.) used *Bronson group* as redefined by Moore in Aug.-Sept., 1932, and this same definition was used by Moore in 1935.]

J. M. Jewett, 1933 (Kans. Acad. Sci. Trans., vol. 36, p. 131). Type loc. of *Bronson group* is near Bronson, Bourbon Co., Kans. The group is recognized from SW. Iowa to northern Okla. Extends from top of Winterset ls. to base of Sniabar ls.

R. C. Moore, May 1, 1935 (Univ. Kans. Bull. 20, table opp. p. 14). Base of Bronson group is base of Hertha ls., which overlies *Bourbon group;* latter includes all rocks down to base of Warrensburg ss.

N. D. Newell, May 15, 1935 (Kans. Geol. Surv. Bull. 21). *Bronson fm.* as first defined by Adams included from top of Dennis ls. to base of Hertha ls. [*Bourbon fm.* included in *Bronson group* on p. 19 and excluded on p. 21.]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 41, 43, 76). *Bronson group* as here used is as defined by Adams. It conformably overlies Bourbon fm. and underlies Fontana sh., basal fm. of Kansas City group as here restricted. Is chiefly ls. Includes beds from base of Hertha ls. up to top of Dennis ls., and corresponds to lower part of Kansas City group as previously defined. Thickness in type region (vicinity of Bronson, Bourbon Co., Kans.), 100± ft.; in Kansas City area, 85± ft.; in southern Kans. 150 to 175 ft.

The U. S. Geol. Survey has not yet given consideration to the revival of *Bronson* and restriction of Kansas City fm., for use in its publications. (See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.)

†Brooke formation.

Lower Cretaceous: Northeastern Virginia.

L. F. Ward, 1895 (U. S. G. S. 15th Ann. Rept., p. 321). Because the beds are most typically developed in vicinity of Aquia Creek, I have decided to give name *Aquia Creek series* to memb. of Potomac fm. designated as "Brooke" by Professor Fontaine. [The compiler has been unable to find that Fontaine published the name *Brooke fm.* prior to 1905. He did, however, in U. S. G. S. Mon. 6, 1883, and Mon. 15, 1889, describe and figure a large fossil flora from vicinity of Brooke Station, 9 mi. N. of Fredericksburg, Va., but he seemed to studiously avoid using the name *Brooke beds.* In U. S. G. S. Mon. 48, p. 360, 1905, L. F. Ward published a letter from Prof. Fontaine dated Feb. 12, 1886, in which the term *Brooke beds* is casually used once. On p. 478 of Mon. 48 Fontaine calls the beds at Brooke locality the *Aquia Creek beds.* On p. 482 he calls them *Aquia Creek horizon or Brooke beds.* On p. 488 he mentions the *Aquia Creek or Brooke beds,* also the *Brooke beds,* and mentions *Brooke beds* on p. 575.]

L. F. Ward, 1905 (U. S. G. S. Mon. 48, pp. 402, 598). *Brooke fm.* replaces *Aquia Creek series.* Admitted on my part that "Aquia Creek" was published by Professor Clark a few months earlier than by me, and must apply to the Eocene beds if used at all, though it is only a portion of Mr. Darton's Pamunkey. For the Potomac beds called by me *Aquia Creek series* Professor Fontaine's term "Brooke" must be retained. *Brooke fm.,* 150 ft. thick, overlies Mount Vernon beds.

The use of the terms "Aquia Creek series" and "Brooke fm." was discontinued years ago. According to W. B. Clark and B. L. Miller (Va. Geol. Surv. Bull. 4, 1912) the beds described under those names are included in Patapsco and Patuxent fms. of present nomenclature.

Brookfield diorite.

Ordovician(?): Western Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, p. 107 and map). *Brookfield diorite* extends from near New Milford southward to Brookfield Center, with length of about 8 mi. and width of 1 mi. Is usually massive, but shows also gneissoid and even schistose phases. Both light and dark types are present in fm. Intrudes Poughquag qtzite [Lower Camb.] and the schists of the region [Berkshire and Hoosac, of Ord. age].

W. M. Agar, 1934 (Am. Jour. Sci., 5th, vol. 27, pp. 354–374). *Brookfield diorite* is older than Thomaston granite and appears to be younger than Bristol quartz diorite, Hartland schist, and Becket granite gneiss.

Brookline conglomerate member (of Roxbury conglomerate).

Devonian or Carboniferous: Eastern Massachusetts (Boston Basin).

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 56–57). *Brookline cgl. memb. of Roxbury cgl.*—Massive cgl., 500 to perhaps 2,000 ft. thick, which contains some layers or pockets of ss. and a few thin lenses of sl. At some places along S. margin of basin its base is a slaty or sericitic qtzite, but at most places it is a coarse ill-sorted cgl. containing some pebbles or small bowlders more than a foot through. Extensively exposed at Brookline. Is basal memb. of Roxbury cgl.

See also L. LaForge, 1932 (U. S. G. S. Bull. 839), where thickness of 1,200± ft. is given.

Brooklyn formation.

Carboniferous: British Columbia.

O. E. Le Roy, 1912 (Canada Geol. Surv. Mem. 21, pp. 19, 26, 33).

Brooklyn moraine.

Pleistocene (Wisconsin stage): Southern Wisconsin. Shown on moraine map (pl. 23) of U.S.G.S.P.P. 106, 1918. Named for Brooklyn Twp, Dane Co.

Brooklyn gneiss.

Pre-Cambrian: New York City.

C. P. Berkey, 1933 (16th Int. Geol. Cong. Guidebook 9, pl. 7).

Brooks bed.

Mississippian: Northwestern Kentucky.

A. F. Foerste, 1910 (Ky. Geol. Surv. Rept. Prog. 1908 and 1909, p. 83). *Brooks div.*—The upper, medium-grained part of Knobstone fm. at Stephensport, Breckenridge Co., may represent *Brooks bed,* and the lower fine-grained part includes New Providence clay sh.

Derivation of name not explained; may be from Brooks, Bullitt Co., Ky.

Brookville clay. (In Allegheny formation.)

A clay bed, 0 to 8 ft. thick, underlying Brookville coal, lying 0 to 25 ft. above base of Allegheny fm. in Pa. and adjacent States.

Brookville terrane.

Cretaceous: Kansas.

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, p. 255). *Brookville terrane,* sss., 150 ft. thick. Underlies Cawker terrane (shales) and overlies Pete terrane (shales). Included in Dakotan. [Derivation of name not stated, but probably Brookville, Saline Co., north central Kans.]

Brookwood coal group.

Pennsylvanian: Central Alabama.

A group of coal beds in upper part of Pottsville fm. Includes Brookwood, Milldale, and Carter coals.

Broomhill facies.

Name applied by P. B. Stockdale (Ind. Dept. Cons., Div. Geol., Pub. 98, pp. 77, 100, etc., 1931) to the lithologic facies of New Providence fm. at its type loc.

Brosseau formation.

Upper Cretaceous: Alberta.

J. A. Allan, 1918 (Canada Geol. Surv. Summ. Rept. 1917, pt. C, p. 12). Included in Belly River series.

Brougher dacite.

Tertiary (upper Miocene?): Central Nevada (Tonopah district).

J. E. Spurr, 1905 (U. S. G. S. P. P. 42, pp. 44, 50, map, etc.). *Brougher dacite.*—Composes Butler, Brougher, Siebert, and Golden Mtns, Tonopah dist. Intrudes earlier andesite, Fraction dacite breccia, Tonopah rhyolite dacite, Siebert tuffs, and overlying basalt. Is apparently of about same age as Oddie rhyolite and of same nature and origin.

J. A. Burgess, 1909 (Econ. Geol., vol. 4, pp. 681–712), assigned this fm. to Plio.; T. B. Nolan (personal communication Jan. 1933) considers it to be same as Oddie rhyolite.

Broughton series.

Pre-Cambrian: Quebec.

J. A. Dresser, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 190).

Brown sand.

A subsurface sand, of Penn.(?) age, in Stephens Co., southern Okla., lying at 2,100 ft. depth in Empire pool, the Smith sand lying at 2,000 ft. and the Blaydes at 2,200 ft.

Brown oil sand.

A subsurface sand in Tri-County oil field, SW. Ind., lying 20 to 60 ft. below Oakland City sand.

Brown zone.

A petroliferous zone, about 250 ft. thick, in Fernando group of Long Beach field, Los Angeles Basin, Calif. Lies lower than Alamitos zone and higher than Bixby zone. Named for fact Petroleum Midway Brown No. 1 well is thought to be the discovery well of this zone.

Brown Creek bed. (In Strawn formation.)

Pennsylvanian: Central Texas (Colorado River region).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 374, 381). *Brown Creek bed.*—Friable white ss., 240 ft. thick, with 25 ft. of blue clay about 40 ft. from top. Memb. of Strawn div. Overlies Big Valley bed and underlies Spring Creek bed.

Named for Brown Creek, Mills Co.

Brownian series.

A term introduced by C. [R.] Keyes to include Browns Park fm. (late Mio. or early Plio.) and Uinta fm. (Eo.) of Utah.

Brown Mead formation.

Lower Ordovician: Newfoundland.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4). *Brown Mead fm.*—Gray shales carrying *Bryograptus*. Basal fm. of Clarenville series. Overlain by Apsey fm. and underlain by Elliott Cove fm. (Upper Camb.). [Derivation of name not stated.]

Browns Mountain group.

Ordovician: Nova Scotia.

M. Y. Williams, 1911 (Canada Geol. Surv. Summ. Rept. 1910, p. 241).

Browns Park formation.

Tertiary (late Miocene or early Pliocene): Northwestern Colorado and northern eastern Utah (Uinta Mountains region).

J. W. Powell 1876 (Geology of eastern part of Uinta Mtns, pp. 40, 44, 168). *Brown's Park group.*—Sss., gravel, lss., concretionary and stratified flints, 0 to 1,800 ft. thick. In some places cgls. having a great development are found at base. Uncon. underlies Bishop Mtn. cgl. [according to geologic column on p. 40, but according to later pp. the two fms. do not appear to be in contact]. Uncon. overlies Bridger group and older rocks. Well represented at Brown's Park, NE. Utah and NW. Colo. and in a dist. stretching to SW. beyond Snake and Yampa rivers. [The early writers used *group* in sense that modern writers use *fm*. The Browns Park "group" of Powell is same as Browns Park *fm.* of present nomenclature, the true Uinta fm. (*Diplacodon* zone), which overlies Bridger fm. in Uinta Basin (S. of Uinta Mtns), being absent in NE. Utah and NW. Colo.]

For many years Browns Park fm. of E. end of Uinta Mtns, in NE. Utah and NW. Colo., was supposed to be same as Uinta fm. of Uinta Basin, which lies to S. of Uinta Mtns, and the two names were used interchangeably.

J. D. Irving, 1896 (N. Y. Acad. Sci. Trans., vol. 15, p. 255). The lithological characteristics of *Brown's Park beds* of Utah are exceedingly peculiar and entirely different from those of any other tertiary in region. The most characteristic strata are a very soft, friable, siliceous silt, everywhere thinly bedded and throughout highly calc. They differ entirely from those of the Eocene Bridger group to N. of the mtns and the Uintah (Eocene) to the S., in containing comparatively little clay and being everywhere very soft. The Bridger is characterized by a grayish or greenish tinge and the Uintah by a prevailing brownish red color, whilst the Brown's Park is always white. But most important difference is in texture. Only fossil found in Brown's Park beds was a fragment of bone which Dr. Wortman, of Am. Mus. Nat. Hist., is of opinion could not have been deposited earlier than Plio. or at most Mio.

J. D. Sears, 1924 (Geol. Soc. Am. Bull., vol. 35, pp. 279–304) and 1926 (U.S.G.S. Bull. 781B, pp. 16, 22). Writer believes Bishop cgl. is=basal memb. of Browns Park fm. of Uinta Mtn region.

W. H. Bradley, 1932 (Wash. Acad. Sci. Jour., vol. 22, No. 11, p. 318) and 1936 (U.S.G.S.P.P. 185, I) demonstrated that Bishop cgl. is older than Browns Park fm., and J. D. Sears accepts Bradley's evidence.

The few fossils that Browns Park fm. has yielded are regarded as Mio. or possibly Plio. The U. S. Geol. Survey tentatively classifies the fm. as late Mio or early Plio.

Brownsport formation.

Silurian (Niagaran): West-central Tennessee and northeastern Mississippi.

A. F. Foerste, 1903 (Jour. Geol., vol. 11, pp. 566–583, 681–708). *Brownsport bed (of Niagara age)*.—Richly fossiliferous white lss. and calc. clays, 120 ft. thick, overlying Dixon red clays and forming top of Sil. section in Tenn. River Valley. Uncon. underlies Linden fm. (Helderbergian), or, where that is absent, the younger Hardin ss. [As thus defined included at top the beds of Cayugan age later separated under name *Decatur ls.* Some geologists, however, still classify the Decatur as Niagaran and include it in the Brownsport. A. F. Foerste stated (Denison Univ. Bull., Jour. Sci. Lab. vol. 30, 1935, pp. 197–198) Decatur fauna is Niagaran.]

Now subdivided into (descending) Lobelville shaly ls. memb., Bob crystalline ls. memb., and Beech River shaly ls. memb. Underlies Decatur ls. and overlies Dixon earthy ls. memb. of Wayne fm.

Named for Brownsport Furnace, Decatur Co.

Brownstown marl (restricted).

Upper Cretaceous (Gulf series): Southwestern Arkansas, northwestern Louisiana, and northeastern Texas.

R. T. Hill, 1888 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 2, pp. 72, 86–87, 188); 1894 (Geol. Soc. Am. Bull., vol. 5, p. 302, pl. 12); 1901 (U.S.G.S. 21st Ann. Rept., pt. 7, p. 340).

A. C. Veatch, 1906 (U.S.G.S.P.P. 46, p. 25). *Brownstown marl*.—This name was first applied by Hill [first reference above] to marl beds typically developed at Brownstown, Ark., which at that time he thought were above the Annona (White Cliffs) chalk. In his rept. on geology of part of Tex., Ind. Ter., and Ark. adjacent to Red River [second reference above] he used *Brownstown* to include all beds btw. Annona chalk and Washington (Nacatoch) beds. Later [1901 reference above], appreciating that the beds at Brownstown are below the Annona chalk, he gave them their right strat. position, but included with them the marls which overlie the Annona chalk. The term is now defined to include the blue clay marls btw. Bingen sand and Annona chalk.

In 1926 L. W. Stephenson and C. H. Dane (U.S.G.S. Press Bull. 8823, Sept. 10), 1927 (A.A.P.G. Bull., vol. 11, p. 8), and 1929 (Ark. Geol. Surv. Bull. 1, p. 46) divided †Bingen sand into Woodbine sand below and Tokio fm. above, and restricted *Brownstown marl* to lower part of Veatch's Brownstown marl, the new name *Ozan fm.* being applied to the upper uncon. part of the Brownstown of Veatch. The village of Brownstown, Sevier Co., Ark., is located on top of Brownstown marl as thus restricted by Stephenson and Dane.

According to L. W. Stephenson, 1928 (Am. Jour. Sci., 5th, vol. 16, p. 492), and 1929 (A.A.P.G. Bull., vol. 13, No. 10), the Brownstown marl overlies Bonham clay and uncon. underlies Annona chalk in NE. Tex.

Brownstown sandstone. (In Kanawha formation.)

Pennsylvanian: West Virginia.

I. C. White, 1903 (W. Va. Geol. Surv. vol. 2, p. 586). *Brownstown ss.*—Massive ss., 25 to 35 ft. thick, lying a short distance below Campbells Creek coal and 35 ft. above Brownstown coal. Has been quarried at Brownstown and Montgomery.

Brownstown Hills sandstone member.

Mississippian: Southern Indiana.

P. B. Stockdale, 1931 (Ind. Dept. Cons., Div. Geol., Pub. 98, pp. 76., 172, 174, 175, 237, 239, 240, 245). *Brownstown Hills ss. memb. of Edwardsville fm.*—The ss. bed or set of beds with a brachiopod fauna dominated by several species of Spirifer, which lies upon Floyds Knob ls. in NW. Washington Co. and in Jackson Co., in general E. of a line running from SW. corner of the Co. NE. of Houston. At Sparksville quarry, 1 mi. E. of Sparksville, it consists of 17 ft. of massive bedded ss. On SW. side of Brownstown Hills, slightly W. of Brownstown, it is 20 ft. thick; near old Goss Mill, 6½ mi. N. of Medora, it is 5 to 6 ft. thick; at Medora Knob it consists of 11 ft. of massive, gray to buff, bedded ss. with thin sh. partings; at Fort Ritner it is 25 ft. thick. Pinches out to S. and E. of McKinley, Washington Co. Named for fact it caps Brownstown Hills of south-central Jackson Co.

†Browntown sandstone. (In Monongahela formation.)

Pennsylvanian: Southwestern Pennsylvania, northern West Virginia, and eastern Ohio.

I. C. White, 1891 (U.S.G.S. Bull. 65, p. 58). *Browntown ss.*—Hard, massive, gray ss., 0 to 35 ft. thick. Lies 5 to 20 ft. below Waynesburg coal and overlies Little Waynesburg coal. Finely exposed along bed and bluffs of Ten Mile Creek, at and below Browntown, Harrison Co., W. Va. It is sometimes called *"Gilboy" ss.*, from a rocky cut of that name near Mannington, Marion Co., W. Va.

I. C. White, 1903 (W. Va. Geol. Surv. vol. 2, p. 150). *Gilboy ss.*—Was formerly termed *Browntown ss.*, from a locality in Harrison Co., but as there is a Brownstown ss. in Kanawha Co., W. Va., it was concluded best to change the name of this ss. to *Gilboy.*

Replaced by *Gilboy ss. memb.*

Brownville slate.

Name listed in U.S.G.S. Bull. 191 and credited to C. T. Jackson, Geol. rept. public lands of Maine, vol. 1, p. 37, 1837. The name was not defined, but only casually referred to, by Jackson on p. cited. He also casually used the name on pp. 76 and 91 of First Rept. on geol. of State of Maine, 1837, but evidently did not intend it as a geologic name.

Brownville limestone. (In Wabaunsee group.)

Pennsylvanian: Southeastern Nebraska, southwestern Iowa, and eastern Kansas.

G. E. Condra and N. A. Bengston, 1915 (Nebr. Acad. Sci. Pub., vol. 9, No. 2, pp. 17, 29). *Brownville ls.*—Basal part of Admire (?) fm. Overlies McKissick Grove shales and is separated from overlying Aspinwall ls. by 10 to 25 ft. of sh. Is light bluish green; upper part somewhat nodular; lower part massive. In section 3 mi. S. and 2 mi. W. of Falls City it consists of 2 lss. separated by 7 inches of bluish sh. and weathered ls. Thickness 2½ to 6 ft.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 73, 74, 81, 89). *Brownville ls.*—Two grayish lss. separated by a thin sh. Thickness 3 to 5 ft. Top ls. is usually thinner; lower one forms rounded blocks. Both beds weather yellowish or brownish. Is basal bed of Admire sh. memb. of Wabaunsee fm. Named for exposures low in Missouri bluffs S. of Brownville, Nemaha Co., Nebr.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3), restricted Admire sh. to beds above Brownville ls., and treated latter as a distinct fm., and this definition was adopted by Moore and Condra in their Oct. 1932 revised classification chart of Penn. rocks of Kans. and Nebr.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 9). *Brownville ls. fm.*—Top fm. of Wabaunsee group restricted. Overlies Pony Creek sh. fm. and underlies Admire group.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

†Brownwood division.

Pennsylvanian: Central Texas.

E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, p. lxvii). [*Brownwood-Ranger series* on p. lxvii and *Brownwood-Canyon* on pl. 3.] Lss. and sss. containing considerable salt and some oil and gas. Overlies Milburn-Strawn series and underlies Waldrip-Cisco series. Named for Brownwood, Brown Co.

R. S. Tarr, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pp. 204–207). *Brownwood div.*—Chiefly ls., but alternating with ss.; no coal. Thickness 1,300 ft. Underlies Waldrip coal div. and overlies Milburn shales.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, p. 98). *Brownwood div.* now includes Milburn div. of Tarr and overlies Richland div. [See 1901 entry under *Milburn shales.*]

C. H. Gordon, 1911 (Jour. Geol., vol. 19, p. 117). *Brownwood div.* now includes Brownwood and Milburn of Tarr, and is =Canyon div.

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, p. 13). *Brownwood* and Milburn of Tarr practically =Canyon group.

Named for Brownwood, Brown Co.

Brownwood shale member (of Graford formation).

Pennsylvanian: Central Texas (Brown County, Colorado River region).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 387, 389). *Brownwood bed.*—Chiefly bluish, slightly sandy clay, though dark blue to black carbonaceous shaly clay, or even sh., is common at southern end, and lenticular beds of ss. of considerable extent occur in places. Fossiliferous. Thickness 200 to 250 ft. Memb. of Canyon div., near base. Underlies Adams Branch ls. and believed to overlie Rochelle cgl., but may belong to same horizon as the Rochelle.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31; Univ. Tex. Bull. 2132). Graford fm. is composed of Adams Branch ls. memb. (at top) and *Brownwood sh. memb.*, which was named by Drake. The Brownwood memb. consists of dark-gray and blue clay sh. weathering to light gray and yellow. It contains some lenses of ss. and a number of thin beds of ls. Is 180± ft. thick at Brownwood and at least 400 ft. thick at Graford. As here defined it overlies Palo Pinto ls. and includes Rochelle cgl. at or near base. Near Brownwood it includes Capps ls. lentil in lower part, and in Palo Pinto Co. it includes a fairly continuous ss. lentil designated Oran ss.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 105, 109), revised the definition of Brownwood by transferring Capps ls. to top of underlying Strawn fm.

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501, p. 201), followed Sellards' definition of Brownwood sh. and Capps ls.

Named for Brownwood, Brown Co.

The U. S. Geol. Survey at present treats Capps ls. as top memb. of Mineral Wells fm., the upper fm. of Strawn group, and does not use *Brownwood*.

Brownwood Canyon.

U. S. G. S. Bull. 191, p. 77, lists *Brownwood Canyon*, Dumble, 1890, Tex. Geol. Surv. 1st Ann. Rept., pl. 3, p. lxvii. On pl. 3 E. T. Dumble showed *Brownwood-Canyon div.* underlying Waldrip-Cisco div. and overlying Milburn-Strawn div. On p. lxvii he called the rocks occupying the same strat. position the *Brownwood-Ranger series*.

Bruce series.

Pre-Cambrian (early Huronian): Western Ontario.

W. H. Collins, 1914 (Canada Geol. Surv. Mus. Bull. No. 8, p. 26). Includes (descending): Serpent qtzite, Espanola ls., Espanola graywacke, Bruce ls., Bruce cgl., and Mississagi qtzite.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), assigned these rocks to early Huronian.

Bruce limestone.

Pre-Cambrian (early Huronian): Western Ontario.

W. H. Collins, 1916 (Canada Geol. Surv. Mus. Bull. No. 22, p. 4). One of fms. of Bruce series.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), assigned these rocks to early Huronian.

Bruce conglomerate.

Pre-Cambrian (early Huronian): Western Ontario.

W. H. Collins, 1916 (Canada Geol. Surv. Mus. Bull. No. 22, p. 4). One of fms. of Bruce series.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), assigned these rocks to early Huronian.

Brule formation (also **Brule clay**).

Oligocene (upper and middle): Western Nebraska and South Dakota, northeastern Colorado, eastern Wyoming.

N. H. Darton, 1898 (U. S. G. S. 19th Ann. Rept., pt. 4, pp. 736, 755–759). The White River beds in their extension from S. Dak. into Nebr. present some differences in strat. range and relations. They expand considerably and include, at top, beds which appear not to be represented in the typical regions. Accordingly, to afford distinct definitions for the members in Nebr. I have introduced the designation *Brule clay* and separated the underlying *Titanotherium* beds as *Chadron fm.* The Brule consists mainly of a hard, sandy clay, of pale-pink color. Thickness about 600 ft. in vicinity of Wyo. line, but diminishes greatly eastward; in vicinity of 103° mer. in NW. corner of Nebr. it is 320 ft. Has not been recognized E. of long. 101°30′, where it appears to sink beneath the surface in Platte Valley. Extends far to NE. in So. Dak.

Is upper fm. of White River group.

Mr. Darton stated (personal communication April 8, 1931) that he named this fm. for the Brule Indians, who once roamed over Pine Ridge Ind. Res. in southern S. Dak., where the fm. covers large areas, and that it is not present in Brule Ind. Res., which occurs farther N. in S. Dak.

Brule schists.

Brule volcanics.

Pre-Cambrian (upper Huronian): Northwestern Michigan (Iron River district).

R. C. Allen, 1910 (Mich. Geol. and Biol. Surv. Pub. 3, geol. ser. 2, p. 34). *Brule volcanics.*—On fresh fracture, dense, fine-grained, and grayish green. Contain ellipsoidal greenstone and green schists equiv. to Quinnesec schists of Menominee dist. [In table on p. 33 this fm. in Iron River dist. is called *Brule schists.*]

Named for exposures N. and S. of Brule River.

According to C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52), the volcanic rocks along Brule River are probably Quinnesec schist.

Brunner sand.

A subsurface sand of Penn. age, 10 to 35 ft. thick, lying at 3,018 to 3,200 ft. depth and 300 to 370 ft. above Cromwell sand, in Cromwell oil field, Okla. Lies higher than Harjo sand, which lies 175 to 250 ft. above Cromwell sand.

Bruno limestone. (In Chase group.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., pp. 38, 40). [See definition under *Blue Springs sh.*]

Brunswick shale. (In Newark group.)

Upper Triassic: New Jersey and southeastern Pennsylvania.

H. B. Kümmel, 1897 (N. J. Geol. Surv. Ann. Rept. State Geol. 1896, pp. 47–55, and Jour. Geol., vol. 5, pp. 547–549). *Brunswick shales.*—Soft shales with a few ss. layers. Chiefly red, but a few purple, green, yellow, and black layers occur in lower 1,000 ft. and at higher horizons. Massive qtzite cgl. beds occur along NW. border of fm., a part of which are correlatives of Brunswick shales. Thickness 12,000 ft. Grade into underlying Lockatong series [fm.]. Top fm. of Newark system [group]. Well exposed in valley of Raritan, particularly near New Brunswick, N. J.

Brunswick conglomerate. (In Newark group.)

Triassic (Upper): Eastern Pennsylvania (Lehigh County).

E. T. Wherry, 1914 (Anniversary history of Lehigh County, by B. L. Miller, vol. 1, chap. 1, p. 8). *Brunswick cgl.*—Pebble rocks, breccias, and cgls. underlying Brunswick sh. Included in Triassic. Deposited at mouths of rivers.

A. I. Jonas, 1917 (Am. Mus. Nat. Hist. Bull., vol. 37, p. 178). *Brunswick cgl.*—Coarse-grained, variegated, reddish purple cgl., with quartz and ls. pebbles, which weather out of matrix, producing a cellular rock; associated with the cgl. is a vitreous red qtzite. Underlies Brunswick sh. Outcrops in region adjoining Boyertown hills [Berks Co.?].

The Brunswick fm. (chiefly sh.), in SE. Pa., as in N. J., rests on Lockatong fm., or, where that fm. is absent, on Stockton fm.

Brush formation.

C. Keyes, 1924 (Pan-Am. Geol., vol. 41, pp. 36, 301). *Brush fm.*—Shales and sss., 100 ft. thick, uncon. beneath Dakota ss. and overlying Junction lss. A middle fm. of Flaming Gorge series in Utah. Assigned to late Jurassic [but Keyes also stated that it may correspond to Fuson fm., which is Lower Cret. Derivation of name not stated.]

According to A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1936 (U. S. G. S. P. P. 183, chart opp. p. 40), these shales are Morrison fm. and Summerville fm. (both Upper Jurassic).

Brush Creek limestone member (of Conemaugh formation).

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q, p. 34). *Brush Creek ls.*—Frequently seen along Brush Creek, Cranberry Twp, Butler Co., Pa., for which it is named. In places it is a black calc. sh. 4 to 5 ft. thick; again it is a very compact ls. 1 to 2 ft. thick. Often has a peculiarly slaty and aren. aspect, and sometimes contains so much iron as to be used as an ore. Underlies Buffalo ss., from which it is in places separated by thin sh., and lies 10 to 15 ft. above Brush Creek coal.

J. P. Lesley, 1878 (2d Pa. Geol. Surv. Rept. Q, pp. 303–305). *Brush Creek ls.* is same as Philson ls. of Somerset Co. [which has priority].

J. P. Lesley, 1879 (2d Pa. Geol. Surv. Rept. Q_2). *Brush Creek (Summit) ls.* underlies Brush Creek fire clay.

According to modern repts of U. S. Geol. Surv. and Pa. Geol. Surv. the Brush Creek ls. lies higher in Conemaugh fm. than Brush Creek coal. In Ohio this bed is a fossiliferous calc. marine sh. and is called *Brush Creek sh. memb.*

Brush Creek sandstone. (In Conemaugh formation.)

Pennsylvanian: Southwestern Pennsylvania (Allegheny County).

J. P. Lesley, 1878 (2d Pa. Geol. Surv. Rept. Q, pp. 305–308). *Brush Creek ss.*—Lies 12 ft. below Brush Creek ls. and above Brush Creek coal.

Brush Creek clay. (In Conemaugh formation.)

Brush Creek fire clay. (In Conemaugh formation.)

Pennsylvanian: Western Pennsylvania.

J. P. Lesley, 1879 (2d Pa. Geol. Surv. Rept. Q_2). *Brush Creek fire clay* underlies Brush Creek coal and overlies Brush Creek (Summit) ls.

According to U. S. G. S. folios of SW. Pa. and recent repts of Pa. Geol. Survey, the Brush Creek ls. lies higher in section than Brush Creek coal and the Brush Creek clay immediately underlies Brush Creek coal.

Brush Creek shale. (In Conemaugh formation.)

Pennsylvanian: Northern West Virginia and western Maryland.

R. V. Hennen and D. B. Reger, 1913 (W. Va. Geol. Surv. Rept. Marion, Monongalia, and Taylor Counties, p. 309). *Brush Creek sh.*—Dark or black sh., 3 to 10 ft. thick, containing marine fossils in upper half and fossil plants in basal part. Underlies Brush Creek ls. and overlies Brush Creek coal.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, pl. 6), applied *Brush Creek sh.* to a sh. lying a short distance below Brush Creek ls. and resting on Brush Creek coal in Upper Youghiogheny Valley, Md.

Brush Creek fire clay shale. (In Conemaugh formation.)

Pennsylvanian: Northern West Virginia.

R. V. Hennen and D. B. Reger, 1913 (W. Va. Geol. Surv. Rept. Marion, Monongalia, and Taylor Counties, p. 315). *Brush Creek fire clay sh.*—Contains layers of ferriferous ls. Underlies Brush Creek coal and overlies Upper Mahoning ss. Thickness 4 ft.

Brush Creek red bed. (In Conemaugh formation.)

Pennsylvanian: Southern Pennsylvania.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, p. 58, pl. 6, pl. 7). *Brush Creek red bed.*—A red bed which in part of Somerset, Pa., area replaces Brush Creek sh., which overlies Brush Creek ls. and underlies lower bench of Buffalo ss.

Brushy Basin shale member (of Morrison formation).

Upper Jurassic: Southeastern Utah (San Juan County).

H. E. Gregory (U. S. G. S. P. P. 188, in press). *Brushy Basin sh. memb.*—Brightly banded shales, thin lss., cgls., and sss. forming top memb. of Morrison fm. in San Juan country. Thickness 350 to 470 ft. Dinosaur remains. Overlies Westwater Canyon ss. memb. Well exposed in Brushy Basin, San Juan Co.

Brushy Creek sandstone. (In McLeansboro formation.)

Pennsylvanian: Southeastern Illinois (Saline County).

G. H. Cady, 1926 (Ill. State Acad. Sci. Trans., vol. 19, pp. 256–258). *Brushy Creek ss.*—A cuesta-forming ss., about 25 or 30 ft. thick, lying 100 to 125 ft. above base of McLeansboro fm. Lies lower than Galatia ss. and higher than Anvil Rock ss. Exposed on N. flank of ridge along Brushy Creek at Town Hall near center of Brushy Twp, and at other places.

†Brushy Creek chert.

Middle Devonian (Onondaga): Southeastern Oklahoma (Ouachita Mountains).

E. O. Ulrich, 1927 (Okla. Geol. Surv. Bull. 45, p. 30). [In Arbuckle uplift column of correlation chart on p. 30 the name *Brushy Cr. chert* appears opposite Middle Dev., 1,000 ft., and is shown as resting conformably on Bois d'Arc ls. and uncon. underlying Woodford chert. On p. 19 reference is made to "the cherty beds on Brushy Creek, center W. side sec. 5 T. 2 N., R. 15 E," referred by Taff to top of his "Hunton" fm. On p. 27 the Brushy Creek section is described, but neither *Brushy Creek chert* nor *Brushy Creek cherty ls.* is used. On p. 33 is statement: "The Arkansas novaculite includes three distinct zones: The lower as determined by scant yet fairly conclusive evidence correlates with *Brushy Creek cherty ls.* mentioned on page 27."]

Named for exposures on Brushy Creek, Pittsburg Co., SE. Okla.

This is only known use of this name, which is preoccupied. Replaced by *Pinetop chert.*

†Brushy Mountain Measures. (In Pottsville group.)

Pennsylvanian: Southeastern Tennessee.

J. M. Safford and J. B. Killebrew, 1900 (Elements of geol. of Tenn., pp. 104, 149–153, 167, 169). *Brushy Mtn Measures.*—Shales and sss. including not less than 14 coal horizons, forming top div. of Coal Measures. Thickness 2,000± ft. Overlies Tracy City Measures in Brushy Mtns, where Bon Air Measures are also present beneath Tracy City Measures.

Divided into several fms. in U. S. G. S. Wartburg folio (No. 40), named (descending) Anderson ss., Scott sh., Wartburg ss., and Briceville sh.

Named for Brushy Mtn, Morgan Co.

Bruzer limestone.

Mississippian: Utah.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, p. 37, table of geologic fms. in Utah). [Misprint for *Brazer ls.*]

†Bryant limestone.

Middle Ordovician: Central eastern Missouri.

C. R. Keyes, 1898 (Iowa Acad. Sci. Proc., vol. 5, pp. 59, 61). *Bryant ls.*—Compact, light-blue or gray, rather thin-bedded ls., with numerous sh. partings; somewhat fossiliferous, and presents marked contrast to underlying and overlying dolomitic lss. Thickness 125 to 150 ft. Underlies McCune ls. and overlies Folley ls. in Pike and Lincoln Counties.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27), showed *Bryant ls.* of eastern Mo. as of Lowville age, as uncon. below Decorah sh., and as = upper part of Plattin ls.

R. S. Bassler, 1915 (U. S. Nat. Mus. Bull. 92, vol. 2, pl. 2), showed Bryant ls.= Kimmswick and Plattin lss.

C. L. Dake, 1922 (Pan-Am. Geol., vol. 37, No. 4, pp. 288–300), treated Plattin and Bryant as synonyms, as did C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 39, pp. 67–70).

See also under *Kimmswick ls.* and *McCune ls.*

Named for exposures along Bryant Creek, Lincoln Co.

Bryant Lake limestone.

Pre-Cambrian: New York (eastern Adirondacks).

H. L. Alling, 1927 (Geol. Soc. Am. Bull., vol. 38, pp. 798, 800). *Bryant Lake ls.* (here named for first time) is somewhat saccharoidal in hand specimen and contains considerable quartz, biotite, and feldspar. Thickness 20 to 40 ft. Underlies Catamount schist and overlies Swede Pond qtzite. [Derivation of name not stated and not indicated on map.]

Bryn Mawr gravel.

Pliocene (?): Southeastern Pennsylvania, northern Delaware, and northeastern Maryland.

H. C. Lewis, 1881 (Phila. Acad. Nat. Sci. Proc., vol. 32, pp. 258–272, 277–278, 288, 296–309). *Bryn Mawr gravel.*—Oldest gravel of consequence in Phila. region. Readily distinguished from other gravels by peculiar materials composing it, and also by occurring at high elevations (325 to 450 ft.), in often isolated patches, capping the gneissic hills. Characterized by presence of sharp or partially rounded fragments of a hard, heavy iron ss. or cgl., often covered by a brownish black iron glaze. One tract of this gravel extends from Bryn Mawr to near Cooperstown. Is 10 ft. thick. Is same as Mount Holly cgl. of N. J. Rests on decomposed gneiss.

W. B. Clark, H. B. Kümmel, and B. L. Miller, 1909 (U. S. G. S. Philadelphia folio, No. 162, p. 12). *Lafayette fm.* (Plio. ?) displaces "Bryn Mawr gravels."

Later work proved that at Lafayette type loc., near Oxford, Miss., the beds designated *Lafayette* are of early Eocene (Wilcox) age, and that the name has been applied to beds of Cret. and other ages. *Lafayette fm.* was therefore abandoned by U. S. Geol. Survey in 1916.

F. Bascom, 1924 (U. S. G. S. P. P. 132H). The name *Brandywine fm.* is here restricted to the late or low-level Brandywine deposits, of probable Pleist. age, and name *Bryn Mawr gravel* is revived for the high-level or early terrace gravels previously included in Brandywine fm. The deposit at Brandywine lies at 200 to 300-foot level; the Bryn Mawr gravel of Lewis lies at 390 to 480-foot level, and is same fm. for which *Bryn Mawr gravel* is here revived. Both fms. were included in "Lafayette" and "Appomattox" of former repts on this region. [These are present commonly accepted definitions of *Bryn Mawr gravel* and *Brandywine fm.*]

Bryson formation. (In Pottsville group.)

Pennsylvanian: Northeastern Tennessee and southeastern Kentucky.

G. H. Ashley and L. C. Glenn, 1906 (U. S. G. S. P. P. 49, pp. 33, 44, 208, and Pl. XLA). *Bryson fm.*—Shales, sss., and coals, 0 to 200 ft. thick, lying above Red Spring coal (top memb. of Hignite fm.) on higher tops of Log Mtns and possibly on highest points of Black Mtns and Reynolds Mtn. Probably included in time interval of upper part of Kanawha fm.

Named for Bryson Peak, Claiborne Co., Tenn.

Bryson sand.

A subsurface sand, of Penn. age, in North Bryson field, Jack Co., north-central Tex., lying at 3,100 ft. depth.

Bucatunna clay member (of Byram marl).

Oligocene (middle): Southeastern Mississippi (Clarke and Wayne Counties) and southwestern Alabama.

B. W. Blanpied et al, 1934 (11th Ann. Field Trip Shreveport Geol. Soc., charts, pp. 3, 4, 12–16, etc.). *Bucatunna memb. of Catahoula group.*—Cross-bedded sands, clays, bentonitic clays and bentonite, sparingly fossiliferous, forming basal 20 to 55 ft. of Catahoula group (Mio.) in Clarke and Wayne Counties. Rests uncon. on Byram marl and older fms. of Vicksburg group. Underlies Lower Chickasawhay memb. of Catahoula group. Type loc. along Bucatunna Creek N. of Denham P. O., which is located in sec. 19–8 N.–5 W., Wayne Co., Miss. The Bucatunna is provisionally assigned to Mio. Is evidently in part marine.

C. W. Cooke, 1935 (A. A. P. G. Bull., vol. 19, No. 8, pp. 1162–1172). *Chickasawhay marl* and *Bucatunna clay* of Blanpied are accepted as *members of Byram marl* (of Vicksburg group, Olig.), in which fm. the beds thus designated have heretofore always been included.

Buchanan gravel.

Pleistocene: Eastern and central Iowa.

S. Calvin, 1896 (Iowa Acad. Sci. Proc., vol. 3, pp. 58–60). *Buchanan gravels.*—Interglacial deposit in Buchanan Co., Iowa, consisting of cross-bedded sands and gravels, 15 to 20 ft. thick, the gravels made up of materials derived from Kansan drift. Overlain by Iowan drift.

Later studies by W. C. Alden and F. Leverett showed that the gravel was deposited in Kansan time and was weathered in Yarmouth, Illinoian, and Sangamon time.

G. F. Kay and E. T. Apfel, 1929 (Iowa Geol. Surv. vol. 34, pp. 258–259). *Buchanan interval* includes Yarmouth, Illinoian, and Sangamon time.

Named for Buchanan Co.

Buchanan sands.

Subsurface sands in Pottsville fm. (Penn.) and in Chester group (Miss.) of Ill. (See Ill. Geol. Surv. Bull. 54, index.)

Buchanan Hill conglomerate.

Devonian or Carboniferous: Northwestern Pennsylvania.

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 2, pp. 1489–1536). Sub-Olean cgl. is = *Buchanan Hill cgl.*, a flat-pebble cgl. that caps Buchanan Hill, in Pa., just S. of N. Y. line.

Buchans series.

Cambrian or Ordovician: Newfoundland.

W. H. Newhouse, 1931 (Econ. Geol., vol. 26, p. 401).

Buck tongue (of Mancos shale).

Upper Cretaceous: Central eastern Utah and western Colorado (Book Cliffs field).

D. J. Fisher, 1935 (U. S. G. S. Bull. 852). A westward-pointing tongue of Mancos sh., 0 to 350 ft. thick, which in part of area [btw. Sunnyside and Colo. State line] wedges in btw. Sego and Castlegate ss. members of Price River fm., of Mesaverde group. Not recognized NW. of Beckwith Plateau. Carries marine invertebrates of Lewis age. Named for Buck Canyon, T. 19 S., R. 23 E., Utah.

This name first appeared in print in U. S. G. S. Bull. 851, 1934, by C. E. Erdmann, in a rept on E. part of Book Cliffs coal field, where he treated the Buck tongue of Mancos sh. as underlying Sego ss. and overlying Castlegate ss., and gave its thickness as 360 ft. (See also 1932 correlation chart of Utah, compiled by M. G. Wilmarth.)

Buckbee oil zone.

Subsurface beds, of Plio age, encountered in wells in Santa Fe Springs oil field, Los Angeles Co., Calif., that lie lower than Nordstrom oil zone and higher than O'Connell oil zone.

Buck Creek formation.

Pennsylvanian: Central northern and northeastern Oklahoma.

C. N. Gould, 1925 (Okla. Geol. Surv. Bull. 35, p. 78). *Buck Creek fm.* proposed by K. C. Heald in unpublished ms. Consists of lss., shales, and sss. extending from top of Pawhuska fm. to base of overlying Grayhorse ls. memb. of Sand Creek fm. Thickness 175 ft.

Named for exposures along Buck Creek in NE. part of Osage Co. The other Buck Creek in Osage Co. also cuts through the fm.

Buck Creek sandstone.

Pennsylvanian: Central northern Texas (Brazos River region).

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, p. 162). The lower water-bearing sand in Millsap Lake fm. lies 500± ft. below top of Brazos River ss., and in interval btw. Brannon Bridge and Barton Creek lss. The rock is coarse-grained, porous, highly permeable, about 25 ft. thick, and appears to be a fairly persistent layer that carries water of good quality. It outcrops on Buck Creek in SW. part of Parker Co., and is here named *Buck Creek ss.* It lies 200± ft. lower than Dobbs Valley ss.

Buckeye shale. (In Sumner group.)

Permian: Northeastern Kansas.

R. C. Moore, 1936 (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 12). [See under *Carlton ls.*]

†Buckhorn limestone.

Mississippian (lower): Central northern Utah (Ophir district).

F. M. Wichman, 1920 (Eng. and Min. Jour., vol. 110, No. 12, p. 563), mentioned "an important ls. bed below Gardner dol., in Ophir mining dist., which is apparently not represented in Tintic dist." "It is locally called the *Buckhorn*." Is a fine to medium-grained, nearly pure ls., which has been the source of considerable ore. Average thickness 30 ft.

S. G. Olmstead, 1921 (Econ. Geol., vol. 16, pp. 438, 442, 449, 453). Middle memb. of Ajax fm. (Lower Ord.) of Ophir mining dist. is locally known as *Buckhorn ls.* It is 30 ft. thick.

J. Gilluly, 1932 (U.S.G.S.P.P. 173, p. 143). Most of production within Madison ls. of Ophir Hill area has been derived from two beds, one at base, the other about 40 ft. higher. The lower part of Madison ls., including these beds, is locally called *"Buckhorn" ls.*

Buckingham gneiss.

Pre-Cambrian: Quebec.

M. E. Wilson, 1914 (Canada Geol. Surv. Summ. Rept. 1913, p. 202).

Buck Lodge diabase.

Upper Triassic: Central northern Maryland.

C. R. Keyes, 1891 (Geol. Soc. Am. Bull., vol. 2, p. 320). [*Buck Lodge diabase* is shown as a dike lying E. of Sugarloaf Mtn, Md.]

Buck Mountain moraine.

Pleistocene (Wisconsin stage): Northeastern New York (Essex County). On E. base of Buck Mtn. See N. Y. State Mus. Bull. 187, 1916.

Buck Point sandstone member (of Nelagoney formation).

Pennsylvanian: Central northern Oklahoma (Osage County).

F. R. Clark, 1918 (U.S.G.S. Bull. 686, I, p. 94). *Buck Point ss.*—Lies 95 to 115 ft. stratigraphically below top of Revard ss. Together with underlying sh. it is well developed at Buck Point and elsewhere around edges of main divide btw. Sand and Buck Creeks in T. 26 N., R. 11 E. On N. side of Buck Creek in secs. 2, 3, and 4, it is characterized by a thin productoid-bearing stratum at top, which is easily traceable and insures definite correlations. The ss. is 45± ft. thick and forms a prominent bench with a vertical cliff below. Is easily traced, but over greater part of area its only distinctive characteristic is presence of a calc. conglomeratic bed at or near base, which at many places is associated with

Fusulina-bearing sand. Except for a thin sh. immediately overlying the Buck Point, the interval btw. Revard and Buck Point sss. is occupied principally by ss.; in a few places the entire interval is sand. [See 2d entry under *Revard ss. memb.*] Below Buck Point ss. is a sh., which at Buck Point is 75± ft. thick and which occupies approx. same strat. position as the sh. below Bigheart ss., but the Buck Point and Bigheart sss. are not continuous and probably not at exactly same strat. horizon. They are therefore given different names.

Buckrange sand lentil (of Ozan formation).

Upper Cretaceous (Gulf series): Southwestern Arkansas.

C. H. Dane, 1926 (U. S. G. S. Press Bull. 8823, Sept. 10). *Buckrange sand lentil.*—Sandy marl or marly sand, 3 to 15 ft. thick, containing as much as 50 percent of coarse glauconite grains. Is basal part of Ozan fm. in Sevier, Howard, and Hempstead Counties. Grades into overlying marl of Ozan fm. Outcrops short distance N. of village of Buckrange, Howard Co., also 1 mi. NE. of village, on road to Nashville. Thins to E. [See also Dane, Ark. Geol. Surv. Bull. 1, 1929, p. 59.]

†Buck Ridge gneiss.

Pre-Cambrian: Southeastern Pennsylvania.

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 1, pp. 80–91, 118). *Buck Ridge gneiss* (also called syenite in Hall's repts C_5 and C_6).—Syenite gneiss forming Buck Ridge.

According to G. W. Stose (personal communication Dec. 23, 1936) the gneiss that forms Buck Ridge is Baltimore gneiss.

Bucks Bridge mixed beds.

Lower Ordovician (Beekmantown): Northern New York (Saint Lawrence Valley).

G. H. Chadwick, 1915 (Geol. Soc. Am. Bull., vol. 26, pp. 289–291). *Bucksbridge mixed beds or fm.*—Approx.=Tribes Hill. Thickness 50 to 70 ft. Uncon. underlies Upper Beekmantown (Ogdensburg) dol. and uncon. overlies Heuvelton ss. Characterized by *Palæophycus beverlyensis* and a lower Beekmantown or Tribes Hill fauna, but as beds differ lithologically from that fm. in Mohawk Valley, exact equivalency is not yet proved and temporary designation *Bucks Bridge* is used.

In 1916 (N. Y. State Mus. Bull. 191) H. P. Cushing applied *Tribes Hill fm.* to beds beneath Ogdensburg fm. in St. Lawrence Valley; but in 1920 (N. Y. State Mus. Bull. 217, 218) Chadwick still called the beds *Bucks Bridge mixed beds.* He described them as consisting of 50 to 75 ft. of dol. and ss.—a white sandy mass, considerably more calc. than underlying Heuvelton ss., passing gradually upward into heavy, dark siliceous dolomites with only rare ss. layers, and these in turn becoming more quartzose as summit is approached. He also stated: "The Bucks Bridge beds are approx. what has been called *Tribes Hill* in Jefferson Co. Fauna is essentially same throughout and distinct lithologically and faunally from fms. above and below and from Tribes Hill fauna of Mohawk Valley. Hewittville calcilutites are tentatively included in fm., at top." Appears to be named for Bucks Bridge, on Nettle Creek.

J. C. Reed, 1934 (N. Y. State Mus. Bull. 297), used *Buck's Bridge mixed beds* for the rocks underlying Ogdensburg dol. and overlying Heuvelton ss. in Potsdam quad. He assigned latter fm. to "probably Camb.," and the *Ogdensburg* and *Buck's Bridge* to Ord., and listed fossils of latter.

†Buckskin limestones.

Descriptive term applied locally to lss. of Dev. age in central Colo. (Gunnison-Chaffee County region), because they weather to a peculiar yellow color resembling buckskin.

Buda limestone. (In Washita group.)

Lower Cretaceous (Comanche series): Southeastern Texas.

T. W. Vaughan, 1900 (U. S. G. S. Bull. 164, p. 18). *Buda ls.*—Hard, whitish or yellowish ls., weathering yellowish or pinkish. Thickness 100 ft. Top fm. of Lower Cret. (Comanche series). Overlies Del Rio clays. Replaces *Shoal Creek ls.*, preoccupied.

Top fm. of Washita group in southern central and eastern Texas. Overlies Del Rio clay and underlies Eagle Ford sh.

Named for Buda, Hays Co.

Buell Run sand.

A subsurface sand in Conemaugh fm. of SE. Ohio that is said to probably be same as Buffalo ss. memb. Encountered in wells along Buell Run, SW. of Elba, Aurelius Twp, Washington Co.

Buena Suerte formation.

Cretaceous: Mexico.

W. F. Foshag, 1934 (Econ. Geol., vol. 29, No. 4, p. 335).

Buena Vista sandstone member (of Cuyahoga formation).

Mississippian: Southern Ohio and north-central Kentucky.

E. Orton, 1874 (Ohio Geol. Surv. vol. 2, pt. 1, pp. 615, 618, 626). *Buena Vista quarries* (also *Buena Vista stone*).—Series of quarry sss. 10 ft. thick, separated from underlying Waverly black sl. by 35 to 50 ft. of blue shales in Ross and Pike Counties, Ohio. Have been called *Waverly brownstone*.

C. S. Prosser, 1904 (Am. Geol., vol. 34, pp. 336–343). *Buena Vista memb. of Cuyahoga fm.* as here redefined consists, at Lithopolis, Fairfield Co., Ohio, of 49⅛ ft. of alternating sss. and shales, including, 5 ft. above the base, the "City Ledge," 2 ft. 10 in. thick, and 45±ft. of beds above the "City Ledge." Overlies Sunbury sh. By some *Buena Vista* has been restricted to "City Ledge." I erroneously so used it in 1902.

J. E. Hyde, 1915 (Jour. Geol., vol. 23, p. 761). *Buena Vista memb. of Cuyahoga fm.* is restricted [?] to "City Ledge." It consists of 1 to 30 ft. of sss. underlying Rarden sh. memb. and overlying Henley sh. memb. (5½ to 226 ft. thick). [This is present approved definition.]

W. Stout and R. E. Lamborn, 1924 (Ohio Geol. Surv., 4th ser., Bull. 28, p. 358), divided Cuyahoga into (descending) Black Hand cgl., Raccoon sh., and *Buena Vista sss.*, the latter overlying Sunbury sh.

Named for Buena Vista, Scioto Co., Ohio.

†Buena Vista shale.

Lower and Middle Cambrian: Central western Virginia.

H. D. Campbell, 1905 (Am. Jour. Sci., 4th, vol. 20, pp. 445–447). *Buena Vista sh.*—Bright variegated sh. Red bands predominate, but green, yellow, and brown colors are common. In lower part mottled blue ls. beds alternate with the sh., and it passes by succession of sh. and ls. beds into underlying Sherwood ls. Thickness 600 to 900 ft. Underlies Natural Bridge ls. Named for Buena Vista, Rockbridge Co.

Name is preoccupied and fm. is now considered same as Watauga sh., and is called by that name.

Bufa sandstone.

Cretaceous or Tertiary: Mexico.

C. W. Botsford, 1909 (Eng. and Min. Jour., vol. 87, p. 692).

Buffalo sandstone member (of Conemaugh formation).

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q, p. 33). *Buffalo (Upper Mahoning) ss.*—Thickness 60 to 80 ft. Underlies Pine Creek ls. and is separated from underlying Brush Creek ls. by 0 to thin layer of sh. Attains max. development along Buffalo Creek, in Buffalo Twp, Butler Co., Pa. Was included in Mahoning ss. of

First Survey, but as there is a massive ss. coming below this, to which term *Mahoning* has always been applied, it is clear that one or other should have a distinct name, for the two rocks are always distinct, and never merge into one mass. Both sss. occur on Mahoning Creek. The name Mahoning is here restricted to the lower ss.

Buffalo shale.

Upper Ordovician and basal Silurian: Northeastern Missouri and southwestern Illinois.

C. R. Keyes, 1898 (Iowa Acad. Sci. Proc., vol. 5, pp. 59, 61). *Buffalo sh.*—Fossiliferous shales, 60 ft. thick, forming top memb. of Ord. in Pike Co., Mo. Generally considered as representing Maquoketa shales of NE. Iowa and Cincinnati shales of Ohio, but doubtful whether they occupy same strat. position. Underlies Noix oolite and overlies McCune ls.

T. E. Savage, 1913 (Geol. Soc. Am. Bull., vol. 24, p. 356; Ill. Geol. Surv. Extract from Bull. 23). Blue sh. at top of Ord. in Jersey, Calhoun, and Pike Counties, Ill., and Pike, Lincoln, and Ralls Counties, Mo. In Ill. has been correlated with Maquoketa sh. In Mo. has been called *Hudson River sh.* and *Buffalo Creek sh.* Upper part corresponds to Orchard Creek sh. of southern Ill. Uncon. underlies Sil.

In later papers (1914, 1915, 1917) C. [R.] Keyes defined *Buffalo sh.* as underlying Girardeau ls. and overlying Thebes ss. The Maquoketa sh. is of Richmond age and is included in Ord. by most geologists. The Orchard Creek sh. is now classified by Savage as post-Richmond and assigned to basal Sil.

Named for Buffalo Creek, Pike Co., Mo.

Buffalo shales. (In Conemaugh formation.)

Pennsylvanian: Near Pittsburgh, Pa.

T. K. Adams, 1903 (Mines and Min., vol. 23, p. 350). *Buffalo shales,* 60 ft. thick, lie btw. Pine Creek ls. and Brush Creek coal.

Buffalo glacial stage.

Pleistocene: Central western Wyoming.

E. Blackwelder, 1915 (Jour. Geol., vol. 23, pp. 310, 328–336). *Buffalo stage,* represented by oldest glacial deposits (called *Buffalo drift*) in central western Wyo., which occur as remnants on flat-topped divides or isolated hills, or on spurs along valley slopes. Named for occurrence of the drift along Buffalo Fork of Snake River.

E. Blackwelder, 1931 (Geol. Soc. Am. Bull., vol. 42, pp. 865–922) correlated this drift with Kansan glacial stage.

Buffalo granite.

Pre-Cambrian: Central southern Virginia (Mecklenburg County).

F. B. Laney, 1917 (Va. Geol. Surv. Bull. 14, p. 36, map). *Buffalo granite.*—Small masses or areas of a coarse porphyritic intrusive granite, with very large feldspar phenocrysts, which occurs in Redoak granite in vicinity of Buffalo Lithia Springs, Mecklenburg Co., Va. Is light gray, coarse-grained, and differs from main granite masses of Virgilina dist. very little except in texture.

A. I. Jonas, 1928 (Va. Geol. Surv. prel. ed. geol. map of Va.). *Buffalo granite porphyritic facies* of Red Oak granite. Is of pre-Camb. age and intrusive into Glenarm series (Algonkian?).

†Buffalo cement bed.

Silurian: Western New York.

G. H. Chadwick, 1917 (see 19[illegible] entry under *Bertie ls. memb.*). [In 1919 (Canada Geol. Surv. Mem. 111, pp. 93–94) Chadwick replaced this preoccupied name with *Williamsville waterlime and sh.* It is top bed of Bertie ls. memb. of Salina fm. at Buffalo, N. Y.]

Buffalo moraine.

Pleistocene (Wisconsin stage): Western New York and southern Ontario. Shown on moraine map (fig. 8) in U. S. G. S. Niagara folio (No. 190), 1913, p. 17. Named for Buffalo, N. Y.

Buffalo group.

Ordovician: Arkansas.

See under *Big Buffalo series.*

Buffalo formation. (In Conemaugh formation.)

Pennsylvanian: Southwestern Pennsylvania (Punxsutawney quadrangle).

G. H. Ashley, 1926 (Topog. and Geol. Atlas Pa. No. 65, Punxsutawney quad., pl. 4, pp. 24–25). *Buffalo fm.* includes beds btw. top of Brush Creek coal and base of Bakerstown coal.

M. E. Johnson, 1929 (Topog. and Geol. Atlas Pa. No. 27). *Buffalo memb.* (of Conemaugh fm.) includes all beds btw. top of Pine Creek [Cambridge] ls. and base of Brush Creek coal and red beds, including Buffalo ss. and Brush Creek ls.

Buffalo Creek bed. (In Strawn formation.)

Pennsylvanian: Central Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 374, 384). *Buffalo Creek bed.*—Clay, 125 ft. thick; lower part in places slightly shaly, sandy, and of blue color; middle and upper parts of blue, purple, and yellowish color. Memb. of Strawn div. Underlies Wilbarger Creek bed and overlies Rough Creek bed.

Named for Buffalo Creek, Mills Co.

†Buffalo Creek sandstone member (of Conemaugh formation).

Name applied by G. H. Ashley, 1908 (Pa. Topog. and Geol. Surv. Comm. Rept. 1906–8, p. 161), to Buffalo ss memb. of Conemaugh fm.

Buffalo Creek shale.

See 1913 entry under *Buffalo sh.* (Upper Ord. and Sil.).

Buffalo Creek limestone. (In Kanawha formation.)

Pennsylvanian: Southwestern West Virginia.

R. V. Hennen and D. B. Reger, 1914 (W. Va. Geol. Surv. Rept. Logan and Mingo Counties, p. 143). *Buffalo Creek ls.*—Hard, brittle, bluish gray, marine, fossiliferous ls., 0 to 15 inches thick. Separated from overlying Buffalo Creek coal by 35 to 80 ft. of fire clay and sh. Underlain by Upper Winifrede ss. Named for association with Buffalo Creek coal.

Buffalo Hart moraine.

Pleistocene (Wisconsin stage): Central western Illinois (Sangamon and Logan Counties). See U. S. G. S. Mon. 38, pp. 74–76. Named for Buffalo Hart, Sangamon Co., by F. Leverett. In 16th Int. Geol. Cong. Guidebook 26, 1932, M. M. Leighton and G. E. Ekblaw stated, regarding the term *Buffalo Hart moraine* as used by them: "Leverett applied the name *Buffalo Hart* to a prominent portion of the moraine, and that name has been adopted for the whole moraine."

Buffalo Hill sandstone. (In Clear Fork group.)

Permian: Central and central northern Texas (Taylor and Runnels Counties).

W. E. Wrather, 1917 (SW. Ass. Pet. Geol. Bull., vol. 1, opp. p. 96). *Buffalo Hill sss.* consist of two thick sss. separated by sh., and lie 80± ft. above base of Tye fm. (basal memb. of Clear Fork beds in Taylor and Runnels Counties). [Derivation of name not stated.]

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 169). *Buffalo Hill ss.* is here included in Vale fm. It lies near base of Clear Fork group. Named for Buffalo Hills, Taylor Co.

Buffalo Peaks andesite.

Tertiary: Central Colorado (Park and Chaffee Counties).

D. B. Gould, 1935 (A. A. P. G. Bull., vol. 19, No. 7, pp. 900, 990, 999, 1000). *Buffalo Peaks andesite*, extrusive, lies on truncated surface of Paleozoic strata (Perm.) affected by the syncline extending northerly from valley of Trout Creek in sec. 3, T. 14 S., R. 77 W., past Pony Spring, to NE. spur of Buffalo Peaks in Salt Creek area, Park and Chaffee Counties.

Buffalo River series.

Ordovician: Arkansas.

See under *Big Buffalo series.*

†Buffalo Run limestone.

Upper Cambrian: Central Pennsylvania (Center County).

C. D. Walcott, 1916 (Smithsonian Misc. Coll., vol. 64, No. 3, Pub. 2370, p. 165). *Buffalo Run ls.*, a provisional name suggested by E. F. Moore, from which a new species of Upper Camb. fossil was collected 2 mi. N. of Benore P. O., Center Co.

The bed mentioned probably refers to Warrior ls., 1,250 ft. thick, defined by C. Butts in 1918 (Am. Jour. Sci., 4th, vol. 46, pp. 523–537).

Buffalo Wallow formation. (In Chester group.)

Mississippian: Western central Kentucky (Breckinridge County) and southern Indiana.

C. Butts, 1917 (Ky. Geol. Surv. Mississippian formations of western Ky., p. 112). *Buffalo Wallow fm.*—Chiefly soft bluish sh., but includes beds of red sh., ls., and ss., which altogether compose a subordinate part of mass. Thickness 150 to 200 ft. in Breckinridge Co. Greater part seems=Clore fm., but Menard ls. seems certainly represented and Palestine ss. may be represented. Overlies Tar Springs ss. Named for Buffalo Wallow, a cirquelike excavation in the characteristic shales of the fm. on highway 2 mi. W. of Cloverport.

Buff Bay beds.

Pleistocene or Pliocene: Jamaica.

R. T. Hill, 1899 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 34, p. 84).

Buffkin formation.

Pennsylvanian: Indiana.

See 1935 entry under *St. Wendell ss.*

†Buhrstone.

†Buhrstone formation.

Eocene (middle and, in S. C., upper): Mississippi, southern Alabama, Georgia, South Carolina.

John Finch, 1824 (Am. Jour. Sci., 1st, vol. 7, p. 38). The siliceous ls. or Buhrstone of Ga. is a fm. decidedly contemp. with above mentioned stratum [Calcaire Silicieuse of Paris basin], although the principal part of the celebrated mill-stones are from a rock higher in the series, the Meuliere sans coquilles, yet some are obtained from the Calcaire Grossier; and to this stratum and the C. Silicieuse I consider the Ga. Buhr stone allied, both by similarity of mineralogical character and nature of fossil remains.

M. Tuomey, 1848 and 1850 (Rept. on geol. of S. C., pp. 140–154, 211, 1848, and accompanying map, dated 1845; Ala. Geol. Surv. 1st Bien. Rept., p. 147, 1850). *Buhrstone fm.*—Thick beds of sand, gravel, grit, clay, and buhrstone, amounting to at least 400 ft., and underlying the calc. beds. Its upper portions are characterized by beds abounding in silicified shells, for most part identical with Claiborne fossils, which has given the name to the fm. [According to C. W. Cooke (personal communication, 1933) the †Buhrstone fm. of Tuomey, 1848, included practically all siliceous Eocene deposits in S. C.]

Nongeographic name. Replaced by *Tallahatta fm.* in Ala. and Miss. and by *McBean fm.* and *Barnwell sand* in eastern Ga. and S. C. See further explanation under †*Choctaw buhrstone* and *Tallahatta fm.*

Bulger limestone bed. (In Monongahela formation.)

Pennsylvanian: Southwestern Pennsylvania (Washington County) and eastern Ohio.

W. T. Griswold and M. J. Munn, 1907 (U. S. G. S. Bull. 318, pp. 38–39, 70+). *Bulger ls.*—At Bulger, Washington Co., it consists of solid brown ls., 1 to 2 ft. thick, breaking with uneven fracture and showing a number of small calcite crystals. West of type loc., in Steubenville quad., it is a foot or more thick, of muddy brown color, and breaks with smooth fracture. Underlain by 20 ft. of green sh. and overlain by 15 to 20 ft. of coarse calc. sh. Lies about 55 ft. above Sewickley coal.

The Bulger ls. bed is uppermost part of Benwood ls. memb. of Monongahela fm. and lies 15 to 20 ft. below Uniontown ls. memb. in Claysville region.

Bulkley eruptives.

Tertiary or Cretaceous: British Columbia.

W. W. Leach, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 63).

†Bull ledge.

Pennsylvanian: Northwestern Missouri (Kansas City).

H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines vol. 13). The lower (nonoolitic) bed of Drum ls. at Kansas City is known as "Bull ledge," and the upper bed as "oolite ledge."

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, p. 40). So-called Drum ls. of Hinds and Greene at Kansas City is Westerville ls., the upper part of which is "Kansas City oolite," and lower (nonoolitic) part the "Bull ledge."

Bull slate.

Lower Cambrian: Southwestern Vermont (Rutland County).

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 401). *Bull sl.*—Sl., usually purplish more or less mixed with green. Comparatively thin fm., of fine, even grain, smooth texture, and banding so faint that as a rule it does not affect the smoothness of the cleavage. Only a few ss. layers; occasionally a small bed of ls. in upper part. No fossils, but age is fixed by fossils in underlying ls. Underlies Beebe ls. and overlies Barker qtzite. Named for the quarry on Bull Hill, 2 mi. N. of Castleton [in Castleton quad.]. It is principal horizon that is worked for the purple and unfading green slates of sl. industry, the principal development of which is in region of Fairhaven, Vt., and Granville, N. Y., a few mi. SW. of Castleton.

Bulla conglomerate.

Miocene (lower): Dominican Republic.

C. W. Cooke, 1920 (Geol. Soc. Am. Bull., vol. 31, p. 219).

Bullard limestone.

A name applied by O. P. Peterson (Am. Inst. Min. and Met. Engrs. Trans., vol. 70, p. 915, 1924) to a ls., 5 to 20 ft. thick, in Bingham qtzite (Penn.) of Bingham dist., Utah. Lies 220 ft. below Parnell ls. and 400 ft. above Yampa ls.

†Bulla striata marls.

Pleistocene: Florida.

W. H. Dall, 1892 (U. S. G. S. Bull. 84, pp. 147, footnote, 157, 322, 336). To distinguish the Pleist. beds containing *Venus cancellata* and *Bulla striata* from the Plio. beds containing same species, the Pleist. beds might be called, from their most abundant fossil, the *Bulla striata marls.*

According to C. W. Cooke these beds are a part of Fort Thompson fm.

Bull Creek sandstone. (In Strawn formation.)

Pennsylvanian: Central Texas (Colorado River region).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 3, pp. 374, 379). *Bull Creek ss.*—Sss., largely in flaggy layers 6 in. to 4 ft. thick; white on fresh surfaces, weathering grayish. Thickness 50 to 75 ft. Memb. of Strawn div. Overlies Horse Creek clays and shales and underlies Big Valley bed.

Named for Bull Creek, Mills Co.

Bull Creek limestone.

Pennsylvanian: Central northern Oklahoma (Osage County)

F. C. Greene, 1918 (A. A. P. G. Bull., vol. 2, p. 121). *Bull Creek ls.*—Well exposed on Bull Creek, in NW. part of T. 23 N., R. 11 E. It is 5 to 15 ft. thick and lies about 100 ft. above Peoples sand and 150 ft. above Stanton ls. Its characteristics N. of Bigheart are not known to writer. To SW. it can be identified in most logs of wells in vicinity of Hominy. Above it lies an interval of irregular shales and sss., 80 to 125 ft. thick, overlain by Wild Horse ls.

†Bull Face slate.

A metamorphic sl. in NW. Ga., called by the people *Bull Face sl.* (G. Little, Ga. Min., Geol., and Phys. Surv. Rept. Prog. Sept. 1 to Dec. 31, 1874, 1875). Is believed to be the sl. underlying Weisner qtzite.

†Bullhead waterlime.

†Bullhead limestone.

Descriptive terms that have been applied to Cobleskill dol. in western N. Y.

Bull Head Mountain sandstone.

Lower Cretaceous: Alberta and British Columbia.

F. H. McLearn, 1918 (Canada Geol. Surv. Summ. Rept. 1917, pt. C, p. 16).

Bull Hill gneiss.

Age (?): Southeastern Vermont (Windham County).

C. H. Richardson, 1931 (17th Rept. Vt. State Geol., p. 221). *Bull Hill gneiss*, new name, is necessary because of rather wide distribution of the gneiss and its characteristic structure. Type loc. is on Bull Hill, E. to NE. of village of Grafton and N. of village of Cambridgeport. [In Saxtons River quad.] The hill reaches altitude of 1,580 ft. and is practically all gneiss. Also well exposed in NE. part of Grafton Twp. The gneiss is profoundly porphyritic; is cut by pegmatite veins. Also occurs near SE. corner of Chester. Structure and texture are markedly different from that of Reading gneiss. It appears to be an orthogneiss.

C. H. Richardson and J. E. Maynard, 1933 (18th Rept. Vt. State Geol., pp. 316–347). *Bull Hill gneiss*, acid intrusive, embraces only those gneisses that are pronouncedly porphyritic.

Bullion dolomite member (of Monte Cristo limestone).

Mississippian (lower): Southeastern Nevada (Goodsprings region).

D. F. Hewett, 1931 (U. S. G. S. P. P. 162, pp. 10, 18, etc.). *Bullion dol. memb.*—Massive light-gray ls. now largely altered to cream-colored and white dol.; chert uncommon. Thickness 185 to 300 ft. Underlies Arrowhead ls. and overlies Anchor ls., all members of Monte Cristo ls. Named for Bullion mine, sec. 23, T. 25 S., R. 58 E. Few fossils (lower Miss.).

Bull Lake glacial stage.

Pleistocene: Central western Wyoming.

E. Blackwelder, 1915 (Jour. Geol., vol. 23, pp. 310, 325–340). *Bull Lake stage.*—The next older moraines, which I have compared with early Wisconsin drift of Illinois, will be called *Bull Lake drift*, from locality of that name on N. slope of Wind River Range. Is later than Buffalo drift and earlier than Pinedale drift. Succeeded the Circle interglacial cycle and preceded the Lenore interglacial cycle. Correlated with early Wisconsin drift of Illinois.

E. Blackwelder, 1931 (Geol. Soc. Am. Bull., vol. 42, pp. 865–922), correlated Bull Lake stage with Iowan stage.

Bull Lake Creek shales.

Cambrian: Western Wyoming (Wind River Mountains).

E. B. Branson, 1917 (Geol. Soc. Am. Bull., vol. 28, pp. 347–350), in several places referred to a shaly fm., 300 to 400 ft. thick, overlying Deadwood ss. and underlying *Shoshoni ls.* in Wind River Mtns, as *Bull Lake Creek shales* (apparently from Bull Lake Creek), and stated that *Bull Lake Creek* and *Shoshoni* were names used by writer in paper in preparation. This is only record of these names.

See also under *Death Canyon memb.*

†Bull Mountain series.

Eocene: Central southern Montana (Yellowstone County).

W. Lindgren, 1886 (U. S. Tenth Census, vol. 15, p. 745, pl. 60). *Bull Mtn series (Upper Laramie)*.—A succession of light-colored clays, soft, white, argill. sss., and heavy benches (10 to 30 ft. thick) of massive yellow ss. with rounded corners and faces and generally carrying round nodules of brown iron ore. Contains the more valuable lignite beds. Thickness 1,550 to 1,660 ft. in Bull Mtns and adjacent territory. Contains abundant fossil leaves and plants.

Approx. same as Fort Union fm., according to T. W. Stanton (personal communication).

Bull Pond limestone.

W. W. Mather, 1843 (Geol. N. Y., vol. 1, pl. 45). [*Bull Pond ls.* is shown on this geol. cross section from Monticello, Sullivan Co., to Croton River near Bulls Bridge, Westchester Co., N. Y.]

Bull Run shales. (In Newark group.)

Upper Triassic: Northeastern Virginia.

J. K. Roberts, 1923 (Pan-Am. Geol., vol. 39, pp. 185–200). *Bull Run shales*.—Shales forming youngest Triassic sediments of northern Va. Occupy middle of Triassic basin. Are younger than Manassas ss.

J. K. Roberts, 1928 (Va. Geol. Surv. Bull. 29, pp. 24–25, 38–43). Manassas ss. is for most part intercalated with *Bull Run shales*. Where not disturbed by faulting and not covered by Recent material or soil the Bull Run shales overlie Manassas ss. Almost the only rocks outcropping over Bull Run Battlefield are Bull Run shales, which vary from an extra fine to a relatively coarse and gritty nature, and include red, gray, blue, black, and decolorized shales.

A part of Newark fm.

Bullwagon dolomite. (In Clear Fork group.)

Permian: Central northern and central Texas.

W. E. Wrather, 1917 (SW. Ass. Pet. Geol. Bull., vol. 1, pl., pp. 96–97). *Bullwagon dol.*—Two distinct strata separated by a sh. or clay parting. Thickness 2 to 5 ft. Thins to N. until it cannot be identified with certainty 35 mi. N. of Tex. and Pacific Ry. Lies 360 to 370 ft. below Merkel dol. Named for Bullwagon Creek, Taylor Co.

J. W. Beede and V. V. Waite, 1918 (Univ. Tex. Bull. 1816). *Bullwagon dol.* is 36 ft. thick on Colorado River, where it is represented by a number of thin dolomites and blue shales. Underlies Choza fm. and overlies Vale fm. [Other repts give thicknesses as great as 65 ft.]

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 169, 176, 181). *Bullwagon dol.* here treated as top *memb. of Vale fm.*, the definition of Vale fm. being modified to that extent.

†Bully Hill volcanics.

Age (?): Northern California (Redding quadrangle).

J. S. Diller, 1905 (Am. Jour. Sci., 4th, vol. 19, pp. 380–385). *Bully Hill volcanics*.—Lavas interstratified with tuffs and shales. Of late Carbf. and early Triassic age.

†Bully Hill rhyolite.

Jurassic(?): Northern California (Redding quadrangle).

J. S. Diller, 1906 (U.S.G.S. Redding folio, No. 138). In Bully Hill region [Shasta Co.] the rhyolite is arranged in flows alternating with tuffs dipping SE. beneath the Pit shales, but in places it cuts lower part of Pit shales and envelops its fragments. For convenience all the rhyolites erupted in Redding quad. during deposition of Pit shales are included under term *Bully Hill rhyolite*, though they represent a considerable range of time. Bedded tuffs, composed largely of crystal fragments of quartz and feldspar, with a smaller proportion of glass and pumice particles replaced by quartz, are common among the Pit shales and are locally associated with sheets of rhyolite. Thickness about 500 ft.

Later work by L. C. Graton (U. S. G. S. Bull. 430, pp. 81–85, 1910) proved this fm. to be intrusive alaskite porphyry, and same as so-called "Balaklala rhyolite." Both geographic names have therefore been discarded as unnecessary. The rock cuts fms. as young as Pit sh. (Middle and Upper Triassic).

Bulwark sandstone.

Cretaceous: Alberta.

S. E. Slipper, 1918 (Canada Geol. Surv. Summ. Rept. 1917, pt. C, p. 8).

†Buncombe group.

Cambrian(?) and pre-Cambrian: Western North Carolina (Blue Ridge Province).

W. C. Kerr, 1869 (N. C. Geol. Surv. Rept. 2, pp. 13–35). *Buncombe group.*—Occupies larger part of great transmontane plateau btw. Blue Ridge and Smoky Mtns. Average breadth of fm. is about 25 mi., and since it is conspicuously developed across whole breadth of Buncombe Co. and may be seen in complete section along the French Broad in its course through that county, it will be in accordance with usage to call it *Buncombe group*. The rocks of this belt manifest an extreme degree of alteration and disturbance. They belong to general description of granitoid or gneissic rocks, and consist of various and recurrent successions of gneissoid slates, quartzose, feldspathic, micaceous, and hornblendic, with frequent beds of gneiss proper, and occasional interpolations of true granite. A large body of reddish porphoroidal feldspathic gneiss is found along NW. edge of the belt, as may be seen a little below Marshall on the French Broad and again in Yancey, some 4 mi. N. of Burnsville. Mica schist also occurs in large development toward E. margin of belt, as may be seen in Asheville and along Swannanoa valley to a point near the gap. The fm. is also characterized throughout its whole extent by frequent occurrence of isolated masses of mag. rocks, ophiolites, serpentines, soapstones, talcose and chloritic slates, with tremolite, asbestos, and actinolite rocks, generally associated with hornblende, sl., and syenite, and usually containing veins of chromic iron. The Buncombe group is limited southeastward by Linville slates.

The following fms. are exposed on French Broad River, in Buncombe Co., N. C. (descending order): (1) Soapstone, dunite, and serpentine; (2) metagabbro; (3) Roan gneiss; and (4) Carolina gneiss. But several other pre-Camb. fms. and many Camb. fms. are exposed in the plateau btw. the Blue Ridge and Smoky Mtns in N. C., as shown on N. C. correlation chart.

Bunger limestone member (of Graham formation).

Pennsylvanian: Central northern Texas (Brazos River region).

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, pp. 133–145). Top memb. of Bunger fm. [For description see 1919 entry under †*Bunger fm.*]

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31; Univ. Tex. Bull. 2132, pp. 129, 130, and charts). *Bunger ls. lentil.*—A ls. memb. of Graham fm. in Brazos River Valley. Underlies South Bend sh. and ss. memb. and overlies Gonzales Creek sh. memb.; all members of Graham fm. Thickness 2 to 8 ft. In places is dark yellowish brown, quite dense and heavy; in other places is light gray, impure, and massively bedded. Lies 60 [50 to 110] ft. below Gunsight ls. memb. Best exposed around N. and W. sides of big curve of Brazos River 5 mi. S. of Graham.

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501, pp. 197, 221–223), used *Bunger ls.* in McCulloch Co., Colorado River Valley, and stated: The ls. called *Bunger* in Colorado River Valley occupies same strat. position as typical Bunger of Brazos River Valley, and agrees in lithology and fossils. But fact that it is a lentil in northern area would make it unlikely that the Bunger of Colorado River area is continuous with the Bunger of Brazos River area. It seems less confusing, however, to use same name for these beds (20 to 25 ft. thick in McCulloch Co.), which lie 50 to 70 ft. below top of Bluff Creek sh. memb. of Graham fm. and 52 to 68± ft. above base of the Bluff Creek memb.

Named for Bunger, Young Co.

†Bunger formation. (In Cisco group.)

Pennsylvanian: Central northern Texas (Brazos River region).

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, pp. 133–145). *Bunger fm.*—Poorly bedded, lenticular, dark-brown sss. and sandy shales with a few thin lss. Locally, in section W of Finis, a dark carbonaceous sh. occurs near bottom of fm. Thickness 230± ft. Top memb. is named *Bunger ls.* It is a persistent ls., 2 to 4 [8] ft. thick; in places dark yellowish brown, dense, and heavy; in other places light-gray and coarsely crystalline. Bunger fm. underlies Gunsight fm. and overlies Jacksboro fm.

Is a part of Graham fm., adopted name.

Named for Bunger, Young Co.

Bunger sand.

A lenticular subsurface sand in upper part of Strawn group of Bunger dist., Young Co., central northern Tex. It lies about 750 ft. below Palo Pinto ls.

Bunker andesite.

Tertiary (Eocene): Central southern Colorado (Silver Cliff-Rosita region).

W. Cross, 1890 (Colo. Sci. Soc. Proc., vol. 3, pt. 3, p. 272) and 1896 (U. S. G. S. 17th Ann. Rept., pt. 2, p. 289). *Bunker andesite.*—Holocrystalline, fine-grained, massive andesite, carrying hornblende, augite, and biotite. Forms greater part of Rosita Hills. Occurs in Bunker Hill, Sugar Loaf, etc.

Bunker slate.

Lower Cambrian: Quebec.

T. H. Clark, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 1, p. 11).

Burbank member (of Cuyahoga formation).

Mississippian: North-central Ohio (Wayne County).

G. W. Conrey, 1921 (Ohio Geol. Surv., 4th ser., Bull. 24, p. 50). *Burbank memb.*—Basal memb. of Cuyahoga fm. in Wayne Co. Grayish blue shales and grayish buff sss. alternating; 150 ft. exposed. Underlies Armstrong memb. and overlies Sunbury sh. Named for Burbank, in N. part of Wayne Co.

Burbank sand.

A subsurface sand, in lower part of Cherokee sh. (early Penn.), 40 to 80 ft. thick in Burbank field, Osage and Kay Counties, Okla., where it lies at depth of 2,700 to 2,900 ft. Also occurs in Woodson, Cowley, Butler, Sumner and Greenwood Counties, Kans. Lies lower than Oswego lime (Fort Scott ls.). Has been called *Bartlesville sand*, but *Bartlesville* is now restricted to a sand lying 50 to 100 ft. lower, and *Burbank* (*Red Fork*) *sand* is now applied to this higher sand. The lower sand is now regarded as true Bartlesville.

†Burches Ferry marl.

Upper Cretaceous: Northeastern South Carolina and eastern North Carolina.

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 12, 14). *Burches Ferry marl.*—Buff-colored high grade marl; greensand marl. Is exposed in Florence Co., S. of Jeffries Creek, and thence along the Great Pee Dee to Topsaw Landing. Is interruptedly exposed along Lynches River from Old Effingham to its confluence with the Great Pee Dee; along Black Mingo from Indianfield Church to Black River; along Black River from Perkins Bluff to confluence of Black Mingo; along the Waccamaw from N. C. to a point near Conway. The uppermost Cret. fm. in S. C. Overlies Black Creek sh. and underlies Black Mingo sh.

Replaced by Peedee fm., the older name.

Named for exposures at Burches Ferry, on W. side of Peedee River, in Florence Co.

Burden conglomerate.

Ordovician: Eastern New York (Columbia County).

A. W. Grabau, 1903 (N. Y. State Mus. Bull. 69, p. 1034). *Burden cgl.*—Calc. cgl. in which the pebbles are chiefly ls. embedded in a siliceous sand, which in turn is held together by a more or less calc. cement. Age unknown. That it belongs to Hudson River series is undoubted, but whether older or younger than Normanskill shales has not been ascertained. No fossils found. May correspond to Trenton cgl. of Rysedorph Hill [Rysedorph cgl.] or it may be still earlier. Areal relations seem to indicate it is older than Normanskill beds of Mount Moreno.

A. W. Grabau, 1906 (N. Y. State Mus. Bull. 92, p. 302). Fragments of Burden cgl. are found scattered over Mount Becraft, and it also occurs at Burden iron mines, 5 mi. S. of Hudson. Its age is probably lower Champlainic [Lower Ord.].

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 36). Age of the Burden has not been definitely determined, but it is thought it may correspond to Rysedorph cgl.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 281). *Burden cgl.* is found near Becraft Mtn and other places in vicinity of Hudson within the Normanskill shales. No fossils have been found. It is thought it may be identical with Rysedorph cgl.

Burditt marl.

Upper Cretaceous (Gulf series): Central Texas (Travis County).

W. S. Adkins, 1933 (Univ. Tex. Bull. 3232, pp. 239, 270, 407, 441, 442, 449). *Burditt fm.* (p. 239), *Burditt chalk marl* (p. 407), *Burditt marl* (heading on p. 449).—Hill included this chalk marl with Austin chalk, and stated that top is transitional to the Taylor. Taff segregated the upper marly lime zone of Austin chalk, and considered it lithologically transitional to Taylor marl. This chalk marl is here called *Burditt*, from Burditt School, Travis Co., and type loc. is along Little Walnut Creek downstream from Austin-Cameron road, where the marl is 40± ft. thick. It is a light gray, somewhat shelly, calc. clay overlying the hard chalk (Austin chalk proper). Stephenson states the Taylor in McLennan Co. uncon. overlies the Austin, and that its base contains a phosphatic pebble zone. There appears to be no marked break in Travis Co., although a prominent layer of phosphatic nodules and fossils occurs in the Burditt near type loc.

According to L. W. Stephenson, 1937 (U. S. G. S. P. P. 186G), the beds called *Burditt marl* by Adkins are no more marly than other lower parts of Austin chalk elsewhere in Tex. If recognized as a separate lithologic unit it should be treated as an upper marly memb. of Austin chalk.

Burge sands member. (In Ogallala formation.)

Tertiary (upper Miocene or lower Pliocene): Northern Nebraska (Cherry County).

F. W. Johnson, 1936 (Am. Jour. Sci., 5th, vol. 31, pp. 467–473). It is proposed to call the extensive channel deposits that contain the "Burge fauna" (described by R. A. Stirton and P. O. McGrew, Am. Jour. Sci., 5th, vol. 29, pp. 125–132, 1935) the *Burge sands memb. of Ogallala fm.* Type loc. is Burge Quarry, on Snake River, SW. of Valentine, Cherry Co. The beds consist of unconsolidated, fine to coarse-grained, gray, cross-bedded, channel sands, often containing nodules and lenses of greenish clay; coarse sand and some gravel noted in nearly all exposures. Thickness 25 to 28 ft. at Burge Quarry; varies up to 30 ft. in other places. Overlain by "cap rock bed" (highly calc. grit), and in many places rest uncon. on greenish gray massive sands of upper part of Valentine beds. Burge sands and "cap rock bed" assigned to lower Plio., and Valentine beds to transitional Mio.-Plio. The beds and their fauna have been traced from Cherry Co. into Brown Co., by M. F. Skinner.

Burgen sandstone.

Middle or Lower Ordovician: Eastern Oklahoma.

J. A. Taff, 1905 (U.S.G.S. Tahlequah folio, No. 122). *Burgen ss.*—Massive, moderately fine-grained, light-brown ss., 5 to 100 ft. thick. Underlies Tyner fm.

J. A. Taff, 1906 (U.S.G.S. Muscogee folio, No. 132). No fossils have been found in *Burgen ss.* Its age is inferred from its strat. position. A study of St. Peter or "Saccharoidal" ss. in northern Ark. and Mo., with which the Burgen is correlated by Dr. E. O. Ulrich, caused him to class it as early Ord.

The U. S. Geol. Survey from 1915 to 1930 used *St. Peter ss.* instead of Burgen ss., Key ss., Saccharoidal ss., Crystal City ss., Pacific ss., Cap au Gres ss., etc. The Okla. Geol. Survey, however, has rather consistently adhered to the Okla. name *Burgen ss.* On 1926 Okla. geol. map, by H. D. Miser, this ss. was called *St. Peter.* C. N. Gould, in the text to accompany that map (Okla. Geol. Surv. Bull. 35, p. 55, 1925), used *St. Peter* ("*Burgen*") *ss.*, but stated that his preference was for the Okla. name *Burgen ss.*

E. O. Ulrich, 1927 (Okla. Geol. Surv. Bull. 45, pp. 30–31), showed *St. Peter or Burgen ss.* of NE. Okla. as = upper part of St. Peter ss. of Minn.

E. O. Ulrich, 1930 (Okla. Geol. Surv. Bull. 40QQ, pp. 11–12). I have long insisted Burgen ss. does not fall into the place to which it is usually assigned by Okla. geologists—that is about middle of the Simpson. It is either older than base of Simpson and of age of some part of Buffalo River series, or it is much younger—probably Black River. Fossil evidence is lamentably indecisive and goes little further than to prove Ord. age of the Burgen. I am, somewhat reluctantly, I confess, forced to conviction that the Burgen is a much younger deposit than St. Peter ss. and probably that it is represented in Arbuckle region by the ss. that is locally developed, especially on NE. flank of that uplift, at base of the Bromide and above the Criner. The sand probably was blown in from eroding surfaces of Buffalo River sss. on W. side of Ozark uplift, which we have every reason to believe was emerged at that time.

I. H. Cram, 1930 (Okla. Geol. Surv. Bull. 40QQ, p. 12). In view of indefiniteness of correlation of Burgen ss. the name *Burgen* should be applied to eastern Okla. beds rather than *St. Peter.* Ulrich's suggestion that the Burgen is basal ss. of Bromide fm. of Simpson group is not entirely out of line with subsurface evidence, but if writer's suggestion that lower Tyner is lower Simpson in age proves to be correct, the Burgen must be older than Ulrich suggests it to be. Possibly it is basal ss. of Oil Creek fm. of Simpson group.

In view of doubt that exists as to Burgen ss. being the same as St. Peter ss., the U. S. Geol. Survey now employs the local name *Burgen ss.* for the ss. underlying Tyner fm. in eastern Okla.

Named for Burgen Hollow, NE. of Tahlequah, Cherokee Co.

Burgen limestone.

Lower Ordovician: Central Oklahoma (Okfuskee County).

J. P. Boyle, 1929 (Okla. Geol. Surv. Bull. 40KK). *Burgen ls.*—A single ls. memb., 30 to 70 ft. thick, underlying Tyner sh. and overlying Burgen ss. throughout NE. Okla. Present over entire area of Okfuskee Co. [The original definitions of Tyner fm. and Burgen ss. (U.S.G.S. Tahlequah and Muscogee folios, Nos. 122 and 132, 1905 and 1906, respectively) do not mention any ls. in lower part of Tyner nor in Burgen ss.]

Burgess shale.

Middle Cambrian: British Columbia.

C. D. Walcott, 1911 (Smithsonian Misc. Coll., vol. 57, No. 3, p. 51).

Burgess oolite. (In Bangor limestone.)

Mississippian: Northwestern Alabama (Franklin and Lawrence Counties).

W. B. Jones, 1928 (Ala. Geol. Surv. Circ. 8, pp. 13–15). *Burgess oolite*, variable in thickness (0 to 40 ft.) and physical properties. Lies 200 ft. below top of Bangor ls. in Russellville dist. (Franklin Co. and W. part of Lawrence Co.). Overlain and underlain by blue fossiliferous lss. of Bangor ls. Type loc. at Burgess quarry, on a comparatively high hill 3 mi. E. of Russellville, Franklin Co., where it has its greatest thickness—at least 40 ft.

Burgess sand.

A subsurface sand of early (?) Penn. age in Okla. and southern Kans. Lies lower than Bartlesville sand. Thicknesses reported, 7 to 60± ft. According to Okla. Geol. Surv. Bull. 40Q, 1928, p. 180, this sand is of Miss. age.

Burgoon sandstone member (of Pocono formation).

Mississippian: Western Pennsylvania, northern West Virginia, and southeastern Ohio.

C. Butts, 1904 (U.S.G.S. Kittanning folio, No. 115, pp. 5, 6, sections). So far as exposed in this quad. the Pocono fm. is composed mainly of a heavy gray to greenish coarse, thick-bedded ss., the Mountain or Big Injun sand of the driller, which is here named *Burgoon ss.*, because it is cut through by valley of Burgoon Run, above Kittanning Point [Blair Co.]. No considerable exposures of the ss. were seen on valley walls, but on S. side abundant boulders of coarse siliceous ss. and a soil that is almost pure sand, indicates its presence close beneath the surface. Thickness 300 ft. Overlies red sh. (Patton sh. memb. of Pocono) and uncon. underlies Pottsville fm. in Kittanning quad., but in Burgoon type region (Blair Co.) and elsewhere the Burgoon is immediately overlain by Loyalhanna ls.

Burgoon group.

Mississippian: Pennsylvania.

J. D. Sisler, G. H. Ashley, and others. 1933 (Pa. Geol. Surv., 4th, Bull. M19, p. 8). Included in Pocono series, and includes Burgoon ss. and Shenango ss.

Burkburnet sands.

Subsurface oil-bearing sands in Cisco fm. of central northern Tex.

Burke formation. (Of Ravalli group.)

Pre-Cambrian (Belt series): Northeastern Idaho (Coeur d'Alene district) and northwestern Montana.

F. L. Ransome, 1905 (U. S. G. S. Bull. 260, pp. 277–285). *Burke fm.*—Gray, flaggy, fine-grained sss. and shales, with interbedded purple qtzitic sss. and white qtzite. Shallow-water features throughout. Thickness 1,700 ± ft. Underlies Revett qtzite and overlies Prichard sl. Typically developed along Canyon Creek from Burke to Gem, Idaho, also in vicinity of Wardner and elsewhere in Coeur d'Alene dist.

Description of general geology of region is based almost wholly on work of F. C. Calkins.

Burket black shale member (of Harrell shale).

Upper Devonian: Central Pennsylvania (Huntingdon to Center Counties).

C. Butts, 1918 (Am. Jour. Sci., 4th, vol. 46, pp. 523, 536) *Burket black sh. memb.* at base of Harrell sh. (of Portage group).

C. Butts (U. S. G. S. Hollidaysburg-Huntingdon folio, No. 227). *Burket black sh. memb.*—Black fissile sh., 80 ft. thick, forming basal memb. of Harrell sh. Overlies Hamilton fm. Named for exposures at Burket, a suburb of Altoona, Blair Co.

B. Willard, 1935 (Geol. Soc. Am. Bull., vol. 46, pp. 1209–1213), transferred this memb. to his Rush fm. and restricted Harrell sh. to overlying beds.

Burkett sand.

A subsurface sand, of Penn. age, in Burkett field, Coleman Co., north-central Tex., where it lies at 360 ft. depth.

Burkeville beds.

Miocene (upper) and Pliocene(?): Western Louisiana and eastern Texas.

A. C. Veatch, 1902 (La. Geol. Surv. pt. 6, Rept. for 1902, p. 136, pl. 37). Fossils collected near Burkville [Burkeville] are regarded by Harris as representing a brackish water phase of Chattahoochee Olig. It is impossible from our present observation to say how far from base of the green clays these fossils occur (it is probably over 100 ft.) and how much, if any, of upper portions of Grand Gulf proper belong to this stage. On map, and in our consideration of Sabine River section, we have made the last hard ss. layer in the Grand Gulf the dividing line. This is of course purely arbitrary. These beds seem to be very nearly = Kennedy's Frio clays. His description, however, seems to partially indicate that he regards these clays as occupying a position beneath the upper sss. If this be the correct interpretation of his meaning we would suggest the name *Burkville beds* for this stage.

See also under *Cold Spring horizon.*

C. L. Baker, 1920 (Univ. Tex. Bull. 1869, pp. 223–225). In vicinity of Burkeville the base of the Fleming is not earlier than late Mio. nor younger than early Plio.

Named for Burkeville [correct spelling], Newton Co., Tex.

Burley lake beds.

Pleistocene: Southern Idaho (Cassia County).

H. T. Stearns, 1932 (Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932) and 1936 (Jour. Geol., vol. 44, No. 4, pp. 434–439). *Burley lake beds.*—Deposited in ancient Lake Burley. Not exposed. Log of city well at Burley, Cassia Co., gives thickness of 150 ft. The beds are essentially horizontal and capped in S. and E. by gravel deposited by Snake River and Goose Creek. Not disturbed by diastrophism since deposition. As the beds reach nearly to old shore line the lake must have practically silted up before it was drained. Older than Minidoka basalt and younger than Sand Spring basalt.

†Burlingame shale.

Pennsylvanian: Eastern Kansas and northwestern Missouri.

E. Haworth, 1895 (Kans. Univ. Quart., vol. 3, p. 278 and pl. 20; Am. Jour. Sci., 3rd, vol. 50, p. 461 and pl. opp. p. 466). *Burlingame sh.*—Shales, with considerable ss., 150 ft. thick, separated from underlying Osage coal by a thin but persistent ls.

Replaced by Scranton sh.

Named for Burlingame, Osage Co., Kans.

Burlingame limestone member (of Wabaunsee formation).

Pennsylvanian: Eastern Kansas, southeastern Nebraska, and northwestern Missouri.

J. G. Hall, 1896 (Univ. Geol. Surv. Kans., vol. 1, p. 105). *Burlingame ls.*—Just W. of Burlingame [Osage Co.], Kans., system No. 5 makes its first appearance. It is 8 ft. thick, brown, shelly, and covers the third and last heavy bed of shales in this section, which is 150 or 200 ft. thick.

E. Haworth, 1898 (Kans. Univ. Geol. Surv. vol. 3, pp. 72, 73, 94, 105). Burlingame ls. proposed by J. G. Hall for ls. system No. 5, consisting of brown shelly ls. 8 ft. thick, overlying Osage sh. ["Osage" as here used included †Burlingame (Scranton) sh.]

Basal memb. of Wabaunsee fm. in Mo. In Kans. the Wabaunsee is treated as a group and the Burlingame as a fm. The present Kans. and Nebr. Surveys use Soldier Creek sh. for the beds overlying Burlingame ls.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 215–216). Soldier Creek sh. and overlying Wakarusa ls. have been included by various writers in Burlingame ls. at several places in central and southern Kans. The name *Burlingame* should be restricted to lower ls., which seems to accord with Hall's original description. Thickness 4 to 16 ft. Has been mapped from southern Nebr. across Kans., and identified 40± mi. S. of Kans.-Okla. line. The ls. makes a fairly prominent escarpment that crosses W. part of Burlingame, Kans.

Burlington limestone. (Of Osage group.)

Mississippian: Iowa, Illinois, eastern Missouri, and western Kentucky.

D. D. Owen, 1852 (Rept. Geol. Surv. Wis., Iowa, and Minn., btw. pp. 90 and 140). *Encrinital group of Burlington* (also called *Burlington beds*).—In descending order: White crystalline and semi-oolitic lss.; brown and flesh-colored encrinital lss., brown earthy crinoidal lss. with crystalline specks; band of cellular buff mag. ls.; oolitic ls.; dark-gray argill. lss. Overlies argillo-calc. group. Separated from overlying Keokuck cherty lss. by brown Encrinital lss. alternating with bands of chert, as near Hannibal [Mo.]. [According to later repts the cherty beds of passage are Keokuck cherty lss. of Owen.]

J. Hall, 1857 (Am. Ass. Adv. Sci. Proc., vol. 10, pp. 53–57). Encrinital ls. of Burlington, or, as we shall hereafter term it, the *Burlington ls.* Very fossiliferous ls. overlying oolitic ls. and argill. ss. belonging to Chemung group of N. Y. and underlying cherty beds of passage (Keokuk cherty lss. of Owen, 60 to 100 ft.

thick) to the higher Keokuk or lower Archimedes ls. Includes Owen's Encrinital group of Hannibal, Mo., which is identical with Encrinital ls. of Burlington. Characterized by great numbers of crinoids.

A. H. Worthen, 1882 (Econ. Geol. Ill., vol. 1, pp. 79, 86). *Burlington ls.* at Burlington, Iowa [type loc.], consists of (1) an upper member of light-gray or nearly white ls. with some brown layers and abundant chert; and (2) a lower memb. of brown mag. ls. locally aren., with abundant chert.

C. R. Keyes, 1895 (Iowa Geol. Surv. vol. 3). *Upper Burlington ls.* is distinguished from *Lower Burlington ls.* by being more thin bedded and containing greater abundance of chert. The upper 30 ft. (the flinty beds of Upper Burlington) are here named *Montrose chert.*

See also under *Keokuk ls.*

S. Weller, 1926 (Jour. Geol., vol. 34, pp. 320–335), considered the Fern Glen "a manifestation of the very lowest Burlington." The Fern Glen is at present treated by U. S. Geol. Survey as basal fm. of Osage group of Mo. and Ill.

Named for exposures at Burlington, Des Moines Co., Iowa.

†Burlington limestone. (In Chemung formation.)

Upper Devonian: Central northern Pennsylvania (Bradford County).

A. Sherwood, 1878 (2d Pa. Geol. Surv. Rept. G, p. 37). *Burlington ls.*, the thickest stratum of ls. I have ever seen in the Chemung group; 40 ft. is exposed, and this does not seem to be all of it. It is nearly a solid mass of sea shells. Occurs about 1 mi. E. of Burlington [Bradford Co.] on farms of W. B. Kline, J. Morley, and C. E. Campbell, and at other places.

Name preoccupied and replaced by Franklindale ls. lentil of Chemung fm. by H. S. Williams and E. M. Kindle in 1905 (U. S. G. S. Bull. 244).

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 571–592). Franklindale ls. of Williams and Kindle is older than "Burlington ls." of Sherwood, and is lithologically different. Writer therefore replaces "Burlington ls." of Sherwood with *Luthers Mills coquinite.*

†Burlington limestone.

Pennsylvanian: Eastern Kansas.

E. Haworth and M. Z. Kirk, 1894 (Kans. Univ. Quart., vol. 2, pp. 110, 120–121, 125). Hard, compact lss. separated into two parts by 8 to 10 ft. of sh. Here called *Burlington or Garnett ls.*, ultimate choice of name being left to future. Overlies Le Roy shales. Separated from overlying Strawn ls. by 75 to 100 ft. of sh.

Same as Oread ls., according to R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22).

Named for Burlington, Coffey Co.

Burls Creek shale member.

Oligocene: Southeastern Alaska (Controller Bay region).

N. L. Taliaferro, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 3, pp. 772–775, 779). *Burls Creek sh. memb.*—Upper memb. of Katalla fm. as here restricted. Conformably overlies Split Creek sh. and ss. memb. Best exposed on Burls Creek. Consists of 3 conformable divisions (descending): (1) 1,700 ft. of dark bluish-gray to almost black platy sh. containing numerous round concretions and lenses of dense blue-gray ls.; (2) 300 to 500 ft. of glauconitic ss. (the organic sh. horizon, which is made up of highly organic shales, often containing numerous grains of glauconite and several thick glauconitic sss.; (3) 700 ft. of dark platy sh., sometimes organic, with occasional thin layers of hard, tightly cemented, fine-grained sss., the sh. containing some ls. concretions. Correlated with fossiliferous beds in Yakataga dist. that are assigned to upper Olig. by B. L. Clark. This memb. is also exposed in Nichawak dist.

The U. S. Geol. Survey classifies typical Katalla fm. as Mio.(?).

Burnet marble.

Cambrian and Ordovician: Central Texas.

B. F. Shumard, 1861 (Am. Jour. Sci., 2d, vol. 32, p. 214). *Burnet marble.*—Upper 90 ft. alternating, nearly pure, brittle ls. and dol.; lower 55 ft. thick beds of very hard brittle ls. May represent Birdseye ls. of N. Y. Underlies Carbf. ls. and overlies Calciferous sand group.

See later description under *Hoover div.*

Named for exposures at Burnet and neighboring parts of Burnet Co.

†Burnetan system.

Pre-Cambrian (Llano series): Central Texas.

T. B. Comstock and E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. lv, 255–267). *Burnetan system.*—Largely gneisses. At base gneisses, granites, and allied rocks (Lone Grove series), overlain by basic hornblende and pyroxene rocks (Long Mtn series), and at top acidic mica and chloritic schists (Bodeville series). Underlies Fernandan system.

Includes parts of Packsaddle schist and Valley Spring gneiss of present nomenclature.

Named for Burnet Co.

Burnett formation. (In Puget group.)

Eocene: Western Washington (Puget Sound region).

B. Willis and G. O. Smith, 1899 (U. S. G. S. Tacoma folio, No. 54). *Burnett fm.*—Top fm. of Puget group. Consists of sss. and shales, generally barren of workable coal seams, but containing 5 beds of inferior coal near top of section at Pittsburg. Thickness 8,270 ft.; 4,770 ft. exposed on South Prairie Creek above Burnett, Tacoma quad. Overlies Wilkeson fm. [In text *South Prairie fm.* is used interchangeably with *Burnett fm.* This is *Pittsburg fm.* of Willis's 1898 rept.; latter name is preoccupied, which probably is reason *Burnett fm.* was introduced.]

Burning Springs sand.

A subsurface sand in Allegheny fm. (Penn.) of W. Va. that is believed to correspond to Butler ss. memb. Named for Burning Springs, Wirt Co., W. Va.

Burns latite (also **Burns latite tuff**).

Tertiary (Miocene): Southwestern Colorado.

W. Cross and E. Howe, 1905 (U. S. G. S. Silverton folio, No. 120). *Burns latite complex.*—Succession of flows, tuffs, breccias, and dikes of dark hornblendic quartz-bearing latite of andesitic habit. Thickness 1,200 ft. Is uncon. overlain by great thickness of pyroxene andesite, and uncon. overlies Eureka rhyolite. *Included in Silverton volcanic series.* The most widely distributed variety of the hornblendic latites is named *Niagara Gulch latite;* another variety is named Canby latite.

Named for exposures in Burns Gulch, Silverton quad.

Burnside sand.

A subsurface sand, of Upper Dev. (Chemung) age, in W. Va. that has been correlated with Warren Second sand. Named for Burnside well, near Good Hope, Harrison Co., W. Va.

Burnt **Bluff** formation.

Silurian: Michigan (Upper Peninsula).

G. M. Ehlers, 1921 (Geol. Soc. Am. Bull., vol. 32, p. 129). *Burnt Bluff fm.*—Includes Fiborn ls. and upper part of Hendricks series of R. A. Smith's tentative classification, and is thought by writer to be of Niagaran age. Discon. underlies Manistique fm. and overlies Mayville fm. Is without doubt a NE. extension of Byron and Lower Coral beds of Wis.

W. A. VerWiebe, 1928 (Papers Mich. Acad. Sci., Arts, and Lett., vol. 8, pp. 330–331), assigned thickness of 111 ft. to Burnt Bluff fm. on Drummond Island, Chippewa Co. Best exposed in Seaman quarry at W. edge of village of Drummond, Chippewa Co.

R. B. Newcombe, 1933 (Mich. Geol. Surv. Pub. 38, pp. 23, 35–36). Recently G. M. Ehlers (unpublished ms.) has included the *Hendricks* and *Byron* as individual members of *Burnt Bluff fm.* Type section of the Burnt Bluff is at Burnt Bluff on Big Bay de Noc, and top is clearly marked by a massive, coarsely crystalline light-brown dol. of Manistique fm. containing molds of *Pentamerus*. This section is 248 ft. thick, and includes *Byron memb.* (below) with 117 ft. of thin-bedded and laminated light-gray dolomitic lss., and *Hendricks memb.* (above), with 121 ft. of strata containing a greater number of dol. beds. Thick beds of brown dol. are prominent in upper part, but in lower part there is more lithologic similarity to Byron memb. Btw. SE. Schoolcraft Co. and southern Chippewa Co. most of Hendricks strata are comparatively pure lss. R. A. Smith named these pure ls. beds in upper part of the Hendricks the *Fiborn ls.* These beds are buff to grayish buff, dense grained to lithographic ls. containing small disseminated crystals of calcite. Smith observed possible lenticular nature of the Fiborn and stated "further field work and faunistic studies may show that Fiborn ls. should be included in Hendricks series." Savage and Crooks (Am. Jour. Sci., 4th, vol. 45, p. 62, 1918) also favored this explanation, and detailed work of Ehlers has added further supporting evidence.

Named for exposures in high cliff called Burnt Bluff, on E. shore of Big Bay de Noc, Delta Co.

See also under *Byron beds*.

Burnt Branch bed. (In Strawn formation.)

Pennsylvanian: Central Texas (Colorado River region).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 374, 375). *Burnt Branch bed.*—Flaggy sss., 125 ft. thick, including 25 or more ft. of clay at base. Memb. of Strawn div., near base. Overlies Lynch Creek bed, where present, and underlies Elliott Creek bed.

Named for Burnt Branch, in Lampasas Co. or vicinity.

Burnt Fork white layer.

Name applied by W. D. Matthew and W. Granger (Am. Mus. Nat. Hist. Mem., vol. 9, 1909, p. 295) to a bed of flinty lime lying at about middle of their horizon C of Bridger fm. in Bridger Basin. (See under *Lone Tree white layer* for their subdivisions of Bridger fm.)

Burnt Meadow syenite.

Post-Carboniferous: Maine.

F. W. Toppan, 1932 (Geol. of Maine, Dept. Geol. Union Coll., Schenectady, p. 26).

Burnt River schist.

Pre-Carboniferous (?): Northeastern Oregon (Baker quadrangle).

J. Gilluly, 1937 (U. S. G. S. Bull. 879). *Burnt River schist.*—Various greenstone schists, quartz schist, conglomeratic schist, and some interbedded ls., sl., and qtzite. Thickness, 5,000+ ft. Tentatively assigned to pre-Carbf. (?). May possibly be Triassic or younger, but believed to be older than Clover Creek greenstone (Perm.) and older than Elkhorn Ridge argillite (Penn.?). Named for exposures in canyon of Burnt River, Twps 11 and 12 S., R. 41 E.

Burntside granite gneiss.

Pre-Cambrian (Huronian): Northeastern Minnesota (Vermilion district).

F. F. Grout, 1926 (Minn. Geol. Surv. Bull. 21, p. 29). *Burntside granite gneiss.*—The older and more gneissic intrusive of Burntside Lake. Is intruded by Vermilion granite. Both assigned to Algonkian.

Burpee formation.

Eocene: Northwestern Oregon (Lincoln County).

H. G. Schenck, 1927 (Calif. Univ. Pub. Dept. Geol. Sci. Bull., vol. 16, No. 12, pp. 455, 456). *Burpee fm.*—Massive blue feldspathic ss. and interbedded micaceous clay sh. [Thickness not mentioned.] Underlies Moody sh. memb. of Toledo fm., of lower Olig. age. May later prove to be = whole or part of Tyee. Only fossils found are leaves of indeterminate genera. Assigned to Eocene because of field relations. Type loc. is the rock quarry on Southern Pacific Railroad at Burpee

Station, on E. bank of Yaquina River, Lincoln Co., midway btw. Toledo and Elk City. Is oldest Tert. fm. in Yaquina dist.

H. G. Schenck, 1928 (Calif. Univ. Pub. Dept. Geol. Sci. Bull., vol. 18, pp. 22–31). *Burpee fm.* is upper Eocene and 3,000± ft. thick. Uncon. underlies Toledo fm.

Burr limestone member.

Pennsylvanian: Southeastern Nebraska, Kansas, and northern Oklahoma.

G. E. Condra and C. E. Busby, 1933 (Nebr. Geol. Surv. Paper No. 1). *Burr ls. memb. of Grenola fm.*—The newly established Grenola fm. is divided into following members (descending): Neva ls., Salem Point sh., Burr ls., Legion sh., and Sallyards ls. The salient lithologic feature of Burr memb. is its lamination. It is calc. throughout and has a carbonaceous sh. in the middle to N. Is of nearshore marine origin. Averages about 11 ft. in thickness from Roca, Nebr., to Burbank, Okla., disregarding the abnormal Pawnee Co., Nebr., section. The upper Burr in Nebr. is light gray, with an extremely dense, carbonaceous lime cap that covers an ostracodal zone. The middle Burr in Nebr. and northern Kans. is black or brownish sh. containing abundant plant remains. The lower Burr in Nebr. consists of 1, 2, or 3 lss. separated by sh., and farther S. it is irregular, shaly, and nodular with dark-gray mottling, and weathers platy or shattered. Type loc., the bluffs and ravines W. of South Fork of Little Nemaha River, in sec. 20, at point ¼ mi. W. of N.–S. road, 2½ mi. NW. of Burr, Otoe Co., Nebr.

G. E. Condra, 1935. (See under *Roca sh.*)

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), transferred this unit to Perm. This change in Perm.-Penn. bdy has not been considered by U. S. Geol. Survey for its publications.

Burrard formation.

Eocene: British Columbia.

W. A. Johnston, 1923 (Canada Geol. Surv. Mem. 135, p. 13).

Burro gravel and tuff.

Tertiary (?): Western Texas.

J. A. Udden, 1907 (Univ. Tex. Bull. 93, pp. 17, 67). *Burro gravels and tuffs.*—Regularly bedded gravels, breccias, sss., and yellow and red tuffs, with a well-worn cgl. at one locality. Directly underlie lava flows that cap Burro Mesa, and some of deposits apparently are interbedded with the lava. Uncon. overlie Crown cgl. Tentatively assigned to Tert.

Named for Burro Mesa, Brewster Co.

Burro quartzite.

Cambrian (?): Southwestern New Mexico (Silver City region).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257–259; Conspectus of geol. fms. of N. Mex., pp. 4, 5). *Burro qtzites.*—Main body of Mid Cambric qtzites which immediately *overlie* Chloridian series of lss. near Silver City. Thickness 500 ft. [On p. 4 it is shown as *underlying* his Chloridian series. Derivation of name not given. The Middle Camb. is absent in N. Mex., according to E. Kirk and others.]

Burroak shale.

Pennsylvanian: Southwestern Iowa, eastern Kansas, southeastern Nebraska, and northwestern Missouri.

G. E. Condra and E. C. Reed, June 1937 (Nebr. Geol. Surv. Bull. 11, 2d ser. pp. 8, 14, 53–54, figs. 1, 2). *Burroak sh.* is a new name herein suggested to replace "Mission Creek sh." of previous publications. Type loc. is in the road cuts and ravines near Burr Oak School, E. ½ sec. 21, T. 71 N., R. 43 W., Fremont Co., Iowa, about 6 mi. S. of Pacific Junction, Iowa, and about 3½ mi. N. of Bartlett, Mills Co., Iowa. "Mission Creek" should be abandoned because the exposures on Mission Creek in NE. Doniphan Co., Kans., correlate with Larsh sh. of northern outcrops. In naming *"Mission Cr. sh."* in 1927, Condra miscorrelated the Rock Bluff and Ozawkie of Iowa Point section with the Haynes and Rock Bluff, respectively, of Weeping Water Valley and Jones Point sections of Nebr. The Burroak sh. is very thin or absent near Big Springs, Kans., SE. of Iowa Point, Nebr., and at Forbes, Mo. It is

1 to 2 ft. thick N. of Thurman, Iowa, and at Jones Point and near Weeping Water, Nebr. It is thin or absent at Macedonia and NE. of Greenfield, Iowa. It consists of bluish gray, argill., fossiliferous sh., often containing a persistent carbonaceous streak near its top.

Burroughs dolomite.

Silurian (early): Western Wisconsin and northwestern Illinois.

F. T. Thwaites, 1923 (Jour. Geol., vol. 31, No. 7, p. 533). In NW. Ill. Ulrich has found a pre-Clinton dol. (*Burroughs dol.*) beneath the Niagaran. Its extent and character are but slightly known.

E. O. Ulrich, 1924 (Wis. Acad. Sci., Arts, and Lett., vol. 21, pp. 71–82). Near top of Burrough's Bluff, at N. end of Savannah, Ill. [Carroll Co., NW. Ill.], and also in and above Charles Miles' quarry near SE. edge of same city, the easily recognized Brainard sh., at top of Maquoketa facies of Richmond group is succeeded uncon. by a variable succession of bluish to grayish yellow irregularly bedded mag. mudstones and brownish dol. aggregating some 50 to 60 ft. in thickness. On weathering, upper half or more of these beds shows more or less of earthy chert in nodules and uneven plates. The bluish gray lower third contains few fossils. The cherty upper beds contain a more varied though not abundant fauna [listed], which is decidedly post-Richmond, is clearly older than Clinton, and evidently falls into some part of intermediate Upper Medina stage in which Edgewood fm. of Mo. is probably a nearer contemporary than the Cataract of Ontario. Lithologically very different from the Edgewood and some doubt as to their strict equivalence, hence *Burroughs* is proposed. The same beds are indicated, though mainly by debris, in the mounds in SW. Wis., where they have been classed with Niagaran dol.

A. C. Trowbridge et al., 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 48), differentiated 35 ft. of Kankakee dol. and 10 to 15 ft. of Edgewood dol. at Savanna, Ill. (type loc. of Burroughs dol.), and stated that because Burroughs dol. of Ulrich "is equiv. to the Edgewood and Kankakee this name should be abandoned."

Burton sandstone. (In Greene formation.)

Permian: Northern West Virginia.

R. V. Hennen, 1909 (W. Va. Geol. Surv. Rept. Marshall, Wetzel, and Tyler Counties, p. 182). *Burton ss.*—Light gray, generally massive, but changes into sandy beds in Marshall Co. and not recognized in Tyler Co. Thickness 20 to 40 ft. Lies 25 to 35 ft. below Nineveh ls. and above Hostetter coal. Named for Burton, Wetzel Co.

Burton formation.

Middle Cambrian: British Columbia.

S. J. Schofield, 1914 (Canada Geol. Surv. Mus. Bull. No. 2, p. 82).

Busby quartzite.

Middle Cambrian: Western Utah (Gold Hill district).

T. B. Nolan, 1930 (Wash. Acad. Sci. Jour., vol. 20, No. 17, Oct. 19, pp. 421–432). *Busby qtzite.*—Basal 50 to 75 ft. is coarse-grained qtzite, containing in places tiny rock fragments in addition to quartz. Thin beds of dark qtzite and green sandy sh. in varying proportions compose remainder of fms., the shales becoming increasingly abundant upward. Mud cracks and fucoid markings present in many of beds. Thickness 450± ft. Top arbitrarily placed at base of lowest ls. bed, although qtzites and shales similar to those in the Busby are present above this line. No fossils, but gradational contact with overlying Abercrombie fm., which contains Middle Camb. fossils, indicates Middle Camb. age of Busby. Grades into underlying Cabin sh. Named for exposures in Busby Canyon, on NE. slope of Dutch Mtn, Gold Hill dist.

See also U. S. G. S. P. P. 177, 1934.

Bushberg sandstone member (of Sulphur Springs formation).

Mississippian: Central eastern Missouri.

E. O. Ulrich, 1904 (Mo. Bur. Geol. and Mines vol. 2, 2d ser., p. 110). *Bushberg ss.*, 10 ft. thick, forms top memb. of Sulphur Springs fm. Overlies Glen Park ls. memb. of the Sulphur Springs.

See also under *Sulphur Springs fm.* R. C. Moore, 1928 (Mo. Bur. Geol. and Mines vol. 21, 2d ser., opp. p. 282), showed *Bushberg ss.* as=lower part of Hannibal sh., and as uncon. overlain by Fern Glen fm.

Named for exposures at Bushberg, Jefferson Co.

Bushveld complex.

See under *Stillwater complex.*

Busseron sandstone member.

Pennsylvanian: Southern Indiana.

E. R. Cumings, 1922 (Hdb. Ind. Geol., pt. 4, Sep. Pub. 21, chart and pp. 524, 529). *Busseron ss.*—Ss. and sandy sh., forming basal memb. of Shelburn fm. Rests discon. on coal No. 7 (topmost bed of Petersburg fm. as redefined by Cumings). Is probably=Anvil Rock ss. of Ky., and is of post-Allegheny age.

Probably named for village of Busseron, Knox Co.

Butano sandstone.

Oligocene? (may be Eocene): Southern California (Santa Cruz Mountains).

J. C. Branner, J. F. Newsom, and R. Arnold, 1909 (U. S. G. S. Santa Cruz folio, No. 163). *Butano ss.*—Massive brown and buff sss. with cgl. at base. Thickness about 2,100 ft. No fossils found. Conformably underlies San Lorenzo fm., and believed to uncon. overlie Eocene ls., but sequence is concealed.

Named for exposures on Butano Ridge, San Mateo Co.

Butler sandstone member (of Allegheny formation).

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q, pp. 40–71, 130). *Butler (Upper Freeport) ss.*—Massive ss. Lies 35 ft. below Upper Freeport ls. and overlies Lower Freeport coal. Thickness 30 ft. Type loc. is in town of Butler, Butler Co., Pa., just below Mr. Muntz's, opposite the mills of Woldo & Bros., where it has been quarried.

†Butler limestone. (In Allegheny formation.)

Pennsylvanian: Western Pennsylvania.

See under *Lower Freeport ls. memb.*, the established name.

Butler sands.

Drillers' terms; western Pa.; strat. order as follows (descending): Butler first sand, Butler gas sand (=Murrysville and =Butler Thirty-foot sand), Butler Second sand, Butler Third Stray sand, Butler Third sand (=Gordon sand), Butler Fourth Stray sand, Butler Fourth sand, Butler Fifth sand. Probably named for Butler Co.

Butler amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan (Ontonagon County).

Name locally in use many years. Used by B. S. Butler (in U. S. G. S. P. P. 144, 1929), who states (personal communication) that the rock was probably named for a Captain Butler, the probable discoverer of the lode. Belongs in lower part of Central Mine group. The mineralized part is the Butler lode.

Butler flow.

Includes Butler amygdaloid and the underlying trap.

Butler clay member (of Rockdale formation).

Eocene (lower): Central and southern Texas between Brazos and Frio Rivers.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 587, etc.). *Butler clay.*—Basal memb. of Rockdale fm. in central and southern Tex. Consists of (a) gray and buff, lenticular, fine-grained, thin-bedded sand containing indurated and laminated rough-surfaced concretions; (b) micaceous clays, in most places rather free of sand, tough and massive, in other places silty and laminated and characterized by limonitic partings; (c) seams and lentils of lignite. Thickness 400 ft. Underlies Simsboro sand memb. of Rockdale fm. and overlies Seguin fm. Typically exposed at town of Butler, Freestone Co.

Butlerville quartzites.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, p. 38). Qtzites, 1,000 ft. thick, composing lower fm. of Panamintan series (Early Cambric) in Utah. [Derivation of name not stated.]

Buttahatchie gravel.

Quaternary (?): Alabama.

R. T. Hill, 1888 (Ark. Geol. Surv. Ann. Rept. for 1888, vol. 2, p. 189). [Mentions deeply ferruginous sands, clays and gravel, of early Quat. age, in SW. Ark., which are "allied by position to older Llano Estacado fm. and *Buttahatchie gravel* of Ala., but no lithologic resemblance to either." All the description there is, and only known use of the name.]

Butte quartz monzonite.

Tertiary? (Eocene?): Central western Montana (Butte region).

W. H. Weed, 1899 (Jour. Geol., vol. 7, pp. 740–750). *Butte granite or quartz monzonite* covers area of several sq. mi. and is prevailing rock of Butte dist., and the one that contains the world-famous copper and silver veins of that place. It is a rather dark colored, coarsely granular rock.

Butte gravels.

Eocene (middle): Northern California (Sutter County).

Howel Williams, 1929 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 18, pp. 112–129). *Butte gravels.*—Coarse gravels, composed of rounded, chiefly very siliceous pebbles, with sandy intercalations and thin beds of massive ss. and siliceous ls. Thickness 450 to 1,200 ft. Overlie White Ione sands, usually with minor discon., but occasionally with erosion uncon. Are overlain by Sutter fm., in some places with sharp contact, in other places almost insensible gradation. Fossils 700 ft. above Ione sands are assigned by B. L. Clark to Meganos (middle Eocene) age. Present at Marysville Buttes.

Butterfield limestone member (of Bingham quartzite).

Pennsylvanian: Central northern Utah (Bingham district).

A. Keith, 1905 (U. S. G. S. P. P. 38, p. 37, map, sections). *Butterfield ls. memb. of Bingham qtzite.*—Chiefly blue and dark-blue lss., usually pure carbonate of lime, but many siliceous layers are present, and occasionally beds of sandy ls. occur, also small chert nodules and round balls; the chert is black, alternating, in the larger nodules, with concentric, dark-gray bands. Thickness 300 ft. Lies much lower than Jordan ls. memb. [Map shows it exposed in Butterfield Canyon, SE. corner of sheet.]

Butting Ram sandstone member (of Talladega slate).

Pre-Devonian, probably Paleozoic: Eastern Alabama.

C. Butts, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14, map, pp. 54, 58). *Butting Ram ss. memb. of Talladega slate.*—Coarse cgl. at bottom, overlain, to W., by thick-bedded qtzite or quartzose ss., and to E. by beds of ss. intercalated with cleaved sl. or phyllite of the usual Talladega character. Thickness probably 1,000 ft. Lies about 7,500 ft. higher stratigraphically than Jumbo dol. memb., and either directly or at no great distance below Jemison chert. Believed to be same as Cheaha ss. memb. Is pre-Dev. and probably Paleozoic.

Named for fact it is believed to form Butting Ram shoals on Coosa River, on border btw. Chilton and Coosa Counties, about 10 mi. NE. of Clanton. Is well exposed on headwaters of Mahan Creek, 4 mi. W.-SW. of Jemison, and has been closely traced from 2± mi. E.-NE. of Jemison, to Coosa River in vicinity of Butting Ram shoals.

Buttle Lake group.

Permian: British Columbia.

H. C. Gunning, 1931 (Canada Geol. Surv. Summ. Rept. 1930, pt. A, p. 59).

button beds.

Miocene: Southern California (Kern County).

F. M. Anderson, 1905 (Calif. Acad. Sci. Proc., 3d ser., vol. 2, p. 170). *Button beds.*—The first sandy beds below Monterey sh. at Temblor. Included in Temblor beds. Thickness 100 ft. Named for great numbers of small discoidal sea urchins (*Astrodapsis*) that characterize them. [See also under *Temblor fm.*]

Buttram sand.

A subsurface sand in Strawn fm. (Penn.) of Buttram and Bryson oil fields, Jack Co., Tex.

Buttsgin formation.

Eocene: Southern Texas (Medina County).

R. A. Liddle, 1921 (Univ. Tex. Bull. 1860, p. 82, map, and columnar section). *Buttsgin fm.*—Yellow, brown, and brown-red aren. shales and clays interbedded with large calc. ss. lenses and hard aren. ls. lenses. Basal part contains more calc. matter, is harder, and forms a range of hills. Upper part weathers to a more sandy soil. Thickness 500± ft. Lower fm. of Wilcox group in Medina Co. Underlies Seco fm. and overlaps Squirrel Creek fm. Typically exposed at Butts Gin, approx. 6 mi. NW. from Yancey, Medina Co., in bed and tributaries of branches of Seco Creek.

Bu-Vi-Bar bed.

Permian: Central northern Oklahoma.

See under *Evansville ss. bed.*

†Buxton formation.

Pennsylvanian: Southeastern Kansas.

F. C. Schrader and E. Haworth, 1905 (U. S. G. S. Bull. 260, p. 447). *Buxton fm.*—Shales, with beds of ss. and coal and lenses of ls.; 320 ft. thick. Underlies Painterhood [Oread] ls. and overlies Piqua [Stanton] ls.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 139). †Buxton fm. includes beds from top of †Piqua (Stanton) ls. to base of †Painterhood (Oread) ls.

Named for Buxton, Wilson Co.

Byer member.

Mississippian: Central and southern Ohio.

J. E. Hyde, 1912 (History of Fairfield County, p. 211) and 1915 (Jour. Geol., vol. 23, pp. 656, 657, 659, 678, 764–765, 771–775). *Byer memb.*—Fine-grained, rather soft, yellow ss., 40 to 150+ ft. thick, forming basal memb. of Logan fm. [as here used includes upper part of Black Hand fm.]. Underlain by Berne memb. of Cuyahoga fm. [expanded Cuyahoga] and overlain by Allensville memb. of Logan fm. [expanded Logan]. Extends from Fairfield Co. to Ohio River.

Named for Byer, Jackson Co.

Byham limestone member.

Mississippian: Northwestern Pennsylvania.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61, p. 134). At base of Harvest Home sh. memb (lower Meadville sh. of early repts) in several ravines S. of Meadville, especially in Buchanan's Ravine, N. of Shaws School (Buchanan Station) and about 1½ mi. W.-NW. of Byham School, there is a ls. similar to West Mead ls. (lower Meadville ls. of early repts). It is proposed that this "middle Meadville ls." be called *Byham ls.* Resembles West Mead ls. lithologically and faunally, both being characterized by iron-ball concretions, fish bones, and a Syringothyrid fauna interspersed with inarticulate brachiopods. In area around Byham School it is 3 to 12 ft. thick and much used in past for lime.

Byram marl. (In Vicksburg group.)

Oligocene (middle): Mississippi, Louisiana, southwestern Alabama, and northwestern Florida.

T. L. Casey, 1902 (Phila. Acad. Nat. Sci. Proc., vol. 53, pp. 517–518). Mr. D. W. Langdon enumerates (Am. Jour. Sci., XXXI, p. 205) the fossils collected by him at Byram Station, on Pearl River. They are all Vicksburgian with exception of *Capulus americanus*, which is Jacksonian. As this species has never been found at Vicksburg, the presumption is that the *Byram beds* are older than true Vicksburgian, and this is further borne out by the fact, which I have noted from personal observation, that the Byram deposit contains, besides the species quoted by Mr. Langdon, a considerable number peculiar to it and apparently occurring nowhere else. The evidence adduced by Mr. Langdon would seem to show that there is a notable thickness of marine, though scarcely fossiliferous, deposits btw. the true Jackson and Byram, and it is probable that during this interval the Red Bluff beds were formed. The order of emergence of the various deposits—which were all more or less local—may therefore be stated to be: (1) Jackson stage, (2) Red Bluff substage, (3) *Byram substage*, and (4) Vicksburg stage. [The strat. position of Byram as here given is now known to be incorrect. See below.]

C. W. Cooke, 1918 (Wash. Acad. Sci. Jour., vol. 8, No. 7, pp. 186–198). *Byram calc. marl.*—Largely sandy marl, but contains thin beds of impure ls., clay, and sand. Thickness 13 to 70 ft. Top fm. of Vicksburg group. Conformably overlies Marianna ls. (of Vicksburg group), and underlies Catahoula ss. Is same as upper Vicksburgian of Casey [at Vicksburg].

The present approved definition is that of C. W. Cooke, but the fm. is now called *Byram marl.* Beds formerly included in upper part of Marianna ls. have since been separated as a distinct fm. (Glendon ls.), so that the fm. upon which Byram marl rests is Glendon ls., instead of Marianna ls. The Red Bluff clay has now been determined to correspond in time to lower part of Marianna ls. The Byram as defined by Cooke included in upper part the beds in Miss. that were later named (by Blanpied) Chickasawhay marl [memb.], and Bucatunna clay [memb.], and they are still included in the Byram by U. S. Geol. Survey.

Named for exposures in bank of Pearl River at Byram, Hinds Co., Miss.

Byram granite gneiss.

Pre-Cambrian: Northern New Jersey and eastern Pennsylvania.

A. C. Spencer, 1908 (U. S. G. S. Franklin Furnace folio, No. 161). The rocks here grouped as *Byram gneiss* include several varieties of granitoid gneiss which are lithologically related by presence of potash-bearing feldspars among their principal mineral components. Composed essentially of quartz, and microcline or microperthite (potash feldspars), with variable proportions of hornblende, pyroxene, and mica. Oligoclase (soda-lime feldspar) usually very subordinate in amount, but here and there it equals the potash feldspar. Accessory minerals are magnetite, zircon, apatite, and titanite. There are several facies of the rock which vary greatly in appearance in the field, but almost without exception show greater resemblance to each other than to varieties of other gneisses with which they are associated. In a broad way the Byram gneiss can be separated into light and dark facies. General tone of dark facies is ordinarily gray in outcrop, but on fresh surfaces brownish accompanied by bronzy effect. A common dark variety contains considerable hornblende in crystals grouped in form of pencils arranged parallel to a common axis. The light varieties are yellowish in outcrop, and pink, light gray, or whitish on fresh surfaces. Usually they are somewhat finer grained and less foliated than the dark facies and carry mica rather than hornblende or pyroxene. The Byram gneiss includes "Hamburg" [Mountain] gneiss, "Sand Pond," and "Edison" gneisses of Wolff, the "Oxford type" of Nason, and gneissoid granite of Breakneck Mtn., on the Hudson. Appears to cut Pochuck gneiss and Franklin ls. Relations to Losee gneiss not known.

The Byram gneiss (predominantly granite gneiss) is now considered as probably younger than Losee gneiss (predominantly diorite). It is classified by E. B. Knopf and A. I. Jonas (U. S. G. S. Bull. 799, correlation chart, 1929) as post-Glenarm. Intrudes Franklin ls. and Pickering gneiss.

Named for Byram Twp, Sussex Co., where good exposures occur in hills NE. of Roseville.

Byron beds.

Silurian: Southeastern Wisconsin.

T. C. Chamberlin, 1877 (Geol. Wis., vol. 2, pp. 345–348). *Byron beds.*—Fine-textured white ls., 110 to 140 ft. thick. Rests on Mayville ls. and underlies Lower Coral beds. Fossils rare. Named for Byron Twp, where it is extensively used for lime, building stone, and flagging. Is =lower part of Waukesha beds. [The equivalency of Byron to basal part of Waukesha was published in many subsequent Wis. repts, by different authors.]

E. O. Ulrich, 1924 (Wis. Acad. Sci. Trans., vol. 21, pp. 71–93). Waukesha dol. of eastern Wis. (250 to 300 ft. thick) is younger than Byron dol. (100 ft. thick). [This was a restriction of Waukesha dol.]

R. B. Newcombe (1933) carried this name into Upper Peninsula of Mich. See 1933 entry under *Burnt Bluff fm.*

A. H. Sutton 1935 (Rept. 9th Ann. Field Conf. K.ns. Geol. Soc., p. 278). *Byron* is pre-Niagaran and correlates with Kankakee of Ill.

Caballos novaculite.

Devonian ? (Oriskany?): Southwestern Texas (Brewster County).

J. A. Udden, C. L. Baker, and E. Böse, 1916 (Univ. Tex. Bur. Econ. Geol. and Tech. Bull. 44, p. 39). *Caballos novaculite.*—Upper part massive bedded, ripple-marked, and much fractured white novaculite, 50 ft. thick; lower part 40 ft. of rather thin-bedded light-brown chert with some layers of white novaculite. Occurs in Marathon region. Named by Baker. E. O. Ulrich regards it as of Oriskany age. Uncon. underlies Santiago chert and uncon. overlies Maravillas chert.

C. L. Baker and W. F. Bowman, 1917 (Univ. Tex. Bull. 1753, p. 93). *Caballos novaculite* redefined to include what were originally called Caballos novaculite and Santiago chert. Later work by senior author appears to indicate that they are really one fm., two members of both the original Caballos and Santiago being included in the section in some localities. It is now thought that in the localities first examined erosion has removed the upper novaculite and upper predominantly green chert. But there is possibility of duplication of beds by shearing or thrusting. Should this finally prove to be the case in the region where the section exhibits two members, both of the white novaculite and the banded, vari-colored chert in the same succession, the name Santiago may be reapplied to the latter. Type loc. of Caballos novaculite is Caballos Mtn, the entire N. face of which is made up of white Caballos novaculite.

P. B. King, 1931 (A. A. P. G. Bull., vol. 15, No. 9, p. 1078). The type Caballos of 1916 publication comprised lower chert memb., lower novaculite memb., middle chert memb., and upper novaculite memb. The type "Santiago" of 1916 publication consisted of middle and upper chert members combined, with upper novaculite memb. nearly absent btw. them. Because of overlapping of typical section, and strat. unity of whole series, writer supports Baker and Bowman's decision to abandon "Santiago."

Named for exposures on Horse (Caballos) Mtn, Brewster Co.

Cabano conglomerate.

Ordovician (?): Quebec.

H. W. McGerrigle, 1934 (Quebec Bur. Mines Ann. Rept. 1933, pt. D, p. 115).

Cabano River limestone.

Silurian (Niagaran): Quebec.

H. W. McGerrigle, 1934 (Quebec Bur. Mines Ann. Rept. 1933, pt. D, p. 116). Included in Temiscouata group.

Cabezon fanglomerate.

Quaternary: Southern California (San Bernardino Mountains).

F. E. Vaughan, 1922 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 13, No. 9, pp. 344, 387–392, and map). *Cabezon fangl.*—A fangl. deposited in Bear and Holcomb

Valleys. Differs from older Coachella fangl. in being more uniform and massive, of yellowish color, and in lying nearly horizontal. The largest area in Bear Valley is broad flat btw. Rathbone Creek and Erwin Lake, where material is almost wholly unsorted angular and subangular qtzite brought down from Sugarloaf Mtn to SE. Holcomb Valley is nearly surrounded by flat ridges of fangl. Those on S. and E. sides are particularly conspicuous and consist of ls., granite, and qtzite from surrounding hills. The fangl. in Bear and Holcomb Valleys is only local representative of a widespread deposition during third cycle of erosion. The Cabezon fangl. is older than Heights fangl. and younger than Coachella fangl.

Named for Cabezon Station, Riverside Co.

Cabin shale.

Lower Cambrian: Western Utah (Gold Hill district).

T. B. Nolan, 1930 (Wash. Acad. Sci. Jour., vol. 20, No. 17, Oct. 19, pp. 421–432). *Cabin sh.*—Dominantly dark green or khaki-colored sh., locally calc. Sandy laminae abundant near top. Thickness 510 ft. Grades rather abruptly into overlying Busby qtzite. Is Lower Camb. Overlies Prospect Mtn qtzite. Named for exposures in Cabin Gulch, S. of North Pass Canyon, Gold Hill quad.

See also U. S. G. S. P. P. 177, 1934.

Cabin Creek sandstone.

Name applied by C. Croneis (Ark. Geol. Surv. Bull. 3, pp. 242–244, 1930) to beds lying btw. 55 and 120 ft. depth in Watkins well No. 1 of Peney Oil and Gas Co. (subsidiary of Columbia Carbon Co.) in sec. 4, T. 8 N., R. 22 W. [Clark Co.] in Knoxville anticline, Ark., said to belong to Hartshorne ss.

Cable formation (or lake beds).

Quaternary (?): Southern California (Kern County).

A. C. Lawson, 1906 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 4, pp. 431–462). *Cable fm.* (also *Cable lake beds*).—Fresh-water lake beds, of well-stratified lss., cherts, gravels, clays, and fine light-colored volcanic tuff. Named for town of Cable, Kern Co. Older than Tehachapi fm. and younger than Tank volcanics.

Cabo Rojo stage.

Quaternary: Puerto Rico.

B. Hubbard, 1923 (N. Y. Acad. Sci., Scientific survey of Porto Rico and Virgin Islands, vol. 2, pt. 1, p. 96).

Cabot Head shale member (of Cataract formation).

Silurian (early): Ontario.

A. W. Grabau, 1913 (Geol. Soc. Am. Bull., vol. 24, pp. 438, 460). *Cabots Head beds.*—Green, calcareo-argill. shales and thin-bedded ls. underlain by 100 to 150 ft. of red shales and some sss. Believed to be westward extension of true Medina sedimentation, which at Niagara is about 125 ft. thick. Rest on Keppel dol. Named for exposures at Cabots Head, on Manitoulin Islands.

C. Schuchert, 1914 (Geol. Soc. Am. Bull., vol. 25, pp. 277–320), recognized his Cataract fm. as divisible in Ontario into (descending) *Cabots Head sh. memb.*, *Manitoulin ls. memb.*, and *Whirlpool ss. memb.*, and restricted *Medina ss.* to beds above Cabots Head sh. and below Wolcott ls. memb. of Clinton fm. [See fuller explanation of Schuchert's subdivisions under *Cataract fm.*] He recognized Cabot Head sh. in Stony Creek, Hamilton, Dundas, Limehouse, Cataract, Collingwood, Owen Sound, Cabots Head, and Manitoulin sections, all in Ont.

M. Y. Williams, 1914 (Canada Geol. Surv. Summ. Rept. for 1913, pp. 179–188), introduced *Grimsby memb.* for 0 to 50 ft. of red and gray ss. with some gray sh. overlying Cabot Head sh. [replaces Williams' preoccupied name *Kagawong*] and underlying Thorold ss. memb. of the Medina.

E. M. Kindle, 1914 (Sci., n. s., vol. 39, pp. 915–918), advocated following names for subdivisions of Grabau's restricted *Medina fm.* (descending): Thorold ss., Grimsby ss., Cabot Head sh., Manitoulin beds, and Whirlpool ss.

M. Y. Williams, 1919 (Canada Geol. Surv. Mem. 111, No. 91 geol. ser.), stated that Schuchert's 1914 classification restricted Medina to Grimsby and Thorold sss., but that Grimsby ss., as well as the overlying Thorold ss., are "only facies of top of Cabot Head sh., although they represent another faunal invasion." He also introduced two new names for dol. beds in *Cabot Head sh. memb. of Medina-Cataract fm.* of Bruce Peninsula and Manitoulin Island (the type loc.), using *St. Edmund dol. lentille* for a bed near top of Cabot Head sh., and *Dyer Bay dol. lentille* for a bed in lower part of upper half of Cabot Head memb.

E. O. Ulrich, 1923 (Md. Geol. Surv. Sil. vol., pp. 334–336), stated that fauna of Dyer Bay dol. is of Niagaran age (middle Clinton), and he restricted *Cataract* to pre-Dyer beds of upper Medinan age, included Grimsby ss. in Medinan, and transferred Thorold ss. to Clinton.

A. F. Foerste, 1924 (Canada Dept. Mines, Geol. Surv. Mem. 138), used Grabau's restricted *Medina* "to include the beds above the Queenston and below the Clinton," and stated that upper part of Cataract fm. in southern Ont. is formed by Thorold ss. memb. and Grimsby ss. memb. and that Whirlpool ss. memb. is base of Cataract fm. from Niagara River to vicinity of Duntroon, about 8 mi. S. of Collingwood, Ont.

Cabotian.

A term applied by N. H. Winchell to lower part of Keweenawan rocks of eastern Minn., extending up to base of a cgl. interpreted by him as corresponding to Puckwunge cgl., and including the †Beaver Bay diabase. (See Minn. Geol. Nat. Hist. Surv. Final Rept, vol. 4, pp. xiv–xx, 215, 295–298, 1899.) Includes lavas, red rock, and gabbro. Named for mtn range that appears at Duluth and eastward and is formed by the gabbro, which Buchette named *Cabotian Range.*

Cabullona group.

Upper Cretaceous: Mexico (Sonora).

N. L. Taliaferro, 1933 (Jour. Geol., vol. 41, No. 1, p. 26).

Cacapon sandstone member (pronounced Că'pŏn). (In Clinton formation.)

Silurian: Northern West Virginia and western Virginia.

N. H. Darton and J. A. Taff, 1896 (U. S. G. S. Piedmont folio, No. 28). *Cacapon ss.*—Red flaggy ss., somewhat resembling the sss. of Juniata fm., but less massive and of brighter red-brown color. Average thickness about 300 ft. Underlies Rockwood fm. and overlies Tuscarora qtzite.

Is a ss. in lower part of Clinton fm.

Named for exposures on slopes of Cacapon Mtn, Winchester quad., Va. and W. Va.

†Cacaquabic granite.

Name used by J. M. Clements (U. S. G. S. Mon. 45, 1903) and some other geologists for granite exposed on shores and islands of Kekekabic Lake, the spelling adopted by U. S. Geog. Bd. Now replaced by *Kekekabic granite.*

Cache formation.

Early Pleistocene or upper Pliocene: Northern California (Lake County).

G. F. Becker, 1888 (U. S. G. S. Mon. 13, p. 219). *Cache Lake beds.*—Freshwater gravels, sand, and calc. beds of Plio. age, 1,000 ft. thick. Occur E. of Clear Lake, about north fork of Cache Creek. The character of the deposits and fact that area occupied by them is continuous with part of Clear Lake led me to infer that Cache Lake might be regarded as representing Clear Lake at a more or less distant period.

C. A. Anderson, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 5, pp. 632–639, 662, map). *Cache fm.*—Fresh-water sediments described by Becker as *Cache Lake beds,* an unfortunate name, because, while some of the rocks are undoubtedly of lacustrine origin, others are probably of fluvial origin. So it seems desirable to refer to these as *Cache fm.* The sediments are interbedded with basalt flows. The topog. during Cache time bore no relationship to present topog., and statements that a

"Cache Lake" was a former extension of Clear Lake are misleading. G. D. Hanna, who has studied the diatoms from both Clear Lake and the diatomites of Cache fm., has remarked (personal communication) that the differences btw. them are sufficient to indicate there was no connection btw. the lakes of Cache time and present Clear Lake. The Clear Lake Basin was formed after the faulting and folding of Cache fm. Best exposed and have max. thickness (at least 1,700 ft.) in area W. of North Fork of Cache Creek. Rest with marked uncon. on Martinez (Lower Eo.). No reliable fossil evidence. Tentatively regarded as Lower Pleist. but may be Upper Plio.

See also under *Clear Lake sediments.*

Cache Creek group. (Also Cache Creek series.)

Carboniferous; British Columbia.

A. R. C. Selwyn, 1872 (Canada Geol. Surv. Rept. 1871–72, pp. 60–61).

Cache Lake beds.

See *Cache fm.*

Cache Valley group.

Pliocene (?): Northeastern Utah and southeastern Idaho (Cache River Valley).

A. C. Peale, 1879 (U. S. G. and G. S. Terr. 11th Ann. Rept., pp. 603–606, 634, 635, 640, 641). *Cache Valley group.*—Soft marls and sands, best exposed in N. side of Cache Valley [NE. Utah and SE. Idaho] and on Bear River below the middle canyon. They are somewhat variegated and horizontal in position. Deposited in lake, which shows a number of levels. Possibly of same age as Malade Valley group and possibly older.

Now considered probably of same age as Salt Lake fm.

Cactus granite.

Probably late Jurassic: Southern California (San Bernardino Mountains).

F. E. Vaughan, 1922 (Calif. Univ. Pub. Dept. Geol. Sci. Bull., vol. 13, No. 9, pp. 344, 364–365, and map). *Cactus granite.*—Medium coarse-grained intrusive granite, pinkish to yellowish gray.

Named for Cactus Flat, San Bernardino Co.

Caddell clay.

Eocene (upper): Eastern Texas.

E. T. Dumble, 1915 (Geol. Soc. Am. Bull., vol. 26, p. 462). *Caddell clays.*—At base greenish clays and sandy clays with some sand and greensand, which are iron-stained. These weather dark brown and carry calc. concretions, which contain more or less sand and greensand, and are geodic in places. These are overlain by grayish-brown sandy clays with seams of sulphur, which are followed by buff sandy clays with plant fragments, and gray-drab clays with gyp. and sulphur. Included in Jackson beds. Separated from overlying Manning beds by clays and sands, and separated from underlying Frio clays by clays and sands that are believed to be the Wellborn. [E. T. Dumble, 1920 (Univ. Tex. Bull. 1869), called the beds underlying his Caddell clay the *Wellborn ss.*] Named for excellent exposures around Caddell, San Augustine Co. [NE. Tex.].

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 685–686). *Caddell memb. of Fayette fm.* was named by Dumble. It comprises 30 to 45 ft. of basal strata of the Fayette of NE. Tex., which consists of chocolate-colored and greenish clays that weather to brownish and purplish hues and contain dark-brown, calc., fossiliferous ss. concretions, large amount of selenite crystals, and minor amounts of glauconite. Some of clay near top contains layers of fine sand 1 inch or less in thickness. Rests on Yegua fm. and is overlain by Wellborn ss. of Kennedy. Miss Ellisor (ms.) during recent detailed subsurface studies has been able to recognize this memb. in well sections throughout Gulf Coast dist. Lower part of Caddell memb. of Dumble is characterized by *Textularia dibollensis.* Dividing line btw. Caddell and overlying McElroy memb. is drawn at base of Wellborn ss.

A. C. Ellisor, 1933 (A. A. P. G. Bull., vol. 17, No. 11). *Caddell fm.*, of Jackson group, is divided into upper chocolate phase and lower marl phase. It is overlain by McElroy fm. (which is divided into (descending) 3 mappable units, namely, Manning beds, Wellborn sands, and Wooley's Bluff clays), and rests conformably on the Cockfield [Yegua] fm. Thickness 150 to 300 ft. [Fossils listed.]

B. C. Renick, 1936 (Univ. Tex. Bull. 3619, table opp. p. 17 and pp. 17–23). *Caddell fm.* (*Moodys marl*) of Walker Co. to Gonzales Co. region is 100 to 200 ft. thick; is basal fm. of Jackson group. It underlies Wellborn fm. (the basal memb. of which is Bedias ss.), conformably overlies Yegua fm., and consists of (1) an upper memb. of chocolate-colored shales and sands, locally lignitic; nonmarine beds and interbedded marine glauconitic shales; and (2) a lower memb., 0 to 25 ft. thick, of gray calc. ss., locally with ferruginous concretions and locally fossiliferous. Dumble confused position of Caddell fm. when he stated that it overlies the Wellborn. [Exposures of Caddell are listed.] The Wooley's Bluff clays of Ellisor are part of Wellborn. At fresh exposures in Angelina Co. and in cores from wells the Caddell fm. is essentially a fossiliferous glauconitic marl. From western Walker Co. to Gonzales Co. the Caddell fm. is mostly gray and tan crossbedded sands and gray and chocolate-colored clays. The glauconitic marl of Caddell fm. is similar in lithology and strat. position to Moodys marl of Miss., and since Moodys has priority perhaps it should be adopted for basal fm. of the Jackson in Tex.

Caddo limestone.

Lower Cretaceous (Comanche series): Southeastern and central southern Oklahoma.

J. A. Taff, 1902 (U. S. G. S. Atoka folio, No. 79). *Caddo ls.*—Clay, calc. marls interstratified with white or yellowish marly ls., and semi-crystalline ls., marly beds thickest near base, lower 60 ft. being composed chiefly of clay marls. Top memb. of fm. is bed of oyster shells. Thickness of fm. 150 ft. Underlies Bokchito fm. and overlies Kiamichi fm.

Named for Caddo, Bryan Co.

†Caddo shale.

Ordovician (Lower and Middle): Southwestern Arkansas.

A. H. Purdue, 1909 (Geol. Soc. Am. Bull., vol. 19, p. 557). *Caddo sh.*—Sh. overlying Crystal Mtn ss. and underlying Bigfork chert.

H. D. Miser, 1917 (U. S. G. S. Bull. 660, pp. 67–68). Crystal Mtn ss. of Purdue, 1909, included Blakely ss. [The Caddo sh. of Purdue, 1909, is therefore exactly = Womble sh. of Miser, 1917.]

Caddo lime.

A term that has been applied by drillers to Home Creek ls. memb. of Caddo Creek fm. (Penn.), also to a ls. in the much older Smithwick sh. (also Penn.), both of central northern Texas. The lime in Smithwick sh. is also called "Smithwick lime," "Breckenridge lime," and "False Black lime" by oil men.

Caddo sand.

A subsurface sand in SW. Okla., correlated with part of Garber ss. (Perm.). The name has also been applied by drillers to a sand correlated with Nacatoch sand (Upper Cret.) in NW. La.

Caddo Creek formation. (In Canyon group.)

Pennsylvanian: Central and central northern Texas.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31, 35). *Caddo Creek fm.*—Top fm. of Canyon group. Discon. underlies Graham fm. and overlies Brad fm., top memb. of which is Ranger ls. Thickness 100 to 150 ft. to N. and 30 to 50 ft. to S. Named for a tributary of Brazos River in Stephens Co., Brazos River region. Divided into Home Creek ls. memb. (above) and Hog Creek sh. memb. (below).

Replaces Eastland fm.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 104), redefined Caddo Creek fm. by including in it Jacksboro ls. and Finis sh., which were originally included in overlying Graham fm. He stated that Home Creek ls. includes Jacksboro ls.

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501, pp. 197+). *Caddo Creek fm.* includes only Home Creek ls. and Hog Creek sh. of Colorado River region. [This definition has been adopted by U. S. Geol. Survey for its publications, and is the one followed by F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534). They included in lower part of overlying Graham fm. the Bunger ls., Gonzales Creek sh., Eastland ss., and Finis sh. of Brazos River region.]

Caddo Gap novaculite.

Devonian (?): Southwestern Arkansas (Montgomery County).

C. L. Cooper, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 211). [See 1933 entry under *Arkansas novaculite.*]

Caddo Levee Board horizon.

Lower Cretaceous: Northeastern Texas and northwestern Louisiana.

See under *Hill sand horizon.*

†Cadent series.

Nongeographic name introduced by H. D. Rogers in 1858 (Geol. Pa., vol. 1, pp. 107, 138–140+, and vol. 2, p. 775). Divided into *Cadent upper black sl.* (*Genesee sh. of N. Y.*), 300 ft. thick in Huntingdon Co., Pa.; *Cadent shales* (*Hamilton group of N. Y.*), 600 ft. thick in Huntingdon Co.; and *Cadent lower black sl.* (*Marcellus sl. of N. Y.*), 250 ft. thick in Huntingdon Co.

†Cadent slates.

†Cadent shales.

See under †*Cadent series.*

Cades conglomerate. (In Chilhowee group.)

Cambrian (Lower): Eastern Tennessee and western North Carolina.

A. Keith, 1895 (U. S. G. S. Knoxville folio, No. 16, p. 2). *Cades cgl.*—Thick beds of sl., ss., graywacke, and cgl. The beds of fine sl. are black and grayish black; the other beds are of various shades of gray. Few beds are over 50 ft. thick, most of them being from 6 inches to 3 ft. thick. Thickness of fm. probably 2,400 ft. Overlies Pigeon sl. and underlies Thunderhead cgl.

Named for exposures near Cade Cove [spelled *Cade Cove* on atlas sheet], Blount Co., Tenn.

Cadiz beds.

Upper Devonian: Western New York (Genesee River region).

G. H. Chadwick, 1934 (Geol. Soc. Am., Prel. list of titles and abstracts of papers to be offered at 47th Ann. Meeting, Rochester, N. Y., Dec. 27–29, 1934, p. 12). *Cadiz beds* introduced for supposed "Volusia" of Genesee-Olean meridian, btw. Cuba and Hinsdale sss., and *Haymaker beds* for those formerly taken for the Chadakoin, btw. Hinsdale ("quarry") ss. and Wolf Creek cgl. The succession [upward] thus becomes Cuba, *Cadiz*, Hinsdale, *Haymaker*.

G. H. Chadwick, 1935 (Geol. Soc. Am. Proc. 1934, p. 71). [See 1935 entry under *Northeast sh.* Type loc. not stated.]

Cadiz formation.

Middle Cambrian: Southeastern California (San Bernardino Mountains).

J. C. Hazzard and J. F. Mason, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 2, pp. 229–240). *Cadiz fm.*—In descending order: (1) Nodular buff and gray ls., 75±ft.; (2) greenish platy sh.; (3) sandy platy ss.; (4) purplish and green sh.; (5) platy ss.; (6) buff, oolitic, cross-bedded ls., tentatively treated as base of fm. Thickness of fm. 375± ft. in Marble Mtns, 550 ft. in Providence Mtns. Middle Camb. fossils. Underlies Bonanza King fm. (Middle Camb.) and overlies reddish ss. and sh. containing Lower Camb. fossils. Type section was measured in W.-E. direction up W. front of high ls. ridge 2± mi. N. of National Old Trails Highway where it crosses Marble Mtns about 3 mi. N. of Cadiz.

Cadomin conglomerate.

Lower Cretaceous: Alberta.

B. R. MacKay, 1929 (Canada Geol. Surv. Summ. Rept. 1928, pt. B, p. 9).

Cadwallader series.

Triassic: British Columbia.

C. W. Drysdale, 1916 (Canada Geol. Surv. Summ. Rept. 1915, p. 79).

Cahil sandstone. (In Franciscan group.)

Jurassic (?): Western California (San Francisco region).

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). *Cahil ss.*—Prevailingly massive, obscurely bedded ss. of dark greenish gray color and medium texture. Includes lenses of pebbly cgl. and beds of dark sh. Includes, 500 ft. above base, a conspicuous foraminiferal ls.—the Calera ls. memb.—60 ft. thick, which is overlain by 2,000 ft. of beds belonging to Cahil fm. On summit of Fifield Ridge a thin lens of obscurely fossiliferous impure ls. occurs in Cahil ss. several hundred ft. above Calera ls. This ls. is apparently not persistent and probably nowhere exceeds 10 ft. in thickness. Thickness of Cahil ss. approx. 2,560 ft. Basal fm. of Franciscan group. Underlies Sausalito chert. Named for exposures on Cahil Ridge, San Mateo Co.

Caimito formation.

Miocene: Panama Canal Zone.

D. F. MacDonald, 1913 (Geol. Soc. Am. Bull., vol. 24, p. 709).

†Cainozoic. See *Cenozoic*, the modern spelling.

Cairo gas sand.

Cairo salt sand.

Cairo oil sand.

Subsurface sands in Pottsville fm. (Penn.) of W. Va. The gas sand is youngest, the oil sand is oldest. The salt sand may correspond to Connoquenessing ss. memb. Named for town in Ritchie Co., W. Va.

Cairo till.

A term applied by C. [R.] Keyes to the oldest (pre-Nebraskan, he stated) till sheet in America. (See Pan-Am. Geol., vol. 58, p. 203, 1932.)

Cajalco quartz monzonite.

Late Jurassic(?): Southern California (Riverside County).

P. H. Dudley, 1935 (Calif. Jour. Mines and Geol., vol. 31, No. 4, map, pp. 491, 502). Late Jurassic(?) intrusive rock that covers large areas in Riverside Co. btw. Monument Peak and Arlington Mtn, including Cajalco Canyon.

Calais granite.

Devonian: Northeastern Vermont (Washington County).

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), listed this name in Dev. of "central Vt.," but without definition. Quarried at Calais, Calais Twp, Washington Co., in quad. adjoining Montpelier quad. on E.

Calapooya formation.

Tertiary (Eocene ?): Southwestern Oregon.

F. G. Wells and A. C. Waters, 1934 (U. S. G. S. Bull. 850). *Calapooya fm.*—Cgls. tuff, breccia, and lava flows, over 5,000 ft. thick in Black Butte-Elkhead area. In places consists mainly of true volcanic breccias; in places it is largely fine tuff; in places lava flows prevail, the flows ranging from basalt to dacite, but nearly everywhere material of andesitic composition greatly predominates. Lavas are more abundant in upper part and the thick masses of cgl. are confined largely to its base. In E. part of Calapooya Mtns the fm. is mostly sed., with cgl. predominating. Farther E. and SE. lava flows become increasingly abundant until along SE. border of Black Butte-Elkhead area only thin beds of cgl. occur. Makes up western and older part of Cascade Mtns. Fossil leaves (3 sp.) from a thin layer of interstratified tuff may be Mio., Olig., or Eocene, according to R. W. Brown of U. S. Nat. Mus., but Chaney says (orally) they are Eocene. Assigned to Eocene (?) in this rept. Named for occurrence along crest of Calapooya Mtn. *Lies uncon. on Umpqua fm.*

Calaveras formation (also **group**).

Mississippian: Northern California (Calaveras and neighboring counties).

H. W. Turner, 1893 (Am. Geol., vol. 11, pp. 307–324, 425). The term *"Calaveras formation"* as used by U. S. Geol. Survey on geol. maps of Gold Belt [then in preparation] includes all Paleozoic sed. rocks of Sierra Nevada. Is characterized by large masses of associated greenstone. Includes sl., cgl. and ls., associated with igneous rocks of apparently same age as enclosing sed. rocks. Uncon. underlies Mesozoic Mariposa slates. So far as yet known is chiefly lower Carbf., but may extend down into Dev. It is not intended to include in it the Sil. beds described by Mr. Diller nor the upper Carbf. strata of Genesee Valley, called by Mr. Diller *Robinson beds.*

Two of U. S. G. S. geol. maps of Gold Belt referred to by Turner were published in 1894 (folios 3 and 11), and others followed later. These folios describe Calaveras fm. as consisting of a conformable series, 4,000 ft. or more thick, of black micaceous clay-sl., argill. schist, qtzite, chert, and mica-schist, with lenses of ls. and some beds of cgl., all associated and in part interbedded with igneous rocks. Is lower fm. of †Auriferous slate series.

Named for prominent development in Calaveras Co.

†Calciferous group.

†Calciferous sandrock.

†Calciferous sandstone.

Descriptive terms applied originally in early N. Y. repts to beds occupying interval btw. †Birdseye (Lowville) ls. above and Potsdam ss. below. Generally included Beekmantown ls. plus Little Falls dol. of present terminology. The name has been applied in other States to rocks of different ages. (See State correlation charts.)

†Calciferous mica schist.

Silurian and Ordovician: Western New Hampshire and Vermont.

C. H. Hitchcock, 1870 (Geol. and Min. N. H. 2d Ann. Rept., geol. map); 1873 (Am. Ass. Adv. Sci. Proc., vol. 21, pp. 134–135); 1877 (Geol. N. H., pt. 2, pp. 658–675); 1896 (Jour. Geol., vol. 4, pp. 44–62 and Geol. Soc. Am. Bull., vol. 7, pp. 510–512); 1906 (Vt. Geol. Surv. 5th Rept., pp. 86, 115).

Said to include Waits River ls. (Lower Ord.) and Vershire schist (Ord.). The rocks mapped as *Calciferous mica schist* by Hitchcock in SW. N. H. are now classified as Sil.

†Calciferous formation.

Lower Ordovician: Northwestern Michigan (Marquette region).

A. C. Lane, 1907 (Mich. Miner, vol. 9, No. 2, p. 9). The *Calciferous fm.* for Mich. may be conceived as taking its name from Calciferous station of Marquette & Southeastern R. R.

R. A. Smith, 1914 (Mich. Geol. and Biol. Surv. Pub. 14, geol. ser. 11, btw. pp. 22 and 32). *Calciferous or Lower Magnesian ss.* (Prairie du Chien) is 200 to 250 ft. thick in wells along Green Bay. Named for Calciferous Creek, a branch of Au Train River, Mich.

Calderwood formation.

Cambrian (?): Central southern Maine (Vinalhaven Island, Knox County).

G. O. Smith, 1896 (Geol. Fox Islands, Maine, pp. 12, 28–29). *Calderwood's Neck schists.*—Sed. rocks, consisting of the dark qtzitic slates, banded schists (quartzose but varying in color and grain), and quite massive qtzites occurring on NE. part of Vinal Haven Island. Felsitic rocks occur in close proximity to the granite and volcanic rocks and undoubtedly represent contact phases of members of Calderwood's Neck series. These are mottled or variegated, generally a light green. Probably older than Niagara.

G. O. Smith, 1907 (U. S. G. S. Penobscot Bay folio, No. 149, p. 4). *Calderwood fm.*—Name applied to rocks earlier described and mapped as *Calderwood's Neck schists*. Probably belong to either Islesboro or Penobscot fm., but isolated position prevents certain correlation. Assigned to Camb. (?).

On 1933 geol. map of Maine, by A. Keith, these rocks on Calderwood Neck are included in the Ord. and Camb. block.

†Calderwood's Neck schists.

See *Calderwood fm.*

Caldwell series.

Cambrian (?): Quebec.

B. R. MacKay, 1921 (Canada Geol. Surv. Mem. 127, pp. 12, 20).

Caldwell Knob member (of Seguin formation).

Eocene (lower): Southeastern Texas (Brazos River to Rio Grande Valley).

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 575, 576, 577, 581). *Caldwell Knob memb.*—Top memb. of Seguin fm. Consists of a layer of oyster shells varying in thickness from a few inches to several ft., the average being about 1 ft. The oysters (in most places *Ostrea multilirata*) lie in matrix of calc. silt, in most places cemented into hard sandy ls. The bed has been traced by Julia Gardner from near Brazos River in Milam Co. to Rio Grande Valley and has been identified on Guerrero structure near Guerrero, Mexico. Is not continuous along outcrops. Type loc. is Caldwell Knob, 10 mi. N. of Bastrop and 2± mi. S. of Colorado River in Bastrop Co.

Caledonia conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. C. Lane, 1911 (Mich. Geol. and Biol. Surv. Pub. 6, geol. ser. 4, pp. 576, 580, 588, 593, 612, and 957). Is cgl. No. 8 [Bohemia cgl.], top fm. of Bohemia Range group.

Probably named for occurrence near old Caledonia mine, Ontonagon Co.

Caledonia group.

Pre-Carboniferous: New Brunswick.

G. A. Young, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 311).

Calera limestone member (of Cahil sandstone).

Jurassic(?): Western California (San Francisco region).

R. Arnold, March 1902 (Sci., n. s., vol. 15, table on p. 416). *Calera ls.*, foraminiferal, 60 ft. thick. [Shown in table as overlain by volcanics that are older than Bolinas ss. and underlain by volcanics that are younger than Pilarcitos ss.]

A. C. Lawson, February 1903 (Geol. Soc. Am. Bull., vol. 13, table on pp. 544–545). [Same as above.]

A. C. Lawson, 1914 (U.S.G.S. San Francisco folio, No. 193). *Calera ls. memb.*—Gray, compact, foraminiferal ls. resembling lithographic ls. and containing lenses of chert. Occurs in lower part of Cahil ss., basal fm. of Franciscan group. Thickness averages about 60 ft.

Named for exposures in sea cliffs at lower end of Calera Valley, San Mateo Co.

Calhoun shale member (of Shawnee formation).

Pennsylvanian: Eastern Kansas, southeastern Nebraska, and northwestern Missouri.

J. W. Beede, 1898 (Kans. Acad. Sci. Trans., vol. 15, p. 29). *Calhoun ss. and sh.*—Soft argill. ss., 12 to 20 ft. thick, overlain by 38 to 45 ft. of fine-textured bluish sh. Included in Upper Coal Measures of Shawnee Co., Kans. Overlies Calhoun ls. [Deer Creek] and underlies Topeka ls.

Adopted by U. S. Geol. Survey as a memb. of Shawnee fm. in Mo., underlying Topeka ls. memb. and overlying Deer Creek (†Calhoun) ls. memb. In Kans. the Shawnee is treated as a group and the Calhoun sh. as a fm.

In 1927 (Nebr. Geol. Surv., 2d ser., Bull. 1) G. E. Condra divided *Calhoun sh.* into (descending) Iowa Point sh., Sheldon ls., and Jones Point sh. In Oct. 1932 (revised correlation chart of Kans. and Nebr.) R. C. Moore and G. E. Condra restricted *Calhoun sh.* to the beds previously called *Iowa Point sh.*, and included their Sheldon ls. and Jones Point sh. in Deer Creek ls. In 1935 (Nebr. Geol. Surv. Paper No. 8, p. 11) Condra reverted to his 1927 definition of Calhoun sh., as did R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22).

G. E. Condra and E. C. Reed, June 1937 (Nebr. Geol. Surv. Bull. 11, 2d ser.) restricted this sh. as explained in 1937 entry under *Topeka ls.*

Named for exposures in Calhoun Bluffs, about 3 mi. NE. of Topeka, Kans. See Kans-Nebr. chart compiled by M. G. Wilmarth, 1936.

†Calhoun limestone.

Pennsylvanian: Eastern Kansas and northwestern Missouri.

J. W. Beede, 1898 (Kans. Acad. Sci. Trans., vol. 15, p. 28). *Calhoun ls.*—Three beds of bluish to yellowish gray ls. separated by layers of sh. Thickness 15 to 20 ft. Upper bed massive ls. 7 to 10 ft. thick. Underlies Calhoun sh. and overlies Tecumseh sh.

Same as Deek Creek ls. (older name), according to Hinds and Greene (1915) and R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22).

Named for Calhoun Bluffs, about 3 mi. NE. of Topeka, Kans.

Caliche Mountain rhyolite.

Age (?): Mexico.

R. T. Hill, 1904 (Greene Consolidated Gold Co., Prospectus, p. 16).

Calico amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name locally in use many years. Used by B. S. Butler in U.S.G.S.P.P. 144, 1929. Derived from variegated color of the rocks, suggesting calico. Lies about 125 ft. above Minesota cgl., according to Butler (personal communication). The mineralized part is the Calico lode. Belongs to Central Mine group.

Calico flow.

Includes Calico amygdaloid and the underlying trap.

†Calico shale.

Descriptive term. See under *Springville sh.* (Upper Dev., SW. Ill.).

Calico marble.

A trade term sometimes applied to beds quarried from Potomac marble of southern Pa. and western Md.

†Calico ledge.

A name applied in some early Mo. repts to Raytown ls.

Calico Bluff formation.

Mississippian (upper): Central eastern Alaska (Nation River region).

A. H. Brooks and E. M. Kindle, 1908 (Geol. Soc. Am. Bull., vol. 19, p. 292, etc.). *Calico Bluff fm.*—Thin-bedded ls., slates, and shales; some igneous rock. Invertebrate fossils of Lower Carbf. age. Conformably overlies Upper Dev. shales and slates. Underlies (uncon.) Nation River fm. Exposed at Calico Bluff and other points on Upper Yukon River, also on Porcupine River.

J. B. Mertie, Jr., 1933 (U.S.G.S. Bull. 836, p. 423), stated that he believed a group of intermediate or transitional rocks, 1,000 to 2,000 ft. thick, exists btw. Nation River fm. and Calico Bluff fm. in Tatonduk-Nation dist., but that this remains to be proved. He assigned Calico Bluff fm. to upper Miss. (Chester), on basis of fossils identified by G. H. Girty.

Calico Peak porphyry.

Tertiary: Southwestern Colorado.

W. Cross and A. C. Spencer, 1900 (U.S.G.S. 21st Ann. Rept., pt 2, pl. 22—map of Rico Mtns). *Dikes of Calico Peak porphyry.* [Text heading is *Porphyry of Calico Peak and vicinity.*]

W. Cross and A. C. Spencer, 1905 (U.S.G.S. Rico folio, No. 130). *Dikes of Calico Peak porphyry* occur on N. slope and elsewhere in vicinity of Calico Peak [about 4 mi. NW. of Rico] and in a sheetlike body in Dakota ss. at head of Priest Gulch. Is a monzonite porphyry characterized by large orthoclase crystals. *Calico Peak porphyry alunitized* (a porphyry changed by solfataric action into a mass consisting chiefly of alunite) forms cone of Calico Peak.

Calico Rock sandstone member (of Everton formation).

Lower Ordovician (Chazy or older): Central northern Arkansas (parts of Baxter, Izard, Fulton, and Stone Counties).

G. C. Branner, 1929 (Ark. Geol. Surv. geol. map of Ark.). [Columnar section on map shows *Calico Rock ss. memb.*, 200± ft. thick, as lying in lower part of Everton ls., possibly a little higher than Kings River ss. memb. of Everton to W. Mapped at and around Calico Rock and other parts of Izard Co., and over parts of Baxter, Fulton, and Stone Counties.]

A. W. Giles, 1930 (Ark. Geol. Surv. Bull. 4, pl. IX and pp. 113+). *Calico Rock ss.*—Named for conspicuous outcrops in river bluffs E. and W. of town of Calico Rock, on White River, in W. part of Izard Co. Lies in lower part of Everton fm., which is of early middle Ord. age and uncon. underlies St. Peter ss. [Mapped over parts of Izard, Shark, Fulton, and Baxter Counties.] Thickness 0 to 150 ft. Interval (0 to 400 ft.) btw. Calico Rock and St. Peter ss. is occupied by beds of massive, white, coarse-grained ss. alternating with thin to massive, blue to gray mag. beds with a few dove-colored layers, the ss. layers being lithologically identical with Calico Rock and St. Peter sss. According to Miser, the Calico Rock ss. rests on beds of Everton age which are not identified as Sneeds ls., the basal memb. of Everton, and which consist of an alternation of blue and gray ls. and some coarse ss. In section W. of Calico Rock measured by writer and Brewster, an uncon. btw. these beds and Calico Rock ss. is suggested. The Calico Rock is unfossiliferous, cross-bedding is common, and ripples conspicuous. In general it is like the St. Peter, very friable; locally it is resistant; is of white or light-cream color; weathers dull brown; green bands are not as noticeable as in the St. Peter, but yellow to brown ferruginous streaks are locally developed along joints and other fractures, as in the St. Peter.

†California sandstone.

See †*San Francisco ss.*

California granite.

Pre-Cambrian: Northwestern New York (Gouverneur quadrangle).

A. F. Buddington, 1929 (N. Y. State Mus. Bull. 281, pp. 52, 61–65). *California granite mass* forms California phacolith, Lake Bonaparte quad., and extends into Antwerp quad. Intrudes Grenville series. [Derivation of name not stated. According to p. 52 the granite belongs to his Alexandria type.]

Callaway limestone.

Middle Devonian (Hamilton): East-central Missouri.

C. R. Keyes, 1894 (Mo. Geol. Surv. vol. 4, pp. 30, 43). *Callaway ls.*—Dark-colored shaly lss., 70 ft. thick, containing Western Hamilton fossils. Overlies Grand Tower ls. and underlies black shales or Louisiana ls.

C. R. Keyes, 1895 (Mo. Geol. Surv. vol. 8, p. 340). The Dev. rocks along Missouri River have been termed *Callaway beds*, and consist of heavy calc. layers overlain by 30 ft. of highly fossiliferous sh. Contain "Western Hamilton" fauna.

C. R. Keyes, 1896 (Mo. Geol. Surv. vol. 11). *Callaway ls.*, 60 to 70 ft. thick, underlies "Black" sh. and overlies Grand Tower ls. Consists of (ascending) compact blue or buff to brown highly fossiliferous ls.; sh. 30 ft.; thin-bedded ls. passing at top into calc. sh., some of which may be "Black" sh.

E. B. Branson, 1918 (Univ. Mo. Bull., vol. 19, No. 15). *Callaway ls.* assigned to *Upper Dev.* Conformably underlies Craghead Creek sh. and discon. overlies Grand Tower ls.

M. E. Wilson, 1922 (Mo. Bur. Geol. and Mines, 2d ser., vol. 16, pp. 49, 52). *Callaway ls.*—Underlies Craghead Creek sh. and uncon. overlies Middle Dev., the top fm. of which is St. Laurent ls. Thickness 0 to 59 ft.; max. in Callaway and Montgomery Counties; pinches out to E. and W. in Warren and Boone Counties. Assigned to *Upper Dev.* [This definition was followed by H. A. Buehler on 1922 geol. map of Mo.]

E. B. Branson, 1923 (Mo. Bur. Geol. and Mines, 2d ser., vol. 17, pp. 24–36). *Callaway ls.* presents several phases. Its thickest parts are light to dark blue, compact, fine-grained ls., in many places highly fossiliferous. A light to dark-brown compact ls. is usually present in 3 or 4 beds having a combined thickness of less than 6 ft. A third phase is white to gray coarsely to finely crystalline ls., which occurs in 1 to 3 lentils ranging in thickness from 6 in. to 4 ft. At many places a highly cross-bedded ss., ranging in thickness up to 20 ft., occurs at base of fm. Is conformably overlain by Snyder Creek sh., or, where that is absent, by either Grassy Creek sh., Sylamore ss., Chouteau ls., or Burlington ls. Rests uncon. on fms. ranging from Mineola ls. (Middle Dev.) to Jefferson City ls. (Lower Ord.). Thickness 0 to 52 ft. 7 in. Is of *late Hamilton age* and may include some beds of early Tully age.

Named for development in Callaway Co. Best developed from Cedar Creek eastward through Callaway Co.

Calliham sand.

Eocene (upper): Southeastern Texas (Atascosa and Karnes Counties).

A. C. Ellisor, 1933 (A. A. P. G. Bull., vol. 17, No. 11, pp. 1302, 1315, etc.). *Calliham sand.*—Gray fossiliferous sand typically exposed on Frio River N. of Calliham, where Whitsett-Calliham road crosses river. Sam Houston, who suggested the name for this sand and who has traced it from Frio River to Karnes Co. line, found it varies from highly fossiliferous, fine-grained gray sand, as in outcrops on Frio River, to rice-grained and conglomeratic sand cropping out in Atascosa Co. S. of Campbellton. Thickness 20± ft.; absent, both on surface and in wells, in western Karnes Co. Is a zone in Whitsett fm. as here defined, underlying Fashing clays and overlying Dubose sands and clays.

Call Mill slate.

Cambrian (Lower): Southern Quebec.

See under *West Sutton sl.*

Calloway limestone.

Middle Devonian: Missouri.

See *Callaway ls.*, the correct spelling of the county for which the ls. was named.

Callville limestone.

Pennsylvanian: Southeastern Nevada (Muddy Mountains).

C. R. Longwell, 1921 (Am. Jour. Sci., 5th, vol. 1, p. 47) and 1928 (U. S. G. S. Bull. 798). *Callville ls.*—Dark-colored ls., with zones of lighter gray at intervals; many layers almost black; hard and dense, coarse granular texture subordinate; beds regular and massive; occasional thin layers; shaly layers rare; chert less abundant than in the Miss. lss. Thickness 1,100+ ft. [2,000±]. Fossils are Pennsylvanian (Magdalena), according to G. H. Girty. Top not defined because not known. Is uncon. overlain by Supai fm. Name is applied to all Penn. lss. in Callville Mtn, Clark Co., but all sections there are incomplete. Overlies Bluepoint ls., probably uncon.

Caloosahatchee marl.

Pliocene (lower): Southern and northern Florida.

W. H. Dall, 1887 (Am. Jour. Sci., 3d, vol. 34, pp. 161–170). *Caloosahatchie beds.*—The marls of the *Caloosahatchie* contain a large number of species of which perhaps one-tenth are supposed to be extinct; many of the others are known only from deep water. How many of the so-called extinct ones will turn out to be still living when the deeper waters of the Floridian coast are thoroughly dredged remains to be seen. The age of the Caloosahatchie beds is much the same as others which have been called Plio. on our Eastern coast. The time has not yet arrived, nor is our knowledge of any part of our later Tertiaries sufficient to enable us to decide finally as to their chronologic relation to each other, except in a most tentative way. But without reference to their place in the system, the geological history of the Caloosahatchie marls is clearly stated in their structure. [On p. 163 Dr. Dall refers to the *Coloosahatchie Pliocene.*]

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept.). *Caloosahatchee marl* redefined so as to include "Nashua" marl, which is so nearly of same age that two names are unnecessary. As here expanded it includes all known marine Plio. deposits in Fla. and a bed containing extinct fresh-water shells, which, according to Dall, lies at top of fm.

Named for exposures on Caloosahatchee River, Lee Co., especially btw. Labelle and Olga.

†Calumet conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. R. Marvine, 1873 (Mich. Geol. Surv. vol. 1, pt. 2, pp. 53–58 and chart). Is cgl. No. 13 of Keweenaw Co.

Same as Calumet and Hecla cgl. of Central Mine group.

Named for occurrence in Calumet mine, Houghton Co.

Calumet amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan (Houghton County).

A. C. Lane, 1907 (Lake Superior Min. Inst. Proc., vol. 12, pp. 89–92). Older than Calumet cgl. and younger than Osceola amygdaloid.

Belongs to Central Mine group. The mineralized part is the Calumet lode.

Named for occurrence at Calumet mine, Houghton Co.

Calumet flow.

Includes Calumet amygdaloid and underlying trap.

Calumet and Hecla conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan.

L. L. Hubbard, 1895 (Mich. Geol. Surv. vol. 5, pt. 1, p. 117, footnote). According to measurements by James Crawford, the Calumet and Hecla cgl. lies 2,050 ft. below Allouez cgl. and 1,500 ft. above Kearsarge cgl. on Kearsarge location. [In C. Rominger's section of Calumet & Hecla mine in volume above cited, and throughout his rept forming pt. 1 of vol. 5, the cgl. referred to by Hubbard is called Calumet cgl.]

According to A. C. Lane (Mich. Geol. and Biol. Surv. Pub. 6, geol. ser. 4, p. 68, 1911) this cgl. is composed almost wholly of pebbles of such extremely angular type that the rock has often been called a felsite breccia.

Belongs to Central Mine group.

Named for occurrence in Calumet & Hecla mine, Houghton Co.

Calvert formation.

Miocene (middle): Eastern Maryland, Delaware, and Virginia.

G. B. Shattuck, 1902. [See under *St. Marys fm.*]

W. B. Clark, 1903 (Md. Geol. Surv. St. Marys Co. Atlas). *Calvert fm.*—Fossiliferous sandy clay, clay, marl, and diatomaceous earth. Thickness 185 ft. Basal fm. of Chesapeake group. Underlies Choptank fm.

G. B. Shattuck, 1904 (Md. Geol. Surv. Miocene vol., pp. lxxii–lxxiv), divided Calvert fm. into Plum Point marl memb. (above) and Fairhaven diatomaceous earth memb., and gave thickness as 50 to 310± ft.

Named for exposures in Calvert Co., Md., especially in Calvert Cliffs, bordering Chesapeake Bay.

Calvert Bluff clay beds (of Rockdale formation).

Eocene (lower): Central and southern Texas (between Brazos and Frio Rivers).

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 585, 586, etc.). *Calvert Bluff clay beds.*—Top memb. of Rockdale fm. in central and southern Tex., especially btw. Brazos and Frio Rivers. Type loc. at Calvert Bluff on Brazos River, Jesse Webb League, Robertson Co. Consist of: (a) Gray sand weathering red and buff, varying from coarse qtzitic sand to very fine silty argill. material that stands up like loess in steep banks; (b) dense, black lignitic beds 1 to 9 ft. thick; (c) dark gray, compact, carbonaceous clay in thick beds or in lentils interbedded with silt. Thickness 1,000 ft. Overlies Simsboro sand and underlies marine Sabinetown fm.

Calvin sandstone.

Pennsylvanian: Central, central southern, and central eastern Oklahoma.

J. A. Taff, 1901 (U.S.G.S. Coalgate folio, No. 74). *Calvin ss.*—Thick-bedded hard ss., 145 to 240 ft. thick, becoming friable, ferruginous, and shaly toward S. Overlies Senora fm. and underlies Wetumka sh.

Named for exposures at Calvin, Hughes Co.

†Calvin sand series.

Pennsylvanian: Central Oklahoma.

A. I. Levorsen, 1927 (A.A.P.G. Bull., vol. 11, No. 7, pp. 658–682). *Calvin series.*—A subsurface term which has come into general use for a series of three or four sands found at depths ranging from 1,700 to 2,000 ft., and which form a good marker in most logs. At outcrop on E., as shown on areal map of Okla., the highest memb. of this series is basal sand of Wewoka fm. The two sands occurring below the highest memb. are=Calvin sand [ss.] on outcrop. [Chart on p. 658 correlates the so-called "Calvin series" with Calvin ss., Wetumka fm., and basal part of Wewoka fm. of south-central Okla., and with Oswego lime of NE. Okla. and Palo Pinto ls. of north-central Tex.] The term originated during development of Cromwell field, T. 10 N., R. 8 E., Seminole Co., Okla.

†Calvins Run limestone.

See *Colvin ls. memb.*

Camajuani formation.

Cretaceous: Cuba.

E. L. De Golyer, 1918 (A.A.P.G. Bull., vol. 2, p. 141).

†Camargo schist.

Lower Cambrian and pre-Cambrian: Southeastern Pennsylvania.

A. I. Jonas and E. B. Knopf, 1921 (Wash. Acad. Sci. Jour., vol. 11, p. 447). *Camargo schist* is name given by writers to a porphyritic albite schist that conformably overlies a dol. of probable Beekmantown age. It forms the ridge that flanks Chester Valley on S. and comprises a portion of the fm. formerly known as *Octoraro schist.* It may represent the metamorphosed equiv. of the Normanskill sh. found near Harrisburg, Pa.

This name is no longer used by its proposers, they having found, by additional work, that the rocks are in part pre-Camb. and in part Camb., and include Antietam schist, Harpers albite schist, and the oligoclase mica-schist facies of Wissahickon fm.

Named for village of Camargo, near Quarryville, Lancaster Co., Pa.

Camas basalt.

Tertiary: Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 99, map). *Camas basalt.*—Chiefly lava flows; tuffs and breccias occur in places but are not characteristic. No sed. intercalations seen. The basalt in S. part of Co. is typically fine-grained, dense, almost black. Thickness 500± ft. along S. side of Camas Prairie. Rests uncon. on older fms., including Gerome andesite. Assigned to Tert.

Camas sandstone.

Upper Cretaceous: Mexico (Sonora). See under *Cabullona group.*

Cambrian period (or **system**).

The time (and the rocks) of the oldest Paleozoic period, preceding the Ord. period. For definition see U. S. G. S. Bull. 769, pp. 92–101.

Cambric.

A variant of *Cambrian* employed by some geologists.

Cambridge slate.

Carboniferous or Devonian: Eastern Massachusetts (Boston Basin region).

N. S. Shaler, 1871 (Boston Soc. Nat. Hist. Proc., vol. 13, pp. 173–175). *Cambridge slates.*—Dense argill. material with little admixture of foreign substances. Thickness more than 200 ft. Best seen at Cambridge. Assumed to belong to same great series of beds as Roxbury cgl.

J. B. Woodworth, 1895 (Boston Soc. Nat. Hist. Proc., vol. 26, pp. 125–126). *Cambridge slates* of Shaler rest on Roxbury cgl., and name is extended to other parts of Boston Basin where fossils similar to those present in vicinity of Mystic River have been found.

See also B. K. Emerson, 1917 (U. S. G. S. Bull. 597).

L. LaForge, 1932 (U. S. G. S. Bull. 839), treated *Tufts qtzite* as top *memb. of Cambridge sl.,* which he assigned to *Dev. or Carbf.* He also introduced *Boston Bay group* to include Cambridge sl. and Roxbury cgl. The U. S. Geol. Survey in June 1910 adopted *Tufts* as a memb. of Cambridge sl., for foregoing rept, the publication of which, however, was delayed until 1932.

M. Billings, 1929 (Am. Jour. Sci., 5th, vol. 18, pp. 99–112), excluded Tufts qtzite from *Cambridge argillite,* as he called the fm., and assigned both to Perm.

Cambridge limestone member (of Conemaugh formation).

Pennsylvanian: Eastern Ohio, western Pennsylvania, and West Virginia.

E. B. Andrews, 1873 (Ohio Geol. Surv. vol. 1, p. 262). *Cambridge ls.,* 0 to 2 ft. thick, lies in Productive Coal Measures, about 225 ft. below Pomeroy coal. Separated from higher Ames ls. by 85 to 90 ft. of sss. and shales.

Adopted as a memb. of Conemaugh fm., for the ls. which in some repts has been called "Upper Cambridge ls." and "Pine Creek ls.;" and *Brush Creek ls. memb.* adopted for what in some repts has been called "Lower Cambridge ls."

Named for exposures near Cambridge, Guernsey Co., Ohio.

Cambridge formation.

Eocene: Jamaica.

R. T. Hill, 1899 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 34, pp. 57–65).

Cambridge red bed. (In Conemaugh formation.)
Pennsylvanian: West Virginia (Wheeling).

C. K. Swartz, 1922 (Md. Geol. Surv. vol. xi, p. 61, pl. 6), applied *Cambridge red bed* to a bed lying a few ft. above Cambridge ls. and underlying the fire clay beneath Anderson coal in Wheeling, W. Va., section. In Freeport, Pa., section he applied the name to beds underlying Upper Bakerstown coal and overlying Lower Bakerstown coal.

Cambridge sand.
A subsurface sand in Cambridge field, Guernsey Co., Ohio, that is said to correspond to Oriskany ss. (See W. Stout et al., Geol. of nat. gas, A. A. P. G., 1935, p. 907.)

Cambridge moraine.

Pleistocene (Wisconsin stage): Eastern Minnesota (Isanti, Sherburne, and Anoka Counties).

F. Leverett, 1932 (U. S. G. S. P. P. 161, p. 80). Second moraine of Rush Lake morainic system. Named for development below Cambridge, Isanti Co.

Cambrovician.
A term proposed by A. W. Grabau "to include the Upper Camb. and Lower Ord. of current usage, these forming a complete pulsation unit." (See Pan-Am. Geol., vol. 66, No. 1, 1936, p. 24.)

†Camden series.
Eocene and Upper Cretaceous: Arkansas, Louisiana, southeastern Oklahoma, and eastern Texas.

R. T. Hill, 1888 (Ark. Geol. Surv. Ann. Rept. for 1888, vol. 2, pp. 49–65, 177, 188). *Camden series.*—Shallow-water, semi-estuarine marine deposits of stratified, micaceous, non-indurated, alternating laminae of sands and clay shales, sandy shales, bituminous shales, lignitic shales, thin sss., etc. Thickness 100 to 700 ft. Includes Arkadelphia shales, Bingen sands, and Cleveland County red lands. Included in Eocene. Underlies Quat. Overlies Cret. rocks.

R. T. Hill, 1902 (Franklin Inst. Jour., vol. 154, No. 2, pp. 143–156, 264–266). *Camden series* includes all rocks from base of Eocene to Nacogdoches oil fm. Kennedy noted strat. unconformities btw. Camden series and overlying Angelina series. [Included Midway fm., Wilcox group, Claiborne group, and Jackson fm.]

Named for exposures in bluffs at Camden, Ouachita Co., Ark.

Camden chert.
Middle Devonian: Western Tennessee.

J. M. Safford and C. Schuchert, 1899 (Am. Jour. Sci., 4th, vol. 7, pp. 429–430). *Camden chert.*—Chert, exposed to a thickness of 60 ft. at Camden, Benton Co., and containing a Lower Oriskany fauna. Overlies Lower Helderberg shaly bluish ls. [Linden fm.]. Occurs also in Henry, Decatur, and Stewart Counties. [Subsequent repts by Safford applied *Camden chert* to all beds in Tenn. btw. Hardin ss. and Linden fm., and assigned it to Oriskany.]

In 1918 (Am. Jour. Sci., 4th, vol. 46, pp. 732–755) C. O. Dunbar restricted Camden chert to upper 200 ft. of beds to which it had formerly been applied, and subdivided the lower part into Harriman chert (0 to 55 ft. thick), underlain by Quall ls. (0 to 10 ft. thick), underlain by Decaturville chert (0 to 6 ft. thick). According to Dunbar the restricted Camden chert is of Onondaga age, the Harriman and Quall are of Oriskany age, and Decaturville chert is of Helderberg age, and the four fms. are uncon. one with the other and also uncon. with both underlying and overlying fms., the Camden chert being uncon. overlain by Pegram ls. and Decaturville chert uncon. underlain by rocks of earlier Helderberg age to which Dunbar has applied name *Birdsong fm.*

Named for exposures along Cypress Creek, SE. of Camden, Benton Co.

Cameron red shale member.

Mississippian: Northwestern Pennsylvania (Cameron County).

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 142). For the red sh. memb. (or composite memb.) that overlies Loyalhanna ls. memb. on Clarion River, SW. Pa., which in past has been called *Mauch Chunk*, the name *Cameron red sh. memb.* is proposed. These red beds are overlain by Greenbrier ls. memb., which is overlain by another red sh. that has been called *Upper Mauch Chunk sh.* The four members (Loyalhanna ls., Cameron red sh., Greenbrier ls., and Upper Mauch Chunk sh.) comprise *Greenbrier series.* The Cameron memb. can be studied from well sections and exposures in Cameron Co.

Cameron sandstone member (of McAlester shale).

Pennsylvanian: Eastern Oklahoma (Muskogee, Haskell, McIntosh, and adjacent counties).

C. W. Wilson, Jr., 1935 (A. A. P. G. Bull., vol. 19, No. 4, pp. 503–520). *Cameron ss. memb. of McAlester sh.*—Commonly thin and regularly bedded, but massive and irregularly bedded in T. 11 N., R. 17 E., and T. 11 N., R. 20 E.; of fine to medium texture; usually light gray but sometimes brown, especially where massive; ripple marks common. Fossils. Thickness in Muskogee-Porum area 15 to 20 ft. Lies 40 ft. above Lequire ss. memb. and 1 to 10± ft. below McAlester (Stigler) coal. Named for exposures NW. and W. of Cameron, in T. 8 N., R. 26 E.

Cameron Bay series.

Pre-Cambrian: Canada (Northwest Territory).

H. S. Robinson, 1933 (Canadian Min. and Met. Bull. 258, p. 615).

Camillus shale member (of Salina formation).

Silurian: Western to east-central New York.

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, pp. 18–19 and chart). *Camillus sh.* (gyp. and platten dolomites), underlies Bertie waterlime and overlies Syracuse salt. Included in Salina beds.

In later repts thicknesses of 40 to 600 ft. are given for *Camillus memb.*, which is next to top memb. of Salina fm.

D. H. Newland, 1928 (Nat. Research Council Reprint and Circ. ser., No. 85, pp. 37–39). The N. Y. Salina, exclusive of basal strata, is dominantly, but to a varying degree, a fm. of chemical precipitates—fine-grained, mostly nonfossiliferous dol. and mag. ls., heavy rock-salt beds, and smaller seams of calcium sulphate usually in form of anhydrite. In N. Y. type sections sh. has been given undue importance in descriptions, because weathering of the impure lss. produces a calc. clay (called marl in early N. Y. repts), and gives impression the Camillus strata, which constitute bulk of Salina section, are largely sh. This is contrary to actual findings in fresh rock sections, where chemical precipitates compose the main persistent members, and where sh. is a variable sporadic element, more in evidence in lower zone close to contact with Vernon sh. The term *Camillus sh.* therefore seems hardly appropriate, although sanctioned by long usage. Writer favors calling this memb. *Camillus beds,* which term conveniently covers the various components, both of the weathered and diminished sections on outcrop and normal full succession encountered in depth.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 317, 318), placed *Camillus sh.* below Bertie and above Syracuse salt, but on pp. 339–340 she stated: *Camillus sh.* includes, besides shales, abundant gyp. and salt beds and flaggy dolomites. The salt-bearing strata are the Syracuse salt, which includes the main salt layers and associated salty sh. and ls. No sharp bdy exists btw. the salt-bearing strata and rest of the Camillus, and it can only be determined from well records and shafts which reach the salt at depth of 800 ft. or more. Camillus sh. is practically unfossiliferous.

Named for exposures at Camillus, Onondaga Co.

Campagrande formation. (In Trinity group.)

Lower Cretaceous (Comanche series): Western Texas.

G. B. Richardson, 1904 (Univ. Tex. Min. Surv. Bull. 9, p. 47). *Campagrande fm.*—Ls. cgl., 25 ft. thick, overlain by 350 ft. of gray ls., generally massive but locally containing nonpersistent thin-bedded ls. grading into sh. Basal fm. of Fredericksburg group. Underlies Cox fm. and uncon. overlies Hueco fm. in central part of Finlay Mtns.

C. L. Baker, 1927 (Univ. Tex. Bull. 2745), transferred this fm. to Trinity group.

Named for Campagrande Draw, in Finlay Mtns, El Paso Co.

†Campan group and †Campan series.

See *Campus fm.*

Campbell sand.

A subsurface sand, of Penn. age, in Garber pool, Garfield Co., central northern Okla., which lies at 1,700 ft. depth, the Belveal sand lying at 1,600 ft. and the Crews sand at 1,800 ft.

Campbell Creek limestone. (In Kanawha formation.)

Pennsylvanian: West Virginia.

I. C. White, 1885 (The Virginias, vol. 6, pp. 7-16). *Campbell Creek ls.*—Layer of impure ls. with cone-in-cone structure. Thickness 1 foot. Makes its first appearance along Campbell Creek [Kanawha? Co.]. May represent Johnstown cement bed of Pa., since according to my identification of the coals it occurs at the right geological horizon for that bed. Lies 50 ft. below Middle Kittanning (Cedar Grove) coal and 20 to 40 ft. above Lower Kittanning (Campbell Creek) coal. [Later studies showed that Cedar Grove coal is much older than Middle Kittanning coal, and that Campbell Creek ls. is a memb. of Kanawha fm., lying 0 to 20 ft. above Campbell Creek coal and 0 to 5 ft. below Lower Monitor ss. of W. Va. Geol. Surv.]

Campbell Creek beds.

Carboniferous: British Columbia.

G. M. Dawson, 1896 (Canada Geol. Surv., n. s., vol. 7, pp. 44B-45B, 129B).

Campbell Creek (Lower) sandstone. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

C. E. Krebs and D. D. Teets, Jr., 1916 (W. Va. Geol. Surv. Rept. Raleigh and western Mercer and Summers Counties, p. 327). *Lower Campbell Creek ss.*, 0 to 30 ft. thick, underlies Campbell Creek coal and overlies Lower Campbell Creek coal.

Campbell Mountain rhyolite.

Miocene: Southwestern Colorado (Creede district).

W. H. Emmons and E. S. Larsen, 1923 (U. S. G. S. Bull. 718). Overlying the Willow Creek rhyolite rather irregularly is a rhyolite flow breccia here named *Campbell Mtn rhyolite.* In most places no evidence was seen of more than one flow, but on East Willow Creek two flows of this type are separated by a few hundred ft. of Phoenix Park quartz latite. Thickness 0 to 1,000 ft. Upper contact of Campbell Mtn rhyolite is everywhere sharp, but some of overlying rocks so closely resemble it that separation was somewhat difficult. Is a fm. in Alboroto group of Potosi volcanic series. Named for Campbell Mtn.

Campbell Run sand.

Drillers' term; western Pa. and W. Va.; probably lies at horizon of Gordon Stray sand, of Catskill(?) age.

Campbell's Ledge black slate. (In Pottsville formation.)

Pennsylvanian: Northeastern Pennsylvania (Lackawanna County).

I. C. White, 1883 (2d Pa. Geol. Surv. Rept. G_7, pp. 37-42). *Campbell's Ledge black sl.*—Highly bituminous black sl., 0 to 10 ft. thick, with plants and insects. Included in Pottsville cgl., but it underlies the massive cgl. and rests on 0 to 3 ft. of hard gray or creamy-white ss., also included in Pottsville. At Campbell's Ledge, near Coxton, Lackawanna Co., it is 5 ft. thick.

D. White, 1900 (U. S. G. S. 20th Ann. Rept., pt. 2, p. 819). The large flora of the dark plant-bearing shales which lie within a few ft. of supposed Mauch Chunk in the very thin section (56± ft.) of Pottsville fm. at Campbell Ledge, near Pittston, cannot be older than Lykens No. 1 coal.

Campbellton formation.

Devonian: New Brunswick.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 207).

Camp Branch sandstone member (of Pottsville formation).

Pennsylvanian: Northern central Alabama (Warrior coal field).

C. Butts, 1910 (U. S. G. S. Birmingham folio, No. 175). *Camp Branch ss. memb.*—Gray ss., medium grained, generally thick bedded, about 40 ft. thick. Is a memb. of Pottsville fm., near its top. Underlies Cobb coal and lies 210 ft. above Pratt coal in Warrior coal field.

Named for exposures along S. bluff of Camp Branch, Birmingham dist.

Camp Colorado limestone member (of Pueblo formation).

Pennsylvanian: Central and central northern Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 387, 418). *Camp Colorado bed.*—Chiefly hard, rather brittle, bluish gray ls., rough weathering, and often much fractured. Contains many black or nearly black chert nodules. Thickness 10 to 25 ft. Memb. of Cisco div. Overlies bed No. 13 (reddish clay) and underlies Watt's Creek bed.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31, 40; Univ. Tex. Bull. 2132, pp. 172–182 and charts). *Camp Colorado ls.* is top memb. of Pueblo fm. in Colorado River and Brazos River Valleys. Remarkably uniform and persistent. Underlies Watt's Creek sh. memb. of Moran fm. and is separated from underlying Stockwether ls. by 65 to 98 ft. of sh., ss., and ls.

Camp Cove series.

Jurassic (?): British Columbia.

C. H. Crickmay, 1927 (Stanford Univ. Abstracts of Dissertations 1924–26, vol. 1, p. 132).

Camp Creek shale member (of Pueblo formation).

Pennsylvanian: Central Texas (Colorado River region).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 387, 416). *Camp Creek bed.*—Red and yellowish sandy clay, with some thin layers of ls. in places and a little ss. Thickness 40 to 50 ft. Memb. of Cisco div. Underlies Coon Mtn bed and overlies Saddle Creek bed.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31; Univ. Tex. Bull. 2132, p. 172 and charts). *Camp Creek sh. memb.*—Basal memb. of Pueblo fm. Underlies Stockwether ls., the Coon Mtn bed of Drake having proved to be largely Cret. sands overlapping several Penn. beds.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 103), treated Camp Creek sh. of Drake as basal memb. of Pueblo fm., underlying Coon Mtn ss. and overlying Saddle Creek sh.

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501, pp. 197+), defined Camp Creek sh. memb. of Pueblo fm. as including all beds beneath Stockwether ls. memb. and above Saddle Creek sh.

The present definition of U. S. Geol. Survey treats Camp Creek sh. memb. as basal memb. of Pueblo fm. It underlies Coon Mtn ss. memb. and overlies Saddle Creek sh. memb. of Harpersville fm.

Named for Camp Creek, Coleman Co.

Camp Creek group.

Pre-Cambrian (Belt series): Central western Montana (Mission Range).

C. D. Walcott, 1906 (Geol. Soc. Am. Bull., vol. 17, pp. 2–7, 9, 18). *Camp Creek* Basal fm. of Triassic in area mapped [see above], consisting of a coarse cgl., brownish wherever exposed, due mainly to preponderence of brown quartz and chert pebbles. Contains much fossilized wood, in some instances whose free trunks from 6 in. to 2 ft. diam. and 6 in. to 10 ft. long; also many bone fragments, especially from vertebræ of reptiles. Rests on Double Mtn group with slight angular uncon. Best exposed at Camp Springs, near center of E. line of ss. 395 ft.

Named for exposures on Camp Creek, Mission Range.

Camp Creek series.

Devonian: Mackenzie.

T. O. Bosworth, 1921 (Geol. Mag., vol. 58, p. 287).

Campito sandstone.

Lower Cambrian: Eastern California (Inyo Range).

E. Kirk, 1918 (U. S. G. S. P. P. 110). *Campito ss.*—Chiefly ss., which on fresh fracture is dense fine-grained grayish rock with conspicuous fine dark lines that indicate highly complex cross bedding. Weathers reddish brown to dark purplish red. Associated with this ss. are some bands of very dense lighter colored qtzitic ss. separated by thin layers of siliceous sl., which occur as partings in the dense ss. Upper third of fm. is somewhat more slaty and includes zones curiously speckled by ferric oxide. Remarkable cross bedding at several horizons. Rests uncon. on Deep Spring fm. and appears to grade into overlying closely related Silver Peak group, the upper limit of the Campito being placed at lowest horizon at which fissile calc. shales and fairly pure masses of ls. appear. Thickness of fm. 3,200 ft. Named for prominent exposures on Campito Mtn.

Campnelson limestone.

Lower Ordovician: Central Kentucky.

A. M. Miller, 1905 (Ky. Geol. Surv. Bull. 2, pp. 9, 12). *Campnelson substage.*—Massive compact ls., with conchoidal fracture, characterized by *Maclurita bigbyi;* 285 ft. thick. Lowest div. of Highbridge stage. Overlain by Oregon bed. [A. M. Miller (1925) gave thickness at Camp Nelson as 285 ft.]

Named for Camp Nelson, Jessamine Co.

†Campobello group.

Silurian: Southeastern Maine (Washington County).

N. S. Shaler, 1886 (Am. Jour. Sci., 3d, vol. 32, pp. 47–60). *Campobello series or group.*—A series of very compact and highly metamorphosed, nonfossiliferous schists, slates, and qtzites, considerably cut by dikes. Comprises a set of dark greenish and grayish siliceous and argill. rocks containing very little lime. Thickness at least 4,000 ft. Rocks appear to be destitute of fossils, though they are not so metamorphosed as necessarily to lose by this change all trace of fossils if they had once contained them. On Quoddy Head the Campobello series is highly metamorphosed. Probably rests on gneissoid and granitic rocks, with some mica schist, all of Laurentian age, and may represent the lower Camb. section. Above these Camb. layers, and without observed contacts with them but with scant place for any intermediate deposits, lie the beds of the Cobscook series, which undoubtedly are uncon. on the Campobello.

Appears to be same as Quoddy sh. (Sil.).

Named for development on Campobello Island, off SW. coast of New Brunswick, adjacent to SE. part of Washington Co., Maine.

Camp Springs conglomerate.

Triassic: Northwestern Texas (Coke County northward to Oklahoma line).

D. D. Christner, 1926 (Univ. Tex. Bull. 2607, pp. 16–17). *Camp Springs cgl.*—Basal fm. of Triassic in area mapped [see above], consisting of a coarse cgl., brownish wherever exposed, due mainly to preponderance of brown quartz and chert pebbles. Contains much fossilized wood, in some instances whole tree trunks from 6 in. to 2 ft. diam. and 6 in. to 10 ft. long; also many bone fragments, especially from vertebræ of reptiles. Rests on Double Mtn group with slight angular uncon. Best exposed at Camp Springs, near center of E. line of Scurry Co., Tex.

Camp Supply beds.

Lower Cretaceous: Western Oklahoma (Custer ? County).

R. T. Hill, 1895 (Am. Jour. Sci., 3d, vol. 50, p. 227). *Camp Supply beds.*—Fossiliferous beds near Camp Supply, G Co., Okla., which are undoubtedly a southern extension of Belvidere beds.

Campton sand.

A subsurface sand, of Dev. age, in eastern Ky.

Campus formation.

Pleistocene: Western California (San Francisco region).

A. C. Lawson and C. Palache, 1902 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 2, p. 398 and map). *Campan series.*—Interbedded fresh-water deposits and volcanic lavas and tuffs. Thickness 800 ft. Includes rhyolite tuff and other tuffs, aggl., cgls., andesites, basalt flows, clays, some ss. and ls., and the Pie Knob andesite. Uncon. overlies Berkeleyan series. Named because of its occurrence within limits of University Campus, Berkeley [on a hill behind the area now covered with buildings].

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). *Campus fm.*, originally named *Campan*, rests uncon. on Moraga and Siesta fms. of Berkeley group.

Camulos formation.

Pliocene (middle or upper): Southern California (Los Angeles and Ventura Counties).

C. [R.] Keyes, 1925 (Pan-Am. Geol. vol. 43, p. 316). [Name proposed for lower part of Arnold's Fernando fm., or probably for part of beds that Kew in 1921 named *Pico fm.*, which are now assigned to middle and upper Plio. Named for railway hamlet of Camulos, a few mi. directly W. of Saugus Junction, Santa Clara Valley.]

†Canaan limestone.

†Canaan dolomite.

Names applied in early repts to Stockbridge ls. of Canaan, NW. Conn. See J. D. Dana, 1872 (Am. Jour. Sci., 3d, vol. 4, p. 370) and 1874 (Am. Ass. Adv. Sci. Proc.). In latter publication Dana called it "Stockbridge or Canaan ls." W. H. Hobbs, 1893 (Jour. Geol., vol. 1, pp. 717–736, 780–802), called the fm. "Canaan dol."

†Canaan formation.

Mississippian: West Virginia and adjacent parts of Maryland.

N. H. Darton and J. A. Taff, 1896 (U. S. G. S. Piedmont folio, No. 28). *Canaan fm.*—Consists of very red clay sh. in lower part; red sandy sh. interstratified with greenish brown to brown fine ss. in upper part. Thickness 570 to 700 ft. Underlies Blackwater fm. and overlies Greenbrier ls. [In Buckhannon quad. it is overlain by Pickens ss.].

Same as Mauch Chunk sh.

Named for exposures in Canaan Mtn, Tucker and Grant Counties, W. Va.

Canaan Mountain fire clay.

Pennsylvanian: Northeastern West Virginia.

D. B. Reger, 1923 (W. Va. Geol. Surv. Rept. Tucker Co., pp. 190, 191, 444). *Canaan Mtn fire clay.*—Flinty fire clay, 5 ft. thick, occurring in midst of Lower Kittanning coal on top of Canaan Mtn, Tucker Co.

Canada Hill granite.

Pre-Cambrian: West Point quadrangle, southeastern New York.

C. P. Berkey and Marion Rice, 1921 (N. Y. State Mus. Bull. 225, 226, map and passim). *Canada Hill granite.*—Medium gray, medium-grained rock varying from faintly to very perceptibly streaked; composed of white and gray feldspar, gray quartz, small crudely oriented biotite crystals, and numerous small, rounded, violet-red garnets. Also includes a pegmatitic facies, which is coarser grained, grading into true pegmatite. Penetrates Grenville series. Type loc., Kings quarry, S. of Garrison. Canada Hill, Putnam Co., is in midst of the granite area.

E. B. Knopf and A. I. Jonas, 1929 (U. S. G. S. Bull. 799, table opp. p. 68), classified this granite as of post-Glenarm age.

Canadaway group.

Upper Devonian: Southwestern New York and northwestern Pennsylvania.

G. H. Chadwick, 1933 (Geol. Soc. Am., Prel. list of titles and abstracts of papers to be offered at 46th Ann. Meeting, Chicago, Ill., Dec. 28–30, 1933, pp. 19, 82, 83, 84). The so-called "Chemung" strata on Genesee River carry a distinct and later faunal assemblage, herewith named *Canadaway fauna (and group)*, which succeeds the true Chemung biota of Tioga Co., Pa. The Canadaway includes from Dunkirk black sh. to Cuba ss. Assigned to Chautauquan.

G. H. Chadwick, Feb. 28, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, p. 351). All brachiopodous ("Chemung") fms. along Genesee River were deposited after close of true Chemung and while "red beds" were making in Chemung area. To these pseudo-Chemung later beds from base of the Dunkirk to base of Cuba ss., writer proposes to apply the substitute and distinctive name *Canadaway group*, and to those from base of Cuba ss. to base of Wolf Creek (or Panama) cgl., in which the fauna has been modified by loss of *Delthyris mesacostalis* and accession of *Camarotoechia (?) duplicata*, the name *Conneaut group*. The respective type sections are along Canadaway Creek, in western N. Y. [Chautauqua Co., near Dunkirk], and Conneaut Creek crossing Pa.-Ohio line. Both are, of necessity, chosen where the fms. are thinner and are, therefore, passing over into the "Naples" (usually called "Portage") facies. Conneaut and Canadaway groups belong to the Chautauquan. [On p. 323 he stated:] Canadaway group includes, on Canadaway Creek, in descending order, Northeast sh., Shumla ss., Westfield sh., Laona ss., Gowanda beds, and Dunkirk black sh.; on Genesee River it includes Machias beds (=Northeast sh.), Rushford sss. (=Shumla ss., Westfield sh., and Laona ss.), Chemung facies, locally Caneadea sh.; and Canaseraga ss. (=Dunkirk sh.). Fall Creek cgl. of Tioga Co., Pa., is included in Dunkirk sh.

G. H. Chadwick, Feb., 1935 (Am. Jour. Sci., 5th, vol. 29, p. 136). Latest count shows 250 true Chemung sp. (assigned to Senecan) fail to cross line into overlying Canadaway group (Chautauquan), as against only 90, mostly long range, forms that do; and in their place 135 new sp. with a dozen new genera appearing for the first time above this line, which corresponds westward with top of the old (type) Portage.

G. H. Chadwick, Nov. 1935 (Am. Mid. Nat., vol. 16, No. 6, pp. 859, 862). The fossiliferous strata formerly called "Chemung" on Genesee River are now known to differ in presence of 130 sp. not found in true Chemung strata below, and in absence of 240 sp. (including many characteristic forms) of typical Chemung fauna, while there are less than 100 sp. in common. These beds, with the "*Athyris angelica* fauna" constitute *Canadaway group*, which traced eastward goes wholly above type Chemung. On Lake Erie the Canadaway is readily subdivided into (descending): Northeast sh. (I. C. White's "Portage"); Shumla ss.; Westfield sh.; Laona ss.; Gowanda (formerly Portland beds, preoccupied); and Dunkirk black sh.

†Canadian series.

†Canadian period (or system).

As originally defined by J. D. Dana (Am. Jour. Sci., 3d, vol. 8, p. 214, 1874, and Man. Geol., 2d ed., pp. 142, 163, 182, 1875) the unit included Chazy and Beekmantown. As now used by some geologists it excludes Chazy and is synonymous with Beekmantown. Named from development in Canada. (See U. S. G. S. Bull. 769, pp. 87–88, for original definition.)

G. H. Ashley, 1923 (Eng. and Min. Jour.-Press, vol. 115, pp. 1106–1108), proposed that *Canadian system* be used to include rocks of all ages occupying time interval from top of Beekmantown to base of Little Falls dol. of N. Y.

Canadian system of E. O. Ulrich corresponds to Beekmantown group of U. S. Geol. Survey and other geologists.

The present definition of N. Y. State Surv. includes in their *Canadian system* not only Beekmantown group but underlying Tribes Hill ls. and Schaghticoke sh. (See W. Goldring, N. Y. State Mus. Hdb. 10, 1931.)

Canajoharie shale.

Middle Ordovician: Eastern New York (Mohawk and Hudson Valleys).

J. M. Clarke, April 1911 (N. Y. State Mus. Bull. 149, pp. 10–12). *Canajoharie sh.*—Contains undoubted upper Trenton fauna, and is therefore separated from Utica sh., in which it was formerly included. Much of the [so-called Utica] sh. along the Hudson and in Albany and Saratoga Counties belongs to this fm., which rapidly thins out westward and does not reach meridian of Utica. Underlies Utica sh.

E. O. Ulrich, August 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27), divided the Trenton of east-central N. Y. as follows (descending): Hiatus representing upper Trenton; *Canajoharie sh.;* Dolgeville sh.; Snake Hill sh.; and basal Trenton. On p. 720 of same vol. R. Ruedemann stated that *Canajoharie sh.* is of upper Trenton age, that it thins out rapidly westward, and is absent at Utica.

W. J. Miller, 1911 (N. Y. State Mus. Bull. 153, pp. 8–38), stated that *Canajoharie black sh.* of Fulton and Saratoga Counties consists of an undet. thickness of dark-gray to black, fine-grained, thin and straight-bedded shales, usually calc., especially toward base, lithologically indistinguishable from overlying Utica black sh., but fauna very different and of uppermost Trenton age. Rests on Trenton ls. Formerly included in Utica sh.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 40). Westward from Mohawk Valley the *Canajoharie sh.* (of Trenton age but formerly included in Utica sh.) passes into middle and lower Trenton ls., while on E., at Hoffmans, it is cut off by a fault, but reappears N. of Schenectady and in Hudson River Valley, where it is overlain by Schenectady beds.

In N. Y. State Mus. Bull. 162, 1912, R. Ruedemann estimated thickness of Canajoharie sh. of lower Mohawk Valley at 1,200 ft., and stated that it is of lower and possibly middle Trenton age, and is overlain by Schenectady fm.

H. P. Cushing and R. Ruedemann, 1914 (N. Y. State Mus. Bull. 169). *Canajoharie sh.* of Saratoga Springs and vicinity is more than 700 ft. thick. Consists of soft, black, carbonaceous, more or less calc. argill. shales. Of lower Trenton age. Underlies Schenectady fm. (middle and upper Trenton fauna) and overlies Glens Falls ls. (basal Trenton). Essentially contemp. with Snake Hill sh., but formed in another basin, and has been brought in contact with Snake Hill sh. through later diastrophic movements.

W. J. Miller, 1916 (N. Y. State Mus. Bull. 182), gave thickness of *Canajoharie sh.* in Lake Pleasant quad., Hamilton Co., as 15 to 20 ft.; R. Ruedemann (N. Y. State Mus. Bull. 227, 228, pp. 108–116, 1921) gave thickness in Champlain region, at Panton, Vt., as 400 to 1,000 ft., all of Trenton age, but formerly considered as Utica. It there underlies Stony Point sh. and overlies Trenton ls. On N. Y. side of Champlain Basin it is replaced by Cumberland Head sh.

R. Ruedemann, 1929 (Geol. Soc. Am. Bull., vol. 40, p. 414), showed *Canajoharie sh.* as of Trenton age, as underlying Schenectady sh., and as overlying Glens Falls ls.

Named for outcrop at Canajoharie, Montgomery Co.

Canal limestone.

Pennsylvanian: Northeastern Pennsylvania (Luzerne County).

C. A. Ashburner, 1886 (2d Pa. Geol. Surv. Ann. Rept. 1885, pp. 445+). *Canal ls.*—Siliceous nonfossiliferous ls., much softer than overlying Mill Creek ls., from which it is separated by 25 to 30 ft. of ss. Thickness about 2 ft. Outcrops on SE. bank of the canal, 800 ft. SW. of mouth of Mill Creek.

†Canandaigua shale.

Middle Devonian: Western and central New York.

Same as Ludlowville sh. See explanation under *Centerfield ls.*

Cananea granite.

Age(?): Mexico.

S. F. Emmons, 1910 (Econ. Geol., vol. 5, p. 319).

Canary lime.

Carboniferous: Cape Breton Island, Nova Scotia.

P. D. Trask, 1929 (Nova Scotia Rept. on Mines 1928, p. 281).

†Canaseraga sandstone.

Upper Devonian: Western New York (Allegany County).

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69). [Shown (in table) as underlying Gowanda, overlying Wiscoy sh., as=Dunkirk sh., and of basal Chemung age.]

G. H. Chadwick, 1924 (N. Y. State Mus. Bull. 251, p. 150). East of the Genesee [River], above Dalton and Swains, the increase in sand is so rapid that in Slader Creek near Canaseraga only two thin courses of black sh. remain in lower part of 150 ft. of heavy aren. beds with full Chemung fauna that we propose to call *Canaseraga ss.* Massive character of the Canaseraga has led to its confusion with the Nunda at some points to E., under name *Highpoint*. It is believed that the Dunkirk-Canaseraga corresponds in horizon with *Dalmanella danbyi* zone at base of Cayuta sh. in Ithaca region.

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60, No. 3, p. 200), showed *Canaseraga* ss.=Dunkirk and as overlain by Caneadea (=Gowanda). On p. 278 he said: Shortly after crossing the Genesee the Dunkirk becomes so predominantly sandy that in its new facies I have temporarily called it *Canaseraga ss.*, meaning the whole mass.

The U. S. Geol. Survey has discarded *Canaseraga ss.*, upon recommendation of G. H. Chadwick and W. H. Bradley, who now call the beds *Dunkirk ss.*, because they are a ss. development of Dunkirk sh.

Cañazas formation.

Age(?): Panama.

O. H. Hershey, 1901 (Calif. Univ. Dept. Geol. Bull., vol. 2, p. 247).

Canby latite.

Tertiary (Olig.? or Mio.?): Southwestern Colorado (Silverton quadrangle).

W. Cross and E. Howe, 1905 (U. S. G. S. Silverton folio, No. 120). *Canby type* (also *Canby latite*).—In SE. part of Silverton quad. the Niagara Gulch latite (of Burns latite complex) gives way to a rock of similar composition but somewhat different texture, which is regarded as representing practically the same magma as Niagara Gulch type. No distinction has been made in mapping, as the differences seem trivial in comparison with the similarities of the two rocks. The Canby latite occurs in several flows of varying textures. Hornblende is prominent and augite is often of equal importance; this distinguishes it from Niagara Gulch latite. Named for prominence in Canby Mtn, Silverton quad.

Is a facies of Burns latite, of Silverton volcanic series.

Canby moraine.

Pleistocene (Wisconsin stage): Southwestern Minnesota.

F. Leverett, 1932 (U. S. G. S. P. P. 161, pp. 93–94). Lies btw. Gary moraine and Marshall moraine. Village of Canby, Yellow Medicine Co., stands on this moraine.

Candelaria formation.

Lower Triassic: Southwestern Nevada (Tonopah and Hawthorne quadrangles).

S. W. Müller and H. G. Ferguson, 1936 (Geol. Soc. Am. Bull., vol. 47, pp. 241–252). *Candelaria fm.*—Essentially shales, sandy shales, and sss, some of tuffaceous aspect, and occasional thin layers and lenticular bodies of ls. Marine invertebrates in belt 75 ft. thick and 150 to 225 ft. above base. Fauna is Lower Triassic, but appears to be older than any of Lower Triassic marine faunas heretofore recorded from N. Am. Thickness 3,000+ ft. Overlain, probably uncon., by Excelsior fm. (Middle Triassic). Rests, with marked erosion uncon., on Perm. strata, and, where these have been eroded, on folded and bevelled Ord. strata. No basal cgl. is present near Candelaria, but a few mi. to E., where Perm. is missing, the basal part of fm. consists of 500± ft. of basal cgl. derived from underlying Ord. chert. Named for mining camp of Candelaria, in low hills S. of Mina. Type loc. is about 2 mi. SE. of Candelaria. This name was first used by J. A. Burgess in an unpublished rept on Candelaria min. dist.

Caneadea shale.

Upper Devonian: Southwestern New York (Olean to Genesee River).

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60, No. 3, p. 200), in a section of rocks from Olean to Genesee River, placed *Caneadea* below Rushford sss., above Dunkirk sh. (=Canaseraga) and opposite Gowanda. On p. 203 he stated: If Gowanda beds of western N. Y. should prove not strictly coterminous with those we have so identified on Genesee River, then to the beds btw. the Dunkirk and the Rushford sss. on this meridian the term *Caneadea sh.* will naturally apply, for it is on Caneadea Creek, below the new power dam (near its mouth), that they have their finest section, just under the type exposures of the Rushford, but, unfortunately, the bottom (i. e., the Dunkirk top) is not reached.

Cane River formation. (In Claiborne group.)

Eocene (middle): Western Louisiana and northeastern and eastern Texas.

W. C. Spooner, 1926 (A. A. P. G. Bull., vol. 10, No. 1, p. 7; No. 3, pp. 220, 224, 227, 235–236). *Cane River beds.*—Name suggested by H. V. Howe, for basal part of St. Maurice fm. as originally defined and heretofore used. In the Cane River are included the 75 to 150 ft. of beds above Wilcox fm. and below the massive Sparta sand, which outcrop in narrow belt trending NE. across southern Sabine and Natchitoches Parishes. Basal memb. consists of glauconitic sand and sandy clay, but in some places marine tuff is present at base. Glauconitic clays predominate in S. part of outcrop, but N. from Bienville Parish they become sandier, until in northern Bossier Parish they are represented entirely by sands, in part glauconitic. The Cane River beds in records of wells drilled E. and SE. of the outcrop are made up chiefly of glauconitic clays with subordinate beds of sand. The fauna was identified by Vaughan in 1900 as corresponding to that of Lisbon beds. Named for excellent exposures on Cane River at Natchitoches, La.

A. C. Ellisor, 1929 (A. A. P. G. Bull., vol. 13, pp. 1339–1346). *Cane River memb. of Claiborne fm.*—As restricted in this paper is a glauconitic, sandy marl and a glauconitic, clayey sand, characterized by *Ostrea sellæformis* var. *lisbonensis* and *Orthophragmina advena.* Type loc. is at Baden Hill on Cane River, ½ mi. N. of Natchitoches, La. Occurs stratigraphically above Wilcox fm. and below Reklaw memb. in La. Is basal memb. of Spooner's Cane River fm., which extended to top of Weches memb. of this rept.

E. A. Wendlandt and G. M. Knebel, 1929 (A. A. P. G. Bull., vol. 13, p. 1355). Near E. edge of Nacogdoches Co., immediately W. of Attoyac Bayou, the Queen City memb. pinches out and the Reklaw and Weches members combine to form *Cane River fm.*

In NE. Tex. *Cane River* is applied by A. C. Ellisor to beds that are said to underlie Reklaw memb. and to compose basal part of Mount Selman fm. In western La. (type loc.) the Cane River has been treated as a marine memb. of St. Maurice fm. (now discarded), including all beds btw. Sparta sand above and Wilcox below, thus including equivalents of Weches, Queen City, and Reklaw of Ellisor. (See H. K. Shearer, A. A. P. G. Bull., vol. 14, No. 4, pp. 433–450, 1930; C. L. Moody, A. A. P. G. Bull., vol. 15, No. 5, 1931; and H. V. Howe, A. A. P. G. Bull., vol. 17, No. 6, pp. 613+, 1933.) The original definition is that in current use by U. S. Geol. Survey.

Caney shale.

Mississippian: Central southern and southeastern Oklahoma.

J. A. Taff, 1901 (U. S. G. S. Coalgate folio, No. 74). *Caney sh.*—Occurs in two small areas in this quad., one in SW. corner and the other in SE. corner. At both places about 800 ft. of rock is exposed, approx. upper half of fm. This part is blue clay sh., with thin beds of clay, ironstone, lenticular concretions, and a few blue ls. septaria. In lower part, in adjoining Atoka quad., the blue sh. grades into black, friable, bituminous sh. with dark-blue ls. segregations. The Caney sh. throughout is laminated, fissile, and friable, and consequently rarely exposed. Underlies Wapanucka ls.

See 1909 and 1924 entries under *Jackfork ss.*

C. N. Gould, 1925 (Okla. Geol. Surv. Bull. 35, p. 24). There has been considerable controversy regarding age of Caney sh., but present consensus of opinion seems to be that upper part of fm. is Penn. and lower part is Miss.

H. D. Miser and C. W. Honess, 1927 (Okla. Geol. Surv. Bull. 44, pp. 11–12). (See 1927 entry under *Jackfork ss.*)

H. D. Miser, 1927 (Okla. Geol. Surv. Bull. 44, pp. 22–23, footnote dated Oct. 5, 1927). Since writing of this paper E. O. Ulrich presented at Tulsa, Okla., in March 1927, a paper that was based on extensive field investigations by him in 1908 and previous years and also on recent office studies of fossils. In his paper he expresses opinion that fauna in the black sh. (his Johns Valley sh.) on top of Jackfork ss. is not in place but has been transported from exposures of Mississippian Caney sh., and that the fauna is now really embedded in a black sh. of Penn. age. After presentation of Mr. Ulrich's paper I spent 3 months making a special field study of age relations of Carbf. rocks in Ouachita Mtns, Okla. Among the things I did was to examine carefully the Caney sh. at its type loc., which is now known as Johns Valley. This locality is also type loc. of Johns Valley sh. of Mr. Ulrich. The sh. in Johns Valley lies on top of Jackfork ss. in a broad, long synclinal basin. In lower 50 to 100 ft. of the sh. there are numerous ice-borne boulders and blocks of many kinds of rock, including ls., flint, and ss. The ls. masses, which are more numerous than the other kinds, range in size from small particles an inch or less in diam. to blocks measuring 30 ft. across, though I observed one block measuring 200 ft. in length, another measuring 110 by 195 ft., and a third about 50 by 369 ft. Fossils obtained from many of the masses have been studied by Mr. Ulrich, and his conclusions concerning them are that the represented faunas range in age from *that of Arbuckle ls. (Lower Ord.) to that of Sycamore ls. (Kinderhook).* The boulder bed just mentioned is apparently overlain by black, platy, hard sh. perhaps several hundred ft. thick. In several fresh clean exposures of the sh. there are hundreds of small phosphate nodules—most of them nearly spherical, like toy marbles—and many concretionary masses of ls. The ls. concretions all lie parallel with bedding of the sh., and the phosphate nodules are rather uniformly disseminated through portions of the sh. The nodules and the ls. concretions contain fossils, all of which belong to fauna of Mississippian Caney sh. Every feature of the sh., as revealed in the exposures, can be matched with exposures of Caney sh. in the areas where it rests upon Woodford chert. The lithology of the shales in the two different strat. positions—one on the Jackfork and the other on the Woodford—is the same. The character and arrangement of the ls. concretions are the same, and also the character and distribution of the phosphate nodules are the same. To me, as well as to several other geologists who accompanied me to Johns Valley in June 1927, the conclusion which we reached while looking at the field relations was obvious that the fauna represented in the phosphate nodules and ls. concretions lived, died, and was buried where it is now found. If the fauna had been transported by floating ice, as is believed by Mr. Ulrich, there would surely have been some admixing of Caney fossils with those of pre-Caney age, and also there would surely have been an admixture of rocks of pre-Caney age. The excellent exposures of the Caney that were examined by me and by my geologist companions do not reveal a single pre-Caney fossil nor a single specimen of rock of pre-Caney age.

E. O. Ulrich, Nov. 1927 (Okla. Geol. Surv. Bull. 45, pp. 6, 21–23). I would restrict *Caney sh.* to Miss. part of beds heretofore included under that name, or to the non-boulder-bearing black sh. which contains a Miss. (Meramec) fauna and is confined to N. and W. of Ouachita area. The black sh. of Penn. age in Ouachita geosyncline, carrying fossiliferous erratic boulders in lower part, which had formerly been included in Caney sh., I have named *Johns Valley sh.* It is younger than Wapanucka ls. [On p. 24 *of book cited* Ulrich *stated*: The Wapanucka should include the shaly lower beds with essentially same early Penn. fauna that Morgan (1924) describes in his rept on Stonewall quad. as "Upper Caney." On p. 25 he stated: There is a break btw. the sh. with the Middle Miss. Caney fauna and the "Upper Caney" with the early Penn. fauna, and this hiatus is very great and= fully 5,000 ft. of strata in SW. Va. Also that the Caney as here restricted rests on the Sycamore. On p. 30 he restricted Caney sh. to Arbuckle uplift, defined it as of middle Meramec age, and as uncon. overlain by Wapanucka ls. and uncon. underlain by Sycamore ls.]

H. D. Miser, 1934 (A. A. P. G. Bull., vol. 18, No. 8). ***Caney sh.*** of some earlier U. S. G. S. repts (Tishomingo and Atoka folios) included (at top) Springer sh. (Penn.), which is overlain by Wapanucka ls. and is=Jackfork ss., Stanley sh., and Hot Springs ss. of western Ark. and adjacent areas in Okla. The name *Caney sh.* is here restricted to the Miss. sh. (of Chester and Meramec age) overlying the Woodford chert (Dev. ?) and underlying Springer sh. This Miss. sh. is not exposed in region that has been cited as type loc. of Caney sh., where all Carbf. rocks beneath Atoka fm. are of Penn. age. [Also further discusses the Johns Valley sh. (Penn.) and the erratic masses of Miss. Caney sh. contained in it.]

Named for Johns Valley, formerly called Caney Basin or Cove, in upper Cane Creek Valley, 6 mi. N. of Eubanks, Pushmataha Co., Okla. There are 6 or 7 Caney Creeks in this part of Okla., and this Caney Creek is now known as Johns Creek, but the Miss. sh. to which the name *Caney sh.* is now applied is not exposed in this region.

Caney sand.

A subsurface sand, of Upper Ord. age, in Ky., said to be same as Upper Sunnybrook sand. Named for Caney Creek, Morgan Co.

Caneyville limestone. (In Wabaunsee group.)

Pennsylvanian: Eastern Kansas, northeastern Oklahoma, and southeastern Nebraska.

R. C. Moore, May 1, 1935 (Kans. Geol. Surv. Bull. 20, table opp. p. 14), showed *Caneyville ls.* underlying Pony Creek sh. and overlying French Creek sh. Not defined.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 49, 143, 241). *Caneyville ls.* is here proposed to include beds from base of ls. previously designated *Nebraska City* up to top of ls. called *Grayhorse.* Field studies have shown Nebraska City ls. is a molluscan bed that represents No. 3 phase of a cyclothem for which no fusulinid-bearing, or No. 5 phase, was known until recently, when outcrops in Chautauqua Co., Kans., of this expected phase were discovered. Above this fusulinid-bearing ls. in Chautauqua Co. is a fragmental, algal and molluscan ls., that clearly represents the No. 7 phase of this cyclothem. It is traced S. into Grayhorse ls. of Osage Co., Okla., and it is thus determined that Nebraska City and Grayhorse lss. are parts of a single cyclothem which includes the unnamed fusulinid-bearing ls. btw. them in southern Kans. Neither *Nebraska City* nor *Grayhorse* is available as a name for the 3 lss. and shales btw. them. Hence *Caneyville* is introduced. No name is proposed for the fusulinid-bearing ls. memb. of the Caneyville, and it is thought that none is needed. The terms *Nebraska City* and *Grayhorse* happen to have been introduced and it is perhaps not necessary to kill them. The *Nebraska City memb.* of Caneyville ls. is bluish or greenish gray rather soft sandy ls. that weathers light yellowish brown, and is 1 to 5 ft. thick, averaging 1½± ft. It is basal memb. of Caneyville ls. The Grayhorse memb. of Caneyville ls. is very different in appearance from the other 2 ls. members. It is medium to coarse-grained; appears fragmental or coquinoid; is rather strongly ferruginous; and thickness averages 1 ft. It lies 5 to 15 ft. above the fusulinid-bearing lss. of the Caneyville ls. Total thickness of Caneyville ls. is 15 to 20 ft. It is named for Caneyville Twp. Chautauqua Co., Kans. Underlies Pony Creek sh. and overlies French Creek sh. Extends from northern Okla. across Kans. to southern Nebr.

Caneyville shale.

Pennsylvanian: Southeastern Nebraska and northeastern Kansas.

G. E. Condra, late in 1935 (Nebr. Geol. Surv. Paper No. 8, p. 9). *Caneyville sh.*, 17 ft. thick, underlies Greyhorse ls. and overlies Nebraska City ls., all included in Pony Creek sh. fm. of Wabaunsee group. Top part of Caneyville is gray and shaly; middle and lower parts shaly or sandy, with plant leaves. [Derivation of name not stated.]

E. C. Reed (Asst. State Geol. Nebr.), 1936 (letter dated Oct. 16). Type loc. of Caneyville sh. is sec. 11, T. 32 S., R. 8 E., Caneyville Twp, Chautauqua Co., Kans.

Cannelton limestone. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

I. C. White, 1885 (The Virginias, vol. 6, pp. 8, 15). *Cannelton ls.* (also *Cannelton cement*).—Frequently exhibits cone-in-cone structure. Is 2 to 2½ ft. thick. Lies 75 ft. below Lower Kittanning [not Lower Kittanning] coal. Once burned for cement at Cannelton, Kanawha Co., by Mr. Stockton, and hence is often called "*Stockton*" *ls.* No fossils found, but is correlated with Ferriferous [Vanport] ls. of Pa. [This correlation has been abandoned in all later repts of W. Va. Geol. Survey.]

I. C. White, 1903 (W. Va. Geol. Surv. vol. 2, pp. 511, 586). *Cannelton* (*Stockton*) *ls.*—The ls. at Cannelton, which Mr. Stockton once burned for cement, is often termed *Stockton cement bed.* It is usually quite siliceous, frequently exhibits cone-in-cone structure, and has no fossils so far as writer knows. Its usual place is 75 to 100 ft. below Campbells Creek coal and 45 to 50 ft. above Eagle coal. If Eagle coal is Clarion bed of Allegheny series then Cannelton ls. would correspond to Ferriferous ls. of western Pa. [According to all later repts of W. Va. Geol. Survey the Eagle coal is much older than Clarion coal and belongs in Kanawha fm., a considerable distance below Campbells Creek coal. See W. Va. chart I. In Logan-Mingo Co. Rept., 1914, the thickness of Cannelton ls. was given as 0 to 4 ft.]

Cannelton sandstone. (In Pottsville group.)

Pennsylvanian: Southwestern Indiana.

Name applied to a massive bed of lemon yellow to light or dark gray ss. quarried at Cannelton, Perry Co. Belongs to Mansfield ss. (See T. C. Hopkins, Ind. Dept. Geol. and Nat Res. 20th Ann. Rept., 1896, p. 314.)

Cannelton shale. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, pp. 151–152, 170+). *Cannelton (Stockton) sh.*—Sandy black sh., 15 to 34 ft. thick, containing marine fossils. Underlies Cannelton (Stockton) ls. and rests on 2 ft. of black sl. containing fossil plants, or, where that is absent, on Matewan coal.

Cannes de Roche formation.

Pennsylvanian: Quebec and New Brunswick.

F. J. Alcock, 1935 (Canada Dept. Mines Bur. Econ. Geol., Mem. 183, p. 93).

Cannon limestone.

Middle Ordovician (Trenton): Central and eastern Tennessee and southwestern Virginia.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pp. 417, 418, 429, pl. 27). *Cannon ls.*—Several hundred ft. of ls. of Trenton age on E. flank of Nashville dome, covering time interval of Bigby, Flanagan, and Perryville lss. and Catheys fm. Thins rapidly to W., and finally wedges out in vicinity of Nashville. Overlies Hermitage fm. and is older than Eden group.

W. A. Nelson, 1924 (A. A. P. G. Bull., vol. 8, No. 4, pp. 455–457). Exact relationship of *Cannon ls.* to Trenton group was worked out during summer of 1922 by R. S. Bassler and E. O. Ulrich. The Cannon is composed of layers of dove and gray ls., both porous and tight. Well exposed just SW. of Kettle Creek pool, in Cannon Co., Tenn., where it is 250 ft. thick, but at Nashville it is absent or only 5 to 25 ft. thick.

E. O. Ulrich, 1924 (Tenn. Dept. Ed., Div. Geol., Bull. 28, p. 34), and C. Butts, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14, chart opp. p. 80), show *Cannon ls.* of Tenn. as underlying Catheys ls., overlying Bigby ls., and as 50 to 300 ft. thick. This is present accepted definition. They extend name into SW. Va., and consider the fm. to be of Trenton age.

Cannonball marine member (of Lance formation).

Upper Cretaceous: Southwestern North Dakota and northwestern South Dakota.

E. R. Lloyd, 1914 (U. S. G. S. Bull. 541, pp. 248, 249). The *Cannonball marine memb.* comprises upper 250 or 300 ft. of Lance fm. It is typically exposed in bluffs of Cannonball River, in Twps 132 and 133 N., R. 8 W. [Morton Co., N. Dak.], where it consists of 144½ ft. of strata, as follows (descending): (1) Calc. ss., 6 inches; (2) gray, partly consolidated ss. containing numerous layers cemented with iron, 10½ ft.; (3) yellow consolidated ss., 5 ft.; (4) hard red ss., 6 inches; (5) dark-gray sh. with "cannonball" concretions, 25 ft.; (6) very dark-gray sh., very sandy, with a layer of marine shells 20 ft. from base and with "cannonball" concretions, 103 ft.; base concealed. Top of above section lies 50± ft. below top of memb. Similar sections are exposed at other places along Cannonball River and in bluffs of Cedar Creek and Heart River. Several collections of marine invertebrates have been identified by T. W. Stanton as belonging to a modified Fox Hills fauna. Underlies Fort Union fm. and rests on 400 to 450 ft. of somber-colored sh., yellow ss., and thin lignite beds composing lower part of Lance fm.

E. R. Lloyd and C. J. Hares, 1915 (Jour. Geol., vol. 23, pp. 523–547). In a large region W. of Missouri River in N. Dak. and S. Dak. the Lance fm. consists of 2 distinct parts, a lower nonmarine part containing a flora very similar to, if not identical with, that of the Fort Union, and an upper marine memb. containing a fauna closely resembling, but not identical with, that of Fox Hills ss. This upper part, on account of its peculiar fauna, has been mapped separately and named *Cannonball marine memb. of Lance fm.* Farther W. nonmarine beds bearing lignite and occupying a similar strat. position have been named *Ludlow lignitic memb. of the Lance.* The Cannonball marine memb. has been mapped from Mandan to a point 4 mi. W. of Haley, N. Dak., a total distance of about 130 mi. The presence of brackish-water fossils, *Ostrea glabra,* near Yule on Little Missouri River in Billings Co., N. Dak., shows that the sea probably extended some distance farther to W. than its sediments have been mapped. The extent of this memb. E. of Missouri River is unknown. Cannonball memb. becomes gradually thinner to W., and sea in which it was deposited perhaps did not extend as far W. as Mont. line. The oyster beds near Yule, Billings Co., may represent western limit of Cannonball sea. This sea presumably advanced into western N. and S. Dak. from E. or NE., and by inference the Cannonball memb. continued with undiminished or with increased thickness to N. and NE., but region is too deeply drift covered to prove this. It is contemp. with Ludlow lignitic memb. and overlies 400 to 525 ft. of somber-colored sh., yellow ss., and thin lignite beds composing the lower (nonmarine) memb. of the Lance. It consists chiefly of dark sandy sh. or shaly ss. with subordinate amount of dark-yellow and gray ss. and some thin lss. All the strata are lenticular and individual beds can be followed for only short distances. [Gives detailed section in some of which beds belonging to Cannonball marine memb. are shown as overlying Ludlow lignitic memb. and in others as grading laterally into the Ludlow.] A peculiar feature of both Fox Hills ss. and Cannonball memb. of Lance is abundance of round concretions commonly known as "cannonballs." They are formed by cementation of the sandy sh. by deposition of calcium carbonate. No definite line could be drawn btw. Cannonball marine memb. and lower part of the Lance, it being impossible to tell where nonmarine beds stop and marine beds begin. [Lower part of Lance later named *Hell Creek memb.*]

See U. S. G. S. Bull. 627, 1916, by D. E. Winchester, C. J. Hares, E. R. Lloyd, and E. M. Parks, and U. S. G. S. P. P. 128A, 1920, by T. W. Stanton. The U. S. Geol. Survey now classifies the Cannonball memb. and the demonstrably equiv. part of Ludlow lignitic memb. as Upper Cret.

See also *Torrington memb. of Lance fm.*

Cannonballian series.

A term employed by C. [R.] Keyes instead of *Cannonball marine memb. of Lance fm.*

Cannon Corners moraine.

Pleistocene (Wisconsin stage): Northeastern New York. Named for Cannon Corners, Clinton Co. See Jour. Geol., vol. 32, pp. 645, 665, 1924.

Cañon rhyolite.

Age (?): Nevada.

J. C. Merriam, 1910 (Calif. Univ. Dept. Geol. Bull., vol. 6, pp. 29, 30, 31).

Canter limestone.

Mississippian: Southern Ohio (Jackson County).

E. B. Andrews, 1871 (Ohio Geol. Surv. Rept. Prog. 1870, pp. 158, 163). [Mentioned occurrence of Maxville ls. near Enoch Canter's (p. 158), and mentioned ore found on *Canter ls.* (*Maxville or lower Carboniferous*) in Hamilton Twp, Jackson Co.]

Cantera.

Cretaceous: Mexico.

J. P. Kimball, 1869 (Am. Jour. Sci., 2d, vol. 48, pp. 379–388).

Canterbury granite gneiss.

Late Carboniferous or post-Carboniferous (?): Eastern Connecticut and southern Massachusetts.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 115, 136, 142, and map). *Canterbury granite gneiss.*—Essentially a muscovite-biotite gneiss, varying from a rock of fine and even grain to one of porphyritic texture with feldspar crystals a quarter of an inch long. Extends for 15 mi. through Pomfret, Brooklyn, Hampton, and Canterbury, and smaller detached areas occur in neighboring towns. Is intrusive.

Canton shale member. (In Carbondale formation.)

Pennsylvanian: Central western Illinois (Fulton County).

T. E. Savage, 1921 (Ill. Geol. Surv. Extr. from Bull. 38). Overlying the calc. sh. above the ls. cap rock of Springfield (No. 5) coal in Avon and Canton quads. there is usually a bed of gray sh. exposed in several places along Big Creek and its tributaries S. of Canton. It is here named *Canton sh. memb.* Thickness is 0 to 30 ft.

Canton schist.

Cambrian or pre-Cambrian: Northwestern Georgia (Tate quadrangle).

W. S. Bayley, 1928 (Ga. Geol. Surv. Bull. 43, pp. 43–46, map). *Canton schist.*—Graphitic garnet mica schist. Possibly same as Hiwassee schist, to which it is remarkably similar, but the two schists are so widely separated in Tate quad. that correlation is not certain; therefore the new local name. Bordered on both sides by Carolina gneiss, into which it grades by inter-layering. Best exposed in neighborhood of Canton, at SW. corner of quad. Is Camb. or Archean.

Canton phacolithic complex.

Pre-Cambrian: Northwestern New York (Canton, Gouverneur, and Ogdensburg quadrangles).

A. F. Buddington, 1929 (N. Y. State Mus. Bull. 281, pp. 65–76). *Canton phacolithic complex.*—The Canton granite masses form a phacolithic complex, consisting of 2 granite shells with an intervening zone of Grenville. Passes through village of Canton. Intrudes Grenville series. Occurs in Canton, Gouverneur, and Ogdensburg quads. [According to p. 52 the Canton phacolith belongs to his Alexandria type of granite.]

Cantrell sand.

A subsurface sand, of Penn. age, in Stephens Co., southern Okla., lying at 1,800 ft. depth in Empire pool, the Surber sand lying at 1,700 ft. and the Shelton sand at 1,900 ft.

Cantua sandstone member.

Eocene: Southern California (north of Coalinga region).

R. Anderson and R. W. Pack, 1915 (U. S. G. S. Bull. 603, pp. 33, 59–63, and map). *Cantua ss. memb.*—A huge lens of massive, medium to fine-grained, gray, concretionary ss. and interbedded clay sh. that forms lower and major part of Martinez (?) fm. within a small area. Max. thickness at least 4,500 ft. Rests uncon. on Moreno fm. Is overlain by and in places grades laterally into dark clay sh. that composes the rest (400 to 1,100 ft.) of Martinez (?) fm. Named for fact it reaches greatest development at head of W. branches of Cantua Creek, Fresno Co.

According to B. L. Clark, 1921 (Jour. Geol., vol. 29), these beds belong to his Meganos group and are younger than the Martinez.

B. L. Clark, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 7, p. 1050). *Cantua ss.* is regarded as memb. of Capay fm. [On pl. 89 he mapped Cantua ss. memb. separately.]

†Cantua shale.

Oligocene or Eocene: Southern California (Coalinga region).

C. C. Church, 1930 (Pan-Am. Geol., vol. 54, No. 1, p. 79). At the well-known loc. of *Cantua sh.* in Phoenix Canyon impressions of foraminifera are abundant and at other places well-preserved fossils have been found. The affinities of the fauna seem to be with Mio. rather than Eo. [The fm. was not defined.]

G. D. Hanna, 1930 (pp. 79–80 of book cited above), mentioned fossils collected from *Cantua sh.* but did not define the fm. He stated that in 1927 52 sp. of diatoms were listed from *Cantua sh.*, mostly from Phoenix Canyon, near Coalinga, and that fossils seem to indicate lower Mio.

In corrected copies of above abstracts of Symposium of 29th Ann. Meeting Cordilleran sec. of Geol. Soc. Am., published in Geol. Soc. Am. Bull., vol. 42, No. 1, 1931, pp. 302–307, the name *Lillis sh.* was used instead of *Cantua sh.*, preoccupied.

Cantwell formation.

Upper Cretaceous: Southern Alaska (Cantwell River region).

G. H. Eldridge, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, p. 16, map). *Cantwell cgl.*—Cgls. and coarse sss.; matrix quartz; pebbles are of dark sl., perhaps derived from Sushitna slates, on which they presumably rest. Outcrop for mi. or two along banks of Cantwell River. Thickness 600 to 700± ft. Older than Kenai series.

This fm. was for many years classified as Eo., on basis of fossil plants derived from it, but with recognition of possibility it might be late Cret., as structural relations seemed to indicate. In Feb. 1937 the Upper Cret. age of the fm. was accepted by U. S. Geol. Survey, on the basis of fossil plants collected from it and identified by R. W. Chaney.

Canville limestone.

Pennsylvanian: Southeastern Kansas and western Missouri.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 91, 97). [See under *Dennis fm.*]

J. M. Jewett, 1932 (pp. 99, 102, 103, of book cited above). *Canville ls.* is proposed for ls. next above Galesburg sh. and below Stark sh. Named for Canville Creek, Neosho Co. Been traced by writer from T. 18 S., to T. 29 S. Generally about 8 ft. thick, bluish gray, fossiliferous. In S. part of its outcrop it sets off the ss. and sandy sh. (Dodds Creek ss.) of underlying Galesburg sh. from overlying black platy Stark sh., and in N. part it separates the yellow sh., the Galesburg, from the black Stark sh. In N. part of Linn Co. it is represented by very calc. sh. less than 1 ft. thick. Its horizon is known at Kansas City by the plane btw. Galesburg and Stark shales, which are easily recognized by their color and fossils.

See also J. M. Jewett, 1933 (Kans. Acad. Sci. Trans., vol. 36, pp. 131–136).

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), stated that Jewett is author of this name.

Canyon formation (also **Canyon group**).

Pennsylvanian: Central northern and central Texas.

W. F. Cummins, 1891 (Tex. Geol. Surv. 2d Ann. Rept., pp. 361–374). *Canyon div.*—Largely massive, heavy-bedded lss., 930 ft. thick. Underlies Cisco div. and overlies Strawn div.

In Palo Pinto Co., type region, consists of 750 ft. of massive lss., sss., and gray shales, with a heavy ls. at base. Canyon group is now divided into (descending) Caddo Creek, Brad, Graford, and Palo Pinto fms.

Named for Canyon, Palo Pinto Co.

†Canyon conglomerate.

Pliocene: Yellowstone National Park.

W. H. Weed, 1896 (U. S. G. S. Yellowstone Nat. Park folio, No. 30). *Canyon cgl.*—Thinly bedded light-colored cgls. and gravels exposed only in stream cuttings along Lamar River and the Grand Canyon. Composed of well-rounded pebbles of Archean gneisses and andesitic material derived from underlying breccias. Capped by recent basalt. Named for occurrence in Grand Canyon of the Yellowstone.

Replaced by geographic name *Tower Creek cgl.*

Canyon City group.

Upper Cretaceous (Montana): Southeastern Colorado (Canyon City region).

F. V. Hayden, 1869 (U. S. Geol. Surv. Colo. and N. Mex. 3d Ann. Rept., pp. 89–91). Near Hardscrabble Creek, a small branch running into Arkansas River just below Canyon City, there is a small area, about 8 mi. square, occupied by coal strata, for which I propose the provisional name of *Canyon City group.* I have but little doubt careful study will show that it is a fragment of the great lignite group of the North.

W. T. Lee, 1917 (U. S. G. S. P. P. 101, pp. 162–169). The coal-bearing strata of Canyon City region belong to Vermejo fm.

Canyon Creek member (of San Juan tuff).

Tertiary (Miocene? or Oligocene?): Southwestern Colorado (Ouray district).

W. S. Burbank, 1930 (Colo. Sci. Soc. Proc., vol. 12, p. 186). *Canyon Creek memb. of San Juan tuff.*—Lower memb. of San Juan tuff in vicinity of Canyon Creek, Sneffels, and Ouray. Is most important cliff-forming part of San Juan. Ranges from fine sandy tuffs to coarse aggl. and breccia, with interbedded conglomeratic beds, which differ from the others by being composed partly or largely of distinctly rounded waterworn boulders of the volcanic rocks. It is mainly by reason of presence of these cgl. beds and their character that the two fold division of San Juan tuff has been made. Thickness 300 to 1,200 ft. Underlies Sneffels memb. of San Juan tuff, which is comparatively free from cgl. layers. The rock fragments composing Canyon Creek memb. comprise a great variety of lavas, many of them porphyritic andesites and latites. Characteristic color of memb. is dull greenish gray, but some reddish or purplish beds are present. The coarse aggls. are commonly chaotic and exhibit bedding only when viewed at a distance, but the tuffs, cgls., and conglomeratic beds with which they are interbedded form distinct layers and give a bedded appearance to whole fm. Along Canyon Creek just below Camp Bird mill this memb. is normally 1,100 to 1,200 ft. thick. Uncon. overlies Telluride cgl.

Canyon Creek slate.

Middle (?) Cambrian: British Columbia.

C. S. Evans, 1933 (Canada Geol. Surv. Summ. Rept. 1932, pt. A2, p. 123).

†Canyon Largo group.

Eocene and older (?): Southwestern Colorado and northwestern New Mexico.

W. H. Holmes, 1877 (U. S. Geol. and Geog. Surv. Terr. 9th Ann. Rept., for 1875, pls. 35, 38), showed *Canyon Largo of Newberry* and underlying Puerco marls of Cope as=Wasatch fm. The compiler has been unable to find that Newberry ever published the term *Canyon Largo group*. He did describe the rocks of Canyon Largo, but did not apply to them, even in a descriptive way, the term *Canyon Largo group*. On pl. 38 of book cited above Holmes, however, used the term *Cañon Largo group*, and on pl. 35 he used *Cañon Largo of Newberry*.

J. B. Reeside, Jr., 1924 (U. S. G. S. P. P. 134, p. 6), showed Canyon Largo group of Holmes, 1877, as=Wasatch, Torrejon, Puerco, and Ojo Alamo fms. of present terminology.

Named for Canyon Largo, in NE. part of San Juan Co. and W. part of Rio Arriba Co., N. Mex.

Canyon Largo sandstone.

Eocene: Northwestern New Mexico.

C. R. Keyes, 1906 (Geol. Soc. Am. Bull., vol. 17, p. 725). *Canyon Largo sss.*, 700 ft. thick, underlie Chaco marls and overlie Torreon fm. [Torrejon]. [Derivation of name not given.]

Appears to be lower part of Wasatch fm. of NW. N. Mex.

†Cap au Gres sandstone.

Lower Ordovician: Northeastern Missouri, western Illinois, and southeastern Iowa.

C. R. Keyes, 1898 (Iowa Acad. Sci. Proc., vol. 5, pp. 59, 60). *Cap au Gres ss.*—Very massive, fine-grained, soft sand rock, homogeneous in texture, of white or yellowish color. Thickness 125 ft. Underlies Folley ls. and overlies Cambrian Winfield dol. Typically developed at Cap au Gres, a headland on Ill. side of Miss. River in [Calhoun Co.] Ill.

Same as St. Peter ss., older name.

Capay formation.

Eocene (middle): Northern California (Sacramento Valley).

T. H. Crook and J. M. Kirby, June, 1935 (Geol. Soc. Am. Proc. 1934, pp. 334–335). *Capay fm.*—Recent reconn. work in Sacramento Valley has resulted in discovery, in Capay Valley W. of Rumsey Hills, of Eo. deposits extending continuously 14 mi.

These grade in character from purely channel cgls. occupying a bed in tilted Cret. shales at N. end to presumably estuarine deposits bearing fauna identical with that in Butte gravels of Marysville Buttes and probably correlative with that of Lillis Ranch, N. of Coalinga. Max. thickness at least 2,400 ft. There is evidence that much of material was locally derived.

B. L. Clark, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 7, pp. 1036, 1050, pl. 89). Lower part of middle Eo. in Riggs Canyon fault zone of Mount Diablo area is=*Capay fm.*, a name proposed by T. H. Crook and J. M. Kirby for a series of Eo. deposits in Capay Valley, W. of town of Winters [Yolo Co.]. These deposits are found along SW. border of Sacramento Valley. In this paper the name is used as a stage name to designate strata which are apparently contemp. with the deposits of type loc. Stratigraphically, the deposits of Capay stage lie btw. those of the Meganos (below) and the Domengine (above). [Page 1036. On pl. 89 Clark mapped *Capay fm.* in Coalinga region, and placed it above Cantua ss. memb. On p. 1050 he described *Capay fm.* N. of Coalinga as mostly dark-colored shales, 1,000 ft. thick, and included in it *Cantua ss. memb.*]

†Cape Ann granite.

Devonian or Carboniferous: Northeastern Massachusetts (Essex County).

C. H. Clapp, 1910 (Igneous rocks of Essex Co., Mass.), stated that *Cape Ann granite* is same as Quincy granite. See B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 188–189 and map). Named for occurrence at Cape Ann, Essex Co.

Cape Barré beds.

Devonian: Quebec.

J. M. Clarke, 1905 (N. Y. State Mus. Bull. 80, p. 151).

†Cape Beaufort coal measures.

Cretaceous: Alaska.

W. H. Dall and G. D. Harris, 1892 (U. S. G. S. Bull. 84, p. 249), and W. H. Dall, 1896 (U. S. G. S. 17th Ann. Rept., pt. 1, pp 819–820). [Assigned to Carbf.]

G. C. Martin, 1926 (U. S. G. S. Bull. 776, pp. 456–457). "Cape Beaufort coal measures" of Dall and of Dall and Harris is Corwin fm. (Cret.). Probably reason Schrader introduced *Corwin*, instead of using the older name "Cape Beaufort," was the suspicion that Carbf. rocks might have been included under latter name.

Cape Blanc formation.

Upper Ordovician: Quebec (Percé).

C. Schuchert, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 161–170). [See under *Whitehead fm.*]

†Cape Blanco beds.

Miocene: Southwestern Oregon (Port Orford quadrangle).

See 1902 and 1913 entries under *Empire fm.* (Mio.).

Cape Bon Ami limestones.

Devonian: Quebec (Gaspe Peninsula).

J. M. Clarke, 1900 (N. Y. State Mus. Mem. 3, vol. 3, pp. 80–81). Mr. Charles Schuchert and writer have thought that the passage beds of Billings (Nos. 3, 4, 5, 6) which are displayed in the fine 700-foot vertical escarpment at Cape Bon Ami W. of Cape Gaspe, may receive the name of *Cape Bon Ami lss.* Underlie Grande Grève lss. (Oriskany) and overlie St. Alban lss. (Helderbergian).

Cape Canon formation.

Upper Ordovician: Quebec (Percé).

J. M. Clarke, 1908 (N. Y. State Mus. Mem. 9, p. 59). *Cape Canon massive.* Silurian, Percé, Quebec.

C. Schuchert, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 161–164). *Cape Canon fm.* is of Upper Ord. age. Oldest known fm. in Percé area. Light-blue, thin-bedded lss. separated by thin zones of black argill. shales. Much disturbed. Exposed thickness 630 ft. Has yielded no fossils to anyone. No Middle Ord. or Sil. are present about Percé. As the younger Whitehead fm. may be 2,000 ft. or more thick, it is probable Cape Canon fm. is only a part of this younger series, and this appears to be proved by the fossils of Limekiln cgl., which was thought by Clarke to be part of Cape Canon fm. All of these fms. are Upper Ord.

Cape Cod series.

Tertiary and Quaternary: Massachusetts.

N. S. Shaler, 1898 (U.S.G.S. 18th Ann. Rept., pt. 2, p. 535). Includes Nashaquitsa and Barnstable series and other unnamed later deposits.

Cape Dauphin formation.

Pennsylvanian: Nova Scotia.

W. A. Bell, 1923 (Canada Geol. Surv. Mem. 133, p. 93).

Cape Elizabeth formation. (In Casco Bay group.)

Carboniferous (Pennsylvanian?): Southwestern Maine.

F. J. Katz, 1917 (Wash. Acad. Sci. Jour., vol. 7, p. 198). *Cape Elizabeth fm.*—Graywacke schists, gray gritty slates, sericite phyllites, and calc. laminae. Included in Casco Bay group.

F. J. Katz, 1917 (U.S.G.S.P.P. 108, p. 170). *Cape Elizabeth fm.*—An assemblage of mostly thin-bedded, light-gray siliceous and sericitic slates, heavier beds of graywacke sl., schist, and qtzite, containing at short intervals thin layers or laminae of black micaceous phyllite and light-bluish calc. schist or sl. Thickness estimated at 600 ft. Basal fm. of Casco Bay group. Underlies Spring Point greenstone and overlies Kittery qtzite. Assigned to Penn. (?). Named for development at Cape Elizabeth, Cumberland Co.

On 1933 geol. map of Maine, by A. Keith, these rocks are mapped as Penn.

†Cape Fear formation.

Cretaceous (Upper): Coastal plain of North Carolina.

L. W. Stephenson, 1907 (Johns Hopkins Univ. Circ. No. 71, pp. 93–99). *Capefear fm.*—Arkosic and micaceous sands and clays and various intergradations of aren. clays and argill. sands. Beds range in thickness from a few ft. to 10 or 12 ft. *Name used tentatively, since future investigations may prove equivalency with* established fms. elsewhere. Believed to be approx. synchronous with Patuxent div. of Potomac series of Md. and Va., although it may include a portion of the Potomac younger than the Patuxent. Thickness 300 ft. Uncon. underlies Bladen [Black Creek] fm.

By 1910 the equivalency of †Cape Fear fm. with the Lower Cret. Patuxent fm. was believed to have been established, and local name "Cape Fear" was dropped. Further work, however, furnished satisfactory proof that the deposits are chiefly if not wholly of Upper Cret. age, and that if they contain any representative of Patuxent fm. it must be in their lower part. (See C. W. Cooke, U.S.G.S.P.P. 140F, pp. 138–139, 1926.) Additional work established fact that these deposits are chiefly if not wholly the northward extension of Tuscaloosa fm., and they are now called by that name, although some beds of Lower Cret. age may be included; but if present they will hereafter be excluded. (See C. W. Cooke, U.S.G.S. Bull. 867, 1936.)

Named for exposures on Cape Fear River.

†Cape Girardeau marble.

Middle Ordovician: Southeastern Missouri (Cape Girardeau County).

B. F. Shumard, 1855 (Mo. Geol. Surv. 2d Ann. Rept., pt. 2, p. 155), divided the so-called Trenton ls. (overlain by *Cape Girardeau ls.*) at Cape Girardeau into (descending): (1) Fine-grained reddish brown argill. ss., 10 ft.; (2) white and bluish white, massive-bedded crystalline ls., of fine texture, carrying Trenton fossils, 60 ft.—the well-known *Cape Girardeau marble;* (3) white crystalline ls., in heavy beds, 35 ft.; (4) blue schistose ls., highly fossiliferous, 2 ft.

Is a part of Kimmswick ls.

†Cape Girardeau limestone.

See *Girardeau ls.*

†Cape Girardeau sandstone.

Upper Ordovician (Richmond): Southeastern Missouri.

B. F. Shumard, 1868 (St. Louis Acad. Sci. Trans., vol. 2, p. 156). *Cape Girardeau ss.*—Ss., 80 to 100 ft. thick, composing middle fm. of Hudson River group in Cape Girardeau Co. Separated from overlying Cape Girardeau ls. by 25 ft. of blue sh. overlain by 25 ft. of yellow sh. Underlain by 60 ft. of dark sh., which overlies Receptaculites ls.

C. L. Dake, 1918 (Mo. Bur. Geol. and Mines vol. 15, 2d ser.). Thebes ss., 0 to 100 ft. thick, is *Cape Girardeau ss.* of Shumard.

J. Bridge, 1930 (personal communication) stated that †Cape Girardeau ss. is = lower part of Thebes ss.

Named for Cape Girardeau, Cape Girardeau Co.

Cape Horn slate.

Mississippian: Northern California (Colfax quadrangle).

W. Lindgren, 1900 (U.S.G.S. Colfax folio, No. 66). *Cape Horn sl.*—The characteristic rocks are fissile typical clay slates, almost black when fresh and weathering to a gray or silvery white color. Small ls. lenses are found below Cape Horn, in Bear River Canyon W. of Dutch Flat, and in canyon of South Fork of Yuba River S. of Relief; they are ordinarily only few ft. thick. Meager fossils not diagnostic as to age. The fm. corresponds to part of Calaveras fm., and is assigned to Carbf. Overlies Relief qtzite and underlies Delhi fm. Named for occurrence at Cape Horn, overlooking North Fork of American River, in Placer Co.

Cape John formation.

Carboniferous: New Brunswick, Prince Edward Island, and Nova Scotia.

H. M. Ami, 1899 (British Ass. Adv. Sci. Rept. 1899, p. 756).

Cape May formation.

Pleistocene (late): New Jersey and southeastern Pennsylvania.

R. D. Salisbury, 1898 (N. J. Geol. Surv. Ann. Rept. State Geol. 1897, pp. 19–20). *Cape May fm.*—Those deposits of late glacial and early postglacial time, which were made beyond region directly affected by the ice or its drainage. Includes much of loam which has heretofore been referred to under name "low-level Jamesburg." In places overlain by high-level loam which in earlier repts was referred to under name "high level Jamesburg loam." Overlies Pensauken fm. Probably at least partly contemp. with drift of last [Wisconsin] glacial epoch. Covers whole of Cape May Co., N. J.

Is top fm. of Columbia group, of nonglacial origin. Now considered to be of same age as glacial deposits of Wisconsin stage.

Cape Neddick gabbro.

Devonian (?): Southwestern Maine (York County).

A. Wandke, 1922 (Am. Jour. Sci., 5th, vol. 4, p. 151). *Cape Neddick gabbro.*—A small oval stock measuring about ½ by ¾ mi. Shows four phases—the contact phase, a dark coarse-grained phase, a very dark, almost black phase, and a light-colored central phase. Of Dev. (?) age. Occurs at Cape Neddick, York Co.

Capistrano formation.

Upper Miocene or Pliocene: Southern California (between Santa Ana and Oceanside).

A. O. Woodford, 1925 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 15, No. 7, pp. 169, 184, 216–217). *Capistrano fm.*—The light-colored Monterey sh. is everywhere overlain by thin-bedded dark gray sh., the contact being nearly or quite conformable. This sh. and the associated ss. cover a large synclinal area centering about Capistrano. Mica is prominent in the gray sh., and foraminifera and other organisms are common both in it and in the sometimes abundant small ls. nodules or lenses. The sh. rarely contains beds of fine ss., which is usually high in quartz, and sometimes highly feldspathic. At top of fm. this ss. predominates. Occasionally the gray sh. has white partings which resemble the Monterey. The Capistrano beds may properly belong with the Monterey, but because of their different lithology and local development of breccia at or near their base, they are here distinguished as a separate fm. The shales are practically identical with those which uncon. overlie the Monterey in the nearby Huntington Beach oil field, and which are commonly called *Fernando Pliocene*. Thickness 1,200 ft. Classified as upper Miocene (?), as uncon. (?) overlying Monterey sh., and as uncon. overlain by San Mateo fm. (Plio.?). Suggests correlation with San Pablo fm. (upper Mio.), but "fossil evidence is inconclusive," and the beds may be lower Plio. [Mapped.]

Named for development around Capistrano, Orange Co.

Capitan limestone. (Of Guadalupe group.)

Permian: Western Texas and southeastern New Mexico (Pecos Valley).

G. B. Richardson, 1904 (Univ. Tex. Min. Surv. Bull. 9, p. 41). *Capitan ls.*—Massive white ls., 0 to 1,800 or more ft. thick. Conformably overlies Delaware Mtn fm. in Guadalupe Mtns. Top not seen but believed to uncon. underlie Castile gyp.

Upper fm. of Guadalupe group. According to N. H. Darton and J. B. Reeside, Jr. (Geol. Soc. Am. Bull., vol. 37, p. 420, 1926) the Castile gyp. uncon. overlies Capitan ls. K. H. Crandall (A. A. P. G. Bull., vol. 13, pp. 941–943, 1929), R. E. King (Univ. Tex. Bull. 3042, p. 13, 1931), W. B. Lang (A. A. P. G. Bull., Feb. 1935), and other geologists are also now satisfied (1) that Castile gyp. is younger than Capitan ls. (although there is diversity of opinion regarding the uncon.); (2) that typical Delaware Mtn fm. of Delaware Mtns includes in its upper part the time equiv. of Capitan ls.; and (3) that the beds underlying Capitan ls. and called Delaware Mtn fm. in Guadalupe Mtns are=only lower part of Delaware Mtn fm. of Delaware Mtns.

P. B. and R. E. King, 1929 (A. A. P. G. Bull., vol. 13, p. 925, etc.), extended *Capitan ls.* into eastern Glass Mtns, and included in it the Tessey, Gilliam, and Vidrio deposits.

R. C. Moore, 1933 (see under †*Glass Mtns fm.*), called the Capitan ls. in Glass Mtns the *Glass Mtns fm.*, a name (preoccupied) proposed by P. B. King.

P. B. King, 1934 (Am. Jour. Sci., 5th, vol. 45, p. 736). *Glass Mtns fm.* abandoned (preoccupied) and *Capitan ls.* applied in Glass Mtns to include (descending). on E. side of the mtns, Tessey massive memb., Gilliam thin-bedded memb., and Vidrio massive memb.; and, in lower part of Capitan ls. on W. side of Glass Mtns, the Altuda shaly memb. (=lower part of Vidrio memb.).

W. B. Lang, 1937 (A. A. P. G. Bull., vol. 21, No. 7). In Pecos Valley of SE. N. Mex. the nonbedded Capitan ls. of reef zone grades laterally into Carlsbad ls. and is in places overlain by a thin wedge of the Carlsbad, and in other places it grades laterally into the Carlsbad ls. (here treated as a distinct fm.). It also grades laterally into upper part of Delaware Mtn fm. of fore-reef zone.

P. B. King, 1937 (U. S. G. S. P. P. 187), treated *Tessey ls.* as a distinct fm., instead of including it in Capitan ls. This is present adopted definition of U. S. Geol. Survey.

Named for El Capitan Peak, El Paso Co., Tex., which is formed of the ls.

†Capitol limestone.

Middle Ordovician: Central Tennessee.

J. M. Safford, 1869 (Geol. Tenn., pp. 277–278). *Capitol ls.*—Ls. having appearance of laminated ss., being in fact a consolidated bed of calc. sand composed of comminuted fragments of shells and corals. Thickness 20 to 25 ft. Included in Nashville fm. Overlies *Orthis* bed [Hermitage fm.], lowest div. of Nashville fm. Underlies Dove ls.

Nongeographic name. Beds represent lower part of Bigby ls., of Trenton age. Have also been called "Mount Pleasant phosphate."

Named for fact the beds supplied the rock to build Tennessee State Capitol.

Capitol Creek shale.

Middle Cambrian: Montana.

A. Rothpletz, 1915 (Die fauna der Belt formation bei Helena in Mont., Munich, 1915).

C. D. Walcott, 1916 (Smithsonian Misc. Coll., vol. 64, p. 291). Capitol Creek sh. of Rothpletz is same as Park sh.

Cap Mountain formation.

Upper Cambrian: Central Texas.

S. Paige, 1911 (U. S. G. S. Bull. 450, p. 23). *Cap Mtn fm.*—At base gradual transition from ss. to ls., but predominantly ls., capped by 15 to 75 ft. of cross-bedded glauconitic ss. Thickness 90 ft. Overlies Hickory ss. and underlies Wilberns fm.

Named for Cap Mountain, Llano Co.

Capote limestone.

Age (?): Mexico.

W. P. Blake, 1905 (Am. Inst. Mg. Engrs. Trans., vol. 35, p. 551).

Capote quartzite.

Pre-Cambrian: Mexico (Sonora).

S. F. Emmons, 1910 (Econ. Geol., vol. 5, p. 319).

Capps limestone member (of Mineral Wells formation).

Pennsylvanian: Central Texas (Brown County, Colorado River region).

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 35; Univ. Tex. Bull. 2132, pp. 96, 97). *Capps ls. lentil.*—A thin lentil of ls. near base of Brownwood memb. of Graford fm. in Brown Co. Very irregular in lithologic character. In places almost nothing but corals; in other places composed of rounded ls. and chert pebbles cemented by calc. carbonate to form a solid ls. layer. Is "Coral" ls. of Drake. Thickness 4 ft. Is traceable for only short distances on either side of Pecan Bayou. To NE. of Brownwood it extends from a point near Capps well to beyond Frisco R. R., a total distance of about 3 mi. To SE. of Brownwood it is exposed from near Santa Fe tracks to Cret. overlap E. of Cedarton. Has not been recognized in borings in Brownwood oil field W. of area of its outcrop. Named for Capps farm, 3 mi. E. of Brownwood, Brown Co., where it is well developed.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 105–109), revised the definitions by transferring Capps ls. from Brownwood memb. of Graford fm. to top of underlying Strawn group.

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501, p. 201), stated, under the heading of Brownwood sh. memb. (of Graford fm): The name *Brownwood* is applied to the shales lying btw. top of Capps ls., or in some places the Rochelle cgl., and Adams Branch ls. Further along, on same page, they stated: In some areas, especially N. of Colorado River, there occurs, near base of Brownwood sh., a thin lenticular ls. known as *Capps ls. lentil.* In section on p. 198 they included Rochelle cgl. in Graford fm., but do not show Capps ls.

The U. S. Geol. Survey at present treats *Capps ls. memb.* as top bed of Mineral Wells fm., the upper fm. of Strawn group.

†Caprina limestone.

A paleontologic name applied in early Tex. repts to the ls. later named *Edwards ls.*

†Caprotina limestone.

A paleontologic name applied in some early repts to Fredericksburg group of Lower Cret. of Tex. and to a part of that group; also to Glen Rose ls. of Trinity group.

Captain Creek limestone member.

Pennsylvanian: Central eastern and northeastern Kansas.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pt. 1, pp. 76–79). *Captain Creek ls. memb.*—Basal memb. of Stanton ls. and most easily recognizable unit of Lansing group in NE. Kans. In Johnson and Miami Counties it is gray to dark-gray, massive, evenly bedded ls., sugary to dense. Thickness 4½ to 10 ft. Underlies Eudora sh. memb. and overlies Vilas sh. Named for stream near Eudora, Douglas Co.

See also Newell, 1936 (Jour. Geol., vol. 44, No. 1, pp. 23–31); R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 132, 191); and Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936. Moore stated (1936) type loc. is on Captain Creek 2 mi. E. of Eudora, roadcut near SE. cor. sec. 3, T. 13 S., R. 21 E.

†Carbon group.

Tertiary: Wyoming.

L. Lesquereux, 1876 (U. S. Geol. Surv. Terr. Bull. 5, 2d ser., pp. 244–248). *Carbon group (middle Mio.)* underlies Green River group (upper Mio.) and overlies Evanston group (upper Eo. or lower Mio.).

Probably same as Wasatch group, of Eo. age.

Carbon.

Upper Cretaceous: Southern Wyoming.

A. C. Veatch, 1907 (Jour. Geol., vol. 15, pp. 547–549, and Am. Jour. Sci., 4th, vol. 24, pp. 18–22), in several places referred to "Laramie (Carbon) group" in Evanston section of southern Wyo. He also expressed opinion that *Laramie* should be restricted to "Upper Laramie," and that a new name should be applied to "Lower Laramie," suggesting, for the latter, "Bow fm. or group" (from Medicine Bow River, Carbon region) or "Golden fm. *or group*" (from Golden, Colo.).

Carbonado formation. (In Puget group.)

Eocene: Western Washington (Puget Sound region).

B. Willis, 1898 (U. S. G. S. 18th Ann. Rept., pt. 3, pp. 400–436). *Carbonado fm.*—Basal fm. of Puget group. Consists of sss., shales, and coals. Is the productive series of Puget group. Includes all the coal veins below Wilkeson ss. down to lowest bed developed in the field. Named for town [in Tacoma quad.]. Thickness 1,100 to 2,000 ft.

B. Willis and G. O. Smith, 1899 (U. S. G. S. Tacoma folio, No. 54), repeated 1898 definition, and stated that *Carbonado fm.* included 20 ft. of massive ss. at top.

Carbondale formation.

Pennsylvanian: Illinois and western Kentucky.

E. F. Lines, 1912 (Ill. Geol. Surv. Bull. 17, p. 74). *Carbondale fm.*—Series of beds of sh., ss., coal, and ls., 200 to 460 ft. thick, extending from bottom of Murphysboro or No. 2 coal below to top of Herrin or No. 6 coal above. Overlies Pottsville fm. and underlies McLeansboro fm. Combines "La Salle fm." and "Petersburg fm." of previous rept.

E. W. Shaw and T. E. Savage, 1912 (U. S. G. S. Murphysboro-Herrin folio, No. 185), also defined Carbondale fm. as extending from base of No. 2 coal to top of No. 6 coal.

Top of underclay of Murphysboro or No. 2 coal is now the U. S. Geol. Survey's accepted base of fm. The Carbondale was correlated by D. White with all but uppermost part of Allegheny fm.

Named for Carbondale, Jackson Co., Ill.

Carbonic.

A variant of *Carboniferous* employed by some geologists.

Carboniferous period (or system).

The time (and the rocks) of the youngest Paleozoic **system, succeeding the** Devonian period and preceding the Triassic period. **Divided by U. S. Geol.** Survey into (descending) Permian, Pennsylvanian, and **Mississippian** epochs (or series). For definition see U. S. G. S. **Bull. 769, pp. 65–78.**

†Carboniferous limestone.

A term applied in some early geologic repts to Mississippian series.

Carbon River [coal] series.

Eocene: Western central Washington (Puget Sound region).

B. Willis, 1886 (U. S. 10th Census, vol. 15, pls. 81, 84). [See under *Evans Creek coal series.*]

Carcajou Mountain beds.

Devonian: Mackenzie, Canada.

E. M. Kindle, 1936 (Sci., n. s., vol. 83, No. 2140, pp. 14–15). *Bosworth ss. and sh.* (preoccupied), replaced by *Carcajou Mtn beds.* Named for mtn 43± mi. below Bosworth Creek.

Cardenas formation.

Cretaceous: Mexico.

V. R. Garfias, 1915 (Econ. Geol., vol. 10, pp. 199, 202).

Cardiff conglomerate.

Pre-Cambrian (Glenarm series): Southeastern Pennsylvania, Maryland, and Virginia.

E. B. Mathews, Feb. 1904 (Am. Jour. Sci., 4th, vol. 17, p. 143). *Cardiff qtzite* [in table on p. 143 he calls it *Cardiff quartz cgl.*].—A somewhat intermittent poorly developed qtzitic cgl. Present in strongly marked synclinal basin with its greatest depth in neighborhood of Cardiff [Harford Co.], Md. Underlies Peach Bottom slates and overlies Wissahickon phyllite, mica schist, and mica gneiss.

W. B. Clark, 1904 (Md. Geol. Surv. Harford Co. geol. map). *Cardiff.*—Qtzite and quartzose cgl. A fm. of slight extent. Underlies Peach Bottom and overlies Wissahickon. Thickness 500 ft.

The conception of Wissahickon fm. has in recent years been modified. The fm. that underlies Cardiff cgl. is now called *Peters Creek schist.* All belong to Glenarm series, which was formerly classified by U. S. Geol. Survey as "Algonkian," but, that term having been discarded, the Glenarm is now classified as *pre-Camb.*

This fm. has also been called "Cardiff qtzite."

Cardiff shale.

Upper Devonian: Western to east-central New York.

J. M. Clarke and D. D. Luther, June, 1904 (N. Y. State Mus. Bull. 63, p. 16). *Cardiff shale.*—Dark calc. and black slaty shales with thin layers of fossiliferous ls., both of which weather light ashen gray. Thickness 50 to 100 ft. Top div. of Marcellus beds or stage [broad sense]. Overlies Stafford ls. and underlies Skaneateles sh. of the Hamilton. Finely shown in and about village of Cardiff, Onondaga Co. [In this same bull. Clarke and Luther recommended that *Marcellus sh.* be restricted to the basal black sh. (see under *Marcellus sh.*).]

In subsequent repts these beds have been both included in and excluded from Marcellus sh. The greatly predominant usage, however, has been to restrict Marcellus sh. to the scantily fossiliferous black shales beneath the Cardiff. These black shales, with the included Cherry Valley ls., aggregate 62 to 145 ft. in thickness btw. Unadilla Valley and Seneca Lake region, to W.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 129–236). *Cardiff memb. of Marcellus fm.*—In 1904 Clarke and Luther subdivided Marcellus into Marcellus and Cardiff in region E. of eastern limit of typical Stafford ls. But they fell into confusion because further W. the sh. below the Stafford is jet black and the sh. above the Stafford is lithologically like the Cardiff. They therefore defined the Cardiff as lying above the Stafford, when actually it lies on the Marcellus and is overlain by the Mottville, which is E. equiv. of the Stafford. Since the Stafford is actually=basal bed of the Skaneateles it is necessary to exclude it from the Marcellus. The Marcellus of eastern N. Y. is here divided into (descending): Cardiff memb. (light-colored); Chittenango memb. (black); Cherry Valley ls. memb. (black); and Union Springs memb. (black). In Cayuga and Seneca Lakes region the Marcellus is divided into (descending): Oatka Creek memb.; Cherry Valley memb.; and Union Springs memb.; the Oatka Creek memb. (black sh., 30 to 50 ft. thick) being correlated with Chittenango (black) and Cardiff (gray sh. and ss.) members. Farther W. the Union Springs (black) and Cherry Valley (black) members thin out and the black Oatka Creek is sole representative of Marcellus. A striking change in facies is seen as Cardiff beds are traced E. and W. from their type section. In Chenango Valley and eastward the Cardiff sh. is represented by three members, a sandy Solsville memb. separating an upper [Pecksport] and lower [Bridgewater] gray sh. memb. West of Chenango Valley the sandy memb. disappears and entire sequence is one of nearly homogeneous dark gray sh. Still farther W. it becomes black sh. and forms part of Oatka Creek sh. The eastward change in facies in Chenango and Unadilla Valleys is attended by marked change in faunal facies. The dark shales of the Cardiff are characterized by a "Leiorhynchus fauna," but as those become sandier in E. part of State, true Hamilton forms replace those of the Cardiff, and in upper part of Marcellus fm. (Pecksport and Solsville members) in Unadilla Valley, Hamilton species predominate. In vicinity of Schoharie and Catskill the jet-black Marcellus is succeeded directly by strata having a Hamilton fauna, the Mount Marion beds, suggesting that the replacement of the "Leiorhynchus or Marcellus facies" by that of the Hamilton is complete in E. part of the State.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369). Skaneateles sh. includes supposed Cardiff sh. with Stafford ls. at base; and it overlies Marcellus sh. and underlies Ludlowville sh. [On p. 392 she stated: *Cardiff sh.* is now regarded as a modified Marcellus facies of Skaneateles sh.; also that it "grades above into Skaneateles sh." Thickness 50 to 175 ft.]

The U. S. Geol. Survey has adopted the definition of Skaneateles sh. that includes in it the Cardiff sh. of N. Y. repts.

Cardium sandstones.

Cretaceous: Alberta.

D. B. Dowling, 1914 (Canada Geol. Surv. Mem. 52, p. 9).

Caribbean group.

Lower Cretaceous (?): Trinidad.

G. P. Wall and J. G. Sawkins, 1860 (Geol. of Trinidad, pp. 13–33). [No age assigned.]

Subsequent repts assigned *Caribbean series* to pre-Cret. and to Paleozoic (?). C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 703), assigned *Caribbean group* of Trinidad to Lower Cret.

Caribbean limestone.

Tertiary (Pliocene): Panama Canal Zone.

D. F. MacDonald, 1913 (Geol. Soc. Am. Bull., vol. 24, p. 710).

Cariboo schists.

Pre-Cambrian: British Columbia.

A. Bowman, 1889 (Canada Geol. Surv., n. s., vol. 3, pt. 1, pp. 22C–25C).

†Caribou formation.

Mississippian: Northern California (Plumas County).

J. S. Diller, 1892 (prel. proof sheet edition of U. S. G. S. Lassen Peak folio, No. 15). *Caribou fm.*—NW. of Caribou bridge [Plumas Co., in SE. part of Lassen Peak quad.] a series of slates and sss., with a heavy mass of fossiliferous ls., forms for several mi. the crest of divide btw. Musquito and Yellow Creeks. The ls. is of Carbf. age and one of most widely distributed strata yet recognized by fossils in northern Calif. It forms a prominent hill near Bass's ranch on Stillwater and on McCloud River opposite U. S. fishery, as well as near Gazelle, NW. of Mount Shasta. Is younger than Grizzly fm. and older than Spanish fm.

J. P. Smith, 1916 (Calif. State Min. Bur. Bull. 72, pp. 28, 29). "The Caribou ls. of Taylorsville region of Plumas Co., with *Fusulina cylindrica*, is mapped under Carbf. heading."

In the published Lassen Peak folio (No. 15) these rocks were mainly included in Calaveras fm.

Carlile shale. (In Colorado group.)

Upper Cretaceous: Eastern Colorado and Wyoming, northeastern New Mexico, Nebraska, South Dakota, Kansas, and southeastern Montana.

G. K. Gilbert, 1896 (U. S. G. S. 17th Ann. Rept., pt. 2, p. 565). *Carlile sh.*—Chiefly medium gray sh.; at top a thin purplish ls. or a thicker yellow ss. Thickness in Arkansas Valley region, eastern Colo., 175 to 200 ft. Top fm. of Benton group. Underlies Timpas ls. and overlies Greenhorn ls. Named for Carlile Spring and Carlile Station, 21 mi. W. of Pueblo, Colo.

The Niobrara and Benton are not now treated as groups, the broader term Colorado group, which includes them both, being considered the more useful group name. Where the Niobrara deposits and Benton deposits are not subdivided, they are called *Niobrara ls.* and *Benton sh.*, respectively. (See also under *Niobrara ls.*)

Carlim limestone.

Lower Ordovician: Central Pennsylvania (Blair to Center Counties).

C. Butts, 1918 (Am. Jour. Sci., 4th, vol. 46, pp. 526, 533, 537). *Carlim ls.*—Dark, fine-grained ls. extensively quarried for flux, with at top *Lemont ls. memb.* Thickness 180 [0 to 400] ft. Underlies Lowville ls. and overlies Bellefonte dol., of Beekmantown group. Is of middle Chazyan age. Correlates with Crown Point ls. of N. Y. Named for quarry town a few mi. NE. of Williamsburg, Blair Co.

Carlinville limestone member (of McLeansboro formation).

Pennsylvanian: Southwestern and central western Illinois (Macoupin and Sangamon Counties).

A. H. Worthen, 1873 (Ill. Geol. Surv., vol. 5, pp. 287, 290–301, 309). *Carlinville ls.*—Hard, compact, brownish gray ls., 6 to 12 ft. thick, upper portion concretionary or pebbly in structure, in Coal Measures of Macoupin and Sangamon Counties, being bed No. 11 in Virden shaft, Macoupin Co. Overlain by argill. sh. and underlain by bituminous sh. including coal No. 9. Probably same as Shoal Creek ls.

According to G. H. Cady, 1921 (Ill. Geol. Surv. Cooperative Min. ser., Bull. 26) and 1926 (Ill. State Acad. Sci. Trans., vol. 19, pp. 257, etc.), the Carlinville ls. lies 100± ft. below Shoal Creek ls. and 20 to 60 ft. above coal No. 8. E. W. Shaw, 1923 (U. S. G. S. Carlyle-Centralia folio, No. 216), also identified Carlinville ls. as older than Shoal Creek ls. According to Wallace Lee, 1926 (U. S. G. S. Gillespie-Mount Olive folio, No. 220), the Carlinville ls. lies 53 to 81 ft. below Shoal Creek ls. H. R. Wanless, 1931 (Geol. Soc. Am. Bull., vol. 42, No. 3, p. 804), placed Carlinville ls. nearly 100 ft. below Shoal Creek ls.

G. E. Ekblaw, 1933 (Ill. State Acad. Sci. Trans., vol. 25, No. 4, pp. 143–145), stated that *Carlinville ls.* is identical with Shoal Creek ls. and that Carlinville should be abandoned.

Named for outcrops in vicinity of Carlinville, Macoupin Co.

Carlinville cyclical formation.

A name applied by H. R. Wanless (Geol. Soc. Am. Bull., vol. 42, 1931, pp. 801–812) to a middle portion of McLeansboro fm. (Penn.) of central western Ill., based upon the rhythmic-cycle theory of sedimentation. Includes Carlinville ls. Derivation of name not stated.

Carlinville sand.

A subsurface sand in Pottsville fm. of central Ill.

Carlos sandstone member.

Eocene (upper): Southeastern Texas (Grimes, Brazos, Lee, Fayette, Gonzales, and Burleson Counties).

B. C. Renick, 1936 (Univ. Tex. Bull. 3619, table opp. p. 17, and pp. 31–32). *Carlos ss. memb.*—Top memb. of Wellborn fm. of Jackson group in Grimes, Brazos, Lee, Fayette, Gonzales, and Burleson Counties, in all of which it is exposed. [Exposures listed.] Consists of massive gray to white ss., more argill. than older Bedias ss. memb. of the Wellborn; locally semiqtzitic; contains impressions of stems. Thickness 5 to 22 ft. Underlies Manning fm. and lies 10 to 120 ft. above Bedias ss. memb. Rests conformably on middle memb. of Wellborn. Well exposed along Southern Pacific R. R. right-of-way, now abandoned, 0.25 mi. N. of Carlos Station, Grimes Co.

Carlsbad limestone.

Permian: Southeastern New Mexico.

O. E. Meinzer, B. C. Renick, and Kirk Bryan, 1926 (U. S. G. S. W. S. P. 580A, pp. 12–13 and map), and N. H. Darton, 1926 (Geol. Soc. Am. Bull., vol. 37, p. 419). *Carlsbad ls. memb. of Chupadera fm.*—Ls., with thin beds of ss. and possibly some rock salt, underlying Castile fm. and overlying Seven Rivers gypsiferous memb. of Chupadera fm. According to Darton it is top memb. of Chupadera fm., and also forms upper part of Capitan ls., which caps El Capitan at S. end of Guadalupe Mtns in Tex. Thickness 40 to 800 or more ft.

A. G. Fiedler and S. S. Nye, 1932 (U. S. G. S. W. S. P. 639): *Carlsbad ls. tongue of Capitan ls.*—In Roswell artesian basin it is almost entirely thin-bedded dolomitic ls., 35 to 40 ft. thick, but disappears entirely E. of Lakewood. Overlies Seven Rivers tongue of Pecos fm.

W. B. Lang, 1937 (A. A. P. G. Bull., vol. 21, No. 7). Further studies show: (1) Uppermost part of *Carlsbad ls.* is younger than Capitan ls. and the rest of it is contemp. with and grades laterally into the Capitan. (2) In places the Carlsbad is overlain by a thin wedge of uppermost part of Castile anhydrite, and in other places its uppermost part grades laterally into Three Twins memb. of Chalk Bluff fm. (3) Lower part of the Carlsbad grades laterally into Seven Rivers gypsiferous memb. of Chalk Bluff fm. (4) In places a thin tongue (Azotea tongue) of upper part of Carlsbad ls. overlies Seven Rivers gypsiferous memb. of Chalk Bluff fm. (5) The Carlsbad rests on Queen sand memb. of Chalk Bluff fm. [This is present approved definition of U. S. Geol. Survey.]

Carlton porphyry.

Pre-Cambrian: Southwestern Oklahoma (Wichita Mountains).

H. F. Bain, 1900 (Geol. Soc. Am. Bull., vol. 11, pp. 135, 136). *Carrollton Mtn porphyry.*—Two types of porphyry, including rhyolites, amygdaloids, and some tuffs. Assigned to Archean (?). The *Saddle Mtn porphyry*, of slightly different type, probably belongs here.

C. N. Gould, 1904 (Okla. Geol. Surv., Dept. Geol. and Nat. Hist., 3d Bien. Rept., pp. 18, 20), mentions *Carlton porphyry*, which apparently is same as Carrollton Mtn porphyry of Bain, the geographic feature being now spelled *Carlton*.

Named for Carlton Mtns, Comanche Co.

Carlton moraine.

Pleistocene (Wisconsin stage): Western New York. Shown on moraine map (fig. 8) in U. S. G. S. Niagara folio (No. 190), 1913, p. 17. Named for Carlton, Orleans Co.

Carlton granophyre.

Pre-Cambrian: Southwestern Oklahoma (Wichita Mountains).

M. G. Hoffman, 1930 (Okla. Geol. Surv. Bull. 52, pp. 39–48). *Carlton granophyre.*—Porphyritic granophyre; fine-grained; purple when fresh; weathers tan. Composes nearly all of Carlton Mtns. Resembles Davidson granophyre, but differs in that it carries phenocrysts of quartz, and orthoclase or microperthite, or both, which comprise about 11 per cent of the rock. Considered later than Davidson granophyre, and is intruded by Lugert granophyre.

Carlton limestone. (In Sumner group.)

Permian: Northeastern Kansas.

R. C. Moore, 1936 (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 12). *Wellington sh.* (*restricted*) divided into (descending): (1) Carlton ls. (thin-bedded ls., massive ls., thin sh., and, at base, cgl.), 17± ft. thick; (2) *Buckeye sh.*, 45± ft. thick. [Derivation of new names *Carlton* and *Buckeye* not stated.]

Carltonian formation.

Pre-Cambrian (Keweenawan): Northeastern Minnesota (shore of Lake Superior).

A. C. Lawson, 1893 (Minn. Geol. Nat. Hist. Surv. Bull. 8, pp. xxi, 22–23). *Carltonian fm.*—New local name for anorthosite intrusive into Archean of Minn. shore of Lake Superior. Assigned to Norian [Laurentian]. Named for extensive exposures in Carlton Peak, NE. Minn.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, p. 374), assigned the anorthosite of Carlton Peak to Keweenawan series, and stated they considered it a facies of Duluth gabbro.

†Carlyle limestone.

Pennsylvanian: Eastern Kansas.

E. Haworth and M. Z. Kirk, 1894 (Kans. Univ. Quart., vol. 2, p. 119). *Carlyle ls.*—Ls., 4 to 20 ft. thick, overlain by Le Roy shales and separated from underlying Iola ls. by 75 ft. of sh.

According to Hinds and Greene (Mo. Bur. Geol. and Mines vol. 13, 1915) the ls. exposed at Carlyle is Plattsburg ls., but the ls. to which name *Carlyle* has been applied is an older bed—the Farley ls. bed in their Lane sh. memb.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 127). Field work shows †Carlyle ls. at type loc. is exact equiv. of Plattsburg ls. Adams was correct in considering †Carlyle a synonym of Stanton, inasmuch as type Stanton is shown to be type Plattsburg ls.

Named for Carlyle, Allen Co.

Carlyle sand.

A subsurface sand in Chester group (Miss.) of Clinton Co., Ill. (See Ill. Geol. Surv. Bull. 54, index.)

Carmack basalt.

Tertiary or Pleistocene: British Columbia and Yukon Territory.

D. D. Cairnes, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 51).

Carmack limestone.

Mississippian (early): Northeastern Mississippi (Tishomingo County).

W. C. Morse, 1928 (Jour. Geol., vol. 36, p. 37). *Carmack ls.*—Uniformly thin-bedded, brownish or bluish gray ls. that breaks into thin shaly layers on exposure. Thickness 100 ft. max. To E., in Ala., it becomes more cherty and grades into chert of Lauderdale fm. Contains early Kinderhook fossils. Named for a small stream (containing a 60-foot fall) tributary to Tenn. River N. of Whetstone Branch [Tishomingo Co., Miss.].

W. C. Morse, 1930 (Miss. Geol. Surv. Bull. 23, passim), gives many details of *Carmack ls.*, which was included in Yellow Creek beds of Lowe.

Carmanah formation.

See under *Carmanah Point beds.*

Carmanah Point beds.

Miocene: British Columbia (Vancouver Island).

J. C. Merriam, 1896 (Univ. Calif. Dept. Geol. Bull., vol. 2, pp. 101–108). *Carmanah Point beds.*—Fossils listed. Fauna seems to be Mio. and older than that of Sooke beds. A section of the rocks near Carmanah Point light-house, forwarded to writer by Dr. C. F. Newcombe, of Victoria, shows 150± ft. of ss., sh., cgl., and drift mantle. The fossils occur chiefly in the cgl.

C. H. Clapp, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 90), 1911 (Canada Geol. Surv. map 17A), and 1912 (Canada Geol. Surv. Mem. 13, p. 136). *Carmanah fm.*, Olig.-Mio., Vancouver Island, B. C.

R. Arnold and H. Hannibal, 1913 (Am. Phil. Soc. Proc., vol. 52, p. 575). Dr. Merriam states he never intended to name a Carmanah Point fm., but the name has passed into the literature. The beds at this point are San Lorenzo shales (Olig.) overlain uncon. by Monterey cgl. in cliff beneath lighthouse. Dr. Newcombe's collection came from San Lorenzo shales, from Sooke boulders in Monterey, and from Monterey itself.

Carmel formation. (In San Rafael group.)

Upper Jurassic: Southern, central, southeastern, and northeastern Utah, southwestern and northwestern Colorado, northwestern New Mexico, and northern Arizona.

J. Gilluly and J. B. Reeside, Jr., 1926 (U. S. G. S. Press Bull. 6064, March 30, 1926). (Name adopted at joint conference of H. E. Gregory, R. C. Moore, J. Gilluly, and

J. B. Reeside, Jr., from area specially studied by Messrs. Gregory and L. F. Noble.) *Carmel fm.*—Dense ls. and buff and red ss. at base; toward top dominantly red and green sh. with thin sss. and heavy beds of gyp. Thickness 200 to 650 ft. Overlies Navajo ss., with possible uncon., and conformably underlies Entrada ss. Is basal fm. of San Rafael group.

Named for occurrence at Mount Carmel, western part of Kane Co., Utah.

For additional details see U. S. G. S. P. P. 164, 1931 (by H. E. Gregory and R. C. Moore), and U. S. G. S. P. P. 183, 1936 (by A. A. Baker, C. H. Dane, and J. B. Reeside, Jr.).

Carmelo series.

Eocene (?): Western California (Carmelo Bay region, southwest coast of San Mateo County).

A. C. Lawson, 1893 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 1, pp. 1–59). *Carmelo series.*—Several hundred ft. of thick-bedded cgls. of dark color and thinly bedded tawny sss. with some argill. shales. No fossils at Carmelo Bay, but the series appears to be identical with the coal-bearing sss. of Malpaso Canyon, about 2 mi. distant, which carry coal and appear, from fragmentary fossils found, to be of Tejon (Eocene) age. Overlain uncon. by Mio. Monterey series, and uncon. underlain by Santa Lucia granite.

H. J. Hawley (Geol. Soc. Am. Bull., vol. 28, p. 225, 1917) and P. D. Trask (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 16, p. 142, 1926) regard these rocks as of Chico age.

Carmichael sand.

A subsurface sand, of Penn. age and 19 to 50 ft. thick, in central northern Okla., reported to correlate with a part of Nelagoney fm. In Tonkawa pool it lies at 2,050 ft. depth, and below Lower Hoover sand and above Endicott sand.

Carmichaels formation.

Pleistocene (Illinoian): Western Pennsylvania.

M. R. Campbell, 1902 (U. S. G. S. Masontown-Uniontown folio, No. 82). *Carmichael clay.*—Clay, sand, and boulders on terraces and in abandoned channels of the larger streams. Thickness 50 to 80 ft. Exposed at Carmichaels, Greene Co.

Carneros sandstone member.

Miocene: Southern California (Kern County).

G. M. Cunningham and W. F. Barbat, 1932 (A. A. P. G. Bull., vol. 16, No. 4, pp. 419–421, from unpublished ms. of A. R. May and J. D. Gilboe). *Carneros ss. memb.*, basal bed of type Temblor; 168 ft. thick; *Scutella merriami.* [Apparently named for Carneros Creek.]

G. C. Gester and J. Galloway, 1933 (A. A. P. G. Bull., vol. 17, No. 10, p. 1169), divided Temblor fm. in McKittrick-Midway-San Emigdio region into (descending): Gould sh., Button bed ss., Media sh., *Carneros ss.*, Santos sh., and *Phacoides* reef.

E. L. Packard and R. Kellogg, 1934 (Carnegie Inst. Wash. Pub. 447, Contr. to Pal., p. 17). *Carneros ss. memb.* is a name used first by H. G. Schenck and F. E. von Estorff in a ms. for the "main reef" of type Temblor. The term has crept into literature and is now fairly well known by local stratigraphers.

Carolina gneiss.

Pre-Cambrian: Northwestern North Carolina and South Carolina, northern Georgia, eastern Tennessee, and western Virginia.

A. Keith, 1901 (U. S. G. S. Washington folio, No. 70, p. 2). *Carolina gneiss.*—Alternating layers of mica gneiss and mica schist, of prevailingly gray color; dark bluish-gray when fresh, greenish or yellowish-gray when weathered. Both kinds of layers highly siliceous. Includes small bodies of granite, schistose granite, and diorite, and in places numerous small crystals of garnet. Thickness doubtless many thousand ft. Oldest rocks in region. Overlain by Archean granite gneiss.

A. Keith, 1903 (U. S. G. S. Cranberry folio, No. 90, p. 2). *Carolina gneiss.*—An immense series of interbedded mica schists, mica gneiss, and fine granitoid layers.

Most of them are light or dark gray in color, weathering to dull gray and greenish gray. Lenses and veins of pegmatite, and some layers of white granitic material. That part of fm. adjacent to overlying Roan gneiss contains some thin interbedded layers of hornblende schist and hornblende gneiss precisely like Roan gneiss, constituting transition btw. the fms. The Carolina gneiss is oldest in this region. Named for its great extent [on the Piedmont Plateau] in North and South Carolina. Both Carolina gneiss and Roan gneiss are Archean.

Carolina slate belt.

A term that has sometimes been loosely applied to the great belt of pre-Camb. rocks of western North Carolina and northwestern South Carolina.

†Carolina bed.

An abbreviation of Ruffin's name "Carolinian bed."

Carolina-Texas sand.

A subsurface sand in Cook Mtn fm. (of Claiborne group) of southern Tex. Lies lower than Webster sand.

†Carolinian bed.

Eocene: Eastern South Carolina and North Carolina.

E. Ruffin, 1843 (Agric. Surv. S. C. 1st Rept., pp. 6–24). *Great Carolinian bed.*—The next oldest fm. of marl in S. C. Extends from E. of the Santee to far across the Savannah. Is younger than Peedee marl (Cret.) and older than the Mio. marl. In general is of dingy yellowish white or pale buff color, of different shades; sometimes a dull greenish color is added to the ordinary shades. Texture close and firm; fracture something like that of chalk, though the mass is generally softer; in a few cases more indurated. Very few fossils. In some places greensand forms a large ingredient of the marl. Exposed on Ashley and Cooper Rivers and their branches, also on Santee River and its branches, and on the Savannah and its branches.

Includes Cooper and Santee marls and other beds. As used by some authors included Mio. (See C. W. Cooke, U. S. G. S. Bull. 867, 1936.)

Named for extensive development in Coastal Plain of S. C. (C. W. Cooke, personal communication.)

†Carolinian.

A term introduced by A. Heilprin (Phila. Acad. Nat. Sci. Proc. 1882, pp. 179–185, 1883) for "Upper Atlantic Miocene deposits of South and North Carolina ('Sumter' epoch of Dana). The South and North Carolina deposits represent approx. the same geological horizon. The Virginia deposits indicate a horizon lower (older) in the geological scale than that of either of the formations just mentioned. The Maryland deposits indicate two well-marked faunal horizons, of which the upper one is the correspondent of the Virginian." Included all of Chesapeake group of current nomenclature.

Caroni series.

Tertiary: Trinidad.

G. P. Wall and J. G. Sawkins, 1860 (Geol. of Trinidad, pp. 41–45).

Carpenter bed.

Upper Cretaceous (Gulf series): Western Texas (El Paso County).

J. A. Taff, 1891 (Tex. Geol. Surv. 2d Ann. Rept., pp. 733, 735.) *Carpenter bed.*—Local name for Eagle Ford or Benton shales in El Paso Co. Consists of (descending): (1) Very fissile, black, slightly aren. clay sh., with numerous Inocerami and oysters, 300 ft.; (2) flaggy, fissile, calc. argill. ss., with numerous oyster shell fragments and Inocerami, 430 ft.; (3) siliceous ls. with oysters, 30 ft. Top fm. of Upper Cret. Overlies Lower Cross Timber or Dakota sand.

Apparently named for Carpenter Spring, E. side of Eagle Mtn, El Paso Co.

Carpenter Creek porphyry.

Tertiary: Central Montana (Little Belt Mountains).

L. V. Pirsson, 1900 (U. S. G. S. 20th Ann. Rept., pt. 3, p. 501). *Carpenter Creek type of granite porphyry* is variant of Wolf Butte type of granite porphyry. Named for occurrence (locally) above Carpenter Creek, Little Belt Mtns.

P. A. Schafer, 1935 (Mont. Bur. Mines and Geol. Mem. 13, map, pp. 10–15). *Carpenter Creek porphyry.*—In valleys of Carpenter and Snow Creeks is a swarm of dikes corresponding to what Weed and Pirrson have called *Carpenter Creek porphyry.* [Assigned to Tert.]

Carper sand.

Devonian or Mississippian: Southeastern Illinois (Clark County).

G. F. Moulton, 1926 (Ill. Geol. Surv. Press Bull. No. 4, pp. 1–2). *Carper sand.*—Fine-grained ss., which occurs in lenticular bodies of considerable areal extent in black sh. underlying the Miss. ls. in Martinsville pool, Clark Co. Yields oil on John Carper farm, sec. 30, T. 10 N., R. 13 W. Commonly the ss. occurs in 2 or more beds separated by 10–15 ft. of sh. In a few places as many as 4 separate beds of ss. are found. Usually the top sand is barren of oil. The second sand is generally the producing memb. of Carper sand zone.

L. A. Mylius, 1927 (Ill. Geol. Surv. Bull. 54, table 5), placed this sand in Kinderhook.

Carpinteria formation.

Pleistocene: Southern California (Santa Barbara County).

R. W. Chaney and H. L. Mason, 1934 (Carnegie Inst. Wash. Pub. 415, pp. 48–52; preprint 1932). *Carpinteria fm.*—Name suggested for the deposits at Carpinteria that contain Pleist. flora, but the name may perhaps be appropriately extended to cover all of Pleist. alluvium mapped by R. Arnold (U. S. G. S. Bull. 321, 1907) along this part of Calif. coast. Deposits on Santa Cruz Island that contain a closely related flora have been termed *Santa Cruz Island fm.* The *Carpinteria fm.* lies horizontally across upturned edges of Monterey fm. as mapped by Arnold in Bull. 321, the relations of the 2 fms. being clearly shown for considerable distance E. and W. along the sea cliff. Thickness 10 to 38± ft. [Thickest section described consists of (descending):] (1) Light-gray to yellowish compact sands, 10 ft.; (2) cobble gravel, well rounded, 3 ft.; (3) light-gray to yellowish sands, 10 ft.; (4) cobble and boulder gravel, with cross-bedded sand pockets containing cones and wood, 15 ft. Most of organic remains occur at about middle of fm. [Flora described.]

†Carquinez series.

Eocene: Western California.

R. Arnold, 1902 (Sci., n. s., vol. 15, p. 416), and A. C. Lawson, 1903 (Geol. Soc. Am. Bull., vol. 13, p. 545). *Karquinez* includes Tejon (2,100 ft. thick) and Martinez (2,200 ft. thick), or all of Eo. of western Calif.

A local geographic name synonymous with *Eocene series* in this region. Probably named for occurrence at Carquinez Bay, Carquinez Point, or Carquinez Strait, connecting Suisun and San Pablo Bays. *Carquinez* is spelling adopted by U. S. Geographic Board.

Carr sand.

A subsurface sand, 35 ± ft. thick, in upper (Trinity) part of the Comanche Cret. of Talco field, Titus and Franklin Counties, Tex., lying higher than Galt sand. Named for fact it was first encountered in C. M. Carr discovery well.

Carrasco limestone.

Upper Cambrian (?): Southwestern New Mexico (Silver City region).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257–259; Conspectus of geol. fms. of N. Mex., pp. 4, 5). *Carrasco ls.*—Main calc. memb. of Late Ordovicic age well displayed back of Carrasco smelter property near Silver City. Thickness 75 ft. [On p. 4 he puts it in "Late Cambric;" on p. 5 in "Late Ordovicic."]

Carrigan black lands.

Pleistocene: Southwestern Arkansas.

R. T. Hill, 1888 (Ark. Geol. Surv. vol. 2, Ann. Rept. 1888). *Carrigan black lands.*—Transported soils covered by gravel and filled with gravelly debris. Included in Prairie de Roan div.

Carrizo sand. (In Claiborne group.)

Eocene (middle): Southern and eastern Texas and just enters Louisiana.

J. Owen, 1889 (Tex. Geol. and Min. Surv., 1st Rept. Prog., pp. 70, 73–74). *Carrizo ss.*—A line drawn from point on Neuces River S. of town of Uvalde to point 10 mi. W. of Carrizo Springs, thence S. to Rio Grande, will represent outcrop of a very loose, coarse, friable sand bed nearly 200 ft. thick. Supplies the numerous wells at Carrizo Springs. Lies conformably on late Cret. rocks. W. line of Dimmit Co. passes near W. limit of Carrizo ss. Top stratum, 40 ft. of red sand; base, gray and brown sand; some of more indurated strata answer for building stone.

E. T. Dumble, 1903 (Am. Inst. Min. Engrs. Trans., vol. 33, pp. 924–932). *Carrizo sands.*—Interbedded sands and sandy clays, of white or yellow color, containing ferruginous matter and nodules, strings of concretions and laminae. Sands somewhat calc. and in places indurated to buff ss. excellently adapted for building purposes. Included in top of Lignitic [Wilcox group]. Strat. equiv. of Queen City beds of Kennedy. Overlie series of red and white clays with iron, forming middle part of Lignitic. In places overlap underlying Lignitic beds and Midway. Underlie Lower Claiborne stage. [In 1911 (Tex. Acad. Sci. Trans., vol. 11, pp. 52–53) Dumble included these deposits in the Claiborne.]

E. W. Berry, 1922 (U. S. G. S. P. P. 131A). The age of *Carrizo ss.* has heretofore been somewhat uncertain. Referred originally to the Wilcox it has been considered by several Tex. geologists to be of Claiborne age. The plants found in it, as well as those found above and below it near Rio Grande, definitely settle its upper Wilcox age, and show that it is in nature of a lens, which becomes thinner toward Rio Grande, where its upper part is replaced with more typical and more argill. Wilcox deposits, also carrying characteristic fossil plants. *Type exposure is in quarries about ½ mi. W. of Carrizo Springs, Dimmit Co.*

A. C. Trowbridge, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 75; U. S. G. S. P. P. 131D), divided Wilcox group of southern Tex. into (descending) Bigford fm., Carrizo ss., and Indio fm. and stated that Bigford fm. is in part contemp. with Carrizo ss. and in part younger, and that the Carrizo rests on Indio fm. with uncon. and overlap. Thickness of Carrizo 118 to 400± ft.

A. C. Ellisor, 1929 (A. A. P. G. Bull., vol. 13, pp. 1339–1346). *Carrizo sands memb. of Claiborne fm.*—In Tex., on W. side of Sabine uplift, occurs a fine-textured, clean, white, micaceous sand below Reklaw memb. of Claiborne and above Wilcox fm. On the surface this sand can be traced into Carrizo sands of Milam Co. It is lithologically different from the Wilcox and separated from it by an uncon. For these reasons it is placed in the Claiborne, rather than in the Wilcox.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, p. 614). Owen did not designate type loc. Berry stated type loc. is the outcrop in the quarries ½ mi. W. of Carrizo Springs. These quarries are now thought to lie in base of the Reklaw and not in the original series of underlying sands defined as Carrizo. Geologists working in dist. agree that if a type loc. is to be designated, it should be the exposure known as Brand Rock on Peña Creek W. of Carrizo Springs. The Carrizo sand is basal fm. of Claiborne group. Grades into overlying Reklaw memb. of Mount Selman fm. and is uncon. on Wilcox. So closely resembles the younger Queen City sand that for long time it was believed to be same as Queen City.

The Carrizo sand is now assigned by most geologists to Claiborne group. (See under *Mount Selman fm.*, 1932 and later entries.) It is treated by Tex. Geol. Surv. and U. S. Geol. Survey as a distinct fm. underlying Mount Selman fm. and overlying the Wilcox. But A. Deussen (1934 and 1936, A. A. P. G. Bull.) treated it as basal memb. of Mount Selman fm.

†Carrizo formation.

Pre-Cambrian: Western Texas (Van Horn region).

See *Carrizo Mtn schist*, 1891 entry.

†Carrizo formation.

Miocene: Southern California (Imperial and San Diego Counties).

J. P. Smith, 1910 (Jour. Geol., vol. 18, No. 3, chart opp. p. 226). *Carrizo fm.*, sss. with *Pecten carrizoensis* and *P. cerrosensis.* Of upper Mio. age. Older than San Diego.

W. S. W. Kew, 1914 (Calif. Univ. Pub. Dept. Geol. Bull., vol. 8, pp. 39–46 and map). [Called *Carrizo fm.* on map; no text heading; throughout description called *Carrizo fm.* and *Carrizo Creek fm.*] At type loc. divided, on lithologic and biologic grounds, into Lower Division and Upper Division. The upper div. is about 2,000 ft. thick in Carrizo Valley, and consists of fine-grained muddy ss. and sh. It extends N. along W. side of Salton Sea to Santa Rosa Mtns, which is most northerly limit of the beds in this region. The lower div. consists of about 200 ft. of more or less coarse arkosic ss., locally conglomeratic, underlain by a coarse angular cgl. of subaqueous origin and reddish color. Total thickness of fm. probably 2,500 ft. Rests on eroded surface of basement complex or, in places, on a flow of andesite.

J. P. Buwalda and W. L. Stanton, 1930 (Sci., n. s., vol. 71, pp. 104–106). *Carrizo fm.* is Mio. or lower Plio.

W. P. Woodring, 1931 (Carnegie Inst. Wash. Pub. 418, pp. 1–25). "Carrizo fm." of Kew (preoccupied) included the marine Imperial fm. (late lower Mio.) and at least basal part of overlying nonmarine deposits of upper or middle Mio. age here named *Palm Spring fm.*

See also †*Carrizo Creek beds* and *Imperial fm.*

Named for exposures in broad valley of Carrizo Creek immediately N. of Coyote Mtn, Imperial Co.

†Carrizo Creek beds.

Miocene: Southern California (Imperial County).

C. R. Orcutt, 1890 (Calif. State Min. Bur. 10th Ann. Rept., p. 915). *Carrizo Creek oyster beds.*—Shales and clays of light-brown or pinkish color, through which Carrizo Creek has been cut. Tentatively assigned to Mio.

T. W. Vaughan, 1917 (U. S. G. S. P. P. 98, pp. 355–386). The fauna of *Carrizo Creek* is related to Plio. and post-Plio. faunas of Fla. and West Indies and can scarcely be older than lower Plio.

W. S. W. Kew, 1920 (U. S. G. S. Press Bull. 447, June 1920). These beds are known as *Carrizo Creek beds*, from extensive outcrops on Carrizo Creek, but can also be seen along W. side of valley around Coyote Mtn, at Yuba Buttes and at Superstition Mtn, as well as at San Felipe Valley, W. of Salton Sea, and at places N. of San Gorgonio Pass, in Riverside Co. Remnants of these beds rest on the crystalline rocks at elev. as high as 2,000 ft. above present level of valley. The Carrizo Creek beds consist mainly of tan-colored well-bedded sandy shales or silts, but include small amounts of ss. and clayey sh. At some places, as on Carrizo Creek, they contain numerous marine fossils, the remains of animals that lived probably in Plio. time.

See also †*Carrizo fm.*, W. S. W. Kew, 1914.

In 1926 (Calif. Acad. Sci. Proc., 4th ser., vol. 14, p. 434) G. D. Hanna named these beds *Imperial fm.*

In 1931 (Carnegie Inst. Wash. Pub. 418, pp. 1–25) W. P. Woodring divided these beds into Palm Spring fm. above (nonmarine) and Imperial fm. (restricted) below (marine).

Carrizo Mountain schist.

Pre-Cambrian: Western Texas (Van Horn region).

W. H. von Streeruwitz, 1891 (Tex. Geol. Surv. 2d Ann. Rept., 1890, pp. 681–683). *Carrizo schists.*—The S. part of Carrizo Mtns is built up of reddish, gray, and lighter and darker greenish crystalline schists, with numerous quartz dykes, tilted and upheaved by this quartz and by granitic and granitoid rocks, which on N. and NW. side protrude through the schists. On S. side these schists disappear under lss., and these under the recent soil of the flats and gravel hills. * * * The crystalline schists cross Texas & Pacific Ry near Allamore, running into a low ridge, which 6 mi. W. of Van Horn Station disappears in the flat at foot of the Carbf. cliffs, which rest on non-fossiliferous red and brown sss. and grit. * * * The grit in its most southern exposure in Carrizo Mtns occurs in Round Mtn at

Allamore, rising above the flat and the low Carbf. ls. hills that run parallel with Texas & Pacific Ry to about 1 mi. W. of Allamore. On E. side of this gritty butte the red schistose rocks disappear under the grit strata, reappearing occasionally in the more northern part of Carrizo Mtns, together with serpentinous, basaltic, and greenstone intrusions.

G. B. Richardson, 1914 (U. S. G. S. Van Horn folio, No. 194, p. 3). *Carrizo fm.*—A complex of qtzite, sl., a variety of schists, and metamorphosed igneous rocks, which outcrops in Carrizo Mtns S. of Texas & Pacific Ry. The schists are chiefly of sed. origin, but a small part of fm. consists of schists which presumably represent igneous sills that were injected in thin layers btw. the sediments. Oldest exposed fm. in Carrizo Mtns in Van Horn quad. Underlies (sequence concealed) Millican fm.

Because of conflict of *Carrizo* with the Eocene Carrizo sand of Tex., the Tex. Geol. Survey and U. S. Geol. Survey now call this fm. *Carrizo Mtn schist.*

Named for Carrizo Mtns, El Paso Co.

Carroll moraine.

See under *Bethlehem moraine.*

Carroll sand.

A subsurface sand in Monongahela fm. (Penn.) of W. Va., that lies at or near horizon of Uniontown ss. memb.

†Carrollton limestone.

Mississippian: Northwestern Arkansas (Eureka Springs-Harrison region).

H. S. Williams, 1900 (Ark. Geol. Surv. Ann. Rept. 1892, vol. 5, pp. 334–337). *Carrollton ls.*—Gray ls., exposed in cliff in ravine in Carrollton [Carroll Co.] carrying fauna evidently more recent than that of Red Marbles [St. Joe ls. memb.] of other parts of State, but sections observed do not present the two fms. in strat. sequence. Contains Burlington and Keokuk fossils and represents about same fauna as that of Boone chert.

Is upper 90 ft. of Boone ls. (See A. H. Purdue and H. D. Miser, U. S. G. S. Eureka Springs-Harrison folio, No. 202, p. 10, 1916.)

Carrollton Mountain porphyry.

See *Carlton porphyry.*

Carson lava.

Age (?): Southwestern Washington (near Carson).

I. A. Williams, 1916 (Oreg. Bur. Mines and Geol., Min. Res. Oreg., vol. 2, No. 3, pp. 95–96). *Carson lava.*—Dark-gray beds of blocky lava that obviously came as a series of heavy flows. Rises above Carson Station, Wash., and extends E. to the deeply incised canyon of Wind River [Skamania Co.].

Carson Creek formation.

Age (?): Northern California (Calaveras County).

F. A. Moss, 1927 (Eng. and Min. Jour., vol. 124, pp. 1010–1011). In Carson Hill area the oldest rocks constitute a sed. and volcanic series at least 5,000 ft. thick, to which I have given local name of "*Carson Creek fm.*" It is best exposed W. of Carson Hill. Sediments in lower part are chiefly cgls. with a few thin partings of ss. Near bottom is a series of hornblende-dacite lava flows and rhyolite tuffs 900 to 1,700 ft. thick. Upper part of fm. is sl., mostly tuffaceous, with several lenses of ls. and beds of andesitic crystal tuff. At top is a thick and massive bed of andesitic tuff, in places containing much admixed sediment.

Carsonian series.

A term proposed by C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 52, 78), "for the Mid Quaternic sands and gravels overlying the Lahontan lake beds, especially well exposed in the valleys of the Carson and Truckee Rivers in western Nevada."

Cartago formation.

Eocene (?): Costa Rica.

E. B. Branson, 1928 (Mo. Univ. Studies, vol. 3, No. 1, p. 62). [Assigned to Eo. (?).]

Carters limestone member (of Lowville limestone).

Middle Ordovician: Central Tennessee (Nashville dome).

J. M. Safford, 1869 (Geol. Tenn., pp. 258–268). *Carter's Creek ls.*—Heavy-bedded, light blue or dove-colored, fossiliferous ls., upper part often gray. Thickness 50 to 100 ft. Top fm. of Trenton or Lebanon [Stones River] group. Underlies *Orthis* bed [Hermitage fm.] of Nashville group, and overlies Glade [Lebanon] ls. [This definition of Carters ls. (for beds underlying Hermitage fm. and overlying Lebanon ls.) was followed in all Tenn. repts up to 1932, although paleontologists have in recent years excluded it from Stones River group and assigned it to Lowville epoch.]

E. O. Ulrich and C. W. Hayes, 1903 (U. S. G. S. Columbia folio, No. 95), included Carters ls. in Stones River group, as did E. O. Ulrich in 1911 (Geol. Soc. Am. Bull., vol. 22).

R. S. Bassler, 1915 (U. S. Nat. Mus. Bull. 92, vol. 2, pl. 1), stated that Lebanon ls. is top fm. of Stones River group, but did not say where Carters ls. belongs.

R. S. Bassler, 1919 (Md. Geol. Surv. Camb. and Ord. vol., p. 51), replaced Carters ls. with Lowville ls., and showed two fms. (which he called *Upper Decorah sh.* below and *Curdsville* above) separating the *Lowville* (*Carters*) from Hermitage ls. in Nashville dome, but without explanation as to whether these two fms. were subtracted from the Hermitage or the Carters of previous Tenn. repts.

J. J. Galloway, 1919 (Tenn. Geol. Surv. Bull. 22), described *Carters ls.* of Rutherford Co., Tenn., as of Black River age, as uncon. underlying Hermitage fm., and as uncon. overlying Lebanon ls., and in his section and map showed no intervening fm., but in his text he stated that Black River group in this Co. possibly includes an unnamed fm. occurring as a lens above the Carters in SE. part of Co., of Decorah age.

P. E. Raymond, 1922 (Geol. Soc. Am. Bull., vol. 33, p. 585), stated that there is no fm. intervening btw. Carters and Hermitage in central Tenn.

E. O. Ulrich, 1924 (Tenn. Dept. Ed., Div. Geol. Bull. 31, p. 16), defined Carters ls. as 110 ft. thick, as of Lowville age, and as uncon. overlain by Hermitage sh. and uncon. underlain by Lebanon ls.

R. S. Bassler, 1932 (Tenn. Dept. Ed., Div. Geol. Bull. 38), restricted Carters to lower beds of Lowville age in Tenn., correlated the upper beds with Tyrone ls. of Ky., and called them *Tyrone* in Tenn. The upper beds of Lowville age (their Tyrone) are said by Ulrich and Bassler not to be present at Carters type loc., but Bassler stated (p. 63) that they outcrop a short distance beyond the Carters Creek area.

A. M. Piper, 1932 (U. S. G. S. W. S. P. 640, p. 52), adopted Bassler's restricted definition, applying *Lowville ls.* to beds called Carters ls. since 1869; restricting *Carters* to lower part of beds heretofore included under that name, or to the massive, compact, white, or light-gray cherty ls., which he designated as *Carters ls. memb. of Lowville ls.*, and did not apply any name to upper memb. of Lowville ls.

Named for exposures on Carters Creek, Maury Co.

†Carters Creek limestone.

Middle Ordovician: Central Tennessee.

See *Carters ls.*, adopted name.

Cartersville formation.

Lower Cambrian: Northwestern Georgia (Cartersville district).

H. K. Shearer, 1918 (Ga. Geol. Surv. Bull. 34, pp. 48–49, 128–163). *Cartersville fm.*—(Name suggested by L. LaForge.) Sh., sl., and feldspathic ss., most of it characterized by an unusually high content of potash. Soft light-colored sh. makes up greater part of fm. The sl. is gray or purplish gray and forms minor beds and lenses, the thickness of any single lens rarely exceeding 50 ft. The fm. contains a number of thin beds of common siliceous ss., some of it so hard as to properly be called qtzite. In vicinity of Cartersville the fm. is entirely soft shales. Thickness about 1,000 ft. Underlies Conasauga fm., and might be considered a memb. of Conasauga, but it carries more potash than latter and lss. are lacking. Overlies Beaver [Shady] ls. Is probably contemp. with Rome fm., Apison sh., and Watauga sh., but exposures are not continuous with those fms. and lithology is very different, hence the local name *Cartersville fm.*

Named for exposures in vicinity of Cartersville, Bartow Co.

Cartersville granite.

Pre-Cambrian: Central Virginia.

A. I. Jonas, 1928 (Va. Geol. Surv. prel. ed. of geol. map of Va.). *Cartersville granite.*—Muscovite granite intrusive into Glenarm series. Mapped at and around Cartersville, Cumberland Co.

Carterville formation.

Mississippian (late): Southwestern Missouri.

C. E. Siebenthal, 1907 (U. S. G. S. Joplin folio, No. 148). *Carterville fm.*—Light to dark shales and shaly and oolitic lss. with some massive soft to hard sss. Thickness 0 to 50 ft. Uncon. underlies Cherokee fm. and uncon. overlies Boone fm., the upper 100 ft. of which, above Short Creek oolite memb., consists of ls. containing the Carthage quarry beds. The Carterville fm. contains Chester fossils (listed). Named for exposures just W. of Carterville, Jasper Co.

E. B. Branson, 1918 (Univ. Mo. Bull. vol. 19, No. 15, p. 71). *Carterville fm.* is contemp. with Aux Vases ss. Was formed in a bay that advanced in SW. Mo.

Carthage limestone. (In McLeansboro formation.)

Pennsylvanian: Western Kentucky and southern Illinois.

D. D. Owen, 1856 (Ky. Geol. Surv. vol. 1, pp. 60, 61) and 1857 (Ky. Geol. Surv. vol. 3, p. 18). *Carthage ls.*—Lies in upper part of Coal Measures of southwestern coal field bordering Ohio River 1 mi. below Uniontown [Union Co., Ky.], where it is about 8 ft. thick. Separated from overlying coal No. 18 by 50 ft. of ss. and sh.

Named for Carthage Settlement (no longer in existence) on Ohio River, in Union Co., Ky., just above mouth of Wabash River.

Lies in upper part of McLeansboro fm.

Carthage limestone.

Mississippian (Warsaw): Southwestern Missouri.

J. A. Gallaher, 1898 (Mo. Geol. Surv. Bien. Rept. pp. 30, 37, 38). *Keokuk or Carthage ls.*—Crystalline ls. distinguished by numerous crinoids. Forms, with Burlington ls., principal country rocks of marvelous lead and zinc deposits of SW. Mo.

E. R. Buckley, 1911 (Types of ore deposits, p. 117). *Carthage ls.* consists of 100 ft. of practically noncherty crystalline ls. forming top memb. of Burlington fm. [not Burlington]. Overlies Short Creek oolite memb. and underlies, uncon., Chester.

Is upper part of Boone ls. The Short Creek oolite and the overlying ls. are now considered to be of Warsaw age.

Named for exposures at Carthage, Jasper Co.

Carthage moraine.

Pleistocene: Northwestern New York (Lewis and Jefferson Counties).

A. F. Buddington, 1934 (N. Y. State Mus. Bull. 296, p. 42). In Antwerp and Carthage quads. Named for town.

Cartright sand.

A subsurface sand in Yegua fm. (Eocene) of Pettus area, Bee Co., SE. Texas.

Carwood formation.

Mississippian: Southeastern Indiana.

P. B. Stockdale, 1929 (Ohio Jour. Sci., vol. 29, No. 4, p. 170). See under *Borden group*.

P. B. Stockdale, 1930 (Geol. Soc. Am. Bull., vol. 41, p. 197).

P. B. Stockdale, 1931 (Geol. Soc. Am. Bull., vol. 42, p. 709). *Carwood fm.*—At S., in Ind., it is at most places a massive, fine-grained ss. or siltstone. Here and there a silty facies displays a shaly appearance where weathered. In places highly fossiliferous. [Fossils listed.] In N. part of unglaciated outcrop area the fm. displays a number of lithologic facies varying from argill. sh. and shaly siltstone to a bedded succession of thin, resistant ss. beds and shaly layers. Thickness 105 to 150 ft. Underlies Floyds Knob fm. and overlies Locust Point fm.

P. B. Stockdale, 1931 (Ind. Dept. Cons., Div. Geol., Pub. 98, pp. 54, 55, 76, 120–124, 147). Above Locust Point fm. is a fm. 115± ft. thick, slightly coarser in texture, more massive in structure, and which weathers less readily to a shaly appearance. It has commonly been referred to as a ss., but in reality is more properly designated a sandy siltstone in Floyd Co. Contains a few small geodes and concretions and locally a fauna of large brachiopods; in some places many bryozoans. In part this fm. is *Holtsclaw ss.* of Butts. A number of factors make it advisable to propose a different name. The term *Carwood fm.* is proposed in this paper, from village of Carwood (Bridgeport), Clark Co., Ind., 4¾ mi. SE. of Borden. Underlies Floyds Knob fm. and overlies Locust Point fm. [On p. 109 he gives thickness of 240 to 275 in southern Ind. and 210 in Jefferson Co., Ky. In this rept. geographic names are applied to several local *facies* of the fm. See also under *Rosewood sh.*]

Cary substage.

Pleistocene: Mississippi Valley.

See under *Mankato substage* and under *Wisconsin stage.*

Casadepaga schist.

Early Paleozoic or pre-Paleozoic: Northwestern Alaska (Seward Peninsula).

P. S. Smith, 1910 (U. S. G. S. Bull. 433, pp. 70–75, maps). *Casadepaga schist.*—Metamorphic schists of igneous origin, seldom auriferous. Assigned to post-Ord. (?). Determination of igneous origin rests more upon areal and structural relations than upon chemical composition. Covers 100 sq. mi. in Solomon and Casadepaga quads, one belt along E. part of quads and another along W. part of quads.

Cascade series.

Carboniferous (?): British Columbia.

A. R. Selwyn, 1872 (Canada Geol. Surv. Rept. 1871–72, p. 60).
G. M. Dawson, 1879 (Canada Geol. Surv. Rept. 1877–78, pp. 63B, 67B, etc.).

†Cascade sandstone. (In Chemung formation.)

Upper Devonian: Northeastern Pennsylvania (Susquehanna County).

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. G_5, pp. 74–79, 82, 98). *Cascade ss.*—Rather coarse, very hard, yellow sand rock, full of shells in lower layers. Thickness 25 ft. in Susquehanna Co. Makes the fine cliffs which wall in Cascade Creek where Erie R. R. crosses it. I identify this Cascade ss. with Mr. Sherwood's Fall Creek cgl. of Rept. G, on Bradford and Tioga Counties, p. 90. [Sherwood called this cgl. on Fall Creek *Chemung cgl(?)*, not *Fall Creek cgl.*] Underlies Mansfield reds, and lies about 130 ft. below top of Chemung.

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, p. 593). Perhaps White's correlation of the Fall Creek with Cascade ss. was nearer the truth than is usually supposed.

†Cascade formation.

Pre-Cambrian: Northwestern Michigan (Marquette district).

M. E. Wadsworth, 1890 and 1891 (Lake Superior along the south shore, by Julián Ralph, pp. 77–99; 1st ed., 1890; 2d ed., 1891). *Cascade fm.*—Hornblende schist and granite of Cascade or Palmer and nonfragmental jaspilite and ore of Ishpeming and Negaunee. Best seen at Cascade Range, Marquette dist. Underlies Republic fm.

Applies to lower part of "Archean," according to C. R. Van Hise and C. K. Leith (U. S. G. S. Bull. 360, p. 147, 1909).

†Cascade formation.

Lower Cretaceous: Central Montana (Little Belt Mountains and Fort Benton region).

W. H. Weed, 1899 (U. S. G. S. Fort Benton folio, No. 55). *Cascade fm.*—Alternating sss. and shales, 225 to 520 ft. thick, overlying Ellis fm. and underlying Dakota fm. Contains Lower Cret. leaves resembling those from Kootanie fm. of Canada.

Includes Kootenai and Morrison (?) fms.

Named for development in Cascade Co.

Cascade formation.

Pleistocene: Central northern Oregon and southwestern Washington.

See under *Cascades fm.*, 1931 and 1932.

Cascade Creek sandstone. (In Chemung formation.)

Upper Devonian: Northeastern Pennsylvania (Susquehanna and Wayne Counties).

J. J. Stevenson, 1892 (Am. Geol., vol. 9, p. 22; Am. Ass. Adv. Sci. Proc., vol. 40, p. 235). *Cascade Creek ss.* is same as Falls [Fall] Creek ss. of Bradford Co., Allegrippus cgl. of Bedford and Huntingdon Counties, and Lower Chemung cgl. of Fulton Co. [I. C. White named it *Cascade ss.*]

Cascades formation.

Pleistocene: Central northern Oregon and southwestern Washington.

I. A. Williams, 1916 (Oreg. Bur. Mines and Geol., Min. Res. Oreg., vol. 2, No. 3). *Cascades fm.*—Andesitic and basaltic lava flows, at least 300 to 500 ft. thick. Younger than Satsop fm. (preglacial Pleist.). Overlies The Dalles tuff btw. forks of Mill Creek. May prove to be a recent valley flow.

J. P. Buwalda and B. N. Moore, 1930 (Carnegie Inst. Wash. Pub. 404, p. 25). *Cascades fm.*—Mainly basaltic lavas and tuffs uncon. overlying The Dalles beds. Age unknown.

E. T. Hodge, 1931 (Geol. Soc. Am. Bull., vol. 42, Dec. 1931, p. 965). *Cascade fm.*—Middle Pleist. Chiefly lava flows; sed. material almost nonexistent. Comprises entire series of flows that form Cascade Mtns. Lies on Dalles fm. (Pleist. or late Plio.).

E. T. Hodge, 1932 (Oreg. Univ. Pub. Geol. ser., vol. 1, No. 5. p. 5). *Cascade fm.* proposed for the great mass of lavas that cap northern two-thirds of Cascade Mtns in Oreg. and that lie on top of Madras fm. and are older than the intercanyon lavas that occur in the valleys cut in its surface. Tentatively, therefore, it includes all lavas younger than Madras fm. and older than Recent. Dominantly andesitic with a few basalts and some trachyte. Btw. the lava flows are thin beds of volcanic ash which thicken to W. [Accompanying geol. map, of a part of central northern Wash. (120° to 121° 30′, 44° to 46°), shows *Cascade fm.* (*Pleist. and Plio.*) underlain by Madras fm. (Plio.), and states that Madras fm. of this map includes beds to N. that have been variously known as *The Dalles beds* and *Satsop fm.*]

Cascadia formation.

Oligocene and Miocene (?): Central northern Oregon (Cascade Mountains).

E. T. Hodge, 1928 (Pan-Am. Geol., vol. 49, pp. 341–356). *Cascadia fm.*—A number of widespread basic aggls., tuffs, and some basaltic lava flows, which constitute an important part of terranal succession on W. sides of the Cascades. Uncon. underlies Columbia basalts and uncon. overlies what looks like typical Clarno rhyolite. Is strat. equiv. of John Day fm. Exposed near Cascadia [Linn Co.]. Assigned to Olig.

Cascadian stage.

Pleistocene: Oregon.

E. T. Hodge, 1930 (Monthly Weather Rev., vol. 58, pp. 405–411). *Cascadian stage* (*Pleist.*).—The older epoch of glaciation in Oreg. Possibly correlates with the Admiralty, the oldest ice epoch in Wash. Separated from the younger (Jeffersonian) glacial stage by Willamettian inter-glacial stage. There is evidence of intense glaciation on E. side of Cascade Plateau.

Cascadian revolution.

A term that has been applied (C. Schuchert, Textbook geol., pt. 2, p. 612, 1924) to the period of uplift of Cascade Mtns, Oreg., beginning in middle Miocene and continuing into present time. The 1933 Textbook geol. of C. Schuchert and C. O. Dunbar assigned this revolution to upper Plio. and Pleist.

Cascadilla shale member.

Upper Devonian: Central New York (Ithaca region).

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 202). *Cascadilla sh. memb.*, 150 ft. thick, basal div. of Ithaca facies subgroup of Ithaca-Enfield group of fms. in Ithaca region. Contains *Paracyclas lirata* fauna in middle. Overlies Middlesex sh. [Derivation of name not stated.]

Casco Bay group.

Carboniferous (Pennsylvanian?): Southwestern Maine.

F. J. Katz, 1917 (Wash. Acad. Sci. Jour., vol. 7, p. 198). *Casco Bay group.*—Occupies an area about 12 mi. wide and 30 mi. long, extending along coast from Saco, Maine, to head of Casco Bay. Consists of (descending) Mackworth sl., Jewell phyllite, Spurwink ls., Scarboro phyllite, Diamond Island sl., Spring Point greenstone, and Cape Elizabeth fm. [See also U. S. G. S. P. P. 108, pp. 170–172.] Assigned to Penn.(?). Named for development in and around Casco Bay.

On 1933 geol. map of Maine, by A. Keith, these rocks are mapped as Penn.

Casey limestone.

Middle Devonian (Hamilton): Southern central Kentucky (Casey County).

T. E. Savage, 1930 (Ky. Geol. Surv., ser. 6, vol. 33, pp. 12, 143–144). *Casey ls.*—Upper 3 to 8 ft. or more consists of thick-bedded, gray, rather fine-grained ls. with numerous irregular masses of chert. Lower 2 or more ft. consists of somewhat sandy ls., in lower part of which is a 2-inch band crowded with shells of *Ambocoelia umbonata.* Is of Hamilton age. Underlies Duffin layer (basal bed of New Albany sh.) and uncon. overlies Beechwood memb. of Sellersburg ls. Exposed near Kidd's store, in SW. part of Casey Co. Named for Casey Co., where relation of this ls. to Beechwood ls. memb. was first distinguished. In central Ky. the Casey ls. is top memb. of Boyle ls.

Casey limestone. (In McLeansboro formation.)

Pennsylvanian: Southeastern Illinois (Clark County).

See 1934 entry under *LaSalle ls. memb.*, which records the only known use of name. Derivation unknown.

Casey sands.

Name applied to some shallow subsurface sands high in Carbondale fm. (Penn.) of Clark, Coles, Cumberland, and Edgar Counties, central eastern Ill. (See Ill. Geol. Surv. Bull. 54, index.)

Caseyville sandstone. (Of Pottsville group.)

Pennsylvanian: Western Kentucky and southeastern Illinois.

D. D. Owen, 1856 (Ky. Geol. Surv. vol. 1, pp. 48, 49, 62, and plate showing section of Lower Coal Measures). *Caseyville ss.* (also *Caseyville cgl.*).—Pebbly ss. and cgl. [thickness not stated] resting on Millstone Grit in western Ky. [In some places in this rept these beds seem to be treated as part of "Millstone grit," but in plate showing section of Lower Coal Measures they rest on "Millstone grit."]

L. C. Glenn, 1912 (Ky. Geol. Surv. Rept. Prog. 1910 and 1911, p. 27). *Caseyville cgl.*—Coarse, cross-bedded, conglomeratic, cliff-forming sss., in 20 to 60-foot beds, alternating with thin beds of sh. up to 20 ft. thick, containing thin coal seams. Thickness about 200 ft. Uncon. overlies Miss. and underlies Tradewater fm. [This is adopted definition.]

Named for Caseyville, Union Co., Ky.

Cashaqua shale.

Upper Devonian: Western and central New York.

J. Hall, 1840 (N. Y. Geol. Surv. 4th Rept., pp. 390–391, 409, 423, 452–455). *Cashaqua sh.*—On the Genesee it consists of a mass of green crumbling sh. 110 ft. thick, occasionally containing thin concretionary layers of ss. On Cayuga and Seneca Lakes, more particularly at Penn Yan, it consists of ss., sh., etc. Named for exposures on Cashaqua Creek [Livingston Co.], above junction of Genesee Valley canal. Occupies interval btw. Ithaca group above and upper black sh. that overlies Tully ls., but in central N. Y. the Ithaca is absent, and Gardeau or Lower Fucoidal group overlies the Cashaqua.

J. Hall, 1843 (Geol. N. Y., 4th dist.). *Cashaqua sh.* is 110 ft. thick on the Genesee, 33 ft. on Eighteen-Mile Creek, on Lake Erie. Overlies Genesee sl. (= Upper Black sl. and Black sh. and sl. of previous Ann. Repts). Included in Portage or Nunda group. [The immediately overlying sh. (which was included in Gardeau "group" of Hall) is now called *Rhinestreet sh.*, and the underlying sh. (which was originally included in Genesee sh.) has been named *Middlesex sh.* This is present generally accepted definition of *Cashaqua sh.*]

Casmalia gypsiferous shale.
Casmalia red beds.

Miocene: Southern California (Santa Maria district).

H. W. Hoots and S. C. Herold, 1935 (Geol. of nat. gas, A. A. P. G., p. 156). *Casmalia gypsiferous sh.*—Gypsiferous clay sh. contemp. with *Casmalia Red Beds* (red beds with ls. lentils), probably of continental origin. Of Mio. age. Thickness 2,800± ft. Occur in Casmalia Hills, Santa Maria dist. Conformably underlie "Monterey" and are younger than, but not in contact with, Vaqueros fm.

Cason shale.

Upper Ordovician (Richmond): Northern Arkansas.

H. S. Williams, 1894 (Am. Jour. Sci., 3d, vol. 48, pp. 325–331). St. Clair ls. of Dr. Penrose includes beds ranging in age from Cincinnati to Niagara, and should be divided into three fms., here named (descending): *Cason ls.* (containing Clinton-Niagara fauna) [later replaced by St. Clair ls. underlain by Brassfield ls.]; *Cason sh.* (the manganese-bearing shales); and *St. Clair ls.* (restricted to beds containing Trenton fauna). The Cason sh. and underlying St. Clair ls. [later replaced by *Polk Bayou ls.* and now divided into Fernvale ls. and Kimmswick ls.] are separated by an erosion uncon., the Cason sh. either resting on St. Clair ls. [Fernvale ls.] or in hollows in it, or in hollows in older Izard ls.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 28, pp. 421, 486, 558, 559) restricted St. Clair ls. to beds of Niagaran age, and extended Brassfield ls. westward to cover the beds of Medina age previously included in St. Clair ls. [The Cason sh. as now defined therefore underlies Brassfield ls., overlies Fernvale ls. (upper part of †Polk Bayou ls.), and contains Richmond fossils.]

Named for Cason tract, near Batesville, Independence Co.

†Cason limestone.

Silurian (Niagaran and late Medina): Northern Arkansas.

H. S. Williams, 1894 (Am. Jour. Sci., 3d, vol. 48, pp. 325–331). *Cason ls.*—Upper part of St. Clair ls. of Dr. Penrose, or beds immediately overlying the manganese-bearing beds here named *Cason sh.* Contains fauna about = Waldron fauna of Ind. and Clinton-Niagara fauna of N. Y. Is lithologically distinct and should be separated from underlying beds, which contain an Ord. fauna. Thickness 100 to 110 ft. Underlies Sylamore ss., or, where that is absent, Eureka [Chattanooga] sh.

H. S. Williams, 1900 (Ark. Geol. Surv. Ann. Rept. 1892, vol. 5, pp. 281–301). Name *Cason ls.* abandoned and name *St. Clair ls.* restricted to ls. overlying the manganese-bearing beds (Cason sh.), which outcrops at St. Clair Springs. For ls. underlying Cason sh., which does not outcrop in region of St. Clair Springs, J. C. Branner's suggested name *Polk Bayou ls.* is adopted. St. Clair ls. as here restricted underlies Sylamore ss. or Eureka sh.

Replaced by St. Clair ls. (restricted sense of E. O. Ulrich, 1911) and Brassfield ls.

Named for Cason tract, near Batesville, Independence Co.

Casper formation.

Pennsylvanian, and in some areas Mississippian: Southeastern Wyoming (Laramie Basin).

N. H. Darton, 1908 (Geol. Soc. Am. Bull., vol. 19, pp. 407, 413, 414, 416, 418–430). From Casper Range southward Tensleep ss., Amsden fm., and Madison ls. give place to *Casper fm.*, 500 to 1,000 ft. thick, consisting of lss. generally lying on and overlain by gray ss. In Laramie region and southward these rocks merge into red grits. [Page 407.] The name *Casper fm.* is proposed for the lss. and sss. constituting greater part of sed. rocks in Casper and Laramie Mtns. These rocks represent SE. extension of Amsden and Tensleep fms., but are so changed in character and indefinite in strat. limits that correlation is not desirable and new name is required. The Casper lies uncon. on pre-Camb. rocks in greater part of area, but possibly to N. the basal ss. represents an attenuated E. extension of Deadwood fm. [Upper Camb.], and in eastern Carbon and Natrona Counties there may also be a small amount of Madison ls. at base, but at present there is no evidence on which to separate these. The plain on which the fm. lies rises to S., so that lowest beds included in N. part of area are not present at Laramie and southward. The fm. caps Casper Mtn and the series of high ridges extending from E. of Freeland nearly to Douglas. It extends along both slopes of Laramie Mtns, but in places is hidden by Tert. deposits, especially in NW. part of Laramie Co. It extends around S. end of Laramie Basin and along W. side of that basin as far N. as Jelm Mtn, beyond which it is dropped far beneath surface by the great fault which follows E. side of Medicine Bow Mtns. In Colo., along E. side of Front Range, the fm. consists mostly of red beds and becomes Fountain fm. As there is overlap of higher beds to S., it is probable that at latitude of Laramie, and even for some distance farther N., the Casper fm. is entirely of Penn. age.

S. H. Knight, 1929 (Univ. Wyo. Pub. Sci., Geol., vol. 1, No. 1). *Casper fm. restricted.*—W. T. Lee (U. S. G. S. P. P. 149, p. 67, 1927) pointed out that Casper fm. as used by Darton is composite fm. and in his opinion name should be abandoned. In view of fact that Casper has for 20 years been used to designate the sediments flanking Laramie Range, and is appropriate, it does not seem advisable to abandon it and substitute the later name *Ingleside,* as suggested by Lee. The Ingleside rests on Fountain fm., and writer considers it as representing the southern attenuate extension of the Casper [restricted]. In this paper *Casper fm.* is restricted to the rocks to which the name was originally applied, except that Fountain fm. and Madison ls. are not included. Writer believes that Fountain and Casper fms. are, in part at least, contemp., and that Casper as here restricted in part overlies Fountain fm. Evidence does not substantiate marked uncon., as suggested by Lee. Thickness of Casper fm. as here restricted ranges from 208 ft. in Centennial section to max. of 695 ft. in Plumbago Canyon section.

A. K. Miller and H. D. Thomas, 1936 (Jour. Pal., vol. 10, No. 8, pp. 715 +). In type region, around Casper Mtn, the lower part of the sequence is Miss. and is now generally eliminated from the Casper. It seems to us that it is impossible, without a great deal of additional strat. knowledge, to devise a satisfactory nomenclature for the beds in Laramie Basin which were called Casper by Darton. For present, therefore, it will perhaps be best in areas where the Fountain is present, as in S. part of Laramie Basin, to use *Casper* in Knight's restricted sense. But in N. part of basin, where the Fountain beds seem to be replaced by others of different lithology, there is no name to use except Casper in Darton's sense, excluding, of course, the Miss. strata which in some places occur btw. the Casper and the pre-Camb. granite.

The U. S. Geol. Survey still uses the local name *Casper fm.* as defined by Darton. As thus defined the fm. rests uncon. on pre-Camb. granite.

Cass limestone.

Pennsylvanian: Southeastern Nebraska.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 41, 58). *Cass ls.,* 12 ft. thick, overlies Plattford sh. and lies 13± ft. below White Cloud sh., all in Scranton sh. Named for exposures along Platte River NW. of South Bend, Cass Co.

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, 2d ser., p. 11). *Cass ls.* is abandoned, as another name [what?] has priority.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 210). †*Cass ls.* abandoned. Does not belong in Scranton sh. [Did not explain where it does belong.]

E. C. Reed (Asst. State Geol. Nebr.), 1936 (letter dated Oct. 16). *Cass ls.* is still being used in Nebr. It is not yet definitely known which bed in Kans. and Mo. is its equiv., and until this is decided *Cass* will be used. We believe it may be = Amazonia or Haskell ls.

Cassada-Garden gravels.

Miocene to Eocene: West Indies (Antigua).

J. W. W. Spencer, 1901 (London Geol. Soc. Quart. Jour., vol. 57, p. 500). [No age assigned. C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 759) assigned *Cassada gravels* of Antigua to "lower Mio. to upper Eo."]

Cassin formation.

A name applied by H. P. Cushing (N. Y. State Mus. Bull. 95, p. 362, 1905), J. F. Kemp (N. Y. State Mus. Bull. 138, p. 68, 1910), and C. A. Hartnagel (N. Y. State Mus. Hdb. 19, p. 34, 1912) to Lower Ord. rocks typically exposed at old Fort Cassin, Addison Co., Vt., and called *Fort Cassin fm.* by other geologists. See explanation under *Beekmantown group.*

Cassville shale member (of Washington formation).

Permian: Northern West Virginia (Monongalia County) and southwestern Pennsylvania.

I. C. White, 1891 (U.S.G.S. Bull. 65, p. 41). *Cassville plant sh.*—Dark gray sh., 5 to 15 ft. thick, which very frequently separates Waynesburg ss. from underlying Waynesburg coal. This sh. is prolific in fossil plants, especially so in vicinity of Cassville, Monongalia Co., W. Va. Is basal bed of Dunkard Creek series (Perm.).

The lower fm. of Dunkard group has for many years been called *Washington fm.*, and *Cassville sh. memb. of Washington fm.* is adopted name of U. S. Geol. Survey.

Castanea sandstone.

Silurian (early): Central Pennsylvania.

F. M. Swartz, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 83, 91, 102, 109). *Castanea ss.*—A body of red and green argill. ss. that overlies the white ss. beds of Tuscarora ss. through central Pa. Many beds are pierced by *Scolithus* tubes, and bedding surfaces are frequently marked by irregular lumpy masses, suggestive of worm castings. Underlies Rose Hill sh., basal fm. of Clinton group. Thickness 58 ft. at Mount Union; 75 ft. in Lock Haven-Williamsport area; 20 ft. near Altoona. In previous repts evidently included in Tuscarora, and would have been considered a memb. of Tuscarora in this paper except for difficulty of treating it in section descriptions without naming the remaining beds. Named for Castanea, a suburb of Lock Haven. Replaces *Howard ss.* (proposed for this fm. in 1933), which is preoccupied.

Castile gypsum (in some areas), **Castile anhydrite** (in Delaware Basin), and **Castile formation** (in New Mexico).

Permian: Western Texas and southeastern New Mexico (Pecos Valley).

G. B. Richardson, 1904 (Univ. Tex. Min. Surv. Bull. 9, p. 43). *Castile gyp.*—Massive white granular gyp., in places of grayish or dark color, in other places stained red by iron oxide. Some thin beds of ls. Thickness 50 to more than 300 ft. Underlies Rustler fm., and believed to uncon. overlie Capitan ls., but may be contemp. with part of Capitan.

R. E. King, 1931 (Univ. Tex. Bull. 3042, p. 13). SE. of reef escarpment [of Capitan ls.] of Guadalupe Mtns the Frijole ls. is overlain by Castile gyp. and Rustler ls. At one time these were believed to be laterally = Capitan ls. The revised interpretation of Frijole ls. (that is = top part of Capitan ls.) now makes it clear that these 2 fms. are younger than the Capitan, as originally announced by Darton and Reeside (Geol. Soc. Am. Bull., vol. 37, p. 420, 1926) and later by Crandall and others.

In Delaware Basin of SE. N. Mex. and western Tex. there occurs, btw. Rustler ls. and Castile gyp. of Richardson, an unexposed series of salt beds (1,400 ft. thick in well borings) known as "upper salt series," in contradistinction to "lower salt series" or Castile anhydrite. To these unexposed rocks W. B. Lang in 1935 (A.A.P.G. Bull., vol. 19, No. 2) applied the name *Salado halite*. Neither the Castile nor the Rustler fm. is restricted by the introduction of the name *Salado*, because in all surface exposures the Rustler rests upon the Castile. (See under *Salado halite.*)

W. B. Lang, 1937 (A.A.P.G. Bull., vol. 21, No. 7), discriminated *Castile anhydrite* much farther N. in Pecos Valley, where it is overlain by Salado halite and rests on Chalk Bluff fm. (new name).

Named for Castile Spring, El Paso Co., Tex., which is in midst of the gyp.

Castine volcanics.

Cambrian (?): Central southern Maine (Penobscot Bay quadrangle).

G. O. Smith, E. S. Bastin, and C. W. Brown, 1907 (U. S. G. S. Penobscot Bay folio, No. 149, p. 5). *Castine fm.*—Light-colored altered lavas and pyroclastics, including rhyolites, dacites, and andesites. Relations indicate Castine fm., Islesboro fm., and North Haven greenstone are nearly contemp. Assigned to Camb. (?). Named for exposures on Castine Peninsula, Hancock Co.

On 1933 geol. map of Maine, by A. Keith, the rocks of Castine Peninsula that were mapped as *Castine fm.* in Penobscot Bay folio are mapped as Dev.

†Castle limestone member (of Madison limestone).

Mississippian (lower): Central northern Montana (Fort Benton quadrangle) and central southern Montana (Little Belt Mountains quadrangle).

W. H. Weed, 1899 (U. S. G. S. Fort Benton folio, No. 55). *Castle ls.*—Massive heavy lss. forming top memb. of Madison ls. Rest on Woodhurst ls. and overlain by Quadrant fm.

W. H. Weed, 1899 (U. S. G. S. Little Belt Mtns folio, No. 56). Upper part of Madison ls. consists of very massive lss. showing no bedding, and designated *Castle ls.*

W. H. Weed, 1900 (U. S. G. S. 20th Ann. Rept., pt. 3, p. 293). *Castle ls.* Named for town of Castle [Little Belt Mtns quad.], where it is well developed.

Castle granite.

Miocene or Pliocene: Central southern Montana (Little Belt Mountains).

W. H. Weed, 1899 (U. S. G. S. Little Belt Mtns folio, No. 56). Intrusive granite that forms central core of Castle Mtn. Light-gray to pinkish; loose textured; well jointed. In S. part of area is a true granite; to N. it grades into true granite porphyry, but whole is mapped as granite. Is of Neocene age.

†Castle conglomerate.

Oligocene: Eastern Colorado.

See *Castle Rock cgl.* (1902 entry), which replaces it.

Castle volcanics.

Pleistocene (late): Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Castle volcanics.*—Bedded cinders, bombs, and spatter composing a partly eroded cinder cone from which a lava flow, over 100 ft. thick, extends for half a mile. Included in middle part of Honolulu volcanic series. Named for occurrence on Castle ranch.

Castlegate sandstone member (of Price River formation).

Upper Cretaceous: Eastern Utah (Wasatch Plateau and Book Cliffs region) and 3½ mi. into western Colorado.

J. B. Forrester, 1918 (Utah Acad. Sci. Trans., vol. 1, p. 24). *Castlegate ss.*, 500 ft. thick, lies at top of Laramie [so-called] coal-bearing series in Book Cliffs coal field, and is materially different from the other sss. in this fm. It is very compact and broken by joints and cross joints into large blocks. Rests on a layer of sh.

E. M. Spieker and J. B. Reeside, Jr., 1925 (Geol. Soc. Am. Bull., vol. 36, pp. 150–151, 445). *Castlegate ss. memb.*—Massive cliff-forming conglomeratic ss. 150 to 400 ft. thick. Contains abundant cgl. Forms basal memb. of Price River fm. Rests, with at least local uncon., on Blackhawk fm. in Wasatch Plateau.

Named for Castlegate, Carbon Co., Utah, where it forms a gate-like passage in Price River Canyon 2± mi. above the town.

Castlegate coal group. (In Blackhawk formation.)

Upper Cretaceous: Central eastern Utah (Book Cliffs).

F. R. Clark, 1928 (U. S. G. S. Bull. 793), applied this name to 100 to 125 ft. of strata overlying Aberdeen ss. memb. of Blackhawk fm. in Book Cliffs, and including (descending) Castlegate C coal, Royal Blue coal, Castlegate B coal, and Castlegate A coal. The Castlegate D coal is same as Kenilworth coal and is younger than the strata for convenience assembled under the name *Castlegate coal group.*

Castle Hayne marl.

Eocene (upper): Coastal Plain of southern North Carolina.

B. L. Miller, 1910 (Geol. Soc. Am. Bull., vol. 20, pp. 674–675; also chart opp. p. 646). *Castle Hayne fm.*—A distinctly calc. fm. with little or no glauconite present. Fine-grained calc. marls or lss. Vaughan states the fossils form an entirely distinct fauna, unlike any known in S. C. or northward. Assigned to Eocene. Uncon. overlain by St. Marys fm. (Mio.), and uncon. underlain by Trent fm.

Later work by T. W. Vaughan established (1918) the Jackson age of the marine Castle Hayne marl. It ranges in thickness from 0 to 50 ft., and is known only S. of Hatteras axis in N. C. Still later studies by L. B. Kellum proved that the Trent marl is of lower Mio. age, and that it overlies the Castle Hayne, which rests on Upper Cret. (See U. S. G. S. P. P. 143, 1926.)

Named for exposures at Castle Hayne, New Hanover Co.

Castle Hill andesite.

Devonian (?): Northeastern Maine (Aroostook County).

H. E. Gregory, 1900 (U. S. G. S. Bull. 165, pp. 114, 169, 174). *Castle Hill andesites.*—Andesites, commonly amygdaloidal or even slightly brecciated and ashy; associated with them is an abundance of true volcanic ash with lapilli. Constitute Castle Hill. There is no common local usage as to limits of Castle Hill, and in this rept the term will be applied to the masses of andesite and volcanic clastics which lie btw. Aroostook River and the State road from Ashland to Presque Isle, partly in Castle Hill Twp and partly in Wade Plantation.

On 1933 geol. map of Maine, by A. Keith, these andesites are assigned to Dev.

Castle Hill tuff.

Devonian (?): Northeastern Maine (Aroostook County).

H. E. Gregory, 1900 (U. S. G. S. Bull. 165, pp. 119, 120–121, 122–125). *Castle Hill tuffs.*—Volcanic tuffs (a normal type and a silicified type) exposed in open fields and along roadside about 1 mi. W. of Castle Hill Hotel, on Castle Hill Ridge, Aroostook Co.

On 1933 geol. map of Maine, by A. Keith, the tuffs of this region are assigned to Dev.

Castle Mountain group.

Lower, Middle, and Upper Cambrian: Alberta and British Columbia.

R. G. McConnell, 1887 (Canada Geol. and Nat. Hist. Surv. Ann. Rept. 1886, pt. D, pp. 15D, 24D–29D).

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804, pp. 1–4). McConnell's typical section studied. He proposed "*Castle Mtn group*" for the great series of lss. and shales btw. the qtzitic sss. and siliceous shales of "Bow River group" below and superjacent Ord. graptolitic shales on W. and Banff ls. on E. This includes upper part of Lower Camb. fauna at base and lower part of Ord. fauna at top. The term "Castle Mtn" is useful for the series, but I think local names can be applied with advantage to several of the fms. It includes (descending) the following fms. herein newly named: Sherbrooke, Paget, and Bosworth fms., all Upper Camb.; Eldon, Stephen, Cathedral, and Mount Whyte fms., all Middle Camb. [The Mount Whyte fm. is now considered to be Lower Camb.]

Castle Rock conglomerate.

Oligocene (lower): Eastern Colorado (Castle Rock region).

W. T. Lee, 1902 (Am. Geol., vol. 29, pp. 96–109). *Castle cgl.*—Youngest fm. in Castle Rock region. Consists of massive compact cgl. overlying the lava and having max. thickness of 90 ft. Contains fragments (some 5 ft. diam.) of rhyolite from the underlying flow, and is composed of coarse, angular, subangular and rounded masses firmly set in finer material. Is upper part of Monument Creek group of Hayden, which is here divided into *Castle cgl.* above and ***Monument Creek fm. restricted*** below. Named for typical development on Castle Rock butte [Douglas Co.].

G. B. Richardson, 1912 (Geol. Soc. Am. Bull., vol. 23, pp. 267–276). *Castle cgl. of Lee* [preoccupied] is here renamed *Castle Rock cgl.* It is of Olig. age, has max. thickness of 300 ft., and uncon. overlies Dawson arkose (Eocene and 2,000 ft. thick). The Castle Rock and Dawson comprise Monument Creek group of Hayden [and Dawson replaces Monument Creek fm. restricted of Lee].

G. B. Richardson, 1915 (U. S. G. S. Castle Rock folio, No. 198). *Castle Rock cgl.*—Outcrops in detached areas on divides btw. tributaries of South Platte River from vicinity of Elbert to vicinity of Sedalia, a distance of 40± mi. Greater part of fm. is in Castle Rock quad. Has max. present thickness of 300 ft.; original thickness unknown, because of erosion. Over large part of its area it is now less than 50 ft. thick, and in places represented only by residual pebbles. A complete section is not exposed. Composition very variable. Is essentially an indurated conglomeratic arkose. Includes a cliff-making basal cgl., usually well developed. Rest of fm. consists of coarse arkosic ss. streaked with lenses of cgl. Cross bedding and lenticular structure common. Lies on eroded surface of Dawson arkose. Vertebrate fossils prove its lower Oligocene age. Is youngest fm. in quad.

Castle Rock sandstone. (In Springer formation.)

Pennsylvanian: Central southern Oklahoma (Carter County).

R. Roth, 1928 (Econ. Geol., vol. 23, p. 45). [See under *Overbrook ss. memb.* Derivation of name not stated.]

Casto volcanics.

Permian (?): Southern central Idaho (Salmon Mountains region).

C. P. Ross, 1927 (Idaho Bur. Mines and Geol. Pam. 25). *Casto volcanics.*—Somewhat altered lava and pyroclastics, comprising lava flows, largely brecciated, and tuffs. At base, at several localities, a cgl. with tuffaceous matrix. Thickness probably 3,000+ ft. Of Perm. (?) age. Covers large area in Casto quad. and extends to NW. and E. beyond its limits.

Catadupa.

Eocene: Jamaica.

R. T. Hill, 1899 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 34, pp. 58–61).

Catahoula sandstone (in southern Texas, **Catahoula tuff**).

Miocene? (lower Miocene?): Louisiana, Mississippi, southern Alabama, and eastern Texas.

A. C. Veatch, 1905 (La. Geol. Surv. Bull. 1, Rept. 1905, pp. 84, 85, 90). *Catahoula (Grand Gulf) ss.*—Name proposed from typical development of fm. in Catahoula Parish, La., and used for lower or typical Grand Gulf of Hilgard as exposed at Grand Gulf, Miss. Includes the ss.-bearing clays btw. Vicksburg and Fleming Olig. Thickness 1,000 ft.

G. C. Matson, 1916 (U. S. G. S. P. P. 98M). *Catahoula ss.*—Nonmarine ss., 0 to 750 ft. thick, representing all or portions of marine Chattahoochee and Vicksburg fms. in Miss. embayment. Underlies Hattiesburg clay. In Miss. and eastern La. overlies marine Vicksburg ls. In western La. and E. border of Tex. the lower part of this nonmarine ss. is contemp. with marine Vicksburg ls., which is absent there, and Catahoula rests on marine Fayette ss., of [Jackson] Eocene age.

Type Chattahoochee fm. is now known to be of lower Mio. age and same as Tampa ls., while Catahoula ss. may be of late Olig. age. According to C. W. Cooke (A. A. P. G. Bull., vol. 19, No. 8, 1935, p. 1162) it appears to be older than Tampa ls. In southern Tex. the Catahoula becomes a tuff, and uncon. underlies Oakville ss. (late middle and early upper Mio.) and uncon. overlies Frio clay, of Olig. (?) age. The Catahoula is unfossiliferous and may be either lower Mio. or late Olig. The U. S. Geol. Survey at present classifies it as Mio. (?).

Catahoula group.

Miocene (?) and Oligocene: Southeastern Mississippi.

B. W. Blanpied et al., 1934 (11th Ann. Field Trip Shreveport Geol. Soc., pp. 4+). *Catahoula group* as here defined uncon. underlies Citronelle fm. and uncon. overlies

Byram marl [restricted], and includes (descending): "Catahoula" of previous repts., Upper Chickasawhay memb., Lower Chickasawhay memb., and Bucatunna memb. [The Chickasawhay and Bucatunna members were included in original definition of Byram marl (top fm. of the Olig. Vicksburg group), and are still so included by U. S. Geol. Survey, which still uses *Catahoula ss.* as originally defined.]

Cataldo quartzite.

Pre-Cambrian (Belt series): Northern Idaho (Coeur d'Alene region) and central eastern Washington.

O. H. Hershey, 1912 (Geol. Soc. Am. Bull., vol. 23, p. 526; Am. Jour. Sci., 4th, vol. 34, pp. 264–267). *Cataldo qtzite.*—Name temporarily applied to a memb. of Belt series not recognized by Ransome and Calkins in their rept on Coeur d'Alene dist., as it is apparently poorly represented there. It consists chiefly of heavy beds, in part cross bedded, of lilac-colored, medium-grained qtzite, differing in appearance from any qtzite above the Prichard. With this are beds of greenish finer-grained sericitic rock. Thickness at least 1,000 ft. Evidently underlies Prichard sl. Beginning a little above mouth of Pine Creek, it is exposed over a great area, thence nearly to station of Rose Lake. It also occurs near town of Tekoa, Wash. It is apparently the basal memb. of Belt series. Outcrops are of light-gray color. That Calkins did not intend to include it in Prichard is proved by his mapping a small area of it as Burke. [Apparently named for town of Cataldo.]

Catalina facies of Franciscan series.

Jurassic (?): Southern California (Catalina Island).

A. O. Woodford, 1924 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 15, No. 3). *Catalina metamorphic facies of Franciscan series.* [Mapped.] On Catalina Island, off coast of southern Calif., and in San Pedro Hill, on adjacent mainland, are areas of unusual metamorphic rocks similar to those forming part of Franciscan series farther N. These rocks are schistose, of variable grain, and made up largely of various combinations of the minerals quartz, albite, muscovite, chlorite, epidote, glaucophane, crossite, actinolite, and lawsonite. The Catalina facies is probably uncon. beneath the Chico, and it has a close lithologic resemblance to the schists of north Berkeley and the Tiburon Peninsula mapped by A. C. Lawson (1914) as *Franciscan.* These facts taken together suggest correlation with Franciscan series. The quartz schists would then be metamorphosed radiolarian cherts, the quartz-albite schists former arkoses derived from a region of quartz diorites, and the remaining types former basic igneous rocks. Soda basalts of type analyzed by Ransome from Point Bonita Franciscan (1893, p. 106, analysis I) may be represented. At this time, however, the correlation can be made only in most general sense, indicating merely that these rocks belong to a great and perhaps heterogeneous group now called *Franciscan series.* It may be that these metamorphic rocks belong to an ancient group which extends northward uncon. beneath typical Franciscan.

A. O. Woodford, 1925 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 15, No. 7, pp. 163, 172, 225). *Catalina facies of Franciscan series.*—Half of Catalina Island is a complex of albitic, amphibolic, chloritic schists, quartz schist, serpentine, etc., and there is a small area of similar rocks exposed in San Pedro Hill on the mainland. They are especially characterized by abundance of albite and by presence of the unusual minerals glaucophane, crossite, and lawsonite.

Catalina schist breccia.

Miocene (lower?): Southern California (southeast end of Catalina Island).

A. O. Woodford, 1925 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 15, No. 7, pp. 211–212). *Catalina schist breccia.*—At SE. end of Catalina Island small areas of schist and qtzite breccia with sandy matrix are involved in the volcanic rocks. As indicated by W. S. T. Smith it is difficult to determine whether these are contemp. with the volcanics or inclusions in them. The breccia blocks are sometimes exclusively subrounded qtzite and gray porphyry. Sometimes glaucophane and other schists are also present, making a rock very similar to San Onofre sandy breccia. [The above description is under center heading "Doubtful correlatives of the San Onofre facies" of Temblor fm. of Monterey series.]

Catamount schist.

Pre-Cambrian: Northern New York (Adirondacks).

H. L. Alling, 1918 (N. Y. State Mus. Bull. 199). *Catamount schist.*—A sillimanite schist, included in Grenville series. Thickness 70–80 ft. Is older than Bear Pond schist and younger than Swede Pond qtzite. Type loc. is Catamount Mtn, W. of Pottersville, Warren Co., of which it forms the slopes.

Cataract formation.

Silurian (early): Ontario and western New York.

C. Schuchert, 1913 (Geol. Soc. Am. Bull., vol. 24, p. 107). Fifty ft. of the Medina at Niagara Falls, N. Y., belongs to a new fm. named the *Cataract.* It has been traced from Niagara Falls to Manitoulin Islands, Lake Huron, where it is 110 ft. thick, the lower 45 ft. consisting of thin-bedded mag. ls. and the upper of red shales barren of fossils. At Cataract, Ont., it is well developed, 82 ft. thick, and replete with fossils. Assigned to Sil.

W. A. Parks, 1913 (Canada Geol. Surv. Guidebook 4, pp. 128–140), described *Cataract fm.* as overlying Queenston (Richmond) sh. and underlying Medina fm. [restricted to "grey band" (Thorold ss. memb.) and some underlying red sss. of uppermost part of original Medina ss.], and as consisting at Hamilton, Ont., of (descending): Red and gray shales, 70 ft.; blue ls., 10 ft.; and Whirlpool ss. of Grabau, 10 ft. He made the following statements: The Cataract fm. represents an invasion from the N. and W. at commencement of Sil. time. It was first officially defined by Prof. Charles Schuchert of Yale Univ. at 1912 meeting of Geol. Soc. Am. The reading of Professor Schuchert's paper evoked considerable discussion, Dr. E. O. Ulrich being strongly of opinion that the fm. should be included in the Medina or at least in the "Medinan." It is to be understood, therefore, that all American geologists are not prepared to accept the classification herein adopted.

The same year (Ottawa Nat., vol. 27, pp. 37–38) M. Y. Williams divided Cataract fm. of Georgian Bay region into Kagawong memb. above and Manitoulin memb. below, while A. W. Grabau (Geol. Soc. Am. Bull., vol. 24, pp. 438, 460, 1913) divided the same beds into Cabots Head beds above and Keppel dolomites below, the latter resting, with probable discon., on Queenston sh.

In 1914 (Sci., n. s., vol. 39, June 19, pp. 915–918) E. M. Kindle recommended the following names for subdivisions of *Medina fm.* (*restricted*), in descending order: Thorold ss., Grimsby ss., Cabot Head sh., Manitoulin beds, and Whirlpool ss.

In 1914 (Geol. Soc. Am. Bull., vol. 25, Sept. 1, pp. 277–320) C. Schuchert divided Cataract fm. of Ontario into (descending): (1) Cabots Head sh. memb. (20 to 75 ft. of greenish somewhat calc. shales with occasional thin beds of mag. ls.); (2) Manitoulin ls. memb. (9 to 60 ft. of heavy-bedded mag. lss., with local reefs of corals and bryozoans, and, to S., thin beds of ss.); and (3) Whirlpool ss. memb. (0 to 22 ft. of coarse, cross-bedded, white, red, or mottled ss., extending from Lockport, N. Y., to near Collingwood, Ont.). He stated that all of these members are present at Cataract, Ont., but he did not apply *Cabots Head* and *Manitoulin* in Niagara Gorge section, where he described Cataract fm. as consisting of (descending): (1) Dark green shales, 5 ft.; (2) thin-bedded green ss. underlain by yellowish mag. and argill. ls. with small black sh. pebbles, 5 ft.; (3) green shales, 10 ft.; (4) dark-green shales with very thin-bedded argill. mag. lss., 5 ft.; (5) dark green fissile shales, 7 ft.; and (6) Whirlpool ss. memb., 22 ft. The beds resting on Cataract fm. in Niagara Gorge he called *Medina fm.* [a greatly restricted use of Medina] and described them as consisting of (descending): (1) Thorold [ss.] memb., 8 ft. thick; (2) 15 ft. of red and greenish gray, much cross-bedded and channeled ss. with very little sh.; (3) thin-bedded red sss. with considerable red shales and two or more zones of localized storm-rolled mud balls, 35 to 40 ft.; (4) gray ss. with sh. partings, 5 ft. He stated that the Medina is of the Appalachian province, while the Cataract is of either the St. Lawrence or the Arctic realm; that the Cataract wedges in below Upper Medina in Niagara Gorge; that the Medina [restricted to uppermost 60 or 65 ft. of original Medina] thins out to NW., so that Cataract thickens in opposite direction; that the Medina [restricted], Brassfield, and Cataract "are correlates of one another," but that "they represent three physical provinces and marine basins," and that the 3 names "should be retained as names for independent marine faunas and formations." The same year (Canada Geol. Surv. Summ. Rept. for 1913, pp. 179–188, 1914) M. Y. Williams adopted Grabau's name *Cabot Head sh.* to replace *Kagawong* (preoccupied) and introduced *Grimsby ss.* for 0 to 50 ft. of beds underlying Thorold ss. and overlying Cabot Head sh., and also overlying Cataract fm. of Schuchert; he also used *Manitoulin memb.* and *Whirlpool ss.* for the rocks underlying Cabot Head sh. His 1919 classification (Canada Geol. Surv. Mem. 111, No. 91 of geol. ser.) employed the same names as his 1914 classification. He called the beds *Medina-Cataract;* stated that they are contemp. with Medina; that Schuchert restricted Medina to Grimsby and Thorold sss. and called the underlying beds *Cataract fm.;* that he (Williams) considered the Grimsby and Thorold are "only facies of the top of Cabot Head sh., although they represent another faunal invasion;" and that name *Cataract* is necessary as the phases of sedimentation are very different from most of the Medina. He also introduced two new names for dol. beds in Cabot Head sh. memb. of Bruce Peninsula and Manitoulin Island, the type loc., using *St. Edmund dol. lentille* for a bed near top of Cabot Head sh., and *Dyer Bay dol. lentille* for a bed in lower part of upper half of Cabot Head sh.

In 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 332, 364) G. H. Chadwick applied *Cataract fm.* to beds btw. Grimsby ss. above and Whirlpool ss. below.

In 1923 (Md. Geol. Surv. Sil. vol., pp. 334–336) E. O. Ulrich stated that fauna of Dyer Bay dol. is Niagaran (middle Clinton), and not Medinan, and he restricted (p. 267) *Cataract* to pre-Dyer beds of upper Medinan age, including Grimsby ss. in Medinan, and transferred Thorold ss. to Clinton.

In 1924 (Canada Dept. Mines, Geol. Surv. Mem. 138) A. F. Foerste used Grabau's restricted *Medina* "to include the beds above the Queenston and below the Clinton," and stated that upper part of Cataract fm. in southern Ont. is formed by Thorold ss. memb. and Grimsby ss. memb., and that Whirlpool ss. memb. is base of Cataract fm. from Niagara River to vicinity of Duntroon, about 8 mi. S. of Collingwood, Ont.

Catarina formation.

Cretaceous: Lower California.

F. M. Anderson and G. D. Hanna, 1935 (Calif. Acad. Sci. Proc., 4th ser., vol. 23, No. 1, p. 8).

Catasauqua ls.

See *Cattasauqua ls.*

Catawissa reds.

Upper Devonian: Eastern New York (Catskill Mountains and to west) and northeastern Pennsylvania.

G. H. Chadwick, 1932 (Eastern States Oil and Gas Weekly, vol. 1, No. 17, p. 7). The Cayuta or lower Chemung turns red as it crosses the Susquehanna, and on the S. outcrops at Catawissa [Columbia Co., Pa.?]; hence we may call its red phase the *Catawissa reds*. It is present in western Catskills along the Delaware, above the true Catskill (Portage) reds, but is not present in eastern Catskills.

Cat Creek sands.

Upper and Lower Cretaceous: Central Montana (Cat Creek oil field).

F. Reeves, March, 1921 (U. S. G. S. Press Bull. on Cat Creek anticline, in Twps 13, 14, 15, Rs. 28, 29, 30, 31 E, Fergus and Garfield Counties). *Cat Creek sand.*—An oil-bearing ss. forming basal bed of Colorado sh. in Cat Creek oil field, where it is principal producing horizon. It is usually spoken of as *first Kootenai sand*, and some oil men call it *Dakota sand*, but it is probably of age of Colorado sh., and is here so treated.

In subsequent repts this sand has been called *First Cat Creek sand*, and two older sss. (in Kootenai fm.) have been called *Second Cat Creek sand* and *Third Cat Creek sand*. In Cat Creek oil field the former lies 100 to 150 ft. higher than the latter, and from 300 to 350 ft. below top of Kootenai fm., and the First Cat Creek sand lies 0 to 5 ft. above top of Kootenai fm.

Cat Head limestone.

Upper Ordovician (Richmond): Manitoba.

D. B. Dowling, 1896 (Ottawa Field Nat. Club Trans. 1895–96, vol. 9, pp. 69–70). *Cat Head beds*, Cambro-Sil., Canada.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 202). *Cat Head lss.*, Ord., Canada.

D. B. Dowling, 1901 (Canada Geol. Surv. Ann. Rept., n. s., vol. 11, p. 74F). *Cat Head ls.*, Ord., Canada.

Subsequent repts assign it to Ord. A. K. Miller, 1930 (Am. Jour. Sci., 5th, vol. 20, p. 211), correlated it with middle part of Bighorn dol. of Mont., which he assigned to the Richmond.

Cathedral granite.

Tertiary: Southern British Columbia and central northern Washington (Okanogan batholith).

R. A. Daly, 1906 (Geol. Soc. Am. Bull., vol. 17, pp. 329–376).

Cathedral limestone.

Middle Cambrian: Alberta and British Columbia.

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804, pp. 2, 4). *Cathedral fm.*—Massive, aren. and dolomitic ls. Thickness, 1,595 ft. in Mount Bosworth section, B. C.; 987 ft. in Castle Mtn, Alberta; 1,600 to 1,800 ft. in Cathedral Mtn and Mount Stephen. Underlies Stephen fm. and [uncon., C. D. W., 1923] overlies Mount Whyte fm. Type loc. is Cathedral Mtn and Cathedral Crags, E. of Mount Stephen and SE. of Mount Bosworth. Contains Middle Camb. fossils.

L. D. Burling, 1916 (Am. Jour. Sci., 4th, vol. 42, pp. 469–472). *Cathedral fm.* of Mount Bosworth, B. C., consists of (1) 775 ft. of lss., underlain by (2) *Albertella sh. memb.* (7 ft. thick), which rests on (3) 375 ft. of lss. It is overlain by Stephen fm. and underlain by Mount Whyte fm., 250 ft. thick. Reference of *Albertella* fauna to Middle Camb. has been confirmed by discovery on Mount Bosworth of the parent ledge of the drift block which has been so often described. The inability of Mr. Walcott and myself to find this bed during the years in which search has been prosecuted is due to fact that its reference to Lower Camb. led us largely to confine our efforts to the series of thin beds underlying Cathedral fm. The fauna actually occurs in a 7-foot band of sh. which interrupts the sedimentation of the massive lss. of this Middle Camb. Cathedral fm. 375 ft. above its base. In 1914 I did not presume to question Walcott's reference of *Albertella* fauna to Mount Whyte fm. Indeed, writer's assignment of that fauna to Middle Camb. necessitates a change in systemic reference of Mount Whyte fm. I am now as thoroughly convinced that all but lowest beds of Mount Whyte fm. are Middle Camb., but discovery that *Albertella* fauna occurs in a sh. memb. embedded 375 ft. up in overlying massive aren. lss. of Cathedral fm., robs me of one of main arguments I used in 1914 for Middle Camb. age of Mount Whyte fm.

C. D. Walcott, 1917 (Smithsonian Misc. Coll., vol. 67, No. 1, Pub. 2444, pp. 1–5). The name *Ptarmigan fm.* is proposed for a series of Middle Camb. lss. and interbedded shales that occur above Mount Whyte fm. (Lower Camb.) and beneath Cathedral fm. (Middle Camb.) in Alberta and British Columbia. At Ptarmigan Pass and Peak the Cathedral ls. is 2,100 ft. thick. The Ptarmigan fm. includes the Middle Camb. *Albertella* fauna about 100 ft. below its top.

C. D. Walcott, 1917 (Smithsonian Misc. Coll., vol. 67, No. 2, Pub. 2445). At Mount Bosworth the Cathedral lss. are 1,086 ft. thick, exclusive of a lower div. of 509 ft., which I have now included in a recently recognized fm. named *Ptarmigan.*

Cathedral Bluffs tongue (of Wasatch formation).

Eocene: Southwestern Wyoming (Sweetwater County) and northwestern Colorado (Moffat County).

A. R. Schultz, 1920 (U. S. G. S. Bull. 702). *Cathedral Bluffs red beds memb. of Green River fm.*—Variegated clay, sh., and ss., in places slightly conglomeratic. Thickness 0 to 1,500 ft. Uncon. underlies Laney sh. memb. and overlies Tipton sh. memb. Produces the highly colored escarpment of Laney Rim and Cathedral Bluffs, Sweetwater Co., Wyo.

J. D. Sears, 1924 (U. S. G. S. Bull. 751G). In basin of Vermilion Creek, in NW. part of Moffat Co., Colo., and southern Sweetwater Co., Wyo., the upper part of Wasatch fm. consists of 600 to 1,200 ft. of clay sh. similar to that in E. part of field, except that here various shades of red are predominant. The upper and lower parts of Wasatch are separated by Tipton tongue of Green River fm. This tongue, which is characterized by gray fissile sh. and oil sh., wedges out southward, and main part of the Wasatch and the upper part (here called *Cathedral Bluffs tongue*) merge into a continuous fm. comparable to that E. of Godiva Ridge. According to Schultz the Cathedral Bluffs tongue (which he called *Cathedral Bluffs red beds memb. of Green River fm.*) passes northwestward by lateral variation into typical grayish Green River shales. To NW., beyond limits of the field in Moffat Co., the Cathedral Bluffs tongue of the Wasatch loses its identity and the older Tipton tongue merges with the overlying Green River shales. [Fig. 23 of this rept shows upper part of the red Wasatch fm. of certain areas in Colo. to be contemp. with and to interfinger in lower part of the grayish Green River fm. of vicinity of Green River, Wyo.]

†Cathedralian series.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 42, p. 289). *Cathedralian series.*—Dolomites, 1,600 ft. thick, underlying Stephensian series, and composing basal div. of Mid Cambric section in Alberta. [Apparently same as Cathedral ls.]

Cathedral Peak granite.

Probably Cretaceous: Yosemite National Park, California.

F. C. Calkins, 1930 (U. S. G. S. P. P. 160, pp. 126–127, map). A coarsely porphyritic rock, in which biotite is more abundant than hornblende. The distinguishing feature of the granite is that it contains unusually large phenocrysts of feldspar. Included in Tuolumne intrusive series, in which it is next younger than Half Dome quartz monzonite and next older than Johnson granite porphyry.

Named for fact it composes Cathedral Peak and adjoining parts of Cathedral Range in Yosemite Nat. Park.

Catheys limestone.

Middle Ordovician: West-central Tennessee.

C. W. Hayes and E. O. Ulrich, 1903 (U. S. G. S. Columbia folio, No. 95, p. 2). *Catheys ls.*—Shales and knotty lss., usually underlain by heavy-bedded subcrystalline ls. and overlain by fine-grained, blue and earthy lss. separated by thin seams of sh.; all more or less highly fossiliferous. Basal part occasionally includes some granular phosphatic layers. Thickness 0 to 100 ft. Of Trenton age. Uncon. overlies Bigby ls. and uncon. underlies Leipers fm.

E. O. Ulrich, 1924 (Tenn. Dept. Ed., Div. Geol. Bull. 28, p. 34), and C. Butts, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14, chart opp. p. 80), show Cannon ls. of Tenn. as underlying Catheys ls. and overlying Bigby ls. This is present accepted definition of Catheys ls.

Named for Catheys Creek, Lewis and Maury Counties.

Cat Hill gneissoid granite.

Pre-Cambrian: Southeastern New York (Putnam County).

C. P. Berkey, 1911 (N. Y. State Mus. Bull. 146, pp. 52, 57). *Cat Hill gneissoid granite* is not essentially different from Storm King type as a physical unit. Its occurrence at a different point (Cat Hill), widely separated by other types from Storm King locality, and in rather large development, is worthy of separate note. Occurs in Garrison dist. [Putnam Co.].

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 20). *Cat Hill granite* is intrusive and of similar type to Storm King granite.

Catoctin schist.

Pre-Cambrian: Northeastern West Virginia, northern Virginia, and western Maryland.

A. Keith and H. R. Geiger, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 155–164). *Catoctin schist* underlies Shenandoah ls. No fossils found.

A. Keith, 1894 (U. S. G. S. 14th Ann. Rept., pt. 2, p. 306 and map). *Catoctin schist,* Algonkian, 1,000 ft. thick. Occupies three-fifths of area of Catoctin belt thus far mapped and a considerable portion of South Mtn belt in Pa. [According to map Catoctin Mtn, Va., is composed of this schist.]

A. Keith, 1894 (U. S. G. S. Harpers Ferry folio, No. 10, p. 2). *Catoctin schist.*—Altered diabase, with lenses of epidote and quartz, and associated with great masses of interbedded eruptive granite. Three varieties of schist are recognized: One of coarser texture, associated with the granite; one of fine grain, with large lenses of epidote and quartz; and one with quartz and epidote amygdules, occurring along the boundaries of the other two varieties. Light bluish green when fresh, dull grayish yellow when weathered. Thickness more than 1,000 ft. Oldest exposed fm. in region. Underlies Loudoun fm.

Also called *Catoctin greenstone.*

Named for Catoctin Mtn, Loudoun Co., Va., and Frederick Co., Md.

Catron formation. (In Pottsville group.)

Pennsylvanian: Southeastern Kentucky.

G. H. Ashley and L. C. Glenn, 1906 (U. S. G. S. P. P. 49, pp. 33, 41, 207, and pl. XLA). *Catron fm.*—Shales, sss., and coals, 300 to 460 ft. thick, overlying Mingo fm. and underlying Hignite fm. in Cumberland Gap coal field. In Log Mtns top of fm. is defined by bottom of Lower Hignite coal and base by bottom of Poplar Lick coal. In Black Mtns the Hignite coal is missing and top of fm. is defined by top of Jesse ss. memb. and base by base of Wallins Creek coal (may=Poplar Lick coal). Probably included in Lower Kanawha of New River.

Named for Catron Creek, Bell Co.

Catskill formation.

Upper and Middle Devonian and Carboniferous (?): New York, Pennsylvania, Maryland, and Virginia.

W. W. Mather, 1840 (N. Y. Geol. Surv. 4th Rept., pp. 212, 213, 227–233). *Catskill Mtn series.*—White, gray, and red cgls.; with gray, red, olive, and black grits, slates, and shales. Overlies Helderberg [Onondaga] ls. series and underlies the coal-bearing rocks of Carbondale, Pa.

W. W. Mather, 1841 (N. Y. Geol. Surv. 5th Ann. Rept., pp. 75–85). *Catskill Mtn series* includes (in addition to younger cgls. and grits and red and gray grits and red shales mottled with green spots) Montrose ss., Chemung group, Ithaca group, Sherburne flags, Hamilton group and Marcellus shales.

L. Vanuxem, 1842 (Geol. N. Y., pt. 3, pp. 186–194). *Catskill group.*—Top div. of New York system. Overlies Chemung group. Includes Montrose and Oneonta sss. of repts. Consists of light-colored greenish gray ss., usually hard; fine-grained red ss., red sh. or sl.; dark-colored sl. and sh.; grindstone grit; and a peculiar accretionary and fragmentary mass appearing like fragments of hard sl. cemented by ls. Very few fossils. No line of demarkation observed btw. Catskill and Chemung groups in N. Y. or Pa. In ascending upwards from Chemung group the first signs of change which usually appeared was a diminution, then a disappearance of fossils of Chemung, a more solid or hard rock succeeding, often accompanied by red ss. or red sh., and the gray ss., sometimes accompanied by thin beds of cornstone; capping the whole was the complex structured ss. Is confined to Otsego, Chenango, Broome, and Tioga Counties, N. Y. [According to C. A. Hartnagel (1912 ed. Hdb. 19) and H. S. Williams (U. S. G. S. P. P. 79, 1913) the red Oneonta ss. is a nonmarine ss. of middle Portage age, separated from the red Catskill sediments by a considerable thickness of typical Chemung deposits. According to Hartnagel (1912 ed. Hdb. 19, p. 82) "Montrose" ss. is same as Oneonta ss.]

W. W. Mather, 1843 (Geol. N. Y., pt. 1, div. 4, pp. 2, 299–317). *Catskill div.*—Cgls., coarse grits, red shales, slates, and grits; gray and greenish gray slaty grits; chocolate-colored grits with red shales and slates. Underlies the Coal series. Includes upper part of Catskill Mtn series and Montrose and Oneonta sss. of repts; lower part of Catskill Mtn series is included in underlying Erie div. The Erie div. includes Chemung, Ithaca, Portage, Genesee, Tully, Hamilton, and Marcellus. The Helderberg div. [not Helderberg of present usage], which underlies Erie div., includes Onondaga ls. down to base of Onondaga salt group [Salina fm., Sil.]. The Montrose ss. of Vanuxem is below top of Catskill series in Catskill Mtns.

E. Emmons, 1846 (Agric. N. Y., vol. 1, pp. 187–197), assigned thickness of 1,800 to 2,000 ft. to Catskill "*group*" (which he defined as overlying Chemung group and underlying Coal series), and defined *Catskill "division"* as including (descending) Catskill group, Chemung group, Portage group, and Genesee sl., and as overlain by Coal series.

H. S. Williams, 1887 (U. S. G. S. Bull. 41, p. 27). There is reason to believe that in Sullivan Co., N. Y., the deposition of the red beds began as early as Hamilton time. This was shown to be a fact in Chenango and Otsego Counties by investigations in 1885.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 86). *Catskill beds,* named for Catskill Mtns, which have their greatest development in Greene Co., where the earliest sediments of this type began in early Portage time. This fm. includes the highest peaks of the Catskills and in point of elev. they are highest sedimentary rocks in State (Slide Mt, 4,204 ft. A. T.). To S. and W. the Catskill type of sedimentation began later and is contemp. with Chemung deposits, and perhaps in its later stages as developed in the Catskills, with the Postdevonic sediments in Allegany and Cattaraugus Counties.

During succeeding years the commonly accepted definition of Catskill fm. was the continental strata, chiefly red, in part contemp. and interfingering with the marine grayish and greenish Chemung and Portage strata and in part younger than Chemung.

G. H. Chadwick, 1932 (Eastern States Oil and Gas Weekly, vol. 1, No. 17, p. 7) and 1933 (Sci., n. s., vol. 77, pp. 86–87, Jan. 20). The original Catskill of Catskill Mtns is all of Portage and Hamilton age, because it interfingers with marine sediments containing Portage and Hamilton fossils; and it is here divided into (descending): (1) *Catskill proper* (of Enfield or upper Portage age), which forms the peaks of all the true or eastern Catskills; (2) *true Oneonta,* of Ithaca or lower Portage age; (3) *Kiskatom red beds* (of Hamilton, Middle Dev., age), formerly erroneously called Oneonta. The Hamilton age of Kiskatom red beds is verified by recent work of G. A. Cooper. *In western Catskills,* along the Delaware, the Catskill proper (of upper Portage age) is overlain by *Catawissa reds* (the red equiv. of Cayuta, of *Chemung* age), which to W. is succeeded by true Montrose ss. (=upper Chemung or Wellsburg), Blossburg, and Cattaraugus (Bradfordian) fms. The name Catskill can no longer properly be used for the red beds farther W. in N. Y. and Pa. that are of Chemung and later age, though they happen to possess the same continental facies.

B. Willard, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 3, pp. 497–498), in order to avoid confusion, advocated the contined use of broad definition of Catskill that has been in general use many years (which is "synonymous with Dev. red beds, continental"), and suggested that the *Catskill-restricted* of Chadwick (the red beds btw. true Oneonta below the Catawissa above) be replaced by "an appropriate term, as *Kaaterskill (?)*."

G. H. Chadwick, 1933 (Am. Jour. Sci., 5th, vol. 26, pp. 480–484), agreed to abandon his proposed restriction of Catskill fm., but proposed that *Katsberg red beds* be used for the restricted unit. (See *Katsberg red beds.*) On p. 484 he stated: In place of Catskill, for present, we may best use the precision terms [upward succession]—Kiskatom (Hamilton reds); Onteora (Tully to Oneonta reds); Katsburg (Enfield reds); Catawissa (Cayuta reds); Montrose (Wellsburg reds); Blossburg (Girard-Chadakoin reds); and Cattaraugus (Venango reds).

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 26). Chadwick's *Katsberg red beds* is more acceptable than Willard's *Kaaterskill* to replace Chadwick's restricted Catskill, inasmuch as type section of Willard's Kaaterskill, on Kaaterskill Cove, appears to be in an exposure of Chadwick's Onteora red beds, of Ithaca age. Nevertheless Willard's name has priority.

G. H. Chadwick, 1935 (Am. Mid. Nat., vol. 16, No. 6, p. 857). Original Catskill fm. of Mather included all of Kiskatom fm. (about 2,500 ft. thick, including the Tully) and perhaps a little of overlying beds of Genesee age. But since later workers extended *Catskill* to the 5,000 ft. of still higher similar beds in these Catskill Mtns, and since *Catskill* has later come to be restricted to these higher beds, which are Upper Dev. (falsely supposed to be supra-Oneonta), it may be best to let the *Catskill* continue in the later significance (covering Genesee-Naples equivalents) excluding from it the Mid Dev. Kiskatom strata. [See also Chadwick's N. Y. State Mus. Bull. 307, 1936.]

The U. S. Geol. Survey applies the name *Catskill fm.* to the nonmarine red sediments contemp. and intertonguing with marine sediments ranging in age from Hamilton to Chemung, both inclusive, and in part later than the Chemung, extending from N. Y. to western Va.

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, p. 571). Writer now, as heretofore, uses *Catskill* as a phase or facies term to include all the continental Dev. beds.

G. H. Chadwick, Jan. 1936 (N. Y. State Mus. Bull. 307, pp. 1–101), discussed "history and value of the name 'Catskill' in geol.," and on p. 101 proposed to restrict *Catskill* to the beds exactly correlating with "what we now understand as the Senecan series of the Upper Dev.," and to exclude beds of Hamilton age.

Named for development in Catskill Mtns, Greene Co., N. Y.

Catskill division.
Catskill group.
See under *Catskill fm.*

†Catskill or Delthyris shaly limestone.
Lower Devonian: Eastern New York.

L. Vanuxem, 1842 (Geol. N. Y., pt. 3, pp. 120–122). *Catskill or Delthyris shaly ls.*—The upper part on Catskill Creek and the Helderberg is very light-gray coarse crystalline ls. which abounds in discoidal shaped fossils, about 2 inches in diameter, resembling a scutella. Lower part is usually a mixture of dark bluish gray sh. (which generally changes to drab) and fine-grained blue ls. Underlies Oriskany ss. and overlies Pentamerus ls. [Coeymans] that rests on water-lime group of Manlius. Named for occurrence on Catskill Creek, near Madison, Greene Co. [Apparently includes Becraft ls. at top and New Scotland ls. below. In later repts the term "Catskill shaly ls." was restricted to beds later named *New Scotland ls.*, because of conflict of name with *Catskill fm.*]

†Catskill Mountain series.
See first entries under *Catskill fm.*

Cattaraugus formation.
Devonian or Carboniferous: Southwestern New York and northern Pennsylvania.

J. M. Clarke, 1902 (N. Y. State Mus. Bull. 52, pp. 524–528). Red and green shales interbedded with flaggy sands, to which it has been proposed to apply the term

Cattaraugus beds. Thickness 200 ft. Underlie Mount Herman or Salamanca cgl. and overlie Wolf Creek cgl. The validity and usefulness of the distinctive term for these strata, which represent those at times referred to Catskill fm. because of their red color and doubtless a western continuation of Catskill sedimentation, is very clearly indicated by the paleontologic evidence which they have furnished. [This definition was used in several repts.]

L. C. Glenn, 1903 (N. Y. State Mus. Bull. 69, pp. 967–989). *Cattaraugus beds*.—Bright-red shales interbedded with green or bluish shales and fine-grained greenish gray, thin-bedded micaceous sss., with three cgl. lentils, named (descending): Kilbuck cgl. lentil, Salamanca cgl. lentil, and Wolf Creek cgl. lentil. Underlie, probably uncon., Oswayo beds, and rest on Chemung beds. Thickness 300–500 ft. Correlated with Catskill fm. to E., and assigned to Dev. [In same bull. (pp. 696–699) J. M. Clarke assigned *Cattaraugus beds* to Carbf. But in 1904 (Geol. Soc. Am. Bull., vol. 14, pp. 522–531) Glenn again assigned them provisionally to Dev. Clarke's 1903 Hdb. included Wolf Creek and Salamanca cgls. in the Cattaraugus, as did Glenn.]

Whether Cattaraugus fm. is late Dev. or early Carbf. is still an open question. (See under *Knapp fm.*) The 1903 definition was followed for many years, and the beds btw. Wolf Creek and Salamanca cgls., to which Clarke originally applied name *Cattaraugus beds*, were not renamed. In Warren Co., Pa., the lithology of Oswayo and Cattaraugus deposits changes, so that they can not be separated, as in N. Y., and in 1910 C. Butts named the combined unit *Conewango fm.*

G. H. Chadwick, 1925 (Geol. Soc. Am. Bull., vol. 36, pp. 455–464), divided beds *below* Riceville sh. in NW. Pa. into (descending): Woodcock horizon, Saegerstown sh., Millers horizon, Amity sh., and LeBoeuf horizon (all included in Venango group, which he described as resting on Chadakoin sh.).

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 203), divided Venango group of NW. Pa. into (descending): Riceville fm. restricted (Oswayo sh. memb.) and *Cattaraugus fm.*, the latter divided into (descending): Woodcock ss. memb., Saegerstown sh. memb., Millers ss. memb., North Warren sh. memb., Watson ss. memb., Amity sh., and Panama cgl. memb. (LeBoeuf, Wolf Creek). His Venango group rested on Chadakoin fm. of Chemung group.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61), excluded Riceville from his Venango stage, and assigned both Riceville and his Venango to Dev. On pp. 57–58 he stated: Cattaraugus fm. of Glenn is exact synonym of original "Venango group" of White. The only proper use of "Cattaraugus" is in a facies sense—*Cattaraugus parvafacies* of an unnamed magnafacies which is characterized by purple shales and cgls.

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, p. 570), applied *Cattaraugus red sh.* to the beds "mostly nonmarine," underlying Salamanca cgl. and overlying Panama cgl. This definition reverts to Clarke's original definition. Willard states (p. 580): The use of "Cattaraugus" in U. S. G. S. folio 93, 1903 (Elkland-Tioga), is erroneous, for it includes beds considerably older than Panama cgl., which makes base of Cattaraugus to W. If a term must be applied to these red beds, *Cherry Ridge* is logical, for they admit of no subdividing. What has been called *Oswayo fm.* in NE. Potter Co. and Tioga Co., Pa., appears to be green Coudersport memb. of Cattaraugus fm. Writer doubts presence of any true Oswayo in that area.

Named for development in Cattaraugus Co., N. Y.

Cattaraugus parvafacies.

See under *Smethport magnafacies* and under *Cattaraugus fm.*, 1934 entry.

Cattasauqua limestone.

Ordovician: Southeastern Pennsylvania (Northampton and Lehigh Counties).

I. C. White, 1882 (2d Pa. Geol. Surv. Rept. G_6, p. 153). The great ls. fm. of Easton and Allentown, No. II, 2,000 ft. thick, underlies Hudson River slates, and at its top are the *Cattasauqua ls. beds*.

Only recorded use of name. The name of the town is spelled *Catasauqua*.

Cattleman sand.

An oil-bearing subsurface ss. lying 50 to 75 ft. above the main shoestring sand horizon of Cherokee sh. in Wiggins field, 6 to 12 mi. N. of Eureka, Greenwood Co., Kans.

†Cauda-galli grit.

Lower Devonian: New York.

L. Vanuxem, 1842 (Geol. N. Y., pt. 3, pp. 127–130). *Cauda-galli grit.*—Fine-grained calc. and argill. ss., usually drab and brownish. Underlies Schoharie grit and overlies Oriskany ss.

Replaced by Esopus grit.

"Named for a fucoid having some resemblance in form to tail of a chicken cock."

†Caudagalli epoch.

Paleontologic term used by A. W. Grabau (see Buffalo Soc. Nat. Hist., vol. 6, p. xviii, 1898) to include time during which Schoharie grit and Esopus sh. were deposited. It has also been used to cover only the time of Esopus (†*Caudagalli*) grit.

Caulfeild formation.

Paleozoic (?) : British Columbia.

W. A. Johnston, 1923 (Canada Geol. Surv. Mem. 135, p. 12).

Causapscal formation.

Devonian: Quebec (Matapedia Valley).

G. W. Crickmay, 1932 (Am. Jour. Sci., 5th, vol. 24, pp. 368–385). *Causapscal fm.*—Shales and argill. lss., 3,000 ft. thick. Basal fm. of Dev. Conformably overlies St. Leon fm. (Sil.), and underlies Gaspe ss. (Dev.). Type section immediately S. of village of Causapscal in bluffs of Matapedia River. Also well exposed on Causapscal River below Causapscal Falls. Fossils (listed).

†Cavanal group.

†Cavaniol group.

Pennsylvanian: Central eastern Oklahoma and western Arkansas.

N. F. Drake, 1897 (Am. Phil. Soc. Proc., vol. 36, pp. 371, 388). *Cavaniol group.*—Shales, with sss., workable coals, and lss., 5,500 ft. thick, underlying Poteau group and extending down to base of Grady coal or top of Tobucksy [Hartshorne] ss.

According to J. A. Taff (U. S. G. S. 22d Ann. Rept., pt. 3, 1902) this name covers McAlester group and Savanna ss.

Named for Cavanal Mtns, N. part of Le Flore Co., Okla.

†Cave limestone.

Pennsylvanian: Eastern Kansas.

G. C. Swallow and F. Hawn, 1865 (Kans. Geol. Surv. Rept. on Miami Co., p. 7). *Cave ls.*—Hard, brittle, brown, gray, and drab ls., 20 to 30 ft. thick, forming bed No. 9 in Coal Measures of Miami Co. Occurs in beds of medium thickness, separated into fragments by vertical fractures. Overlain by 15 to 18 ft. of ss. and underlain by Einstine ss.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 118). Field work has shown that excepting at Lecompton (where the beds belong to a very much higher horizon) the †Cave ls. of Swallow is Wyandotte ls.

Apparently named for occurrence in it of many caves and crevices from which bold springs usually flow.

†Cave-rock series.

Pennsylvanian: Eastern Kansas.

G. C. Swallow, 1866 (Kans. Geol. Surv. Prel. Rept., pp. 20–21). *Cave Rock series.*—Applies to beds No. 156 (Cave ls., 15 to 30 ft. thick) and No 157 (Einstein or

Einstine ss., 45 to 60 ft. thick) of geol. section of eastern Kans. Underlies Stanton ls. series and overlies Spring Rock series.

Not a geographic name. Includes Plattsburg ls. and underlying sh.

Cave Creek formation. (In Cimarron group.)

Permian: Central southern Kansas and northwestern Oklahoma.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, pp. 3, 27). *Cave Creek gypsums or fm.*—Gyp.-bearing fm., 50 ft. thick, consisting usually of either a single stratum of massive gyp. or two such strata separated by red clay sh. Includes (descending) Shimer gyp., Jenkins clay, and Medicine Lodge gyp. Overlies Flowerpot shales and underlies Dog Creek shales. Is top fm. of Salt Fork div. [In 1897 (Am. Geol., vol. 19, pp. 351–363) Cragin made Dog Creek shales top fm. of his Salt Fork div.]

C. N. Gould, 1927 (Obsolete Okla. names: Univ. Okla. Bull, Proc. Okla. Acad. Sci., vol. 6, pt. 2, p. 236). In Okla. a third gyp. memb., the Ferguson, occurs, and the 3 gypsums (Shimer, Medicine Lodge, and Ferguson) with associated dolomites and clays are now known as the *Blaine.*

Named for Cave Creek, Comanche Co., Kans.

Cavell formation.

Lower Cambrian: Alberta (Jasper Park).

P. E. Raymond, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 292–293, 300). *Cavell fm.*—Lower Camb. qtzites well displayed on E. face of Mount Edith Cavell. Thickness at least 4,000+ ft. Rests on pre-Camb. Underlies Bosche ls. and sh.

Cavendish schist.

Upper Cambrian: Southeastern Vermont (Windsor County).

C. H. Richardson, 1929 (16th Rept. Vt. State Geol., pp. 210, 223). *Cavendish schist (Upper Camb.).*—Name is necessary because characteristics of the terrane will not permit it to be included in any group hitherto named. Cavendish is selected because this terrane is essentially the one in which the postglacial gorge so widely known as Cavendish Gorge [just E. of Cavendish village, Ludlow quad.] has been cut. Essential mineral composition is quartz and biotite. It is often hornblendic, and hornblende sometimes replaces nearly all of biotite. Is of dark gray color. Underlies all members of Upper Camb. Missisquoi group, of which Gassetts schist is oldest memb. Contact with Gassetts schist can be seen in the road cut a few rods N. of Gassetts station. Not determined that it either underlies or overlies Bethel schist, but writer has reached conclusion it is time equiv. of Bethel schist. [See also long description of this schist, by Richardson, in 17th Rept. Vt. State Geol., 1931, pp. 213–237.]

Cave Rock series.

See *Cave-rock series.*

Cave Springs sandstone.

Pennsylvanian: Southern Kansas.

E. Haworth, 1898 (Kans. Univ. Geol. Surv. vol. 3, p. 66). *Cave Springs ss.* suggested by G. I. Adams for ss. separating the two lss. composing Elk Falls ls. in vicinity of Cave Springs, Elk Co. In some areas the beds separating these lss. are shales.

G. I. Adams, 1903 (U. S. G. S. Bull. 211, p. 47). The sss. that occupy interval of Tecumseh sh. S. of Elk River were called *Cave Springs sss.* by Haworth (1898).

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 178). [Refers to Adams' statement above, and abandons name, without explanation.]

†Caw Caw formation.

†Caw Caw sands.

Eocene (middle): Central South Carolina (Orangeburg County).

E. Sloan, 1908 (S. C. Geol. Surv., ser. 4, Bull. 2, pp. 449, 454, 457–459). Warley Hill phase of earlier repts divided into *Upper or Warley Hill marl* and *Lower or Caw Caw shales and marls.* The Lower Warley Hill fm. lithologically represents a transition from Congaree shales [below] to later marls and comprises both shales and marls, often intergrading. Faunally they are distinctly characterized by first appearance of *Ostrea sellæformis* in S. C. and by abundant association of *Pteropsis lapidosa.* Succeeding a coarse glauconitic sand, a pea-green clay, now in the form of a slightly laminated sh., occupied the shoal areas, while pale yellow-green and gray marls formed in the deeper waters, and intergraded with the shales along their dividing zone. In some areas an irregular deposit of yellow to gray marls extended over the basal pea-green shales, but along the shoal areas renewed silting covered this broken bed of marl with a very fossiliferous pale yellow-green sh., in which casts of a large *Venericardia planicosta, Pteropsis lapidosa, Ostrea sellæformis* are found. At Kennedy's Scarp on Tinkers Creek this pea-green sh. incloses a matted mass of soft shells at base of the scarp. Some erosion, solution, or other degradation of the top shales of Lower Warley Hill phase occurred preliminary to deposition of Upper Warley Hill series. At some localities the Upper Warley Hill is represented by a bed of dark-gray, slightly glauconitic, fine-grained laminated sh.; it is coarser grained near its base and includes rounded gravel. Its greatest thickness is approx. 24 ft. The most extensive area of Upper Warley Hill phase exposes the characteristic Warley Hill glauconitic marl, which at Warley Hill may be seen resting on the slightly irregular surface of Lower Warley Hill series. It is exposed along Santee Valley as far down as Pinckney's Landing, and along Edisto River from Branchville to Sullivan's Bridge. Its greatest observed thickness does not exceed 25 ft. The Warley Hill marl is of a dirty gray-green color, compact, hard, and very harsh to the touch; the latter feature is accentuated by the large angular grains of glauconite. At one locality small semispherical crystals of wavellite appear to have been derived from the weathered glauconitic mass.

Is a local development of McBean fm., a marine deposit of Claiborne age. According to C. W. Cooke, 1936 (U. S. G. S. Bull. 867), it is lower part of McBean fm.

Named for exposures at Caw Caw Swamp, Orangeburg Co.

Cawker terrane.

Cretaceous: Kansas.

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, p. 255). *Cawker terrane*, shales, 50 ft. thick. Underlies Graneros and overlies Brookville (sss.). Included in Dakotan. [Derivation of name not stated, but probably Cawker City, Mitchell Co., north central Kans.]

Cawood sandstone member (of Hance formation).

Pennsylvanian: Southeastern Kentucky and northeastern Tennessee.

G. H. Ashley and L. C. Glenn, 1906 (U.S.G.S.P.P. 49, pp. 31, 33, 37, 120, 158). *Cawood ss. memb.*—Ss., 80 to 100 ft. thick, in Hance fm., lying 250 ft. below top of the Hance.

Named for Cawood, Bell Co., Ky.

Cayetano formation.

Cretaceous: Cuba.

E. L. De Golyer, 1918 (A.A.P.G. Bull., vol. 2, p. 140).

Same as *San Cayetano fm.*, Dickerson and Butt, 1935.

Cayuga group.

Silurian (late): New York, Pennsylvania, western Maryland and Virginia.

J. M. Clarke and C. Schuchert, 1899 (Sci., n. s., vol. 10, pp. 874–878). *Cayugan period or group.*—Includes Manlius ls., Rondout waterline, and Salina beds, which are knit together by lithologic and faunal characters and are distinctly Ontaric [Silurian]. Outcrops are typically exposed about N. end of Cayuga Lake, N. Y.

In 1903 (Am. Geol.) C. Schuchert redefined Rondout, restricting name to upper part and introducing *Cobleskill ls.* for lower part of the beds formerly called *Rondout*. The Cayuga group (or Cayugan) has, therefore, for years been divided into these four fms.; but G. H. Chadwick in 1908 (Sci., n. s., vol. 28, p. 347, table and text) excluded Salina fm. from his *Cayugan*, while E. O. Ulrich in 1913 recommended the transfer of Rondout to Lower Dev. This is still an open question. (See further explanation under *Manlius ls.*) At present the U. S. Geol. Survey adheres to the old classification for N. Y. In Pa. and Md. the Cayuga group is divided into (descending) Tonoloway ls., Wills Creek sh., and McKenzie fm. In SW. Va. the Cayuga deposits are not differentiated and the rocks are called *Cayuga ls.*

†Cayuga dolomite.

Silurian: Canada.

See 1st entry under *Bertie ls. memb.*

Cayugan.

A time term covering the interval during which the rocks of the Cayuga group were deposited. Also used by N. Y. State Geol. Survey as a group name. (See under *Cayuga group.*)

Cayuta shale member (of Chemung formation).

Upper Devonian: West central New York.

H. S. Williams, 1906 (Sci., n. s., vol. 24, pp. 365–372). Chemung fm. of Ithaca region divided into (descending): Fall Creek cgl. lentil, 0 to 10 ft.; Wellsburg ss. memb., 600 to 650 ft.; *Cayuta sh. memb.*, 600 ft. The Cayuta memb. contains typical Chemung fauna. Exposed along Cayuta Creek from Cayuta Lake to its discharge into Susquehanna River. Rests on Enfield sh. memb. of Nunda fm.

H. S. Williams, 1909 (U. S. G. S. Watkins Glen-Catatonk folio, No. 169). *Cayuta sh. memb.*—Drab to bluish sh. and intercalated thin-bedded ss., 600 ft. thick. Underlies Wellsburg ss. memb. of Chemung and overlies Enfield sh. memb. of Portage fm.

This memb. is included in Chemung fm. in subsequent repts, including W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369), and G. H. Chadwick, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2).

Cazenovia group.

Middle Devonian: East-central New York (Madison County).

T. A. Conrad, 1841 (N. Y. Geol. Surv. 5th Rept., p. 31). [*Cazenovia group* appears in table as underlying Oneonta group and overlying Tully ls.]

L. Vanuxem, 1842 (Geol. N. Y., pt. 3, pp. 150–160). Hamilton group includes *Cazenovia group.* Largest part of town of Cazenovia is covered by it. The hills around Cazenovia village are composed chiefly of coarse sh., which forms the Cazenovia shales of Conrad.

C. S. Prosser, 1893 (Am. Jour. Sci., 3d, vol. 46, pp. 212–230). *Cazenovia group* belongs below Tully ls., and not above it, as Conrad stated in 1841. [As Tully ls. is base of Upper Dev., these beds are a part of Hamilton group (Middle Dev.).]

Only recorded uses of name.

†Cedar limestone.

Upper and Middle Devonian: Eastern Iowa.

D. D. Owen, 1852 (Rept. Geol. Surv. Wis., Iowa and Minn., p. xix). SW. [of Upper Mag. ls. area] we come upon the Cedar lss., contemporary with the Dev. fm. of English geologists, separating the Mag. lss. of N. from the Carbf. lss. and the great coal field of Iowa and Mo. [On map accompanying this rept the rocks are described as "Formations of the Valley of Cedar River belonging to the Devonian period." As mapped by Owen the "Cedar lss." of his text include the Upper Dev. Lime Creek sh. and the Middle Dev. Cedar Valley and Wapsipinicon lss.]

Some later writers have used "Cedar ls." for Dev. ls. underlying Lime Creek sh., also for Dev. ls. underlying Grassy Creek sh. and Sweetland Creek sh., in which sense it is apparently a shortened term for *Cedar Valley ls.* Named for valley of Cedar River, eastern Iowa.

Cedar formation.

Upper Triassic: Northern California (Lassen Peak region).

J. S. Diller, 1892 (prel. proof-sheet edition of U.S.G.S. Lassen Peak folio) and 1895 (published Lassen Peak, folio, No. 15). Although there are slates and sss., with occasional traces of cgl., the principal stratum of *Cedar fm.* is ls., which forms conspicuous ledges on road a few mi. W. of Buzzard's Roost. This ls. is rich in Triassic fossils, which clearly show it is same horizon as Hosselkus ls. of Genesee Valley. Named for exposure on Cedar Creek, along toll road btw. Redding and Round Mtn, where it is overlain by Bend fm.

H. W. Turner, April 1894 (Am. Geol., vol. 13, pp. 229–249). The *Cedar fm.* includes Hosselkus ls. and underlying slates [meaning Swearinger sl., which is now known to overlie Hosselkus ls.].

Cedar volcanic series.

Oligocene: British Columbia.

C. Camsell, 1913 (Canada Geol. Surv. Mem. 26, p. 82).

Cedar Bay granite.

Mesozoic(?): Southeastern Alaska (Prince William Sound region).

U. S. Grant and D. F. Higgins, 1910 (U. S. G. S. Bull. 443, pp. 41–43, 46). *Cedar Bay granite.*—Light gray, even-grained. Surrounds two-thirds of Cedar Bay and forms core of neck of land btw. Wells Bay and passage NW. of Glacier Island. Cuts Valdez group.

Cedar Butte basalt.

Pleistocene: Southern Idaho (Power County).

H. T. Stearns, 1932 (Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932) and 1936 (Jour. Geol., vol. 44, No. 4, pp. 434–439). *Cedar Butte basalt.*—Aphanitic blue pahoehoe basalt with fresh green olivine phenocrysts. Thickness exceeds 200 ft. where it dammed Snake River near Massacre Rocks. Behind this dam the American Falls lake beds accumulated. Rests, with local uncon., on thick series of early Pleist. blue and gray basalt flows which generally contain phenocrysts of olivine and feldspar. Type loc. Cedar Butte, T. 8 S., R. 29 E., Power Co.

Cedar Cliff limestone lens. (In Wills Creek shale.)

Silurian: Western Maryland and northern West Virginia.

C. K. Swartz, 1923 (Md. Geol. Surv. Sil. vol., p. 41). *Cedar Cliff ls. lens.*—Hard blue or in places pink ls. Some of basal strata consist of nodules and resemble a cgl. Thickens westward and thins eastward. Can be traced from Keyser [W. Va.] to Hancock [Md.]. Occurs in midst of Bloomsburg red ss. memb. of Wills Creek fm. Well exposed at Cedar Cliff, Md., SW. of Cumberland.

†Cedar Creek beds.

Tertiary (middle Oligocene): Northeastern Colorado.

W. D. Matthew, 1901 (Am. Mus. Nat. Hist. Mem., vol. 1, pt. 7, pp. 355–374, 444). *Cedar Creek beds.* [See under †*Martin Canyon beds.*]

H. F. Osborn, 1909 (U.S.G.S. Bull. 361, pp. 65, 105). *"Cedar Creek beds"* = lower (or middle Olig.) part of Brule fm.

Named for Cedar Creek, Logan Co.

Cedar Creek limestone.

Pennsylvanian: Southeastern Nebraska.

G. E. Condra and N. A. Bengston, 1915 (Nebr. Acad. Sci. Pub., vol. 9, No. 2, pp. 7, 12, 21, 36). *Cedar Creek ls.*—Light-colored and massive except upper part, which is thin bedded. Thickness 1½ to 8 ft. Lies 13 to 30 ft. below top of Platte shales, and is separated from underlying Cullom ls. by 6 to 8 ft. of sh.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., p. 48). *Cedar Creek ls.*, in middle of Tecumseh sh., is 2 to 9 ft. thick. Best developed at type loc. on Cedar Creek, 1½ mi. SW. of town of Cedar Creek [Cass Co., Nebr.]. Probably does not extend to Mo. and Kans. [The sh. in which this ls. occurs is now known not to be Tecumseh sh. (See R. C. Moore, Kans. Geol. Surv. Bull. 22, 1936, p. 178. Moore also abandoned the name.)]

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, 2d ser., p. 11). *Cedar Creek ls.* is abandoned for another name, which has priority. The supposed Cedar Creek ls. of Bull. 1 is thought to be Iola ls.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Cedar Creek argillite.

Paleozoic(?): Northeastern Washington.

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 80; map). *Cedar Creek argillite.*—Medium to dark gray argillite that grades alternately into calc. argillite, carbonaceous argillite, and quartz mica schist. Usually fine-grained and finely laminated or bedded. Thickness 2,500± ft. Relations to other named units not determined. Extends to Int. Bdy and is part of Pend Oreille group of B. C. Exposed along wagon road up Cedar Creek to Frisco-Standard mine and on N. slopes of Red Top Mtn.

Cedar District formation.

Cretaceous: British Columbia.

C. H. Clapp, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 99).

Cedar Grove sandstones. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and D. B. Reger, 1914 (W. Va. Geol. Surv. Rept. Logan and Mingo Counties, pp. 169–178). *Upper Cedar Grove ss.*—Massive grayish brown, micaceous, medium grained, 10 to 40 ft. thick. Lies 5 to 20 ft. below Williamson coal and 20 to 50 ft. above Cedar Grove rider coal. Seth ls. not observed and evidently replaced by Upper Cedar Grove ss. Named for association with Cedar Grove coal. *Middle Cedar Grove ss.*—Massive, gray, fine grained, micaceous, sometimes containing a thin coal. Thickness 0 to 60 ft. Lies 0 to 10 ft. below Cedar Grove coal and overlies Lower Cedar Grove coal. *Lower Cedar Grove ss.*—Massive, persistent, similar in color and character to Middle Cedar Grove ss. Thickness 20 to 30 ft. Lies 1 to 10 ft. below Lower Cedar Grove coal and overlies Alma A coal.

Cedar Hills sandstone. (In Cimarron group.)

Permian: Central southern Kansas.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, pp. 3, 24). *Cedar Hills ss.*—Chiefly unevenly hard, in part massive, concretionary, fine-grained, bright red sss., 50 to 75 ft. thick, locally underlying Flower-pot shales and overlying Salt Plain measures in Barber Co., Kans. Included in Salt Fork div.

Named for Cedar Hills, Barber Co.

Cedar Hills anhydrite.

Permian: Central Kansas.

R. G. Moss, 1932 (Kans. Geol. Surv. Bull. 19), applied *Cedar Hills anhydrite* to a bed of gyp., 20 to 60 ft. thick, forming basal bed of Cimarron group in Ness and Hodgeman Counties, which he stated is "tentatively correlated with Cedar Hills fm."

Cedarian series.

A term applied by C. [R.] Keyes to approx. the same beds designated *Cedar Valley ls.* by other geologists.

Cedar Mesa sandstone member (of Cutler formation).

Permian: Southeastern Utah (San Juan County).

A. A. Baker and J. B. Reeside, Jr., 1929 (A. A. P. G. Bull., vol. 13, No. 11, pp. 1420, 1421, 1423, 1441, 1443, 1445, 1446). *Cedar Mesa ss. memb. of Cutler fm.*—

Massive white ss., 500 to 1,000± thick, underlying Organ Rock tongue (red) of Cutler fm., and overlying Halgaito tongue (red) of the Cutler. Well exposed on Cedar Mesa, Utah, on San Juan River, W. of Mexican Hat (Bluff P. O.). In earlier repts called Coconino ss.

†Cedar Mountain beds.

Miocene (upper): Central Nevada (Cedar Mountains).

A local term applied by some geologists to Esmeralda fm. (upper Mio.) in Cedar Mtns. See J. C. Merriam (Univ. Calif. Pub., Bull. Dept. Geol., vol. 8, No. 12, p. 277, 1914; vol. 9, pp. 163–172, 1916); J. P. Buwalda (Univ. Calif. Pub. Bull. Dept. Geol., vol. 8, No. 16, p. 305, No 19, pp. 335–363, 1914); and H. F. Osborn (Am. Mus. Nat. Hist. Mem., n. s., vol. 2, pt. 1, pp. 21, 27, 1918), who assigned them to upper Mio. or lower Plio.

A. Knopf, 1921 (U. S. G. S. Bull. 725H: "Ore deposits of Cedar Mtn., Nev."). Buwalda has shown that the lake beds lying on both sides of Cedar Mtn are a part of Esmeralda fm., and they are here called Esmeralda.

Cedar Park member. (In Fredericksburg group.)

Lower Cretaceous (Comanche series): Eastern Texas (Williamson County).

W. S. Adkins, 1933 (Univ. Tex. Bull. 3232, pp. 239, 331). South of Florence, Williamson Co., much of position of the Walnut [clay] is occupied by a ls. lentil here designated *Cedar Park memb.* Type loc. quarries about 2 mi. NW. of Cedar Park. It occurs over a considerable area in western Williamson Co. and grades out northward into Walnut of type facies. It consists typically (field work of H. C. Fountain) of about 58 ft. (in core tests) of ls. crystalline and porous above and more marly and nodular below. Upper 15 ft. is a solid, medium-grained, grayish ls. weathering yellow, with a few scattered fossils. This is underlain by a few ft. of porous ls. with fossils. The basal memb. is somewhat nodular and fossiliferous. The base is 5± ft. of typical Walnut marl with many *Exogyra texana* and other usual fossils. These 3 portions are exposed in a facies transitional to type Walnut on bluffs of the South San Gabriel at highway crossing N. of Leander, where they overlie the Glen Rose. In Cedar Park area the ls. lentil in basal Fredericksburg reaches 125 ft. in thickness and probably covers several sq. mi.

†Cedar Point shales and shaly limestones.

Permian: Central Kansas.

L. C. Wooster, 1905 (The Carbf. rock system of eastern Kans.). *Cedar Point (Matfield) shales and shaly lss.,* about 92 ft. thick, overlie Wreford ls. and underlie Florence flints. Included in Florence beds.

According to its proposer is same as Matfield sh., older name. Probably named for Cedar Point, Chase Co.

Cedar Rapids phase (of Otis limestone).

Middle Devonian: Central eastern Iowa.

W. H. Norton, 1921 (Iowa Geol. Surv. vol. 27, p. 378). *Cedar Rapids phase of Otis ls.*—This phase includes the wide variety of lithologic types, usually but slightly mag., seen in upper 30 ft. of Otis ls. in quarries at Cedar Rapids and at numerous other exposures.

Cedarton shale member (of Graford formation).

Pennsylvanian: Central Texas (Colorado River region).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 387, 391). *Cedarton bed.*—Sandy clay containing some usually gritty or conglomeratic ss. Prevailingly blue, but purple, red, and yellowish outcrops occur. Thickness 40 to 90 ft. Memb. of Canyon div. Overlies Adams Branch ls., and underlies Clear Creek bed.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31, 35; Univ. Tex. Bull. 2132, pp. 109, 114). *Cedarton sh. and ss.*, 20 to 100 ft. thick, is basal memb. of Brad fm. in Colorado River Valley. Underlies Clear Creek ls. and overlies Adams Branch ls. memb. of Graford fm. Consists of blue sandy sh. (in places weathering red and purple) with ss. lentils and a few thin beds of cgl. Named for Cedarton, Brown Co.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 104, 111), restricted Brad fm. to Placid sh. memb. of Plummer and Moore and Ranger ls. memb., and included Cedarton memb. in Graford fm.

Wallace Lee and C. O. Nickell have introduced (in a rept soon to be published by Tex. Geol. Survey) *Winchell memb.* for the beds overlying Cedarton sh. memb. and forming top memb. of Graford fm. in both Brazos River and Colorado River regions.

Cedartop gypsum member (of Blaine gypsum).

Permian: Southwestern Oklahoma.

C. N. Gould, 1902 (Okla. Geol. Surv. 2d Bien. Rept., pp. 42, 56). *Cedartop gypsum.*—Massive white gyp., 18 to 20 ft. thick, in midst of red clay sh. which separates Haystack gyp. below from Collingsworth gyp. above. Included in Greer div.

C. N. Gould, 1924 (A. A. P. G. Bull. vol. 8, No. 3, pp. 324–341). Cedartop gyp. memb. is provisionally considered=Medicine Lodge gyp. memb.

This gyp. is believed to be same as Medicine Lodge gyp. memb. of the Blaine, according to H. D. Miser.

Named for Cedartop Butte, Roger Mills Co.

Cedarvale shale. (In Scranton shale.)

Pennsylvanian: Southeastern Nebraska and eastern Kansas.

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, p. 53). The Nebr. Geol. Surv. now restricts White Cloud sh. to that part of Scranton sh. below Happy Hollow ls. and applies *Cedar Vale sh.* to interval btw. Rulo ls. above and Happy Hollow ls. below. Type loc. is E. of Cedar Vale, Kans.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 212). *Cedar Vale sh.* is bluish to yellowish brown, includes clayey and sandy beds, and, near top, the Elmo coal. Thickness averages 25± ft. Is traceable from southern Nebr. to northern Okla. Is exposed in E. bluff of Caney River, sec. 12, T. 34 S., R. 8 E., Chautauqua Co., Kans. Overlies Happy Hollow ls. and underlies Rulo ls. [Moore discarded Scranton sh. and treated this sh. as a fm. in his redefined Wabaunsee group.]

Cedar Valley limestone.

Upper Devonian: Eastern Iowa and southwestern Illinois (Calhoun and Jersey Counties).

W J McGee, 1891 (U. S. G. S. 11th Ann. Rept., pt. 1, p. 314). *Cedar Valley ls.*—Predominantly lss., ranging from pure to argill., dolomitic, or perhaps carbonaceous; sometimes regularly divided by smooth bedding planes, again massive, elsewhere finely laminated; usually brecciated in peculiar manner; some strata horizontal, others locally inclined at all angles. Thickness more than 60 ft. Overlaps underlying Independence sh. and underlies Hackberry sh. Extends from Minn. line to Muscatine Co., Iowa, in belt 50 mi. wide. [As thus defined includes upper part (Davenport beds of repts) of Wapsipinicon ls.]

See *Davenport beds.*

C. L. and M. A. Fenton, 1924 (Univ. Mich. Pub., Contr. Mus. Geol., vol. 1, frontispiece), divided Cedar Valley ls. of central northern Iowa into (descending) Nora ls., Shell Rock, and Lower Cedar Valley. [The Nora was originally included in Lime Creek sh.]

T. E. Savage, 1925 (Jour. Geol.), classified Cedar Valley ls. as Upper Dev. According to E. O. Ulrich, 1911 (Geol. Soc. Am. Bull. vol. 22, pl. 28), it is of Middle and Upper Dev. age and=upper Hamilton and Tully ls. of N. Y.

C. H. Belanski, 1927 (Am. Mid. Nat. vol. 10, No. 10), restricted Cedar Valley ls. to Middle Dev. beds uncon. below his Mason City substage. Subsequent repts of Iowa Geol. Surv., however, have continued to use Cedar Valley ls. for all beds below Lime Creek sh. and above Wapsipinicon ls.

C. H. Belanski (1928) included Upper Davenport beds (Middle Dev.) of Iowa Geol. Surv. in Cedar Valley ls. (See second entry under *Davenport beds*.)

The Rept. 9th Ann. Field Conf. Kans. Geol. Soc., 1935, fig. 1, adopted Belanski's 1927 restricted definitions of *Cedar Valley ls.* and *Shellrock fm.* (see under *Shell Rock ls.*), gave thickness of Cedar Valley (restricted) as 90 to 150 ft., divided it into 3 members, named (descending) Coralville, Littleton, and Linwood (the latter two being new names), and assigned it to Upper Dev.

Named for exposures in valley of Cedar River.

Cedarville limestone.

Silurian (Niagaran): Southwestern Ohio.

E. Orton, 1871 (Ohio Geol. Surv. Rept. Prog. 1870, pp. 271, 277–278, 297–8, 301, 304–6). *Cedarville, Guelph, or Pentamerus ls.*—Series of mag. lss., 10 to 90 ft. thick, characterized by abundance of large and noticeable fossils, most prominently *Pentamerus oblongus* and *Megalomus canadensis;* also includes series of very thin-bedded and fragile lss. in which *Pentamerus* rarely occurs but which are largely composed of fossil remains of other shells. Forms top fm. of Niagara group in Highland Co. and northward in SW. Ohio, except near Hillsboro and at a few other places, where it is overlain by Hillsboro ss. Underlain by Blue Cliff or Springfield ls. Best exposed at Cedarville, Greene Co.

A. F. Foerste gave further details in Denison Univ. Bull., Jour. Sci. Lab., vol. 30, 1935, pp. 154–158.

Cedarville sandstone. (In Monongahela formation.)

Pennsylvanian: Northern West Virginia and western Maryland.

D. B. Reger, 1916 (W. Va. Geol. Surv. Rept. Lewis and Gilmer Counties, p. 124). *Cedarville ss.*—Massive, greenish gray, medium coarse and hard, with flakes of mica and spots of iron peroxide. Thickness 32 to 41 ft. Lies 7 ft. below Sewickley ls. and overlies Redstone coal. Forms cliff at E. end of Cedarville, Gilmer Co.

Cedarville series.

Miocene: Northeastern California (Modoc County).

R. J. Russell, 1928 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 17, No. 11, pp. 402–416 and map). *Cedarville series.*—A series of andesitic rocks; at least 7,500 ft. thick, divided into: (1) Upper Cedarville (andesitic tuffs, aggls., intercalated flows, and about 5 per cent of non-volcanic sediments); (2) andesitic lava flows 150 to 500 ft. thick; and (3) Lower Cedarville (3,700+ ft. of andesitic aggls., tuffs, cgls., intercalated flows, and about 5 per cent of non-volcanic sediments. The Upper Cedarville contains fossil flora considered by Chaney to be of Mascall (Upper and Middle Mio.) age. [Mapped over large part of Warner Range, W. of Cedarville.]

R. S. LaMotte, 1936 (Carnegie Inst. Wash. Pub. 455). Upper Cedarville fm. (Plio.) of Modoc Co., Calif., is overlain by Alturas fm., but at Camp 49, Nev., the Alturas is absent, and Warner basalt rests on the Upper Cedarville.

Cedarville andesite.

Miocene: Northeastern California (Modoc lava-bed quadrangle).

H. A. Powers, 1932 (Am. Min., vol. 17, No. 7, pp. 253–282). *Cedarville andesite (Mio.).*—Oldest volcanic rocks in Modoc lava-bed quad.

Ceja Glorieta sandstone.

A name applied by C. [R.] Keyes (Pan-Am. Geol., vol. 64, No. 4, 1935, p. 263) to the Permian ss. of N. Mex. that has long been called "Glorieta ss." by other geologists.

†Cement series.

Descriptive term applied in a titular sense in some early N. Y. repts to Manlius, Rondout, and Cobleskill lss. and Salina fm., which comprise Cayuga group of present terminology.

†Cement shale.

Upper Devonian: Western Colorado (Gunnison County).

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, pp. 281, 289). *Cement shales.*—Shales, 100 ft. thick, composing top fm. of Yulean series and Ordoyicic system in Colo. Take title from [exposures on?] Cement Mtn, a few miles from Crested Butte, Gunnison Co.

E. Kirk, 1930 (Am. Jour. Sci., 5th, vol. 22, pp. 222–239), stated that this sh. is of Upper Dev. age, and therefore belongs to Chaffee fm.

Cement City limestone bed. (In Kansas City formation.)

Pennsylvanian: Northwestern Missouri and eastern Kansas.

H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines, vol. 13, 2d ser., pp. 7, 27–28, 118). *Cement City ls. bed.*—Thin but fairly persistent bed of gray, buff, or cream-colored ls., 5 to 10 ft. thick, lying 5 to 20 ft. above base of Chanute sh. memb. of Kansas City fm. Is believed to be Parkville ls. of Gallaher. At Kansas City it is known as "Gray ledge" or "Building ledge." Named for Cement City, Jackson Co., Mo.

R. C. Moore, 1932 (see under *Drum ls.*), divided Drum ls. into Corbin City ls. above and Cement City ls. below, and this definition of Cement City ls. was followed by Moore and G. E. Condra in their Oct. 1932 revised classification chart of Penn. rocks of Kans. and Nebr.

G. E. Condra, 1933 (Nebr. Geol. Surv. Paper No. 4, p. 11). *Cement City ls.*, according to Moore, is true Drum ls. at type loc.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pp. 43+). *Cement City ls.* is basal part of true Drum ls. This has been verified by R. C. Moore. The Chanute sh. of Hinds and Greene included true Chanute, true Drum, and underlying Quivira sh. of this rept. The Quivira is top part of Cherryvale sh. The Corbin City and Cement City ls. members of Drum ls. are uncon.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Cemetery limestone.

Upper Cambrian: Western central Montana (Elkhorn region).

W. H. Weed, 1901 (U. S. G. S. 22nd Ann. Rept., pt. 2, map, pp. 434, 437). *Cemetery ls.*—Great thickness of light-blue, thin to thick-bedded ls., mottled with dark-blue spots, overlain by 100 ft. of white or light gray granular ls. thin to thick bedded, varying to straw-yellow dolomitic marble. Lower part consists of 50 ft. of dark-blue granular ls. that weathers light gray, underlain by 70 ft. of blue lss. Total thickness 650 ft. Underlies Elkhorn sh. and overlies Hobo Gulch fm. Named for occurrence at Elkhorn cemetery.

Cenocene series.

A name proposed by C. [R.] Keyes (Iowa Acad. Sci. Proc., vol. 22, 1915, p. 260) for latest Quat. deposits in N. Mex.

Cenozoic era.

A major time term, meaning recent life, employed to cover the Quaternary and Tertiary periods. For definition see U. S. G. S. Bull. 769, 1925, p. 8.

Centennial limestone.

Lower Ordovician and Upper and Middle Cambrian: Central northern Utah (Tintic district).

G. W. Crane, 1915 (Am. Inst. Min. Engrs. Bull. 106, pp. 2149–2151). *Centennial ls.*—Four relatively thick horizons of massive dark-blue ls. interspaced by as many relatively thin horizons of thinly bedded, light-gray ls. and one 6-ft. memb of thinly laminated light-green sh. Thickness 798 ft. Underlies 920 ft. of white lime sh. [Opohonga ls.] and overlies Golden Ray ls. [Evidently named for Centennial mine.]

These rocks were later subdivided into 4 fms., Ajax ls., Opex dol., Cole Canyon dol., and Bluebird dol.

Center iron sandstone. (In Clinton formation.)

Silurian (Niagaran): Central southern Pennsylvania (Perry County).

C. K. and F. M. Swartz, 1931 (Geol. Soc. Am. Bull., vol. 42, pp. 625, 628, 629, 634, 638). *Center iron ss.*—Massive red-brown iron ss. with interbedded sh. similar to that above. Thickness 36 ft. in vicinity of Center and 17 ft. at Harrisburg. Seen at Center village (4 mi. W. of Loysville) and vicinity. Base lies 96 ft. below top of Rose Hill fm. (lower or pre-Rochester Clinton). Lies higher in Rose Hill fm. than Swatara iron ss., which lies 511 to 631 ft. above base of the Rose Hill.

Centerfield limestone member (of Ludlowville shale).

Middle Devonian: Central and western New York.

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, p. 22). In Ontario Co. the succession of Hamilton beds from base up is: Shaffer sh. [=Skaneateles sh.]; *Centerfield ls.; Canandaigua sh.* [=Ludlowville sh. less Centerfield ls.]; Encrinal (=Menteth) ls.; Moscow sh. The Ludlowville shales do not maintain their integrity far from typical section on Cayuga Lake.

J. M. Clarke and D. D. Luther, 1904 (N. Y. State Mus. Bull. 63), used *Canandaigua sh.* in Canandaigua and Naples quads., for beds beneath Tichenor ls. and above Skaneateles sh., which are "probably equiv. in part to the Ludlowville shales of Hall," because they were not certain the Encrinal ls. of Hall (the fm. overlying the Ludlowville sh.) is same as Tichenor (Encrinal) ls. The *Centerfield ls.* was treated as basal memb. of Canandaigua sh.

D. D. Luther, 1909 (N. Y. State Mus. Bull. 128), included *Centerfield ls.* in Ludlowville sh.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 67). In Ontario Co. the lower calc. beds of Ludlowville sh., which are characterized by their fossil contents, have been designated *Centerfield ls.* (1903 Clarke). The calc. beds at and near base of the Ludlowville extend as far W. as Erie Co. and also for some distance E. of Ontario Co. The strat. equivalence of *"Canandaigua"* and Ludlowville have now been established.

D. D. Luther, 1914 (N. Y. State Mus. Bull. 172, pp. 6–30), treated *Centerfield ls.* as top memb. of Skaneateles sh.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, p. 223). *Centerfield ls.* is basal memb. of Ludlowville fm. Identified from Murder Creek, western N. Y., to E. of Skaneateles Lake. Is especially characterized by variety and perfection of preservation of its fossils, most notably its corals. Characterized by *Spirifer divaricatus*. In Livonia salt shaft it is 19 ft. thick; at Blossom, 4½ ft.; is probably 1½ ft. thick in cliff at Bayview, Lake Erie. Type section is on Schaffer Creek, 1 mi. N. of Centerfield.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369), included this ls. in Ludlowville sh., but B. Smith, 1935 (N. Y. State Mus. Bull. 300, pp. 11, 39, 44), included it in Skaneateles sh., although stating that it is usually included in the Ludlowville.

The U. S. Geol. Survey treats *Centerfield ls. memb.* as basal bed of Ludlowville sh.

Center Hall formation.

Lower Ordovician: Central and central southern Pennsylvania.

R. M. Field, 1919 (Am. Jour. Sci., 4th, vol. 48, pp. 404, 417–419, 422). *Center Hall fm.*—A zone of impure ls., 15 ft. thick, overlying Valentine fm. (pure quarry rock) and underlying Rodman ls. Thickens to E. Is not faunally or lithologically very different from Carlim ls., which underlies Valentine fm. The Valentine thins to E. and its beds are successively replaced by the upper beds of the Carlim, the younger of which appears to be synchronous with the Center Hall at Bellefonte. Included in Stones River group. Named for village of Center Hall [Center Co.].

Centerville limestone.

Silurian (Niagaran): Western Tennessee.

A. F. Foerste, 1901 (Geol. Soc. Am. Bull., vol. 12, pp. 397, 402, 407). *Centerville ls.*—Includes Baker (Clinton) ls., South Tunnel bed (Osgood shaly clay), and Whites Bend (Laurel) ls. At Centerville the Osgood bed is lithologically simply a softer phase in general Sil. section, although paleontologically it separates fauna of Clinton ls. below from that of Laurel ls. above. South of Harpeth River, where Clinton-Osgood-Laurel beds form practically a single lithological unit, the name *Centerville ls.* may prove convenient as a general name for this series.

Named for exposures at Centerville, Hickman Co.

Centerville formation.

Silurian (earliest): Southwestern Ohio (Montgomery, Clark, and Greene Counties), and southeastern Indiana.

A. F. Foerste, 1931 (Ky. Geol. Surv., ser. 6, vol. 36, pp. 173, 184–185). Until recently the Brassfield ls. was regarded as oldest Sil. fm. in area traversed by Cincinnati anticline. The Belfast is merely a local phase of base of the Brassfield. In Ind. and Ohio the base of the Brassfield is underlaid by a clay sh., all of which, until recently, was referred to Elkhorn memb. of the Richmond. Several years ago, however, a Sil. fauna was discovered locally in uppermost part of this clay. At quarry E. of Centerville [Montgomery Co., Ohio] the following distinctly Sil. fauna was collected [listed]. Such an association of fossils having a Sil. aspect with others having an Ord. aspect is known also in Edgewood fm. of SW. Ill. and adjacent parts of Mo. Hence the Ohio faunules here mentioned are correlated provisionally with the Edgewood, although no species known to be diagnostic of the Edgewood have been found. But presence of *Platymerella manniensis* at base of the Brassfield at Lawshe, Adams Co., Ohio, appears to confirm this correlation. Provisionally the term *Centerville fm.* is proposed for the supposed Ohio equiv. of the Edgewood.

Foerste gave further details in 1935 (Denison Univ. Bull., Jour. Sci. Lab., vol. 30, pp. 145, 148), when he stated this fm. is exposed at large quarry ½ mi. NE. of Centerville, Ohio.

Centinela gravels.

Pleistocene: Southern California (Baldwin Hills, Los Angeles County).

A. J. Tieje, 1926 (A. A. P. G. Bull., vol. 10, No. 5, p. 510). The post-Palos Verdes alternating [fresh-water] blue-clay and gravel beds, however, of trench 10 may be correlated with a series of marine gravels which carry a fauna of still more warm-water aspect than that of Palos Verdes strata, and which may be tentatively styled *Centinela gravels,* since they were exposed S. of Centinela Creek, in trench 6. On other hand, these Centinela gravels may represent a new submergence of Baldwin Hills region.

†Central limestone and shale group.

Upper, Middle, and Lower Ordovician: Central and eastern Tennessee.

J. M. Safford, 1856 (Geol. Reconn. Tenn. 1st Rept., pp. 149, 154–156). *Central ls. and sh. group.*—Nearly horizontal blue lss., 800 to 900 ft. thick in Central Basin of Tenn., double or more than double that thickness in eastern valley of E. Tenn. Easily divisible into two nearly equal members. The Stones River or lower memb. is series of blue and dove-colored lss., more or less cherty, not generally as argill. as those of succeeding memb., and often remaining thick bedded when weathered; contains, however, several thin-bedded argill. divisions. Nashville or upper memb. is blue, argill., more or less sandy, compact, and highly fossiliferous ls., generally weathering into thin-bedded rough layers, often separated by shaly seams. Stones River and Nashville subgroups distinctly separated by fossil characters, the former being in general=Black River and lower Trenton, and latter=Hudson River, Utica sl., and Upper Trenton of N. Y. Underlies Clinch Mtn ss., and overlies Camb. (?) Magnesian ls. and sh. group or Calciferous ss.

Includes all Ordovician fms. in central and eastern Tenn..

Named for central basin of middle Tenn.

†Central limestone.

Lower Ordovician: Central Tennessee.

J. M. Safford, 1869 (Geol. Tenn., pp. 258–267). *Central ls.*—Thick-bedded, cherty, fossiliferous lss., of light-blue or dove color, 100 ft. thick. Basal fm. of Trenton or Lebanon [Stones River] group. Underlies Pierce ls. Bottom rock of Central Basin. Outcrops in approx. circular area around Murfreesboro.

Nongeographic name. Replaced by Murfreesboro ls.

Named for fact it outcrops in exact center of State.

Central marble bowlder member. (In Davis formation.)

Upper Cambrian: Southeastern Missouri.

E. R. Buckley, 1909 (Mo. Bur. Geol. and Mines vol. 9, pt. 1, p. 33). *Central marble bowlder memb.*—Soft blue sh. and large ls. boulders, lying 63 ft. below top of Davis fm. Is persistent over large areas.

Nongeographic name.

†Central group.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. C. Lane, 1911 (Mich. Geol. and Biol. Surv. Pub. 6, geol. ser. 4, pp. 409, 436, 450, 455, 463, etc.). An abbreviation of *Central Mine group*.

Central City granite.

Pre-Cambrian (?): Central northern Colorado (Gilpin County).

J. Underhill, 1906 (Univ. Colo. Studies, vol. 3, No. 4, p. 272; also Colo. Sci. Soc. Proc., vol. 8, pp. 103–122). *Central City granite.*—A hypidiomorphic arrangement of quartz, feldspar, and biotite, no muscovite; classed with alkali granites or granitites. So far as known occurs only on each side and a little S. of head of Spring Gulch, just S. of Central City R. R. station. Intrudes the surrounding gneiss.

Centralia limestone. (In McLeansboro formation.)

Pennsylvanian: Southwestern Illinois (Marion County).

J. R. Ball, 1934 (Ill. Acad. Sci. Trans., vol. 26, No. 3, p. 97). *Centralia ls.*, lying 17± ft. above Shoal Creek ls. and 17± ft. below Macoupin ls., which it resembles, is very fossiliferous, and fauna differs from that of Macoupin ls. [Derivation of name not stated, but probably is Centralia, SW. corner of Marion Co.]

Centralian epoch (and series).

Term proposed by G. F. Kay (Geol. Soc. Am. Bull., vol. 42, pt. 1, pp. 449–452, 1931) to include Sangamon (interglacial) and Illinoian (glacial) stages of Pleistocene epoch (and series), which Kay would elevate to Pleist. period (and system). Named for Centralia, Marion Co., Ill., where Illinoian till and Illinoian gumbotil are well developed over a large area surrounding the village.

Central Mine group.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. C. Lane and A. E. Seaman, 1907 (Jour. Geol., vol. 15, pp. 680, 689). *Central Mine group.*—Mainly lavas of augitic ophite type, with infrequent sediments. At top is "Mesnard epidote" and just beneath the heaviest flow, over 1,000 ft. thick at times, known as the *Greenstone*. Includes "Greenstone group," "Phoenix Mine group," but only a part of Pumpelly's "Portage Lake series," and just about that part included and well exposed in workings of Central mine on a cross-fissure, exposing a good section (sections 24, 25, 36, T. 58 N., R. 31 W.). This is a new name we would introduce and define as extending from Bohemia cgl., Marvine's cgl. 3 or 8, to "St. Mary's epidote," a sediment, volcanic ash, just above the "Greenstone" and Marvine's cgl. No. 15. Characterized by very heavy flows of ophite, some of them hundreds of ft. thick, so that, for instance, the "Greenstone," the one at top of the series, extends beneath Lake Superior, from one side to the other; often proportionately coarse grained. On Black River there are possibly 25,000 ft. including flows. At Portage Lake say 8,000 ft.

Because of uncon. at base of †Mesnard epidote and closer relations of that fm. with overlying rocks, the †Mesnard epidote is now included in Ashbed group. Lane included it in that group in his 1911 publication.

†Central Mine conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan.

Local name for Houghton cgl. in Central mine.

Central Valley beds.

Pre-Cambrian (Keweenawan): Northern Michigan.

R. D. Irving, 1883 (U. S. G. S. Mon. 5, p. 187). *Central Valley beds.*—Layers not well exposed, but evidently chiefly fine-grained diabases and amygdaloids, with a number of thin porphyry cgls., in all respects like underlying group. Thickness about 5,540 ft. Rests on Bohemian Range group and is overlain by the Sub-Greenstone group, 1,600 ft. thick.

Believed to extend from top of Bohemia cgl. up to top of Wolverine ss., thus covering lower part of Central Mine group.

Derivation of name not stated.

Centre Point division.

Pleistocene: Southwestern Arkansas.

R. T. Hill, 1888 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 2, pp. 29, 35–42, 188). *Plateau gravel or Centre Point gravel, phase, or div.*—Red gravels and red sandy clays, 0 to 200 ft. thick, forming uplands of N. half of interior margin of the region, becoming more and more conspicuous to W. toward Choctaw line, and attaining greatest development in central portions of Howard, Pike, and northern Hempstead Counties. In places overlies Arkadelphia shales, in other places rests on *Exogyra costata* clays and in other places rests on Camden series.

Named for exposures at Centre Point, Howard Co.

†Ceratops beds.

Upper Cretaceous (includes some Eocene in certain areas): Wyoming, northwestern Colorado, Montana, and North Dakota and South Dakota.

O. C. Marsh, 1889 (Am. Jour. Sci., 3d, vol. 38, p. 501). The geological horizon of these strange reptiles—the huge horned dinosaurs—is a distinct one in upper Cret., and has now been traced nearly 800 mi. along E. flank of Rocky Mtns. It is marked almost everywhere by remains of these reptiles, and hence the strata containing them may be called *Ceratops beds*. They are fresh-water or brackish-water deposits, which form part of the so-called Laramie, but are below the uppermost beds referred to that group. In some places at least they rest upon marine beds which contain invertebrate fossils characteristic of Fox Hills deposits. The fossils associated with the Ceratopsidae are mainly dinosaurs representing two or three orders and several families. Plesiosaurs, crocodiles, and turtles of Cret. types, and many smaller reptiles have left their remains in the same deposits. Numerous small mammals, also of ancient types, a few birds, and many fishes, are likewise entombed in this fm. Invertebrate fossils and plants are not uncommon in the same horizon.

Replaced by geographic name *Lance fm.*

Cercado formation.

Miocene: Santo Domingo.

C. J. Maury, 1919 (Sci., n. s., vol. 50, p. 591).

†Cerithium rock.

Paleontologic term formerly applied to a facies of Tampa ls. (lower Miocene) of Fla.

Cerro till.

Cerro glacial stage.

Pleistocene (pre-Wisconsin): Southwestern Colorado.

W. W. Atwood and K. F. Mather (U. S. G. S. P. P. 95, p. 14, pl. 1, 1915; Geol. Soc. Am. Bull., vol. 35, p. 122, 1924; U. S. G. S. P. P. 166, 1932). *Cerro till.*—Oldest Pleist. glacial drift in SW. Colo., the next younger Pleist. drift being named *Durango till*. The time covered by deposition of the till is called *Cerro glacial stage*. Replaces "San Juan glacial epoch" and "San Juan moraine," the name *San Juan* being preoccupied. Named for Cerro Summit [about 12 mi. E. of Montrose, Montrose Co.]. It is possible that some deposits referred to Cerro stage may be as old as Nebraskan, but we believe that most of these deposits are comparable to either Illinoian or Kansan.

Cerro Gordo clay.

Lower Cretaceous (Comanche series): Southwestern Arkansas.

R. T. Hill, 1888 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 2, pp. 111, 188). *Cerro Gordo blue chloritic clays.*—Pale and yellowish green clay marls forming upper part of Washita div. in SW. Ark. Overlie massive semicrystalline lss. called Upper Little River ls. Underlie the poor lands from Cerro Gordo [Little River Co.] to within 6 mi. of Rocky Comfort, extending E. to Cane Creek.

According to C. H. Dane (personal communication, Dec. 1936), this name covered Kiamichi clay and may also include some of lower part of Woodbine fm.

Cerro Gordo substage.

Upper Devonian: Central northern Iowa.

C. L. Fenton, 1919 (Am. Jour. Sci., 4th, vol. 48, pp. 355–376). *Cerro Gordo substage.*—Upper part or *Spirifer* zone, 20 ft. thick at Hackberry Grove, consists of yellowish, very calc. shales, shaly clays, and occasional bands of shaly lss., very fossiliferous, containing three distinct faunules. Lower part or *Striatula* zone, 7 to 25 ft. thick, consists of calc. shales and shaly lss., slightly gritty; contains large amounts of iron pyrite and near base many calc. concretions; lower portion largely heavy ledges of strongly iron-stained and seemingly dolomitic ls. Basal part of Hackberry stage [restricted]. Underlies Owen substage of Hackberry stage and uncon. or discon. overlies Sheffield fm. [Juniper Hill fm. of Van Tuyl, 1925], which was referred to the Hamilton by Webster in 1889.

Named, apparently, for exposures in Cerro Gordo Co.

The Rept. 9th Ann. Field Conf. Kans. Geol. Soc., 1935, fig. 1, treated *Cerro Gordo memb.* as middle part of Lime Creek sh.

Cerro Gordo moraine.

Pleistocene (Wisconsin stage): Central and northeastern Illinois. Described in U. S. G. S. Mon. 38, pp. 218–222. Belongs to Shelbyville morainic system. Named for Cerro Gordo, Platt Co.

Cerros de Sal formation.

Miocene (upper): Dominican Republic.

T. W. Vaughan et al., 1921 (Dominican Republic Geol. Surv., Mem. 1, p. 75).

Cevicos limestone.

Miocene (lower): Dominican Republic.

C. W. Cooke, 1920 (Geol. Soc. Am. Bull., vol. 31, p. 219).

Chaco marl.

Eocene: Northwestern New Mexico.

C. R. Keyes, 1906 (Geol. Soc. Am. Bull., vol. 17, p. 725). *Chaco marls* (Eo.), 1,000 ft. thick, underlie Chama clays (Mio.) and are separated from underlying Torreon fm. [Torrejon] by Canyon Largo sss., 700 ft. thick. [Derivation of name not given.]

Appears to be upper part of Wasatch fm. of NW. N. Mex.

Chacra.

A name applied by C. [R.] Keyes to 150 ft. of sss. described as forming top memb. of Mesaverde fm. in Colo., N. Mex., and Ariz. Derivation of name not stated. (See his Conspectus of geol. fms. of N. Mex., 1915, pp. 2, 6.)

Chacra sandstone member (of Mesaverde formation).

Upper Cretaceous: Northwestern New Mexico (Chacra Mesa region).

C. H. Dane, 1936 (U. S. G. S. Bull. 860C). *Chacra ss. memb.*—Buff, gray, and copper-colored ss., gray sh., some carbonaceous sh. and sub-bituminous coal. Thickness 0 to 360 ft. Top memb. of Mesaverde fm. in Chacra Mesa coal field. Replaces Cliff House ss. as used by M. Bauer and J. B. Reeside, Jr., in this region. Appears to be same as Chacra sss. of Keyes.

Chadakoin beds.

Upper Devonian: Western New York (Chautauqua County) and northwestern Pennsylvania.

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69). Upper Dev. of Chautauqua Co. divided into (descending): Knapp beds; Conewango fm. (with Panama cgl. at base); Chadakoin; Volusia sh. (=Girard sh. of Pa.).

G. H. Chadwick, 1924 (N. Y. State Mus. Bull. 251, p. 154). *Chadakoin beds* succeed Volusia sh. in Chautauqua gulf section W. of Mayville, and on Chautauqua Lake they include some shales of distinctly reddish or chocolate color. Named for exceptional exposure in the shale-brick quarries at Dexterville (Jamestown) on Chadakoin River. Pass southward and eastward into upper "Chemung" of Warren folio and Olean region, which is characterized by such chocolate shales. In Elmira area they must lie wholly above true Chemung and in the Catskill, which there also is distinctly chocolate rather than red. Upper limit of Chadakoin fm. is presumably at base of Panama cgl. or of equiv. Le Boeuf ss. of Pa.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369), included *Chadakoin beds* in Chemung, and called underlying beds Cuba ss.

G. H. Chadwick, 1935 (Geol. Soc. Am. Proc. 1934, p. 71). [See 1935 entry under *Northeast sh.*]

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61, pp. 62–70). *Chadakoin stage* (*Chadakoin monothem*) underlies Panama cgl. memb. and overlies Girard sh. Divided into (descending) Ellicott sh. memb. (which includes, near top, "Tanner's Hill red" band), Dexterville sh. memb., and Lillibridge ss. memb.

Chadron formation.

Oligocene (lower): Western Nebraska and South Dakota, eastern Wyoming, and northeastern Colorado.

N. H. Darton, 1899 (U. S. G. S. 19th Ann. Rept., pt. 4, pp. 736, 759, pl. 82). *Chadron fm.*—A thin sheet of light greenish sandy clay, underlying Brule clay and forming basal memb. of White River series. Formerly called "Titanotherium beds." Rests uncon. on Pierre clay. Thickness 30 to 60 ft. in outcrops along foot of Pine Ridge, but thickens considerably in vicinity of Adelia, where there are included some masses of dark gray and buff ss. of coarse texture. Appears not to extend far E. in southern Nebr., and is absent along Republican River. Underlies parts of Colo. and S. Dak.

Is lower fm. of White River group.

Mr. Darton stated (personal communication April 8, 1931) that he named this fm. for exposures at Chadron, Nebr.

Chaffee formation.

Upper Devonian: Colorado.

E. Kirk, 1931 (Am. Jour. Sci., 5th, vol. 22, pp. 229–230). *Chaffee fm.*—A name applied to the Dev. deposits, of protean lithologic character, in areas to N. and E. of typical region of Ouray ls. and Elbert fm. of San Juan region, SW. Colo., of which it is considered the approx. equivalent. The area of Chaffee fm. extends from Salida to Crested Butte quad. and Glenwood Springs on W.; to N. at least as far as Alma dist., and to S. as far as Kerber Creek dist. The fm. consists of a variable series of sss., shales, dolomites, and relatively small amounts of ls., and is characterized throughout by Dev. invertebrate fauna so well known in Ouray ls. In Leadville and Alma districts the Parting qtzite is basal memb. of Chaffee fm. Thickness of fm. in a section near Salida 161± ft.; in Gold Brick dist. 204± ft.; in Crested Butte quad. 175 ft.; in Leadville dist. 102± ft.; at Gilman 70 ft. Named for Chaffee Co., in which it is well exposed S. of Arkansas River about 5 mi. SE. of Salida, and on W. slope of Monarch Mtn, at Monarch, 15± mi. SW. of Salida.

Chaffin limestone member (of Thrifty formation).

Pennsylvanian: Central Texas (Colorado River region).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 410–412). *Chaffin bed.*—South of Home Creek, massive, hard, brittle, bluish white ls. of slightly nodular structure, in places replaced by massive ss.; N. of Home Creek, 2 to 3 ft. of massive, brown-weathering ls. above and 1 to 5 ft. of crumbling white ls. below, separated by 25 to 50 ft. of clay. Memb. of Cisco div. Underlies Waldrip bed and overlies Parks Mtn bed.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, p. 24; Univ. Tex. Bull. 2132, p. 158). *Upper Chaffin bed* of Drake is Breckenridge ls. memb. of Thrifty fm. and Lower Chaffin bed of Drake is probably Blach Ranch ls. memb. of Thrifty fm. of Brazos River region.

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501, p. 233). The Breckenridge ls. (top memb. of Thrifty fm. of Colorado River area) was described by Drake as *Chaffin bed,* and was correlated with Breckenridge ls. of Brazos River area by Plummer and Moore. The bed lies directly on Chaffin coal.

The present definition of U. S. Geol. Survey treats Chaffin ls. as top memb. of Thrifty fm. in Colorado River region, its type area, and as overlying Parks Mtn ss. memb. of the Thrifty and underlying Harpersville fm.

Named for Chaffin coal mine, 2 mi. E. of Waldrip, McCulloch Co.

Chagres sandstone.

Pliocene: Panama Canal Zone.

D. F. MacDonald, 1919 (U. S. Nat. Mus. Bull. 103, p. 532).

Chagrin shale.

Upper Devonian: Northern Ohio.

C. S. Prosser, 1903 (Jour. Geol., vol. 11, p. 521). *Chagrin sh.*—Grayish sh. and thin sss., underlying black Cleveland sh. and overlying black Huron sh. Replaces Erie sh. (preoccupied).

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69); 1924 (N. Y. State Mus. Bull. 251, p. 157); 1933 (Pan-Am. Geol., vol. 60, pp. 195, 351). Upper Chagrin is of Bradfordian age and=Conewango fm. (Oswayo and Cattaraugus), and Lower Chagrin is of Chautauquan age and=Chadakoin and Girard. [On p. 195 of Pan-Am. Geol., vol. 60, he called the rocks *Chagrin group.*]

H. P. Cushing, 1931 (U. S. G. S. Bull. 818, on Cleveland, Berea, and Euclid quads., Ohio), defined *Chagrin sh.* as uncon. underlying Olmsted sh. memb. of Cleveland sh. and as resting on shales of Portage age. This is present accepted definition of Chagrin sh. Its relations to Huron sh. are now questioned. Named for exposures on Chagrin River, Cuyahoga Co. Assigned to Chemung epoch.

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60, No. 4, pp. 280, 281), said *Chagrin sh.* is later than Chemung and of Conewango age, as did K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71). Also that the sh. called "of Portage age" in U. S. G. S. Bull. 818 is real Chemung and not of Portage age.

Chagrin magnafacies.

Upper Devonian: Northwestern Pennsylvania.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 28). The Big Bend magnafacies is transformed into an olivaceous, still fine-grained, sh. and ss. in the next seaward-adjoining province. For this magnafacies the name *Chagrin* is being used. The Chagrin "fm." of O. is in reality a terrane, and this usage of the term for this important magnafacies, which is almost if not quite as important as the Big Bend magnafacies, has decided advantage over any other available name. The parvafacies of Chagrin magnafacies within Venango stage is being termed *Irvineton parvafacies.* Venango stage included in Conewango series.

Chainman shale.

Mississippian: Eastern Nevada (Ely region).

A. C. Spencer, 1917 (U. S. G. S. P. P. 96, pp. 24, 26, map). *Chainman sh.*—Essentially soft, fissile, clay sh. grading locally into fine-grained sandy sh. Contains much carbonaceous matter and beds are almost uniformly of very dark hue. In a few places they contain cobble-like segregations of iron carbonate, which becomes rusty on exposure. In NW. corner of Ely quad. a bed of qtzite 30± ft. thick lies in middle of fm., but elsewhere no sandy beds were seen. Locally there are intercalations of gray ls. in upper part of fm. Alternations of ls. and sh. in upper part show transition into overlying Ely ls. In mapping intention has been to draw upper bdy of fm. just above uppermost sh. bed of transition zone. Thickness 200 to 250 ft. Near Veteran the fm. has apparent thickness of 1,000 ft., but this is attributed to duplication by folding and crumpling. Is top fm. of Mississippian. Fossils listed. Overlies Joana ls. Named for Chainman mine, near Lane, Ely quad.

Chaleur series.

Silurian (Niagaran): Quebec (Gaspé Peninsula).

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 204).

C. Schuchert and J. D. Dart, 1926 (Canada Geol. Surv. Bull. 44, p. 42).

W. A. Parks, 1931 (Geol. Soc. Am. Bull., vol. 42, p. 787).

S. A. Northrop, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, p. 271). The *Chaleur series* (middle Sil.) rests uncon. on Mictaw series (of late Trenton to early Eden age). Its 6 fms. are correlated by their faunas with Clinton, Lockport, and Guelph.

Chalk Bluff formation.

Permian: Southeastern New Mexico (Pecos Valley region).

W. B. Lang, 1937 (A. A. P. G. Bull., vol. 21, No. 7). *Chalk Bluff fm.*—Comprises all sediments lying btw. San Andres ls. (below) and Salado halite (above). Consists of anhydrite, dolomitic anhydrite, sss., red beds, and dolomitic lss. Contains numerous beds of greenish bentonite, some 5 ft. or more thick. Is essentially a back-reef fm., but is contemp. with fms. of the reef zone. Thickness, 1,000± ft. Interfingers with upper (Azotea) tongue of Carlsbad ls., also with underlying part of the Carlsbad, and with the still older Dog Canyon ls. Exposed in Chalk Bluff, on E. bank of Pecos River SE. of Artesia.

Chalk Mountain nevadite.

Eocene: Tenmile district, Colorado.

W. Cross, 1886 (U. S. G. S. Mon. 12, pp. 345–349). Almost wholly quartz and feldspar.

Forms mass of Chalk Mtn, Eagle and Summit Counties.

Chalk Mountain dacite.

Recent (?): Northern California (Lake County).

C. A. Anderson, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 5, pp. 656–657). *Chalk Mtn dacite* intrudes Cache fm. (upper Plio. or lower Pleist.), and may be of Recent age. It is brilliant white, and composes most of Chalk Mtn, a small conical hill rising 400 ft. E. of North Fork of Cache Creek.

Chalky Mount group.

Age (?): Barbados.

E. H. C. Craig, 1913 (Rept. on oil fields of Barbados, p. 3).

Challis volcanics.

Tertiary (late Oligocene or early Miocene): Southern central Idaho (Custer County).

C. P. Ross, 1930 (Idaho Bur. Mines and Geol. Pam. 33, March 1930). *Challis volcanics.*—Lava flows and associated pyroclastics of probable Mio. age in mtn region of south-central Idaho. Named for Challis National Forest and town of Challis, Custer Co.

C. P. Ross, 1932 (Idaho correlation chart, compiled by M. G. Wilmarth). *Challis volcanics* divided into (descending): (1) Tuffaceous beds present in places; (2) Yankee Fork rhyolite memb., 0 to 1,600± ft.; (3) Germer tuffaceous memb., 0 to 2,000+ ft.; (4) andesitic beds, 0 to 2,000 ft. Of Olig. (?) age. Uncon. underlies Mio. intrusives and uncon. overlies intrusives related to Idaho batholith.

More fully described by C. P. Ross in U. S. G. S. Bull. 854, 1934, on Casto quad.

Chama clay.

Miocene (?): Northwestern New Mexico.

C. R. Keyes, 1906 (Geol. Soc. Am. Bull., vol. 17, p. 725). *Chama clays,* 300 ft. thick, underlie Santa Fe sands and overlie Eocene Chaco marls. [Derivation of name not given.]

Chaman series.

A term employed by C. R. Keyes (Iowa Acad. Sci. Proc., vol. 14, pp. 223–228, 1907) to cover his Chaco marls and Canyon Largo sss. of N. Mex., both Eocene, which correspond to Wasatch fm. of present terminology. Overlies Torrejon fm. Derivation of name not stated. He has also applied the name in Colo. and Ariz.

Chamberlain shale.

Pre-Cambrian (Belt series): Central southern Montana (Little Belt Mountains).

C. D. Walcott, 1899 (Geol. Soc. Am. Bull., vol. 10, pp. 199–215). *Chamberlain shales.*—Dark, siliceous, and in places aren. shales, 1,500 ft. thick, overlying Neihart qtzite and ss. and underlying Newland ls. Type localities are on ridges btw. Chamberlain and Sawmill Creeks, SE. of Neihart.

W. H. Weed, 1900 (U. S. G. S. 20th Ann. Rept., pt. 3, p. 282). *Chamberlain shales.*—Dark gray, almost black, shales, frequently aren., occasional ripple marks; essentially slaty in fracture, but beds are jointed and form cliffs along stream courses. These beds form middle part of fm. At base the admixture of aren. and micaceous material indicates transition into underlying Neihart qtzite, while in upper part calc. beds appear alternating with the black sh., the latter becoming less and less prominent and the calc. sh. becoming true ls. It thus grades into overlying Newland ls. Estimated thickness in Little Belt Mtns 2,000 ft. Typically developed along Chamberlain and Sawmill Creeks, S. of Neihart. Estimated thickness on Sawmill Creek 2,078 ft.

Chamberlin's Brook formation.

Cambrian: Newfoundland.

B. F. Howell, 1925 (Bulls. Am. Pal., vol. 11, No. 43, p. 60).

Chambersburg limestone.

Middle Ordovician: Central southern Pennsylvania, western Maryland, and northwestern Virginia.

G. W. Stose, 1906 (Jour. Geol., vol. 14, p. 211). *Chambersburg ls.*—Crystalline and thin shaly lss., more than 1,000 ft. thick, containing in upper part fossils identified by E. O. Ulrich as of Black River and Chazy age. Top fm. of Shenandoah group. Underlies Utica sh. and overlies Stones River ls. Exposed along edge of sh. belt W. of Chambersburg, Franklin Co.

G. W. Stose, 1909 (U. S. G. S. Mercersburg-Chambersburg folio, No. 170). *Chambersburg ls.* contains fossils identified by E. O. Ulrich as of Chazy, Black River, and basal Trenton age. Thickness 100 to 750 ft.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27), transferred to Martinsburg sh. the shaly beds [0 to 245 ft. thick] at top of Chambersburg ls., thus including in the Martinsburg all beds of Trenton age. This modified definition was adopted by U. S. Geol. Survey in 1927.

C. Butts and G. W. Stose, 1932 (16th Int. Geol. Cong. Guidebooks of Appalachian region), removed Lowville ls. memb. from Chambersburg ls. (because it is a distinct and mappable fm. over a large area) and restricted Chambersburg ls. to beds of post-Lowville Black River age. This is present approved definition of Chambersburg ls.

A. A. L. Mathews, 1934 (Va. Geol. Surv. Bull. 40), named the post-Lowville Black River beds of Giles Co., SW. Va., *Eggleston ls.* The U. S. Geol. Survey has not yet had occasion to consider this name for its publications.

Chambly member (of the Lorraine).

Upper Ordovician: Quebec.

A. F. Foerste, 1916 (Canada Geol. Surv. Mem. 83, p. 30).

Chamiso formation.

Upper Cretaceous: Southwestern New Mexico (Alamosa Creek Valley Socorro County).

D. E. Winchester, 1920 (U. S. G. S. Bull. 716A). *Chamiso fm.*—Soft yellow sss. and sandy shales with intercalated carbonaceous beds and coal beds at 3 general horizons, the one 75 ft. above base being important. Wholly nonmarine. Abundant Mesaverde flora but no invertebrates. Probably includes rocks older than Mesaverde, hence local name. Thickness 1,850 ft. Rests on Bell Mtn ss. memb. of Miguel fm. and uncon. underlies Datil fm. (late Tert.). Named for Chamiso Creek, T. 2 N., R. 9 W., Socorro Co.

Champaign morainic system.

Pleistocene (Wisconsin stage): Western Indiana and eastern Illinois. Shown on moraine map in U. S. G. S. P. P. 106. Named for Champaign, Ill.

Champion shell bed. (In Kiowa shale.)

Lower Cretaceous (Comanche): Central southern Kans.

F. W. Cragin, 1895 (Am. Geol., vol. 16, pp. 358–371). *Champion shell bed.*—Gray shell cgl., 1 to 1½ ft. thick; zone of *Gryphaea hilli.* Overlies Cheyenne ss. and underlies Kiowa sh.

Included in Kiowa sh. as Kiowa was originally defined, but in later repts it has been both excluded from and included in Kiowa sh. The U. S. Geol. Survey includes it in Kiowa, as does Kans. Geol. Surv. (See W. H. Twenhofel, Kans. Geol. Surv. Bull. 9, 1924.)

Named for Champion Draw, an arroyo on Medicine Lodge River crossed by A. T. & S. F. Railway at Belvidere, Kiowa Co., a few rods W. of railway station.

†Champlain group.

Cambrian, Ordovician, and probably some Silurian: New York.

E. Emmons, 1842 (Geol. N. Y., pt. 2, div. 4, geol. 2d dist., pp. 99–126, 429). *Champlain group* includes all rocks btw. top of Gray ss. that underlies Medina ss. and base of Potsdam ss. Named for Lake Champlain.

†Champlain period (also †Champlain era).

Terms applied by J. D. Dana to part of Pleistocene epoch. See Am. Jour. Sci., 3d, vol. 5, pp. 198–211, 1873, wherein he stated: "The Champlain era, as the term has been used by me, includes all the time from near the beginning of the melting of the glacier, down to that in which these old alluvial or Champlain deposits became terraced in consequence of a general rising of the land, when what I have called the Terrace or Recent epoch began."

†Champlain clays.

A term applied in early geologic repts to the late Pleist. marine clays deposited in New England region after the ice front had retreated northward beyond St. Lawrence River. Has also been called "Lake Champlain clays," "Lawrentian clay," "St. Lawrencian terrane." Also see *Hochelagan fm.* *Champlain* was preoccupied (1842) in same general region when introduced for these clays (about 1867).

†Champlain division.

A term used in some early repts to include Lorraine sh. [Upper Ord.] to †Calciferous sandrock [Lower Ord. and Camb.?], both inclusive.

Champlain.

Name applied to a glacial lake, of Pleist. age, in Lake Champlain region. Also called *Vermont.*

†Champlainian system.

A term that has been applied to Ord. system and also to middle part only of the Ord., that is, to Mohawkian series plus the underlying Chazy.

†Champlainic system.

A term that has been applied by some geologists to Ord. system. For definition see U. S. G. S. Bull. 769, pp. 85, 88–89.

Chanac formation.

Pliocene: Southern California (Tejon Hills, Fresno County).

J. C. Merriam, J. P. Buwalda, and B. L. Clark, 1916 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 10, pp. 111–115). *Chanac fm.*—Mammal-bearing beds, 400 to 600 ft. thick, apparently of terrestrial origin. Consist of angular sands and coarser angular materials; the particles mainly rhyolitic, and display white, yellow, and striking reddish brown colors in exposures; not sharply bedded. Should be termed *fangls.* [Fossils described.] Of early Plio. or latest Mio. age. In southern part of Tejon Hills the Chanac fangls. rest on old crystalline rocks without observed discordance. Exposed along Chanac Creek.

H. W. Hoots, 1929 (U. S. G. S. Bull. 812, pp. 275, 291). *Chanac fm.* is=Tulare, Etchegoin, and Jacalitos fms, but is geographically separated from them.

Chancellor formation.

Cambrian: British Columbia.

C. D. Walcott, 1912 (Smithsonian Misc. Coll., vol. 57, No. 7, p. 230).

Chancellorian series.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 42, p. 288). *Chancellorian series.*—Shales, 1,435 ft. thick, underlying Ottertailian series and overlying Sherbrookian series in Alberta. Of Late Cambric age. Includes Mons fm. [Probably same as Chancellor fm.]

Chanchelulla formation.

Devonian (?): Northwestern California (Klamath Mountains).

N. E. A. Hinds, 1931 (Geol. Soc. Am. Bull., vol. 42, pt. 1, p. 292). *Chanchelulla fm.*—Very thick. At base chiefly thinly and thickly bedded cherts, now recrystallized to qtzite, and subordinate graphitic and micaceous schists, cgl., qtzite, and crystalline ls. At top of fm. the proportion of chert is somewhat less. Is intruded by great numbers of sills and dikes of basic igneous rock now altered to greenstone and greenstone schist. Appears to underlie rocks correlated with Copley meta-andesite, which in turn is uncon. below the Middle Dev. Kennett fm. in Redding quad. Uncon. overlies Abrams and Salmon beds. Name is suggested because of wide exposure on and near Chanchelulla Peak, in NE. corner of Red Bluff quad.

N. E. A. Hinds, 1932 (Univ. Calif. Pub., Dept. Geol. Sci. Bull., vol. 20, No. 11, pp. 375–410) and 1933 (Calif. Jour. Mines and Geol., vol. 29, Nos. 1 and 2), described *Chanchelulla sediments*, 5,000± ft. thick, as uncon. overlying Siskiyou terrane (his group name for Salmon and Abrams fms.), as underlying Copley volcanics, and as intruded by *Chanchelulla greenstone* ("intrusive bodies of andesite and andesite porphyry cutting the *Chanchelulla sediments*"). He also called the intrusives *Chanchelulla meta-andesite.*

Chanchelulla greenstone.

Chanchelulla meta-andesite.

Devonian (?): Northwestern California (Klamath Mountains).

N. E. A. Hinds, 1932 (Univ. Calif. Pub., Dept. Geol. Sci. Bull., vol. 20, No. 11, pp. 375–410). [See 1932 entry under *Chanchelulla fm.*]

†Chandler formation.

Pennsylvanian: Central Oklahoma.

C. T. Kirk, 1904 (Okla. Dept. Geol. and Nat. Hist. 3d Bien. Rept., p. 9). The Red Beds interlap with both the Perm. and the Penn. The contact, then, extends through the Red Beds, leaving a large area of these in the Carbf. to E. This embayment of red shales and sss. in the Coal Measures forms an irregular segment reaching 250 mi. in length and 50 ft. in width. This group of rocks has been known provisionally as the *Chandler,* from a town of that name in its midst, but as the area has no independent place in geologic scale, probably the name will not be retained for it. [On pl. 1 of U. S. G. S. W. S. P. 148 certain areas are mapped as *Chandler fm.*, but the fm. is not mentioned in text. Only known description is that quoted above.]

Named for Chandler, Lincoln Co.

Chaney gypsum member (of Blaine gypsum).

Permian: Southwestern Oklahoma.

C. N. Gould, 1902 (Okla. Geol. Surv. 2d Bien. Rept., pp. 41, 55). *Chaney gyp.*—Hard massive gyp., 3 to 5 ft. thick, usually white, but sometimes gray or bluish; often distinctly stratified or apparently cross bedded. Basal gyp. memb. of Greer div. Older than Kiser, Haystack, Cedartop, and Collingsworth gypsums and Mangum dol.

C. N. Gould, 1924 (A. A. P. G. Bull., vol. 8, No. 3), provisionally correlated Collingsworth gyp. with Shimer gyp.; Cedartop gyp. with Medicine Lodge gyp.; and Haystack gyp. with Ferguson gyp. members of Blaine fm., but did not assign the Kiser and Chaney gypsums to either the Greer (=Cloud Chief gyp.) or to the Blaine. They are now, however, classified as members of Blaine fm. by U. S. Geol. Survey.

Named for Chaney salt plain, on Elm Fork of Red River, Harmon Co.

Chaneysville sandstone member.

Middle Devonian (Hamilton): Central Pennsylvania (Bedford County).

B. Willard, 1935 (Geol. Soc. Am. Proc. 1934, June 1935, p. 361). [See this citation under *Mahantango fm.* Not defined.]

B. Willard, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 8, Aug. 31, pp. 1279, 1282, 1283). Near Chaneysville, Bedford Co., Pa., Mahantango fm. is divided into 3 intergrading members (descending): Frame sh. memb., 343 ft.; *Chaneysville ss. memb.*, 182 ft; and Gander Run sh. memb., 850 ft. The Chaneysville is hard, olive-gray, brown-weathering, platy to submassive, fossiliferous ss. Named for the village (which is also spelled Cheneysville). In northern Bedford Co. it is split by a sh. (10 ft. thick at Imler) in the NW., and by a thin ls. in the NE. Possibly represented in Blair Co.

Channahon limestone.

Silurian (early): Northeastern Illinois (Will County).

T. E. Savage, 1910 (Ill. Geol. Surv. Bull. 16, p. 334). *Channahon ls.*—Dark-gray argill. ls., 4 ft. thick, carrying interesting assemblage of fossils, which are more closely related to fauna of Edgewood fm. than to that of any other known fauna. Regarded as representing about same general period of deposition as Edgewood fm. Included in Alexandrian series.

T. E. Savage, 1912 (Ill. Acad. Sci. Trans., vol. 4, pp. 97–103). *Channahon ls.*, 0 to 10 ft. thick, outcrops in S. bank of Des Plaines River 1± mi. SE. of Channahon, Will Co. Small remnants or outliers occur only in Will and Kankakee Counties. Consists of (descending): (1) 1½ ft. of dark-gray to brown, rather fine-grained, impure, fossiliferous ls. in layers 3 to 6 in. thick; (2) 2½ ft. of dark ls., fine-grained matrix embedded with numerous simple corals and other fossils; (3) 5 ft. of fine-grained, yellowish gray, laminated, nonfossiliferous ss., markedly different from overlying ls. Rests on Maquoketa sh. and underlies Essex ls. Assigned to Alexandrian series, of pre-Clinton Sil. age.

T. E. Savage, 1913 (Geol. Soc. Am. Bull., vol. 24, pp. 111–112, 351–376; Ill. State Geol. Surv. Bull. 23). Name *Channahon ls. memb.* will be retained for easy reference to the strata seen only along Desplaines River 1 mi. SE. of Channahon, Will Co. This ls. is considered=some part of Edgewood fm., but cannot yet be correlated with any particular part of that fm. because of complete isolation of area from other exposures of Edgewood ls. and slight difference in its fauna from that of typical Edgewood ls. of SE. Mo. and SW. Ill., although fauna is more closely related to that of Edgewood fm. than to any other known fauna. Included in Edgewood fm.

T. E. Savage, 1914 (Am. Jour. Sci., 4th, vol. 38, pp. 28–37). Cyrene ls. memb., basal memb. of Edgewood fm.="Channahon ls. memb." Sedimentation was continuous from bottom of Channahon memb. up to top of brown ls. corresponding to Bowling Green memb. (top memb. of Edgewood fm.).

In his later papers Savage continued to include this ls. in Edgewood fm.

A. H. Sutton, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 270–274). *Channahon ls. memb.*, 0 to 20 ft. thick, is probably near middle of Edgewood fm.

Chanute shale. (In Kansas City group, Kansas.)

Chanute shale member (of Kansas City formation, Missouri).

Pennsylvanian: Eastern Kansas, southeastern Nebraska, and northwestern Missouri.

E. Haworth and M. Z. Kirk, 1894 (Kans. Univ. Quart., vol. 2, p. 109). *Chanute shales.*—Shales and sss., with some coal, 100 to 150 ft. thick, underlying Iola ls. and overlying Erie ls.

As thus defined apparently overlies Drum ls., the top div. of †Erie ls. as defined. Subsequent repts defined Chanute as overlying Drum ls. and underlying Iola ls., which was definition later (1915) followed by H. Hinds and F. C. Greene (Mo. Bur. Geol. and Mines vol. 13), although, according to recent repts, the Iola and Drum lss. of Hinds and Greene are not true Iola and true Drum. Hinds and Greene treated Chanute fm. as a memb. of Kansas City fm. (In Kans. the Kansas City is treated as a group and the Chanute sh. as a fm.)

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pp. 18, 43, 51). True Chanute sh. underlies true Iola ls. and overlies Drum ls. The Chanute sh. of Mo. geologists included true Chanute sh., true Drum ls., and underlying Quivira sh., which is top part of Cherryvale sh. of SE. Kans. The Iola ls. of Hinds and Greene is Argentine-Frisbie ls. members of Wyandotte ls.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 109–111). Chanute sh. as here recognized underlies Iola ls. and overlies Drum ls. Early usage of *Chanute sh.* is somewhat confused because of miscorrelations of lss. above and below. It is clear, however, it was intended to designate the sh. and thin sss. that form plain extending E. from Chanute to the prominent escarpment made by the Bronson lss. The Iola ls. is well exposed in vicinity of Chanute and it can be traced without difficulty to Iola, about 20 mi. to N. †Thayer sh. is synonym of Chanute sh. There is discon. at base of Chanute sh. in part of SE. Kans. and northern Okla., also in vicinity of Chanute, where Drum ls. and underlying sh. are eroded, so that ss. of basal Chanute rests directly on different beds of upper part of Dennis ls., which is uppermost div. [?] of †Erie ls. Thickness of Chanute ranges from 10± ft. near Kansas City to 100± ft. in southern Kans.; av. in NE. Kans. is 25± ft. [On p. 45 Moore shows Chanute sh. of "old classification" as extending from top of Westerville ls. to base of Wyandotte ls.]

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Named for development in vicinity of Chanute, Neosho Co., Kans.

Chapala beds.

Pleistocene (?): Mexico.

R. H. Palmer, 1926 (Pan-Am. Geol., vol. 45, p. 127).

Chapapote formation.

Eocene (upper): Mexico (Tampico Embayment).

W. S. Cole, 1927 (Bulls. Am. Pal., vol. 14, No. 51, p. 9).

Chapelton formation.

Eocene (upper): Jamaica.

R. T. Hill, 1899 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 34, pp. 61–65).

Chapin beds. (In Kinderhook group.)

Mississippian: Central northern Iowa.

F. M. Van Tuyl, 1925 (Iowa Geol. Surv. vol. 30, pp. 52, 91, 104, 108). *Chapin beds.*—Massive ls., lower part at some localities altered to dol., followed by fine-grained yellow ss. Thickness 20 to 30 ft. Fossiliferous. A fm. of Kinderhook group. Underlies Mayne Creek fm. and overlies Sheffield sh. Named for exposures in small abandoned quarry 1 mi. W. of Chapin, Franklin Co. [where, according to Laudon, 1931, only the upper oolitic beds are exposed].

L. R. Laudon, 1931 (Iowa Geol. Surv. vol. 35, pp. 388–396). *Chapin memb. of Hampton fm.* (basal memb. of the Hampton in north-central Iowa) consists (above) of 8 ft. of oolitic ls. grading into dark-brown sugary dol., very fossiliferous; and below of 24 ft. of thin-bedded hard gray ls. containing *Productus ovatus.* The fossiliferous brown dol. (7 ft. thick) that is found in upper part of Chapin memb. as described by Van Tuyl is here placed in base of *Maynes Creek memb.* of Hampton fm. for these reasons: Lithologically and faunally it is almost identical with overlying Maynes Creek memb.; it carries typical Wassonville fauna that marks base of Wassonville memb. of Hampton fm. in SE. Iowa province, which is also a dol. filled with fossiliferous chert; the oolitic ls. memb. that underlies it is faunally and lithologically like the oolitic ls. that caps top of North Hill memb. in SE. Iowa province; the gray ls. that forms base of the memb. corresponds to lower part of North Hill memb. of SE. province; it is a natural break btw. hard gray lss. beneath and brown chert-filled dol. above. This makes possible a correlation of memb. with memb. The oolitic ls. then is considered top of Chapin memb. It is locally dolomitized but is always easily separable from overlying cherty dol. The *Maynes Creek memb,* as here defined consists above of 37 ft. of brown, hard, slabby ls. and dol. interbedded with much very fossiliferous chert, and below of 7 ft. of very fossiliferous massive soft brown dol.

L. R. Laudon (1935) stated these beds should be removed from Hampton fm. See 1935 entry under *Hampton fm.*

R. C. Moore, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 245), correlated Chapin ls. with Chouteau ls. of Kinderhook group.

Chapman dolomite.

Permian: Central Oklahoma (Blaine County).

F. W. Cragin, 1897 (Am. Geol., vol. 19, pp. 353, 358). *Chapman dol.*—Large body of light-gray laminated dolomites composing upper memb. of Dog Creek fm. in central Okla., where lower part of the Dog Creek consists chiefly of dull red shales with laminae of dol. and one lamina-built amphitheater ledge of dol., called Amphitheater dol. Underlies Red Bluff fm. [Whitehorse ss.].

C. N. Gould, 1927 (Obsolete Okla. geol. names: Univ. Okla. Bull., Proc. Okla. Acad. Sci., vol. 6, pt. 2, pp. 235–238). Chapman dol. of Cragin (1897) was never in common use.

Named for Chapman's amphitheater, at head of Salt Creek, Blaine Co.

Chapman sandstone.

Lower Devonian (Helderberg): Northeastern Maine (Aroostook County).

H. S. Williams, 1899 (Am. Jour. Sci., 4th, vol. 8, p. 360, footnote). The ss. at Edmund's Hill contains an Eodevonian fauna which corresponds closely with that of Gaspé ss. I have given it the name of *Chapman ss.* Is older than Mapleton ss.

H. S. Williams, 1900 (U. S. G. S. Bull. 165, pp. 21, 78–88). *Chapman ss.*—Mainly thick-bedded sss., some shaly layers. Thickness 500+ ft. Fauna seems to correspond closely with Lower Oriskany of N. Y. as recognized at Becraft, and indicates the fm. is older than Mapleton and Moose River sss. and younger than Square Lake ls. Type loc. along E. bank of south branch of Presque Isle Brook, about 1 mi. from S. line of Chapman Twp, and about 1 mi. W. of Tweedy on road running SW. from Presque Isle.

H. S. Williams and C. L. Breger in 1916 (U. S. G. S. P. P. 89) assigned this fm. to late Helderbergian time.

†Chapman trachyte.

Devonian (?): Northeastern Maine (Aroostook County).

H. E. Gregory, 1900 (U. S. G. S. Bull. 165, pp. 109, 110, 162–163). *Chapman trachyte.*—Trachyte occurring in NW. corner of Chapman Twp, Aroostook Co.

On 1933 geol. map of Maine, by A. Keith, the trachyte of this region is assigned to Dev.

Chapman Ranch formation.

Lower Ordovician: Central southern Oklahoma (Murray County).

See under *McKenzie Hill ls.*, also 1933 entry under *Arbuckle group*, Decker, 1933.

Chappel formation.

Mississippian: Central Texas (Llano region).

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 91–92, 96). A thin ls. of Boone or Osage age here named *Chappell fm.* Known max. thickness in surface exposures only a few ft. Underground to N. and W. of Llano uplift it is absent or ranges in thickness up to 150 ft. Is hard, medium dark, abounds in crinoid fragments. Rests discon. on Ellenburger (Ord.) ls. and discon. underlies Barnett (Miss.) fm. Lowermost part contains, according to Goldman, as inclusions, small pelletts of Ellenburger ls. Type loc. is 3 mi. SE. of San Saba. [Geographic feature not mentioned, but there is a village called Chappel SE. of San Saba.]

Chaquaqua shale.

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257–259; Conspectus of geol. fms. of N. Mex., pp. 3, 6). *Chaquaqua shales.*—Alternating red sss. and shales, 150 ft. thick, finely exposed in Chaquaqua Canyon, in NE. N. Mex. Uncon. underlie Comanchean and overlie Travester shales. Included in Morrisonian series [Upper Jurassic].

Chaquaqua member.

Triassic (?): Southeastern Colorado (Las Animas, Otero, and Bent Counties).

J. T. Duce, 1924 (Colo. Geol. Surv. Bull. 27, pt. 3, pp. 81–82). A series of brick red sandy shales and crinkled purplish limy sss., forming lower memb. of Lykins fm. in this area. Thickness exposed 122 ft., consisting of (descending): 2 ft. of maroon shales; 21 ft. of massive dark red ss.; 5 ft. of maroon sh.; 36 ft. of brick red sandy sh.; 18 ft. of purplish, limy, crinkled ss.; 30 ft. of brick red ss.; and 10 ft. of purplish limy ss. Underlies Red Canyon memb. of Lykins fm. and is oldest rock exposed in area.

Named for exposures in Chaquaqua Canyon, Las Animas Co.

Chardon sandstone.

Mississippian: Northeastern Ohio.

C. S. Prosser, 1912 (Ohio Geol. Surv., 4th ser., Bull. 15, pp. 219, 229). *Chardon ss.*—Thin-bedded shaly ss., 7′ 8″ to 9⅔ ft. thick, in middle part of Orangeville fm. in Lake and Geauga Counties. Underlies Brecksville sh. and separated from underlying Berea ss. by 29 ft. of sh. forming lower part of Orangeville fm. [This sh. is now called *Sunbury sh.*] Latter sh. interval is twice or three times as thick as sh. btw. Berea ss. and Aurora ss. of Cleveland region, hence correlation with Aurora is doubtful.

Named for Chardon Twp, Geauga Co.

Charette limestone.

See under *Charrette ls.*, the correct spelling.

Chariton conglomerate member (of Pleasanton formation).

Pennsylvanian: Southeastern Iowa and northern Missouri.

H. F. Bain, 1896 (Iowa Geol. Surv. vol. 5, pp. 394–398). *Chariton cgl.*—Coarse and fine cgl., 14 or more ft. thick, at top of Des Moines stage in Appanoose Co., Iowa. Overlies Appanoose beds and underlies glacial drift. Named for exposures along Chariton River near mouth of Snort Creek, Appanoose Co., Iowa, where it consists of (descending) coarse cgl., 2 ft.; fine cgl., 10 ft.; coarse cgl., 2 ft. The matrix is reddish ferruginous ss.

J. H. Lees, 1909 (Iowa Geol. Surv. vol. 19, pp. 598–604), stated that Chariton cgl. lies 30 to 118½ ft. below top of Appanoose fm. in Iowa. (See under *Appanoose fm.*)

†Charles limestone.

An abbreviated form of *St. Charles ls.* (of Utah) employed by C. [R.] Keyes.

Charleston sandstone.

Pennsylvanian: West Virginia.

M. R. Campbell and W. C. Mendenhall, 1896 (U. S. G. S. 17th Ann. Rept., pt. 2, pp. 487, 508). *Charleston ss.*—Coals and sediments, latter usually coarse, overlying Kanawha black flint, and extending upward to the red shales [*"Pittsburgh Reds"?*] are all exposed in bluffs back of Charleston. The sss. are usually feldspathic and friable; the beds are frequently conglomeratic, but the pebble-bearing horizons vary greatly in different parts of field. Thickness 320 to 420 ft. Overlies Kanawha fm.

Includes Allegheny fm. and lower part of Conemaugh fm.

Named for exposures at Charleston.

Charlestown moraine.

Pleistocene (Wisconsin stage): Rhode Island (Narragansett Bay region).

J. B. Woodworth, 1896 (U. S. G. S. 17th Ann. Rept., pt. 1, table opp. p. 988).

Named for occurrence at Charlestown, Washington Co.

Charleton formation.

Ordovician: Anticosti Island.

C. Schuchert and W. H. Twenhofel, 1910 (Geol. Soc. Am. Bull., vol. 21, pp. 695, 697).

Charlevoix stage.

Middle Devonian: Northwestern Michigan (Traverse Bay region).

E. R. Pohl, 1930 (U. S. Nat. Mus. Proc., vol. 76, art. 14, pp. 2–25). *Traverse group* of northern counties (Traverse Bay region) of Lower Peninsula is here divided into (descending): (1) *Petoskey fm.*, 13 to 100 ft.; (2) uncon. and overlap; (3) *Charlevoix stage*, 13 to 28 ft.; (4) erosion uncon.; (5) *Gravel Point stage*, 35 to 120 ft.; and (6) *"Bell sh.,"* 40 to 100 ft. in wells. The physical evidence for separation of Gravel Point and Charlevoix beds has not been sufficiently studied to warrant establishment of formational rank of these faunally distinct stages. [Details of beds and faunal zones given.] The *Charlevoix stage* is characterized by fragmental deposition throughout, frequent occurrence of bituminously laminar beds, presence of a coarse calc. oolite near middle, and recurrence of fine-grained beds at top. [Appears to be named for Charlevoix Co., although he says Gravel Point stage is exposed 1½ mi. W. of town of Charlevoix.] The *Gravel Point stage* comprises oldest known Middle Dev. strata in W. part of Lower Peninsula. It is exposed in a series of undulating ledges and low bluffs at water level on and S. of Gravel Point, 1½ mi. W. of Charlevoix. Is basal div. of Traverse group in Mich. Consists of 0 to 11 ft. of blue sh. underlain by lss. with some thin shaly beds. [Pohl recognized "Bell sh." in wells beneath his Gravel Point stage.]

R. B. Newcombe, 1933 (Mich. Geol. Surv. Pub. 38, pp. 19–64), correlated the subdivisions of *Traverse group* as follows (descending): Thunder Bay series = Petoskey fm.; Alpena ls. = Charlevoix stage; Long Lake series and underlying "Bell sh." = Gravel Point stage.

Charlotte morainic system.

Pleistocene (Wisconsin stage): Southern Michigan. Shown on moraine map (pl. 32) in U. S. G. S. Mon. 53. Named for Charlotte, Eaton Co.

Charlton formation.

Tertiary? (Pliocene ?): Southeastern Georgia and extreme northeastern Florida.

J. O. Veatch and L. W. Stephenson, 1911 (Ga. Geol. Surv. Bull. 26, pp. 60, 392–400). *Charlton fm.*—Soft, white, argill. ls. and laminated, fossiliferous, greenish clay, exposed in banks and bluffs of St. Marys River, from Stokes Ferry, 11 mi. S. of St. George, Charlton Co., Ga., to Orange Bluff, near Kings Ferry, Fla. From studies of fossils Dr. Vaughan has classified the fm. as probably Plio. Older than Okefenokee and Satilla fms. (Pleist.). Thickness undet.; only 12 or 15 ft. seen in natural exposures. [The fm. as mapped in this rept and in U. S. G. S. W. S. P. 341, 1915, extends along St. Marys River from south-central part of Camden Co. to Fla. line in extreme SE. part of Charlton Co., Ga.]

Named for development in Charlton Co., Ga.

Charlton group.

Pre-Cambrian: Canada (Northwest Territories).

C. Lausen, 1929 (Canadian Min. and Met. Bull. 202, p. 382).

Charrette limestone.

Middle Ordovician: Eastern Missouri.

G. C. Broadhead, 1873 (Mo. Geol. Surv. Rept. 1855–71, pp. 49–50). *Charette ls.*—Upper part, 4 inches to 26 ft. of fossiliferous whitish or light-gray coarse ls. (the Receptaculite ls. of Shumard); lower part, 1 to 8 ft. of fossiliferous red or brownish gray to dark reddish brown ls. Underlies Upper Sil. Crinoidal ls. and overlies Middle Trenton ls. Included in Trenton ls. of Warren Co.

J. H. Bradley, Jr., 1925 (Jour. Geol. vol. 33, p. 49). While Ulrich was first to demonstrate unity of Kimmswick ls. on faunal and lithologic basis, and his term has been generally accepted, it should be mentioned Broadhead recognized lithological uniqueness of this pure, light-colored crystalline ls. and called it *Charette ls.*, from exposures in Warren Co., where it is 34 ft. thick and thins rapidly to W., being absent a short distance W. of E. bdy of Callaway Co. Faunal and strat. relations can best be studied at Ulrich's type loc., in Jefferson Co.

J. Bridge, 1930 (personal communication), stated that this ls. probably represents Kimmswick ls. as now restricted.

Named for *Charrette*, Warren Co.

Chartresan series.

A term proposed by C. [R.] Keyes to include the Mississippian rocks which he designates as (descending) Kaskaskia, Aux Vases, [Ste.] Genevieve, and [St.] Louis. He, however, would restrict Miss. to the pre-St. Louis and post-Kinderhook part of the Miss. of other geologists. The name is derived "from old French Fort Chartres, which once occupied a spot near mouth of Kaskaskia River just above the present hamlet of Chester," Ill. (See Pan-Am. Geol., vol. 60, No. 1, pp. 45, 49, 1933.)

Chase group.

Permian: Eastern Kansas, central northern Oklahoma, and southeastern Nebraska.

C. S. Prosser, 1895 (Jour. Geol., vol. 3, pp. 771–786). *Chase fm.*—Massive lss. and flints separated by vari-colored shales; 265 ft. thick. Overlies Neosho fm. and underlies Marion fm.

Adopted as group term, to include the following fms. (descending): Winfield ls., Doyle sh., Fort Riley ls., Florence flint, Matfield sh., and Wreford ls. This definition has been followed for many years by both Kans. Geol. Surv. and U. S. Geol. Survey. In Sept. 1936, however, R. C. Moore (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 12) shifted the upper bdy to top of Luta ls., which he treated as top memb. of Winfield ls. This change has not yet been considered by U. S. Geol. Survey for its publications.

Named for Chase Co., Kans.

Chase quartzite member. (In Shuswap series.)

Pre-Cambrian: British Columbia.

R. A. Daly, 1913 (12th Int. Geol. Cong. Guidebook 8, p. 123).

†Chatham series.

Upper Triassic: North Carolina (Chatham County).

E. Emmons, 1857 (American Geology, pp. iv, v, vi, 19), applied *Chatham series* to the rocks of Chatham Co., N. C., now known as *Newark group* (Redfield, 1856).

Chatham granite.

Late Devonian or late Carboniferous: Northern New Hampshire (North Conway quadrangle, White Mountains).

M. Billings, 1928 (Am. Acad. Arts and Sci. Proc., vol. 63, map, p. 82, etc.). *Chatham granite.*—Coarse nonporphyritic two-mica granite, which often intrudes Montalban group in lit-par-lit fashion. Covers many sq. mi. in Chatham Twp

[North Conway quad.]. Assigned to pre-Camb. (?); may be early Paleozoic. For a fine-grained and somewhat younger phase of Chatham granite, which intrudes the injection gneisses, I propose the term *Randolph granite.*

L. Kingsley, 1931 (Am. Jour. Sci., 5th, vol. 22, pp. 139–167), assigned this granite to pre-Camb (?). "Is definitely older than extrusive and intrusive rocks of White Mtns batholith."

W. F. Jenks, 1934 (Am. Jour. Sci., 5th, vol. 28, pp. 321–340). *Chatham granite* completely surrounds Pleasant Mtn, Fryeburg quad., Maine. Is coarse-grained granite and granodiorite. Believed to be same as Billings's Chatham group of intrusives of N. H., which it may be said broadly are post-Dev. and probably pre-Mesozoic.

On 1933 geol. map of Maine, by A. Keith, the granites of Fryeburg region are mapped as Carbf. On 1932 geol. map of U. S. the granites in Chatham region are mapped as pre-Camb., but Billings (also Jenks) now regards them as late Paleozoic.

M. Billings, 1935 (letter dated Aug. 27). *Chatham granite* belongs to New Hampshire magma series [which he classifies as late Dev. or late Carbf.].

Chatooga zone.

Pre-Cambrian: Northwestern South Carolina.

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C. advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 6, 7, 12). The *Chatooga zone* (*Archean*) comprises narrow parallel belts of Carolina gneiss series and of Table Rock granite, and thick bands of Roan gneiss series. It includes the narrow belt btw. Chatooga River and a line extending southwesterly from a point on N. C. line about half way btw. Toxaway and Whitewater Rivers, to Tugaloo River slightly above its confluence with Brasstown Creek. The northwesterly belt of this zone exhibits a granite similar to Table Rock granite of Saluda zone, which is slightly schistose in structure, but granitic in texture, the color being a "pepper and salt" gray. The southeasterly belt, which sharply abuts the ls. series (Chauga zone), consists of highly schistose gneissoids, granites, mica schists, etc., of Carolina gneiss series; it includes pegmatites, peridotites, etc. Thin lines of Roan gneiss (hornblende series) are observed in this area. This zone is essentially Archean.

Named for exposures on Chatooga River, on NW. bdy of Oconee Co.

Chatsworth morainic system.

Pleistocene (Wisconsin stage): Northeastern Illinois. See F. Leverett, 1899 (U. S. G. S. Mon. 38, p. 259). Named for Chatsworth, Livingston Co. Now said to be same as Farm Ridge moraine.

†Chattahoochee.

Eocene (lower): Alabama.

E. A. Smith, 1888 (Ala. Geol. Surv. Rept. Prog. 1884–88, map of Ala.). [On this map the name *Chattahoochee* is listed in a table of geol. fms. of the State, without other definition than that it underlies Black Bluff [Sucarnoochee clay], overlies the Ripley, and includes *Midway and Fort Gaines.* As thus defined the name corresponds to Clayton fm., basal fm. of Eocene and of Midway group. Type loc. not stated and the geol. fms. are not mapped.]

†Chattahoochee formation.

Miocene (lower): Georgia (extreme southern part) and Florida.

D. W. Langdon, Jr., 1889 (Am. Jour. Sci., 3d, vol. 38, pp. 322–324). *Chattahoochee group.*—Southward from Rock Island, 9 mi. by water, above Chattahoochee or River Junction, Fla., the white orbitoidal ls. disappears, and in lieu thereof there is a rock more argill. and siliceous in character resembling some phases of Eocene Buhrstone. This ls. is very well developed in a railroad cut about ½ mi. E. of Chattahoochee River, Ocheesee, 15 mi. below railroad bridge, and again at Rock Bluff, 2 mi. below Ocheesee section at Ocheesee, Fla.

1. Argill. ls., greenish yellow. No fossils seen. 10 ft.
2. A purer, more granular ls., creamy white and soft, resembling "chimney rock" phase [Marianna ls.] of Vicksburg group. Contains few obscure corals to water's edge, 5 ft.

Rock Bluff, about 30 ft. high, is made up of strata of ls. varying in purity, as at Ocheesee. For this older memb. of Miocene or newest memb. of Eocene White ls., writer suggests provisional name *Chattahoochee group*. Only fossils found were a large Pecten about 3 inches by 3½ inches and an oyster resembling very closely our *Ostrea virginica*. This group, estimated to be 250 ft. thick, differs materially in lithologic characteristics from any phase of White ls. yet observed in Ala. or Miss. On the rich black loam, derived from disintegration of these slightly phosphatic lss., the unique *Torreia taxifolia* or "Stinking Cedar" is found growing.

D. W. Langdon, Jr., 1891 (Ga. Geol. Surv. 1st Rept. Prog., p. 97). *Chattahoochee series*.—Argill. and sandy ls. alternating with strata of purer character. Contains a Pecten and an Ostrea very close to our recent Virginica. This may be termed *Chattahoochee group*, as it is well developed there and along E. river bank for next 10 mi. Thickness 25 [250] ft. Underlies Alum Bluff series and overlies White ls. series. [Same description is given by Langdon in Geol. Soc. Am. Bull., vol. 2, pp. 604, 605, 1891, except Chattahoochee *ls.* is used instead of *series* or *group*, and on p. 604 the thickness is stated to be 25 ft., but on p. 605 it is given as 250 ft.]

G. C. Matson and F. G. Clapp, 1913 (Fla. Geol. Surv. 2d Ann. Rept.). *Chattahoochee fm.*—Lss., marls, and some chert, 100 to 250 ft. thick, underlying Alum Bluff fm. [group] in western Fla. and uncon. overlying Vicksburg group. Considered contemp. with Tampa fm. of southern Fla.

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept.). *"Chattahoochee fm."* abandoned, because it seems to be of same age as Tampa ls., and in spite of fact that it contains more impurities than typical Tampa ls. and might by some people be regarded as a distinct facies worthy of a separate name. If future studies of faunas bring to light unsuspected differences in age, "Chattahoochee" can be restored to formational rank.

Named for exposures along Chattahoochee River, especially at Chattahoochee Landing, Gadsden Co., Fla.

†Chattahoochee bed proper.

Miocene (lower): Southwestern Georgia and adjacent parts of Florida.

A. F. Foerste, 1894 (Am. Jour. Sci., 3d, vol. 48, pp. 41–54). *Chattahoochee bed proper*.—Main element is peculiar gray or white ls. tinged with yellow; a soft friable rock well exposed at Old Chattahoochee Landing. Thickness 100 ft. The middle and major part of Chattahoochee series. Underlies Griffin bed.

According to C. W. Cooke this name as used by Foerste applied to Tampa ls. (†Chattahoochee fm.) of present usage.

Named for exposures at Old Chattahoochee Landing, Gadsden Co., Fla.

Chattanooga shale.

Devonian (also Devonian? and Devonian or Carboniferous; see explanation beyond): Tennessee; eastern Kentucky south of Somerset, Pulaski Co.; northwestern Georgia; northern Alabama; northeastern Mississippi; western Kentucky; Illinois; Missouri; Arkansas; and Oklahoma.

C. W. Hayes, 1891 (Geol. Soc. Am. Bull., vol. 2, p. 143). *Chattanooga black sh.*, of Dev. age, 0 to 35 ft. thick. Equiv. to Black sh. of Smith and Safford. In NW. Ga. underlies Fort Payne chert (Carbf.) and overlies Rockwood fm. (Sil.).

Named for Chattanooga, Tenn., which is situated on the belt of sh. mapped by Safford as "Black sh.," a non-geographic term, which *Chattanooga* was intended to replace, and which, as defined by Safford, occupied interval btw. †Siliceous group [Fort Payne chert and Grainger sh.] and Helderberg ls.

The age of this black sh., which occurs at approx. the same horizon in several States, has been under discussion for a long time. For many years it was classified as Dev., and it is still so regarded by many geologists, but some geologists and paleontologists now consider it to be in part at least of Miss. age, while others regard its deposits, especially at type loc., where thickness is only 15 ft., as wholly Miss. In 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 29) E. O. Ulrich assigned the black Chattanooga sh. of Miss. Valley, Tenn., Allegheny Front, Appalachian Valley, and Ozark uplift to his post-Dev. Waverlyan system, although he stated (pl. 28) that Middle and Upper Dev. were partly represented in Chattanooga and Grainger fms. of NE. Tenn., but were absent in Ala. and western Tenn. Since that time a voluminous literature on the age of this black sh. has appeared, as a result of which the U. S. Geol. Survey at present classifies the Chattanooga sh. of different areas as follows:

Typical Chattanooga sh. of southern Tenn. and adjacent parts of Ala., Ga., and Ky.: *Dev. or Carbf.* In most of this region the sh. underlies Fort Payne chert (Miss.) and overlies Red Mtn fm. (Sil.), except locally in Ala. and Ga., where it rests uncon. on Frog Mtn ss. (Middle Dev).

Chattanooga sh. of western Tenn. and Ky., southern Ill., and Mo.: *Dev. or Carbf.*

Chattanooga sh. of Batesville dist., Ark., has yielded Genesee fossils near base and Portage (?) fossils, and is classified as *Upper Dev.* Elsewhere in northern Ark. and in Okla. the sh. has not yielded fossils and is classified as *Dev. (?)*.

In SW. Va. the sh. formerly called Chattanooga sh. is now divided into 3 fms. (descending): Big Stone Gap sh. (*Dev. and Carbf.*), Portage sh. (*Upper Dev.*), and Genesee sh. (*Upper Dev.*).

For the names by which this black sh. is now known in other States, see under †*Black sh.*

Chattanoogan series.

A time term employed by some geologists to cover the epoch during which Chattanooga sh. and its assumed equivalents were deposited. See E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 29); C. Schuchert, 1924 (Textbook geol., p. 335).

Chatte River limestones.

Silurian: Canada.

H. M. Ami, 1900 (Roy Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 204).

Chauga zone.

Cambrian (?): Northwestern South Carolina.

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2) and 1907 (Summary of mineral resources of S. C., pp. 6, 10, 12). *Chauga zone (Cambrian?)*.—Comprises a narrow band bounded on NW. by Chatooga zone; and on SE. by a line extending from near point where Toxaway River enters S. C. to Tugaloo River, slightly below its confluence with Brasstown Creek. Fine-grained dark shimmering quartz schist, mica schists, graphite slates, ls., etc. This group probably corresponds to Keith's "Brevard Schist," assigned to Camb.

Named for exposures along upper half of Chauga River, Oconee Co.

Chaumont formation. (In Black River group.)

Middle Ordovician: New York.

G. M. Kay, 1929 (Jour. Geol., vol. 37, No. 7, pp. 664–671; and A. A. P. G. Bull., vol. 13, No. 9, p. 1214). *Chaumont fm.*—Includes (descending) Watertown ls., Glenburnie ls. (in Ontario), and Leray ls. Overlies Lowville [excluding Leray memb.] and underlies Trenton group. Named for Chaumont Bay, Lake Ontario [Jefferson Co., N. Y.], in vicinity of which the members are well exposed.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10), apparently does not mention this name, as it is not listed in index or tables.

†Chautauqua sandstone.

Pennsylvanian: Southeastern Kansas.

G. I. Adams and E. Haworth, 1898 (Univ. Geol. Surv. Kans., vol. 3, pp. 57–60). The wide zone through which Lawrence shales are exposed, being from 15 to 25 mi. wide S. of Neosho River, is an exceedingly sandy and hilly country. The sss. alternating with the softer shales have produced by erosion an irregular topography difficult to describe and unequaled in general irregularity anywhere in state. From Burlington and Neosho Falls to SW. by way of Yates Center, Benedict, New Albany, Buxton, Colfax, Sedan, Peru, and Chautauqua, this ss. and the corresponding irregular surface occupy the whole country. Doctor Adams has suggested that the ss. here is sufficiently prominent to merit a distinct local designation, and has proposed for it the name *Chautauqua ss.* The following description of the area is taken from his notebook: Passing S. from Neosho River the shales grade into sss., so that at Yates Center they become conspicuous, producing the hill on which town is built. The area broadens to S., its eastern border passing W. of Buffalo, Fredonia, and Tyro, while its western border runs approx. from Yates Center to Toronto, Fall River, Elk Falls, Sedan and Elgin. To this region the name *Chautauqua Sandstone Hills* may be here given. The name is already employed somewhat in common usage. These ss. hills are as characteristic a feature of SE. Kans. as are the Flint Hills.

Is a sandy development of Lawrence sh.

Named for Chautauqua Sandstone Hills, which extend through parts of Chautauqua, Woodson, Wilson, Montgomery, Greenwood and Elk Counties.

†Chautauqua conglomerate.

A name applied in some early repts to Olean cgl. of Chautauqua Co., N. Y. (See first entry under *Olean cgl.*)

Chautauquan group.

Upper Devonian: New York.

J. M. Clarke and C. Schuchert, 1899 (Sci., n. s., vol. 10, pp. 874–878). *Chautauquan period or group* includes Chemung beds and Catskill ss., local facies. Named for exposures in Chautauqua Co.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19), followed above definition.

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69), included in *Chautauquan* at top the lower part only of the Catskill, and at base certain beds (Dunkirk sh., Gowanda sh., Laona ss., etc.) that had previously been included in the Senecan and in Portage group of western N. Y. In 1924 (N. Y. State Mus. Bull. 251, pp. 149–157) Chadwick again employed his modified definitions of Senecan and of Portage group. His charts show that the beds he transferred to Chautauquan (and to the Chemung) he correlates with Cayuta sh. and Wellsburg ss. members of Chemung of central N. Y.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369). *Chautauquan* of western N. Y. includes Chadakoin beds at top and Dunkirk sh. at base.

Chaves shale.

Permian: Southeastern New Mexico (Guadalupe Mountains).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, p. 258; Conspectus of geol. fms. of N. Mex., pp. 3, 6). *Chaves shales.*—Lowermost section of red shales, 425 ft. thick, which rest on the great Capitan lss. in Guadalupe Mtns, N. Mex. [Derivation of name not given. See also Pan-Am. Geol., vol. 65, No. 1, Feb. 1936, pp. 42, 46, 49.]

Chazy group (**limestone** where not divided).

Lower Ordovician: Eastern New York (Champlain Valley).

E. Emmons, 1842 (Geol. N. Y. pt. 2, div. 4, geol. 2d dist., pp. 107, 315, 429). *Chazy ls.*—Dark, irregular, thick-bedded ls., 130 ft. thick in second dist. of N. Y. [On another page he gives thickness of 150 ft. for Clinton Co.] At Chazy [Clinton Co.] it contains many rough, irregular flinty or cherty masses. Underlies Birdseye [Lowville] ls. and overlies Calciferous sandrock [Beekmantown group].

In 1888 (Am. Geol., vol. 2, pp. 323–330) E. Brainerd and H. M. Seely divided typical Chazy into 3 divisions (descending): Group C, 157 ft., characterized by *Rhynchonella;* group B, 265 ft., characterized by *Maclurea magna;* and group A, 310 ft., which was included in "Calciferous" [Beekmantown] by Emmons. In 1897 (N. Y. State Geol. 15th Ann. Rept., vol. 1, pp. 503–574) H. P. Cushing stated that *Chazy ls.* is 740 ft. thick at Chazy, where lower 100 ft. is lacking, and 890 ft. thick on Valcour Island, which affords most complete section. In 1905 (N. Y. State Mus. Bull. 95) Cushing applied *Valcour ls.* to group C of Brainerd and Seely, *Crown Point ls.* to group B, and *Day Point ls.* to group A. In 1908 (Geol. Soc. Am. Bull., vol. 19, pp. 155 +) Cushing applied *Pamelia ls.* to beds of Chazy age in Theresa and Alexandria Bay quads., Jefferson Co., 40 to 140 ft. thick, which he stated appear to occupy strat. position btw. Valcour ls. and Crown Point ls., but which rest uncon. on Camb. Theresa fm. and are uncon. overlain by Lowville ls. Later (N. Y. State Mus. Bull. 145, 1910) Cushing applied *Pamelia* (*Stones River*) *ls.* to these beds, and stated that the Stones River is of Chazy age but laid down in separate basin.

The Chazy group of N. Y. has for many years been divided into (descending) Valcour ls., Pamelia ls., Crown Point ls., and Day Point ls. The Pamelia does not occur in same section with the other lss., but is overlain by Lowville ls. and rests on Theresa fm. or on Tribes Hill ls., and there has, in recent years, arisen doubt in minds of some geologists whether it may not be of Middle Ord. (Black River) age. (See under *Pamelia ls.*). At present the U. S. Geol. Survey classifies Pamelia as Lower Ord.

Chazyan.

A time term proposed by A. W. Grabau, 1909 (Jour. Geol., vol. 17, pp. 209–252), to include Chazy ls. (Lower Ord.) and Black River group (Middle Ord.). E. O. Ulrich, 1911 (Geol. Soc. Am. Bull. vol. 22), included in his Chazyan only the rocks btw. base of Lowville ls. and top of Beekmantown group, which is commonly accepted usage of the term.

Cheaha sandstone member (of Talladega slate).

Probably Paleozoic: Eastern Alabama.

C. Butts, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14, map, pp. 54, 58). *Cheaha ss. memb. of Talladega sl.*—Chiefly thin-bedded rather soft ss., with occasional layers of purplish phyllite; basal 200 ft. is coarse quartz cgl. Lies in middle of Talladega sl. and higher than Brewer phyllite memb. No fossils. Is probably Paleozoic and pre-Dev.

Named from fact that Cheaha Mtn, Clay Co., is formed by the ss.

Cheboygan moraine.

Pleistocene (Wisconsin stage): Northern Michigan. Shown on moraine map (pl. 32) of U. S. G. S. Mon. 53. Belongs to Port Huron morainic system. Named for Cheboygan.

Checkerboard limestone member (of Coffeyville formation).

Pennsylvanian: Northeastern and central Oklahoma.

L. L. Hutchison, 1911 (Okla. Geol. Surv. Bull. 2, pp. 151–164). Lenapah ls. is same fm. that is known as "Checkerboard ls." in region of Glenn pool.

L. C. Snider, 1913 (Petroleum and nat. gas in Okla., pp. 44–49). *Checkerboard ls.* is probably 100 ft. above Lenapah ls.

A. E. Fath, 1917 (Okla. Geol. Surv. Bull. 19, pt. 2, pp. 369–372). The ls., 2 ft. thick, locally known as *Checkerboard lime,* outcrops in creek bed at old "Checkerboard Crossing" near E-W.¼ line of sec. 22, T. 15 N., R. 11 E.

D. W. Ohern, 1918 (A. A. P. G. Bull., vol. 2, p. 122). *Checkerboard ls.* lies about 70 ft. above Lenapah ls.

R. W. Clark and C. M. Bauer, 1921 (A. A. P. G. Bull., vol. 5, pp. 282–292). *Checkerboard lime* is a hard blue ls., 4 ft. in average thickness, which contains peculiar semicircular markings caused by presence of fossil brachiopods. Weathered surface usually of light cream or very light yellow color. Breaks into blocks, nearly cubical and 4± ft. on each side. Remarkable for persistent character, such as thickness, color, resistance to weathering, peculiar fossil markings, jointing, etc. Has been mapped for a distance of 20 mi. Can be traced from Deep Fork in sec. 19, T. 14 N., R. 11 E., through Mounds and Jenks, over Turkey Mtn and into Tulsa, but can not be followed continuously SW. from Deep Fork. Lies 100 to 120 ft. above Seminole cgl.

A. W. McCoy, 1921 (A. A. P. G. Bull., vol. 5, No. 5, pp. 541–550). According to general strat. relation of *Checkerboard ls.* to Lenapah ls. of Okla., as described by Ohern, the Checkerboard ls. has been tentatively regarded as = base of Kansas City fm. or the Hertha ls.

C. N. Gould, 1925 (Okla. Geol. Surv. Bull. 35, p. 72). *Checkerboard ls. memb. of Coffeyville fm.* lies near base of that fm. It is 2½ to 3 ft. thick, fine-grained, fossiliferous, bluish white on fresh surfaces but weathers yellowish white. In bare areas it presents a "checkerboard" appearance, due to solution channels along joints, which occur in two sets, the one crossing the other. From this feature the ls. was for years known as "Checkerboard lime," but the geographic loc. which is here designated as its type loc. is the exposures on Checkerboard Creek in T. 15 N., R. 11 E. A good exposure may be seen at "Checkerboard Crossing" of the creek, near E.-W. quarter line of sec. 22, T. 15 N., R. 11 E.

Chediski white sandstone member (of Troy quartzite).

Cambrian(?): Central eastern Arizona (Fort Apache Indian Reservation).

E. F. Burchard, 1931 (U. S. G. S. Bull. 821C). *Chediski white ss. memb. of Troy qtzite.*—White ss., fine to medium grain, with white sericitic interstitial cement. Thickness 50 to 100 ft. Basal memb. of Troy qtzite. Rests on banded chert, ferruginous in places, which forms top memb. of Mescal ls. Forms cliff on NE. face of Chediski Mtn, and is conspicuous for many miles.

Chegoggin Point formation.

Age (?): Nova Scotia.

E. R. Faribault, 1920 (Canada Geol. Surv. Summ. Rept. 1919, pt. F, p. 15).

Chehalis sandstone.

Eocene: Southwestern Washington.

A. C. Lawson, 1894 (Am. Geol., vol. 13, pp. 436–437). *Chehalis ss.*—Soft, friable sss., generally clayey, bluish gray to yellowish, with thick beds of lignite associated with them in vicinity of Chehalis. It is very probable that the sss. in which the fossils occur and those in which the lignites occur are part of same geological series. Marine fossils in a portion of the sss. at Chehalis, which T. W. Stanton says are either Eocene or Mio. and correlatable with nonmarine Puget group.

R. Arnold and H. Hannibal, 1913 (Am. Phil. Soc. Proc., vol. 52, pp. 566, 567). *Chehalis fm.*—Ss. and shaly ss. Upper beds marine; lowest beds probably fresh water. Redefinition of Lawson's name Chehalis ss. Underlies Olequa fm. The Chehalis and Olequa are of Tejon Eocene age and belong to zone of *Venericardia horni* Gabb. The Chehalis fm. of Weaver 1912 is Mio. Broadly speaking Puget group is=Tejon.

L. G. Hertlein and C. H. Crickmay, 1925 (Am. Phil. Soc. Proc., vol. 64, No. 2, pp. 225–242). Chehalis may be younger than Olequa fm. [See 1925 entry under *Olequa fm.*]

Chehalis formation.

Miocene (lower): Southwestern Washington.

C. E. Weaver, 1912 (Wash. Geol. Surv. Bull. 15, pp. 10–22). *Chehalis fm.*—Sandy shales and shaly sss., the former predominating. Gray to brownish. Thickness 7,000 ft. Uncon. underlies Montesano fm. (Upper Mio.) and rests uncon. on Blakeley fm. (Lower Mio.). Part of fauna ranges down into Blakeley and part ranges up into Upper Mio. Named for Chehalis River, in Chehalis [Grays Harbor Co.].

Chelan physiographic stage.

Pleistocene: Central Washington (Cascade Range).

B. Willis, 1903 (U. S. G. S. P. P. 19). Type loc., gorge of Lake Chelan and terraces of Columbia River. Latest glacial epoch.

Chelan granodiorite.

Late Jurassic(?): Central Washington (Entiat Mountains).

A. C. Waters, 1932 (Jour. Geol., vol. 40, No. 7, p. 605). Presumably in late Jurassic the Entiat Mtns were invaded by an enormous batholith of basic granodiorite. The confines of batholith have never been mapped but it is known to extend over an area of more than 800 sq. mi. It is here called *Chelan granodiorite,* from Chelan Mtns, where it is typically exposed. Assigned to late Jurassic (?).

†Chelly sandstones.

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, p. 250). Sss., 125 ft. thick, uncon. underlying Shinarump cgls. and overlying Adamana shales. Topmost fm. of Moenkopian series and Carbonic system in Ariz.

Probably an abbreviated form of *De Chelly ss.*

Chelmsford sandstone.

Pre-Cambrian (upper Huronian): Ontario.

A. P. Coleman, 1905 (Ont. Bur. Mines Rept., vol. 14, pt. 3).

Chelsea sandstone lentil (of Cherokee formation).

Pennsylvanian: Northeastern Oklahoma (Rogers County).

This name was first used by D. W. Ohern in unpublished ms. on Nowata and Vinita quads.

G. C. Clark and C. L. Cooper, 1927 (Okla. Geol. Surv. Bull. 40H, fig. 3). [Show Welch coal as in interval btw. Fort Scott coal and *Chelsea ss. lentil,* and as lying 60± ft. below Fort Scott coal, and show Cherokee coal as in interval btw. Chelsea ss. and Bluejacket ss., and as lying 100± ft. below Chelsea ss. The Chelsea ss. is shown as 250± ft. below Fort Scott coal (top of Cherokee sh.) and as 200± ft. above Bluejacket ss.]

C. D. Smith, 1928 (Okla. Geol. Surv. Bull. 40U, map). [*Chelsea ss.* mapped in upper part of Cherokee fm. Lies lower than Verdigris ls. and higher than Bluejacket ss.]

C. L. Cooper, 1928 (Univ. Okla. Bull., Proc. Okla. Acad. Sci., vol. 7, p. 161). The *Chelsea ss.* lies 200± ft. above Bluejacket ss. It forms a prominent escarpment from upper branches of Whiteoak Creek, thence S. and W. to Chelsea.

Cheltenham fire clay.

Economic term for a persistent bed of fire clay in basal part of Penn. deposits in St. Louis Co., Mo. Named for development at Cheltenham, St. Louis Co. The name has also been applied to a clay in basal part of Pottsville fm. of SW. and central western Ill., that is supposed to be the same as Cheltenham clay of Mo. (See E. F. Lines, Ill. Geol. Surv. Bull. 30, 1917, pp. 62, 64, etc.)

Chemehuevi gravel.

Pleistocene: Western Arizona.

W. T. Lee, 1908 (U. S. G. S. Bull. 352, p. 18). *Chemehuevis gravel.*—A series of unconsolidated gravels that lie uncon. on Temple Bar cgl. in terraced bluffs along

Colorado River from Grand Canyon to the Gulf. Thickness 700± ft. max. Occupy a measurably narrow belt along the river, having been deposited as valley filling during an aggrading stage of Colorado River. Named for Chemehuevis [now spelled without the final *s*] Valley, S. of The Needles.

Chemung formation.

Upper Devonian: New York (western, central, and eastern), Pennsylvania, and western Maryland and Virginia.

J. Hall, 1839 (N. Y. Geol. Surv. 3d Rept., pp. 322–326). *Chemung group.*—Rocks and fossils very distinct from underlying Ithaca group. Essential difference is lithological characters of the ss. of this group, absence of argill. matter in most layers, these being a nearly pure siliceous rock, harsh to touch, and generally porous, while a large proportion of mass consists of compact shales and argill. sss. softer than those below. Occurs in valley of Chemung River and well defined in town of Chemung, Chemung Co., N. Y., but nowhere in county is it so well exposed as at Chemung upper narrows, about 11 mi. below Elmira. A group so well defined in the valley, and particularly in town of Chemung, merits appellation of *Chemung group.*

L. Vanuxem, 1840 (N. Y. Geol. Surv. 4th Rept., p. 381). A series of thin ss. flags with fucoides resembling those below the Ithaca separates *Chemung group* from Ithaca group.

J. Hall, 1840 (N. Y. Geol. Surv. 4th Rept., pp. 389–395, 402–409, 452–455). *Chemung group.*—Underlies red ss. equiv. to Old Red ss. of Europe, and overlies Portage or Upper Fucoidal group. Consists of (descending): (1) Green shales with thin beds of ss.; (2) dark, nearly black, sandy, highly micaceous sh. with septaria, iron pyrites, and thin interstratified masses of gray ss. containing Chemung fossils; (3) greenish-olive sandy sh. or very shaly ss., never slaty.

L. Vanuxem, 1842 (Geol. N. Y., pt. 3, pp. 179–185). *Chemung group.*—Underlies Catskill group or Old Red ss. and overlies Ithaca group (which rests on Portage or Nunda group). No precise line of division observed btw. Ithaca and Chemung group. A high ridge was seen rising above the inclined plane at Ithaca; the rocks to S. contained none of brownish ss. of Ithaca group and there were different fossils noticed in the two; upon these differences the Chemung group was founded. Best section for examining the two groups is from head of Cayuga Lake to Factoryville. At Chemung Narrows the evidence of difference appeared to be conclusive; so also in Tioga and Broome Counties, where, probably with one exception in Broome Co., no lower rocks than Chemung group exist.

E. Emmons, 1846 (Agric. N. Y., vol. 1, pp. 190–193). *Chemung group.*—Underlies Catskill group and overlies Portage group. Includes Ithaca group, because there is no necessity for separating the Ithaca from the Chemung group. Consists of flags and slates in thinner beds than those of Portage group; flags are gray, olive, and brown, with impure calc. bands of fossils; the shales are green and olive but sometimes black.

In 1857 and in several editions of his Textbook of geol. J. D. Dana used the term *Chemung period* to include the Chemung and Portage of later nomenclature. *Chemung group* has also been used to include Portage, Chemung, and Genesee.

In 1905 (N. Y. State Mus. Bull. 81) J. M. Clarke and D. D. Luther restricted *Chemung* (as *Chemung ss. and sh.*) to what they stated to be the beds included in it by Hall in his 1839 definition, which they described as 800 ft. of light and dark shales and light blue-gray siliceous sss., with a basal bed of crumpled black sh., overlying Prattsburg sh. (In 1904 (N. Y. State Mus. Bull. 63) they had included the Prattsburg and underlying High Point ss. in the Chemung.)

In 1906 (Sci., n. s., vol. 24, pp. 356–372) and 1909 (U. S. G. S. Watkins Glen-Catatonk folio, No. 169) H. S. Williams divided *Chemung fm.* of its typical region into (descending): (1) Thin cgl. that is supposed to be same as Fall Creek cgl. memb. of Bradford, Pa.; (2) Wellsburg ss. memb.; and (3) Cayuta sh. memb.; and he defined it as resting on Enfield sh. memb. of Portage fm.

C. A. Hartnagel's 1912 Hdb. 19 of N. Y. State Mus. followed Williams' subdivisions of Chemung fm., and divided the underlying Portage of western N. Y. into (descending): Wiscoy sh., Nunda ss. (including Laona ss. at base), Gardeau flags, Dunkirk sh., Grimes ss., Hatch sh. (= Hanover sh., and Angola sh.), Rhinestreet sh., Cashaqua sh., and Middlesex sh., all of which were said to carry the Naples fauna.

In 1919 (Geol. Soc. Am. Bull., vol. 30, p. 157), 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69), and 1924 (N. Y. State Mus. Bull. 251, pp. 149–157) G. H. Chadwick made the following changes in correlations of Chemung and Portage strata: (1) Fall Creek cgl.=Cuba ss.; (2) Wellsburg ss.=Northeast sh., Shumla ss., Westfield sh., and Laona ss.; (3) Cayuta sh.=Gowanda and underlying Dunkirk sh.; (4) the underlying beds he called *Portage group* and the overlying beds *Girard and Chadakoin fms.*

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369), divided Chemung of western N. Y. into (descending): Chadakoin beds, Cuba ss., Northeast sh., Shumla ss., Westfield sh., Laona ss., Gowanda sh., and Dunkirk sh., and divided Chemung of central N. Y. (type area) into (descending) Fall Creek cgl., Wellsburg ss., and Cayuta sh. "The Chemung fauna is a modified Ithaca-Hamilton fauna and is characterized by *Spirifer disjunctus*."

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, pt. 1, pp. 202–203). *Chemung group* (of which Chadakoin is top memb. in NW. Pa.) underlies Panama cgl. (basal memb. of Cattaraugus fm.) and is top group of Chautauquan series. Panama cgl = Wolf Creek cgl., Le Boeuf ss., and Venango 3d oil sand.

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60, No. 3, p. 200). Chemung of Olean to Genesee River, N. Y., region includes (descending) Northeast sh., Shumla, Westfield, Laona, Gowanda, and Dunkirk, and is older than Girard and Chadakoin, which underlie Wolf Creek (Panama) cgl.

K. E. Caster, 1934 (Bulls. Am. Pal. vol. 21, No. 71, table opp. p. 61), dropped Chemung from classification of rocks of NW. Pa., and divided his Chautauquan series into Chadakoin stage and Girard stage, with Cuba ss. at base.

G. H. Chadwick, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, pp. 313–326, 338–351, 352). *Canadaway group* (pseudo Chemung) includes (descending) Northeast sh., Shumla ss., Westfield sh., Laona ss., Gowanda beds, and Dunkirk black sh., and is younger than true Chemung. Type Chemung has proved itself to be only the brachiopodiferous facies of "Portage" (Nunda) group, and therefore must be classified as top part of Senecan. Senecan series is divided into:

Chemung group	Wellsburg memb.	Hanover unit.
		Pipe Creek unit.
		Portage unit.
	Cayuta memb.	Letchworth (sh.) unit.
		Gardeau unit.
		Grimes unit.
Naples group	Enfield or Attica memb.	Hatch unit.
		Rhinestreet unit.
	Ithaca or Sonyea [new] memb.	Cashaqua unit.
		Middlesex unit.
Genesee group	Sherburne memb.	Standish unit.
		West River unit.
		Genundewa unit.
	Gorham memb. (Clarke).	Geneseo unit.

Dunkirk sh. (basal fm. of Canadaway group of overlying Chautauquan series) includes Fall Creek cgl. [p. 323.] Type Chemung exposure at Chemung Narrows is plainly below Wellsburg memb. [See also under *Portage group.*]

G. H. Chadwick, 1935 (Am. Mid. Nat., vol. 16, No. 6, p. 858). *Chemung group* of Genesee River region is divided into (descending): (1) Hanover olive shales; (2) Pipe Creek black sh.; (3) Portage (incorrectly "Nunda") ss. or bluestone; (4) *Letchworth sh.* (Hall's Portage and most of Clarke's "Gardeau"); (5) *Table Rock ss.;* (6) "Gardeau" sh. as finally restricted; and (7) Grimes ss. The Pipe Creek and Hanover on Genesee River combine into Wiscoy sh.

For many years *Chemung fm.* has been employed in Pa., Md., and northern Va. as the name of a series of marine sss. and shales, of gray, green, and brown colors and Upper Dev. age, which are in part older and in part grade laterally into the continental red beds long known as *Catskill fm.*, and which overlie sss. and shales containing what has been known as the *Portage fauna* and commonly designated as *Portage fm.* In western N. Y. and NW. Pa. the beds that have for many years been called *Chemung fm.* are overlain by a series of Dev. or Carbf. beds commonly called *Conewango fm.* (in places divisible into Oswayo and Cattaraugus fms.), which is in turn overlain by Knapp fm.

†Chemung conglomerate.

A term applied in some early repts to upper cgl. of Chemung fm. in western N. Y. See also *Jamestown cgl.*

Cheneysville sandstone member.

See *Chaneysville ss. memb.* The U. S. Postal Guide spells the town *Chaneysville.*

Chengwatana series.

Pre-Cambrian (Keweenawan): Eastern Minnesota (Kanabec and Pine Counties).

C. W. Hall, 1900 (Am. Ass. Adv. Sci. Proc., vol. 49, p. 191). *Chengwatona series.*—Volcanic rocks first identified by [T. C.] Chamberlin as belonging to Lake Superior copper-bearing fm. Consists of basic eruptions (lava flows of typical structure), with 5 intercalated cgl. beds varying in thickness from 5 to 104 ft. Not less than 45 lava flows were counted and neither top nor bottom flow was seen. Thickness actually exposed 10,000 ft. Exposed along Snake River almost continuously for 2 mi.

C. W. Hall, 1901 (Geol. Soc. Am. Bull., vol. 12, p. 327). *Chengwatana series.*—A series of eruptive and clastic rocks of unusual extent. Consists of 65 lava flows containing not less than 6 cgl. beds. Thickness 4,000 to 10,940 ft. Belongs to Keweenawan series. Outcrops on Snake River at Chengwatana [the approved spelling].

Chepultepec dolomite.

Lower Ordovician (Beekmantown): Northern Alabama, eastern Tennessee, and western Virginia.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pp. 549, 638–640, pl. 27). In Ala. (Murphrees, Birmingham, and Cahaba Valleys) another fm., about 1,000 ft. thick, characterized by abundant soft mealy chert, for which *Chepultepec* is proposed, is intercalated btw. top of typical Knox and overlying Canadian [Beekmantown] ls. and dol. At Chepultepec the Canadian ls. and dol. are absent and the Chepultepec is uncon. overlain by the Stones River. The Chepultepec is a highly cherty mag. ls., the chert always soft and more or less mealy. Fossils common in upper 300 ft. Not recognized in Tenn. Rests on beds younger than Copper Ridge chert, which are supposed to represent "Upper Knox" of Tenn. Represents last of Ozarkian deposits in this province. Correlates with Gasconade of Mo. Basal part is = upper part of Little Falls dol. of N. Y., and rest of fm. is younger than Little Falls dol. and is not present in either east-central N. Y. [typical Little Falls region] or in Champlain Valley. Correlates with part of Oneota dol. of upper Miss. Valley.

In 1915 (U. S. Nat. Mus. Bull. 92, vol. 1, p. vii, and vol. 2, pls. 1 and 2) R. S. Bassler, who collaborated with Ulrich, redefined the Chepultepec as=so-called †Upper Knox in Tenn., and as resting conformably on Copper Ridge chert in both Tenn. and Ala. He correlated it with *top bed* only of Little Falls dol. of Champlain Valley, N. Y. and with Gasconade of Mo., and showed typical Little Falls dol. of N. Y. as much older than Copper Ridge. Bassler repeated this definition and correlation in 1919 (Md. Geol. Surv. Camb. and Ord. vol., p. 51). In both of these repts Bassler placed Chepultepec and Little Falls dol. as older than Beekmantown, included them in *Ozarkian*, and included "Ozarkian" in Camb.

In 1924 (Tenn. Dept. Ed., Div. Geol. Bull. 28, p. 34, and Bull. 31, p. 16) Ulrich placed *Chepultepec* uncon. below Tribes Hill, included former in his Ozarkian system, included latter in his Canadian system, and recognized Chepultepec in eastern Tenn. uncon. beneath Longview dol. and conformably above Copper Ridge dol.

In 1926 C. Butts (Ala. Geol. Surv. Spec. Rept. No. 14) defined the Chepultepec as resting conformably on Copper Ridge dol. and in Ala. uncon. overlain by Longview ls., of Beekmantown age. Butts has since discriminated the fm. as far N. as Strasburg, Shenandoah Co., Va.

Named for exposures near Chepultepec, Blount Co., Ala., 30 mi. NE. of Birmingham.

Originally the U. S. Geol. Survey classified Chepultepec dol. as *Camb. or Ord.*, and later as *Upper Camb.* In Jan. 1936, however, the age designation *Lower Ord.* (*Beekmantown*) was adopted, as explained under *Beekmantown group.*

Chequamegon sandstone.

Pre-Cambrian (upper Keweenawan): Northwestern Wisconsin (Bayfield and eastern Douglas Counties).

F. T. Thwaites, 1912 (Wis. Geol. Nat. Hist. Surv. Bull. 25, p. 33). *Chequamegon ss.*—Red and white ss., predominantly of quartz grains, with thin lenticular beds of red sandy sh. Thickness 1,000 ft. Top fm. of Bayfield ss. group. Overlies Devils Island ss. Named for exposures on Chequamegon Bay.

†Cheraw cobbles.

Pleistocene and Pliocene(?): Northeastern South Carolina (Chesterfield County)..

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 12, 20). *Cheraw* (*Lafayette*) *phase.*—A fresh-water deposit. The fm. designated *Cheraw Cobbles*, the equiv. of the Lafayette, has been variously assigned to Plio. and to Pleist. It has apparently resulted from vast fresh-water floods which extended over a great flat, constituted by the median three-fifths of the Coastal Plain, the character of whose waters excluded life forms from its deposits. These waters also extended up the greater valleys to foot of Blue Ridge Mtns. The inauguration of the great floods is marked in favored places by the survival of enormous deposits of more or less stratified sands, which followed the shore line as it retreated inland; then appear the cobbles and pebbles, which were deposited high on the scarps of the inclosing ridges of the Savannah, Congaree, Wateree, and Great Pee Dee Rivers, along their courses from the mtns to and beyond the fall line. But let it be carefully observed that there are no marginal beds of cobbles along either the Edisto or Black Rivers, whose waters originated in the Coastal Plain.

E. Sloan, 1907 (Hdb. of S. C., p. 92). *Cheraw cobbles.*—Freshwater deposit equiv. to Lafayette. Apparently resulted from vast fresh-water floods which extended over a great flat. Has been variously assigned to Plio. and to Pleist.

C. W. Cooke, 1935 (personal communication). The †Cheraw cobbles of Sloan is in part probably Plio. and in part Pleist.

Named for development around Cheraw, Chesterfield Co.

†Cherokee slates.

Lower Cambrian: Western North Carolina.

W. C. Kerr, 1869 (N. C. Geol. Surv. Rept. 2, pp. 13–35). *Cherokee slates.*—Semimetamorphic clay slates and shales, sss., grits, qtzites, cgls., and ls. Occupy in direct cross section a space of more than 10 mi. Occur along Smoky Mtns, on NW. border of N. C. Believed to be = Linville slates. Conspicuous on Valley River and therefore called *Cherokee slates*. They pass in NE. course up Laurel Valley and through Smoky or Unakee Mtns into Tenn.

The rocks described are now divided into several fms. (See North Carolina chart.)

Named for development in Cherokee Co., N. C., along Valley River.

†Cherokee limestone.

Mississippian: Southwestern Missouri and southeastern Kansas.

W. P. Jenney, 1893 (Am. Inst. Min. Engrs. Trans., vol. 22 (author's edition August 1893), pp. 178, 186, 191–202). *Cherokee ls.*—Ls., irregularly interstratified with layers of chert, 185 to 220 ft. thick. Probably representative of Warsaw or St. Louis epoch. Forms top div. of Subcarboniferous in SW. Mo., SE Kans., and northern Okla. except where locally Subcarboniferous shales overlie it.

Practically same as Boone ls.; older name, and conflicts with Cherokee sh.

Named for Cherokee Co., Kans.

Cherokee shale.

Pennsylvanian (early): Eastern Kansas, southeastern Nebraska, northwestern Missouri, and northeastern Oklahoma.

E. Haworth and M. Z. Kirk, 1894 (Kans. Univ. Quart., vol. 2, pp. 105–106). *Cherokee sh.*—Ashy white to black shales, 500 ft. thick, containing many beds of coal, ss., and ls. Suggest that term be applied to all shales above Galena ls. and below Oswego ls., unless Swallow ls. should prove to be more extensive in Cherokee Co., Kans., than now seems probable. Should such be the case the term should apply only to shales below Swallow ls. [The underlying ls. was years ago proved not to be Galena ls., but to be of Miss. age.]

H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines, vol. 13). *Cherokee sh.* underlies Fort Scott ls. memb. of Henrietta fm. and uncon. overlies Miss. in NW. Mo. Is basal fm. of Des Moines group and of Penn. Includes, near top, Lexington coal (=Mystic coal), and lower down, at different (descending) horizons, Summit coal, Mulky (Macon City) coal, Bevier coal, and Tebo (Lower Ardmore) coal.

F. C. Greene, 1933 (Mo. Bur. Geol. and Mines 57th Bien. Rept., App. II). Lexington or Butler coal occurs in lower part of Labette sh.; the upper Fort Scott or Summit coal occurs in Fort Scott ls., 0 to 15 ft. above its base; the lower Fort Scott or Mulky coal lies in upper 10 ft. of Cherokee fm. in west-central Mo.; the Bevier or Williams coal lies in upper part of Cherokee sh., 60 to 100 ft. below Mulky coal.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 42, 61). Lexington coal (=Mystic coal of Iowa) occurs in lower part of Labette sh.; Summit coal occurs in lower part of Fort Scott ls.; Mulky and Bevier coals lie in upper part of Cherokee sh.

In NE. Okla. Cherokee sh. uncon. overlies Morrow fm. (of Penn. age), and contains so much ss. and ls. that it is called *Cherokee fm.*

Named for prominent exposures in Cherokee Co., Kans.

Cherokee zone.

Cambrian (?): Northwestern South Carolina.

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C. advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2) and 1907 (Summary of mineral resources of S. C., pp. 6, 11, 12). *Cherokee zone* (*Cambrian ?*).—This zone comprises a small area bounded on SE. by a line which extends SW. from point where King's Creek crosses the N. C. line, by Silver Mtn across Broad River, and thence across Thicketty Creek below mouth of Limestone Creek to a point W. of their confluence, where it encounters Anderson-Spartanburg zone; which zone thence bounds it on W. and NW. to N. C. line; the State line constitutes the bdy on N. Some corresponding fms. of probable equivalence are interruptedly exposed in a narrow, much obscured band, which extends towards Saluda River, along the line which separates Anderson-Spartanburg zone from Abbeville-York zone, across Laurens Co.; exhibited at Frenchman's Creek, at Mahaffey Kiln, at Masters Kiln and at Raysors Kiln. Siliceous slates (slightly carbonic), qtzite, hornblende slates variously merging to ls. and marble; ottrelite schists; itacolumite; slates interbedded with hematite; lithia granite; gneiss; black slates; mica slates; metamorphosed igneous mag. rocks with lenticles of magnetite and bodies of asbestos; siliceous and mag. hematite, and specular iron ores intercalated with slates; massive fine grained gray mica slates; intrusive diabase (distinctly foliated).

Probably named for exposures in Cherokee Co.

†Cherokee limestone.

Cambrian (probably Lower): Northwestern South Carolina.

E. Sloan, 1908 (S. C. Geol. Surv., ser. 4, Bull. 2, p. 432), under heading "Cherokee zone," referred to, but did not define, *Cherokee ls.* and *upper Cherokee ls.*

A. I. Jonas, 1932 (Am. Jour. Sci., 5th, vol. 24, p. 237). "Cherokee ls." of Sloan was called *Gaffney marble* by Keith [which Miss Jonas assigns to pre-Camb.].

Cherric period.

Pre-Cambrian: Montana.

See under *Bitterroot period.*

Cherry limestone.

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, p. 136), in quoting Drake's section along Colorado River, used *Cherry* for the ls. called *cherty* by Drake. E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 104), used "Cherry ls., Plummer, 1919," for this ls. The name appears to be a typographic error.

Cherry shale.

Lower Ordovician: Eastern Nevada (Ely region).

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 53, 78). *Cherry shales*, 200 ft. thick, underlie Willow lss. and overlie Egan lss. [On p. 78 of book cited the *Cherry shales* are defined as the thick argill. beds forming upper part of *Mid* Ordovicic section in Egan Range.] Fully exposed on Cherry Creek, N. of Ely.

A part of Pogonip ls.

Cherry Creek group.

Pre-Cambrian: Central southern Montana (Three Forks quadrangle) and southwestern Montana.

A. C. Peale, 1896 (U. S. G. S. Three Forks folio, No. 24). *Cherry Creek fm.*—Interlaminated gneiss, mica schist, marbles, crystalline ls. and qtzite, all highly inclined and perfectly conformable with one another. Thickness 7,000+ft. Uncon. underlies Belt fm. and rests on Archean gneiss and schist. Occupies area of 30 to 40 sq. mi. in foothills W. of Madison River. A limited area of these beds occurs on E. side of Madison Valley at W. edge of Madison Range. Between Cherry Creek [SW. corner of Three Forks quad.] and Wigwam Creek, on W. side of Madison Valley the upturned edges of this group are overlain by unchanged Camb. beds.

According to J. T. Pardee (personal communication) the rocks named *Cherry Creek* by Peale do not resemble the Belt series but do very closely resemble the rocks mapped by Peale as "Archean."

Cherry Grove sand.

Subsurface sand, western Pa., of Chemung age. Supposed=Gartland oil sand, Garfield sand, and Balltown sand. Named for Cherry Grove, Warren Co., Pa.

Cherry Ridge group.

Upper Devonian or Mississippian: Northeastern Pennsylvania.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. G_5, p. 64). *Cherry Ridge group.*—Consists of an upper div., divided into (descending): (1) Cherry Ridge cgl., 20 to 25 ft.; (2) Cherry Ridge shales, 20 to 25 ft.; (3) Cherry Ridge ls., 5 ft.; and a lower div. consisting of Cherry Ridge red sh., 110 ft. thick. Well exposed near Cherry Ridge P. O., Wayne Co. Overlain by Elk Mtn lower sands and underlain by Honesdale ss. group, all included in Catskill fm.

I. C. White, 1882 (2d Pa. Geol. Surv. Rept. G_6, p. 78). *Cherry Ridge group* of section extending from N. line of Monroe Co. SE. to Kittatinny (Blue) Mtn, consists of (descending): Cgl., 30 ft.; sh., 20 ft.; cgl., 25 ft.; red sh. and ss., 500 ft.

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, p. 577). *Cherry Ridge* is another of I. C. White's names, but it was rather ill chosen, for Cherry in Wayne Co. gives an indifferent exposure of these beds, but good exposures are rare, and a complete section of the fm. is unknown. White treated Cherry Ridge as a group of 5 lithologically unlike members, to each of which he applied name *Cherry Ridge* with an appropriate lithologic designation. Most of these are so local that they can be disregarded, and the situation be clarified by using *Cherry Ridge red beds* for the dominantly red succession of somewhat varied lithology which separates Elk Mtn ss. (above) from Honesdale ss. (below). Such subdivisions as are useful will be renamed. Thickness 170 ft. (in Wayne Co., as reported by White) to 275 to 300 ft. on Pocono Plateau, btw. 300 and 400 ft. along Lehigh River (where, however, its upper bdy is vague), 600 ft. in Susquehanna Valley, and 1,000± in parts of Bradford and Tioga Counties. It continues W. to Susquehanna and Juniata Valley in Perry Co. In western Potter and McKean Counties it becomes the red Cattaraugus fm. [which U. S. G. S. classifies as Dev. or Carbf.]. At least 2 units of the Cherry Ridge deserve attention. White reported a cgl., distinguished by red quartz pebbles, in upper part of fm. This is persistent bed across Pocono Plateau, where it forms small ridges and hills concentric to E. escarpment. Because of its occurrence so far E. on the Plateau there seems no reason for placing it in the Mount Pleasant rather than in the Cherry Ridge beds. It is here named *Pimple Hill cgl.*, for one of the knobs which it supports—Pimple Hill, Monroe Co. It is exposed along Lehigh River, where, however, other cgls. of similar nature, particularly in lower part of the Cherry Ridge, help support Bear Mtn, SE. of Mauch Chunk, and the corresponding ridge across the River N. of Packerton. Possibly more than 1 cgl. is present on the Plateau, but the Pimple Hill is thought to be the most persistent. West of Lehigh River the Cherry Ridge carries 1 or more cgls., probably the lower ones, all the way to Susquehanna Valley. [The other important unit in his Cherry Ridge red beds is his *Dyberry glomerate*, q. v.]

Cherry Ridge sandstone.

Upper Devonian or Mississippian: Northeastern Pennsylvania.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. G_5, p. 64). *Cherry Ridge ss.*—Gray, current bedded, pebbly ss., 15 ft. thick. With underlying Cherry Ridge ls. it forms a conspicuous rock ledge at hundreds of places in all parts of Wayne Co. Followed S. it becomes coarser and finally well supplied with reddish white quartz pebbles. Overlain by Cherry Ridge shales. All included in Cherry Ridge group.

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, p. 577), discarded this name, as explained in 1936 entry under *Cherry Ridge group*.

Cherry Ridge shales.

Upper Devonian or Mississippian: Northeastern Pennsylvania.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. G_5, p. 64). *Cherry Ridge shales.*—Usually of greenish or olive color. Thickness 20 to 25 ft. A part of Cherry Ridge group. Underlies Cherry Ridge cgl. and overlies Cherry Ridge ss.

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, p. 577), discarded this name, as explained in 1936 entry under *Cherry Ridge group*.

Cherry Ridge conglomerate.

Upper Devonian or Mississippian: Northeastern Pennsylvania.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. G_5, p. 64). *Cherry Ridge cgl.*—Grayish white, very hard rock, filled with reddish quartz pebbles through S. half of Wayne Co., but in N. half of that county the pebbles are scattered through it only at some localities. Thickness 20 to 25 ft. A calc. breccia often occurs at base; in eastern Susquehanna Co. this breccia is a black stratum 5 ft. thick. The cgl. caps Collins high knob just W. of Cherry Ridge P. O., Wayne Co. Is top memb. of Cherry Ridge group. Overlain by Elk Mtn lower sands and underlain by Cherry Ridge shales.

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, p. 578), replaced this name with *Pimple Hill cgl.*, and retained *Cherry Ridge* in broad sense in which White used the name.

Cherry Ridge red shale.

Upper Devonian or Mississippian: Northeastern Pennsylvania.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. G_6, p. 66). *Cherry Ridge red sh.*—Red sh. 110 ft. thick. Often subdivided by a middle bed of 15 to 20 ft. of gray current-bedded ss. and in some places including 2 or 3 additional thinner sss. Persistently underlies Cherry Ridge ls. throughout the region. Is basal div. of Cherry Ridge group.

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, p. 577), discarded this memb. name and applied *Cherry Ridge red beds* to all of *Cherry Ridge group* of White, q. v.

Cherry Ridge limestone.

Upper Devonian or Mississippian: Northeastern Pennsylvania.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. G_5, pp. 65–66). *Cherry Ridge ls.*—An aggl. of chips of sl. or sh., fish-bone fragments, pieces of fossilized wood, and often a large quantity of sand, all cemented together by lime. In respect of amount of carbonate of lime in the rock it cannot be said to deserve the name of ls. Is one of most remarkable and persistent of Catskill strata. Extends over large part of Wayne Co. Included in Cherry Ridge group. It always immediately underlies Cherry Ridge ss., and in fact is a part of it, for while the average thickness of the calc. part of the rock may be called 5 ft., it varies greatly, rising here and there into the ss. beds, and the sand descending elsewhere into the ls. bed. In N. Y. State repts for 1844 this rock is properly referred to as *Catskill ls.*

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 571–578), replaced this name with *Dyberry glomerate,* as explained under that name.

Cherryvale shale. (In Kansas City group, Kansas.)

Cherryvale shale member (of Kansas City formation, Missouri).

Pennsylvanian: Eastern Kansas, southeastern Nebraska, and northwestern Missouri.

E. Haworth, 1898 (Kans. Univ. Geol. Surv., vol. 3, pp. 47–48, 102). *Cherryvale shales.*—Shales, 120 ft. thick, prominent from Coffeyville almost to Neosho River. Overlie Mound Valley ls. and underlie Independence ls.

G. I. Adams, 1903 (U. S. G. S. Bull. 211). *Cherryvale sh.* of SE. Kans. underlies Drum ls. (=Independence ls., preoccupied) and overlies Dennis ls. (=Mound Valley ls.).

E. Haworth and J. Bennett, 1908 (Kans. Acad. Sci. Trans., vol. 21, pt. 1). *Cherryvale sh.* underlies Drum ls. and overlies Dennis ls. But Adams confused the Dennis with the older Mound Valley ls., which underlies Galesburg sh. We retain *Dennis* for the upper ls.

In 1912 the equivalency of Independence ls. with Drum ls. was considered established, and *Independence ls.* was discarded for *Drum* by the U. S. Geol. Survey, and *Winterset ls.* was adopted (priority) for the ls. underlying the Cherryvale, its correlation with Dennis ls. being regarded as established. (See H. Hinds and F. C. Greene, Mo. Bur. Geol. and Mines vol. 13, 1915.) This definition of Cherryvale sh. (as underlying Drum ls. and overlying Winterset ls.) was continued by Kans. Geol. Survey until 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3), when R. C. Moore stated that the true Drum ls. is a higher ls. than the Drum of Hinds and Greene (=De Kalb ls.), and he included the De Kalb ls. in the Cherryvale sh. This definition of Cherryvale was adopted by Moore and G. E. Condra in their Oct 1932 revised classification chart of the Penn. rocks of Kans. and Nebr.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pp. 18, 34+). *Cherryvale sh.* of SE. Kans. underlies true Drum ls. and overlies Winterset ls. memb. of Dennis ls. It corresponds to beds here named (descending) Quivira sh., Westerville ls., Wea sh., Block ls., and Fontana sh. The Drum ls. of Hinds and Greene at Kansas City is the true Westerville, and their Cherryvale sh. includes only Wea sh., Block ls., and Fontana sh.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 98). Type Cherryvale sh. overlies Winterset ls. and underlies Drum ls. It is 60 ft. thick about 2 mi. S. of Cherryvale. It appears that Cherryvale sh. of type region is very lenticular and that it is lower than other fairly thick sh. and ss. locally occurring above flaggy lss. and below Drum ls. Correlation of Cherryvale sh. with Fontana and other fms. btw. Winterset and Drum lss. of Kansas City area is very uncertain. It is not advisable at present to use *Cherryvale* except in vicinity of Cherryvale. [On p. 45 Moore placed Cherryvale sh. of "old classification" opposite Wea sh., Block ls., and Fontana sh. of "revised classification."]

Named for exposures in vicinity of Cherryvale, Montgomery Co., Kans.

Cherry Valley limestone. (In Marcellus shale.)

Middle Devonian: Central and east-central New York.

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, chart). [In central and east-central N. Y. columns there appears: *Marcellus sh. incl. Cherry Valley ls.*]

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, pp. 64–65 and chart). Marcellus black sh. includes near its base at Cherry Valley a ls. with *Anarcestes plebeiformis* and the *Agoniatites* ls. The latter ls. extends in force from Schoharie to Ontario Co. West from there the basal sh. becomes more calc., and in Erie Co. the Agoniatite layer and the strata below it have become so far assimilated with Onondaga ls. as not to be readily distinguished from it. For these calc. layers specially characterized by the goniatites found therein, the name *Cherry Valley ls.* (1903 Clarke) has been suggested.

T. C. Hopkins, 1914 (N. Y. State Mus. Bull. 171, pp. 6–26), gave thickness of *Cherry Valley or Agoniatites ls.* in Syracuse quad. as 3 ft., and described it as impure ls., very fossiliferous, lying 15 ft. above base of Marcellus sh.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 131–132), applied *Union Springs memb.* to basal beds of Marcellus sh., separating Cherry Valley ls. from underlying Onondaga ls.

Chesaning moraine.

Pleistocene (Wisconsin stage): Central Michigan. Shown on moraine map (pl. 32) in U. S. G. S. Mon. 53. Named for Chesaning, Saginaw Co.

Chesapeake group.

Miocene (upper and middle): Eastern Maryland, Delaware, Virginia, and North Carolina.

N. H. Darton, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 431–450, map). *Chesapeake fm.*—The Mio. [marine] deposits of eastern Va. and Md., which attain their greatest development adjacent to Chesapeake Bay. Basal part is mainly dark-colored clays and fine mealy sands containing the extensive and well-known diatomaceous deposits. These are overlain by lighter-colored clays and sands with occasional local inclusions of blue marl. Upper part is coarser-grained and consists chiefly of white beach sands containing shells and deposits of shell fragments and occasional argill. members. Thickness of fm. 1,000 ft. It is a physical unit and can hardly be separated faunally into Marylandian and Virginian, as proposed by Heilprin. The faunal change is transitional. Uncon. underlies Appomattox fm. and uncon. overlies Pamunkey fm. (Eocene).

W. H. Dall, 1892 (U. S. G. S. Bull. 84, p. 123). For the Mio. strata extending from Del. to Fla., but best developed in Md., Va., and the Carolinas during Yorktown epoch of Dana, including a large part of Heilprin's Marylandian, Virginian, and Carolinian, I propose the name *Chesapeake group*. These beds are displayed in all their breadth on Chesapeake Bay and its estuaries. I have been unable to use Heilprin's names, as they have never been recognizably defined, nor am I convinced that they apply to any definite geologic facts, although there is a gradual change in fauna from older to newer beds. For the strata bordering on the Chesapeake in Md. and Va. which belong to the Mio., Darton has proposed (Bull. G. S. A., vol. 2, 1891, p. 443, but not known to writers till this essay was practically finished) the name *Chesapeake fm.* This term as used by him is = "Miocene" as heretofore understood in these states, and is strat. homonym of the chronologic "Yorktown epoch" of Dana. The term *Chesapeake group*, as independently suggested, here includes as typical Darton's Chesapeake fm. and also all other beds belonging to same horizon and containing same general fauna on Atlantic and Gulf coasts of U. S.

In Md. the Chesapeake group, as the Mio. deposits are now called, is divided into (descending) St. Marys, Choptank, and Calvert fms.; in eastern Va. into Yorktown, St. Marys, Choptank, and Calvert fms.; in eastern North Carolina N. of Hatteras axis into Yorktown and St. Marys fms., while S. of Hatteras axis the Duplin marl is sole representative of the group. In some early repts the name was used in Florida, but that usage no longer prevails.

Cheshewalla sandstone member (of Nelagoney formation).

Pennsylvanian: Central northern Oklahoma (Osage County).

D. E. Winchester, K. C. Heald et al., 1918 (U. S. G. S. Bull. 686G, pp. 60–61). *Cheshewalla ss.*—The first heavy bed of massive ss. below Labadie ls. in T. 25 N., R. 10 E. Thickness 20 to 50 ft. Is separated from the Labadie by 60± ft. of sh. and thin hard sss., with, in a few localities, a very thin ls. a few ft. above the Cheshewalla. The Cheshewalla is fine grained, moderately well cemented, rather soft, and cross bedded. Few fossils. Along most of its outcrop in this Twp it appears as a single heavy bed without interbedded sh., but locally it contains lentils of red sh. a mi. or less long, which cause the formation of benches. It lies 60 or 70 ft. above Revard ss. Is well developed near point where Cheshewalla Creek empties into Nelagoney Creek, in SE¼ sec. 9.

Cheshire quartzite.

Lower Cambrian: Western Massachusetts and Connecticut, southwestern Vermont, and southeastern New York.

B. K. Emerson, 1892 (U. S. G. S. Hawley sheet. i. e., proof sheets of geol. maps and text intended for a geol. folio, but never completed and published in that form, although cited in U. S. G. S. Bull. 191, 1902). [*Cheshire qtzite* is shown as overlying Becket gneiss and underlying [it overlies] Dalton phyllite.]

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, p. 18). [*Cheshire white granular qtzite* is shown as underlying Hoosac schist and overlying Becket gneiss in Berkshire Hills and Conn. Valley. As thus defined it included Dalton fm.]

B. K. Emerson, 1899 (U. S. G. S. Bull. 159). *Cheshire qtzite.*—White sugary qtzite, often tourmaline bearing. Divided on map into: (1) Phyllite at top of Cheshire qtzite; (2) Cheshire qtzite; (3) mica schist in Cheshire qtzite. Underlies Stockbridge ls. and overlies Becket gneiss in eastern Berkshire Co., including Dalton type loc. at N. [As thus defined and mapped *Cheshire* included Dalton fm.]

B. K. Emerson 1917 (U. S. G. S. Bull. 597, pp. 32–34 and map). *Cheshire qtzite.*—A granular quartz rock of very massive habit, rather fine and even grain, and colorless or slightly iron tinted. In places very feldspathic. Grades into underlying Dalton fm. and is overlain by Stockbridge ls. Typical exposures at and near Cheshire, Berkshire Co., Mass. [This is present approved definition of Cheshire.]

†Cheshire schist.

A name casually applied by R. Pumpelly (U. S. G. S. Mon. 23, 1894) to Berkshire schist in Cheshire, Mass.

†Chester sandstone.

Mississippian: Illinois and Missouri.

G. C. Swallow, 1858 (Am. Ass. Adv. Sci. Proc., vol. 11, pt. 2, p. 5). *Chester ss.*—Topmost ss., 75 ft. thick, of Lower Carbf. in Mo. Underlain by Upper Archimedes ls. (250 ft. thick) at Chester, Ill., succeeded below by Ferruginous ss. (195 ft. thick), and St. Louis ls. (225 ft. thick).

S. Weller, 1920 (Ill. Geol. Surv. Bull. 41, p. 123). *Chester ss.* of Swallow (Am. Ass. Adv. Sci. Proc., vol. 11, pt. 2, p. 5, 1858) is Palestine ss.

In some early Ill. Geol. Surv. repts. the term "lower Chester ss." was applied to †Ferruginous ss. and treated as basal fm. of Chester group.

Named for exposures at Chester, Randolph Co., Ill.

Chester group.

Mississippian (upper): Illinois, southern Indiana, eastern Missouri, Kentucky, Tennessee, and northern Alabama.

A. H. Worthen, 1860 (Am. Ass. Adv. Sci. Proc., vol. 13, pp. 312–313). *Upper Archimedes or Chester ls.* usually consists of 3 subdivisions: (1) Upper ls., 40 to 60 ft. thick in Pope Co., Ill., massive, gray, in regular beds with argill. partings; (2) aren. or calcareo-argill. material, which in Pope Co. contains shaly ss. with terrestrial plants; (3) lower ls.

A. H. Worthen, 1866 (Ill. Geol. Surv. vol. 1, pp. 40, 77, 284–292, 305–308). *Chester group.*—In 1853 I designated in my notes the beds at Chester as *Chester ls.* In 1856 Hall read a paper before Albany Inst. His reasons for substituting *Kaskaskia* for *Chester ls.* do not appear, and we [Worthen and F. B. Meek] prefer to retain the name first given to it, when its true position in the series was determined. The group consists of 3 or more lss. with intercalated beds of aren. and argill. shales and sss., 500 to 800 ft. thick, underlying Coal Measures and Millstone grit and overlying St. Louis group [Meramec group]. Includes Ferruginous [Aux Vases] ss. at base.

In succeeding years *Chester group* acquired the greatly preponderant usage as the name for these rocks, and in 1911 the U. S. Geol. Survey decided to adopt that name for its publications, in preference to ***Kaskaskia*** *group*.

According to Worthen's definition of Chester group the †Ferruginous ss. was its basal fm. in Ill., its type area. According to original definition of Ste. Genevieve ls. (Shumard, 1860), that fm. underlies the †Ferruginous ss. and overlies St. Louis ls. (restricted to pre-Ste. Genevieve beds) in Ste. Genevieve Co., Mo., the Ste. Genevieve type area. In 1892 C. R. Keyes introduced the geographic name *Aux Vases ss.* to replace the descriptive term *Ferruginous ss.* of Shumard and others. The type loc. of Aux Vases ss. is on Aux Vases River, Ste. Genevieve Co., Mo. In subsequent repts the Cypress ss. was miscorrelated with Aux Vases ss., but it is now known to be younger.

In southern Ill. the Chester group is now divided into (descending): Kinkaid ls., Degonia ss., Clore ls., Palestine ss., Menard ls., Waltersburg ss., Vienna ls., Tar Springs ss., Glen Dean ls., Hardinsburg ss., Golconda fm., Cypress ss., Paint Creek fm., Yankeetown chert, Renault fm., and Aux Vases ss. There has long been disagreement as to whether the underlying Ste. Genevieve ls. belongs in whole or in part to Chester group or to Meramec group. (See under *Ste. Genevieve ls.*) The U. S. Geol. Survey did not for many years assign the Ste. Genevieve to either group, but in May 1937 it was decided to adopt Weller's interpretation that "Upper Ohara" of repts belongs to Renault fm., and to transfer the remainder of Ste. Genevieve ls. to Meramec group, as classified by Ill. Geol. Survey. For subdivisions of Chester group in other States, see the State correlation charts.

Named for Chester, Randolph Co., Ill.

†Chester limestone.

See 1st entry under *Chester group.*

Chester amphibolite.

Ordovician: Western Massachusetts and Connecticut and southeastern Vermont.

B. K. Emerson, 1892 (U. S. G. S. Hawley sheet, i. e., proof sheets of geol. maps and text intended for a geol. folio, but never completed and published in that form, although cited in U. S. G. S. Bull. 191, 1902). *Chester amphibolite,* with beds of saxonite, serpentine, steatite, emery and magnetite. The unique emery bed at Chester gives the name. Underlies Savoy schist and overlies Rowe schist.

B. K. Emerson, 1894, as reported by R. Pumpelly (U. S. G. S. Mon. 23, pp. 29-30). *Chester amphibolite.*—Hornblende schist, often with serpentine. Thickness from a feather edge to 3,000 ft. Overlies Rowe schist and underlies Plainfield schist.

B. K. Emerson, 1898 (U. S. G. S. Holyoke folio, No. 50; also U. S. G. S. Mon. 29, pp. 78-156 and pl. 34). *Chester amphibolite.*—Dark green, flaggy hornblende schist, in places changed to serpentine and emery, with beds of altered ls. which are believed to be contemp. with Bellowspipe ls. Underlies Savoy schist and overlies Rowe schist. Named for the unique emery bed at Chester, Mass., which occurs in it. [See also B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 41-42).]

Chester County gneiss.

Pre-Cambrian(?): Southeastern Pennsylvania.

T. D. Rand, 1900 (Phila. Acad. Nat. Sci. Proc. 1900, pt. 1). *Chester County gneiss.*—Sometimes resembles a pegmatite, often a very feldspathic gneiss; occasionally it is a hornblende or mica schist or a micaceous gneiss. Name is provisional. Well exposed in Williams' quarry, on Phoenixville Branch of Pa. R. R., near Aldham Station.

According to G. W. Stose (personal communication Dec. 1936) the rock exposed at locality mentioned above is granite or pegmatite.

Chesterfield group.

Upper Triassic: Eastern Virginia (Richmond Basin).

N. S. Shaler and J. B. Woodworth, 1899 (U. S. G. S. 19th Ann. Rept., pt. 2, pp. 435-436). *Chesterfield group* mapped over most of Chesterfield Co. Is divided into Otterdale sss. above and Vinita beds below. Top group of Newark system in Richmond Basin. Overlies Tuckahoe group.

Chesterfield zone.

Pre-Cambrian: Northern South Carolina.

See *Edgefield-Chesterfield zone.*

Named for exposures in Chesterfield Co.

Chesterfield limestone.

Pre-Cambrian: Northern New York (Adirondacks).

H. L. Alling, 1918 (N. Y. State Mus. Bull. 199, pp. 114-115 and fig. 25). *Chesterfield ls.*, 50 ft. thick, seems to be a new one in Grenville stratigraphy, although it may be a phase of Faxon ls. Uncertainty as to rock that underlies it, as exposures are rare [but on map it is shown above Dresden amphibolite]. Is overlain by "Dixon" schist.

Chesterian.

A time term applied by some geologists to the epoch during which the Chester group of rocks was deposited.

†Chester Valley limestone.

See under †*Valley ls.*

Chestnut sandstone member (of Pottsville formation).

Pennsylvanian: Central Alabama.

C. Butts, 1910 (U. S. G. S. Birmingham folio, No. 175, p. 10). *Chestnut ss. memb.*—Persistent quartzose ss., 100 ft. thick, making Chestnut Ridge, and occurring in lower part of Pottsville fm. in Cahaba coal field. Immediately overlies Gould group of coals.

Named for Chestnut Ridge, Jefferson Co.

†Chestnut Hill schists and gneisses.

Pre-Cambrian (Glenarm series): Southeastern Pennsylvania.

C. E. Hall, 1881 (2d Pa. Geol. Surv. Rept. C_6, map and pp. 24-27). *Chestnut Hill garnetiferous schists* [on map], *Chestnut Hill group* of garnet schists, serpentines, and gneisses [in text]. Extends from vicinity of Chestnut Hill to Delaware Co. line at Bryn Mawr. Is younger than Manayunk group. [On his map of Delaware Co., Pa., he used *Chestnut Hill schists and slates.*]

In part Wissahickon fm., in part igneous rocks.

Chetamon limestone.

Upper Cambrian: Alberta (Jasper Park).

P. E. Raymond, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 291, 300). *Chetamon ls.*, 200 ft. thick. Assigned to Upper Camb. [on p. 300]. [Appears to be named for Mount Chetamon.]

Chetang limestone.

Cambrian: British Columbia and Alberta.

C. D. Walcott, 1913 (Smithsonian Misc. Coll., vol. 57, No. 12, pp. 335, 338).

Chetopa shales.

A term employed by C. [R.] Keyes to replace Cherokee sh. (Penn.), because of prior use [long ago abandoned] of Cherokee in N. C. (See Pan.-Am. Geol., vol. 56, p. 349, 1931, and vol. 57, pp. 217, 219, 223, 1932.) Named for R. R. station near Kans.-Okla. line, across Grand River from Cherokee Co., Kans.

Cheverie formation.

Mississippian: Nova Scotia.

W. A. Bell, 1921 (Am. Jour. Sci., 5th, vol. 1, p. 162).

Chewacla marble.

Pre-Cambrian: Eastern Alabama (Lee County).

W. F. Prouty, 1916 (Ala. Geol. Surv. Bull. 18, pp. 94–95). *Chewacla dol. marble.*—A highly crystalline dol., for most part a beautiful pearly white stone. Occurs as a narrow NE.–SW. strip about 5 mi. SE. from Opelika, Lee Co. Has been extensively quarried.

G. I. Adams, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14, map, p. 33). *Chewacla marble* tentatively assigned to Algonkian.

In view of fact that "Archean system" and "Algonkian system" have been discarded, this fm. is now classified by U. S. Geol. Survey as pre-Camb.

Chewaucan formation.

Pleistocene: Central southern Oregon.

W. D. Smith, 1926 (Oreg. Univ. Commonwealth Rev., vol. 8, pp. 207–214). *Chewaucan fm.*—Oxidized gravel, containing pebbles and small boulders of all older fms. of region. Thickness 25 to 100 ft. Typically exposed along Chewaucan River in vicinity of Chewaucan Marsh, Lake Co.

Chewelah argillite.

Paleozoic: Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 63, map). *Chewelah argillite.*—Interbedded quartz mica schists, phyllites, argillites, calc. argillites, dolomitic lss., argill. lss., and narrow bands of qtzite; the quartz mica schists more abundant than in any other fm. of Stevens series, and range from silver white to shades of red and gray. Thickness 4,000± ft. Rests on Addy qtzite with apparent conformity, and to W. underlies Colville qtzite with apparent conformity. To N. it underlies Old Dominion ls. and Colville qtzite. Exposed btw. North and South forks of Chewelah Creek and to N. and S. of Chewelah.

Cheyenne sandstone.

Lower Cretaceous (Comanche series): Central southern Kansas.

F. W. Cragin, 1889 (Washburn Coll. Lab. Nat. Hist. Bull. 2, No. 10, p. 65). *Cheyenne ss.*—Obliquely laminated, mostly incoherent (rarely hard) ss., 20 to 40 ft. thick, often gray but in large part gorgeously decorated with crimson, purple, scarlet, orange, yellow, brown and other colors. Forms bed No. 6 of section at Belvidere, Kans. Supposed to be referable to Trinity div. of Tex. and Ark.

F. W. Cragin, 1890 (No. 11 of publication cited above). *Cheyenne ss.* of southern Kans. underlies Neocomian shales and rests uncon. on Triassic. [*Neocomian* is a European time term for basal Lower Cret. deposits.]

F. W. Cragin, 1894 (Colo. Coll. Studies 5th Ann. Pub., p. 49), introduced *Kiowa sh.* for the fm. overlying Cheyenne ss.

In 1895 Cragin divided Cheyenne ss. into the several "members" mentioned under *Elk Creek beds*. All of these "memb." names were discarded by U. S. Geol. Survey in 1921, being applied to local facies of the Cheyenne.

The commonly accepted definition of Cheyenne is that it underlies Kiowa sh. and rests uncon. on Perm., the Triassic and Jurassic being absent.

W. H. Twenhofel, 1924 (Kans. Geol. Surv. Bull. 9). Writer does not consider it possible definitely to recognize any memb. of Cheyenne fm. beyond limits of one locality. Cragin's divisions are considered to have no validity for more than local application, and as his 3 members were not differentiated in same section it is possible 2 of them may be one Cheyenne ss. appears to be confined to E. part of area of Kiowa sh.

Named for Cheyenne Rock, at Belvidere, Kiowa Co.

Chibougamau complex.

Pre-Cambrian: Northern Quebec (Opemiska district).

C. Tolman, 1932 (Jour. Geol., vol. 40, No. 4, p. 356). Granitic intrusives include Opemiska granite, Presqu'ile granite, and *Chibougamau complex*. Is pre-Camb., and much younger than Opemiska series.

†Chicago group.

Silurian.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 28). [On chart forming pl. 28 the name *Chicago* is applied, in "General time scale" column, to all rocks btw. top of Rochester sh. memb. of the Clinton and base of Cayugan, including Lockport dol. of N. Y.; and in the Central States to all beds btw. base of Laurel ls. and top of Louisville ls., some of which are shown to be older and some younger than Lockport dol. of N. Y.]

E. O. Ulrich, 1914 (12th Int. Geol. Cong., Canada, chart opp. p. 666), replaced *Chicago group* of his 1911 classification with *Lockport group*.

E. O. Ulrich and R. S. Bassler, 1923 (Md. Geol. Surv. Sil. vol., pp. 259–260), abandoned *Chicago group* for *Lockport group*, as explained in 1923 entry under *Guelph dol.*

Chicago formation.

Silurian (Niagaran): Northeastern Illinois (Chicago).

D. O. Taylor, 1930 (Ill. Acad. Sci. Trans., vol. 22, pp. 473–477). *Chicago fm.*—Upper fm. of Niagaran series exposed in Chicago Ave. tunnel at Chicago, Ill., whence the name proposed. Consists of interbedded fine-grained green sh. and fine-grained non-porous dol. Thickness 51± ft. Rests conformably on Port Byron fm., of Niagaran series. Savage states (personal communication) these beds are certainly Niagaran and correspond to strata at Le Claire that overlie Port Byron fm. Because of isolated occurrence it seems that a separate name should be tentatively given them, hence *Chicago* is proposed. Definitely determined to have E.-W. extension of at least 3 mi.

Chicago limestone.

See 1921 and 1932 entries under *Hidden Treasure ls.*

Chicago.

Name applied to a glacial lake, of Pleist. age, in Lake Michigan region. (See U. S. G. S. Mon. 53, 1915, p. 469.)

Chickachoc chert lentil (of Atoka formation).

Pennsylvanian: Central southern Oklahoma.

J. A. Taff, 1901 (U. S. G. S. Coalgate folio, No. 74). *Chickachoc chert lentil.*—White, calc., stratified but massive, cherty ss., 0 to 80 ft. thick, near base of Atoka fm.

Occurs in SE. part of Coalgate quad., extreme NE. corner of Atoka quad., and in SE. part of McAlester quad.

Named for post office called *Chickachoc* in 1901 and located at or near present station of *Chockie*, on Missouri, Kansas, and Texas R. R., just E. of border of Coalgate quad. and near type exposures of the chert lentil. (Letter from J. A. Taff dated Jan. 26, 1931.)

Chickaloon formation.

Eocene: Central southern Alaska (Cook Inlet region).

G. C. Martin and F. J. Katz, 1912 (U. S. G. S. Bull. 500, pp. 15, 42–52, map). *Chickaloon fm.*—Rather monotonous succession of shales and sss., the shales predominating and being gray to drab, rather soft, poorly bedded; the sss. are yellowish, rather soft, of diverse grain. Thickness appears to be at least 2,000 ft. Flora shows it to be certainly Tert. and probably Eo. Rests on 2,000± ft. of arkose, cgl., and sh. of Eo. age. Underlies Eska cgl. (Mio.?). Covers greater part of valley of Chickaloon River S. of Castle Mtn.

The flora of this fm. is now regarded as Eo.

Chickamauga limestone.

Upper, Middle, and Lower Ordovician: Northern Alabama, northwestern Georgia, eastern Tennessee, and southwestern Virginia.

C. W. Hayes, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 143, 148. Paper read in Dec. 1890). *Chickamauga ls.*—Blue lss., 1,200 to 1,800 ft. thick, forming middle div. of Sil. west of Coosa River, in southern Appalachians, and = Trenton, Chazy, or Maclurea of Smith and Safford. Underlies Rockwood fm. and overlies Knox dol. On E. side of valley [in NW. Ga.] is almost entirely replaced by Rockmart slates [which also underlie Rockwood fm.].

The lss. which in early repts were assembled under name *Chickamauga* are now in most areas divided into several fms. (see various State charts), but the name is still found useful in some areas.

Named for exposures along Chickamauga Creek, E. of Chattanooga, Tenn., and branches of that creek in Ringgold quad., N. W. Ga.

†Chickasaw formation.

†Chickasaw group.

†Chickasawan formation.

†Chickasawan stage.

Eocene: Arkansas, Louisiana, Mississippi, and southern Alabama.

W. H. Dall, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, pp. 344–345). *Chickasawan fm.*—Name suggested by E. W. Hilgard. This group represents upper part of what has been loosely termed Lignitic or lignite-bearing beds of the Eocene, which lie beneath the Orangeburg, Tallahatta, or Buhrstone fm. It is not the Lignitic of several authors, who have applied the term to the whole or part of the strata formerly included in so-called Laramie fm. It does not include the earliest lignite beds of Gulf coast region, nor even the youngest of such beds. It was called Northern Lignitic by Hilgard (Agric. and Geol. Miss., 1860, p. 110); Heilprin has termed it *Eolignitic* (Proc. Acad. Nat. Sci. Phila. for 1881, p. 159, footnote), a name less accurate and otherwise equally objectionable. A portion of it is believed to be included in Camden series of R. T. Hill, of Camden, Ouachita Co., Ark. (Ann. Rept. Geol. Surv. Ark., vol. 2, 1888, p. 49), but these beds are not characteristic and not thoroughly known. Believing that, to conform to international rules for geologic nomenclature, it is desirable that a definite geographic term should be substituted for the present petrologic name, the subject was laid before Messrs. E. W. Hilgard and E. A. Smith, with request that they should suggest a suitable term to be adopted. Prof. Hilgard writes, under date of December 20, 1895: "The entire Northern Lignitic is within the 'Chickasaw Purchase,' and its most characteristic and conspicuous outcrops are on the four Chickasaw bluffs, of which the Memphis bluff is the last. It would thus seem eminently proper to let the name be Chickasaw, which I think is not preoccupied." Since communicating with Prof. Hilgard I have been informed by Prof. Shaler that the name Chickasaw was, he thinks, proposed for this group in some manuscript prepared for Ky. Survey at time it was under his direction, and while he is not sure that it ever got into print, he remembers distinctly that it was colloquially in use among members of the Survey for the fm. exposed, as stated by Prof. Hilgard, at bluffs of same name. Prof. Smith entirely accords with Prof. Hilgard's substitution; so that those chiefly interested having accepted the change, and a careful search not revealing any conflicting use of the term, nothing seems to stand in the way of its adoption. The relations of the Lignitic or Chickasaw stage with the Cret. and Lower Claibornian in NW. La. are discussed by Vaughan, U. S. G. S. Bull. 142, 1896, pp. 14–27, and Harris, The Lignitic Stage; pt. 1, Bull. Am. Pal. No. 9, June 15, 1897, vol. 2, pp. 195–294.

In table on p. 334 of U. S. G. S. 18th Ann. Rept., pt. 2, Dall shows *Chickasawan* as occupying interval btw. Claibornian above and Midwayan below. This interval corresponds to Wilcox group of present classification. But †Northern Lignitic of Hilgard, which †Chickasawan was introduced to replace, as originally defined by Hilgard (in 1860) included Midway group. In 1871, however, Hilgard stated that greater part or all of his †Northern Lignitic was included in the Claiborne. The upper Chickasaw bluffs (type loc. given for †Chickasawan fm.) are now considered to be of Jackson age, and "Chickasaw Purchase" (which included northern Miss., NW. Ala., and SW. Tenn.) to include Midway, Wilcox, Claiborne, and Jackson deposits.

Named "for the four Chickasaw bluffs, of which Memphis bluff is the last," along Mississippi River in NW. Miss., within the "Chickasaw Purchase."

See also under †*Northern Lignitic.*

Chickasawhay marl member (of Byram marl).

Oligocene (middle): Southeastern Mississippi (Clarke and Wayne Counties)and southwestern Alabama.

B. W. Blanpied et al., 1934 (11th Ann. Field Trip Shreveport Geol. Soc., charts; pp. 3, 4, 12, 16–19, etc.). Overlying Bucatunna memb. of Catahoula group there occurs throughout Wayne Co., Miss., in Smith and Jasper Counties, Miss., and in Washington and Clarke Counties, Ala., a series of marine beds which heretofore has been considered in published literature to be of Olig. Byram marl age. Detailed study of these beds and their faunas has been made, and the name *Chickasawhay* has been applied to this Mio. group. The *Upper Chickasawhay memb.* of Catahoula group consists of 25 ft. of fossiliferous claystones, marls, and blue clays, and the conformably underlying *Lower Chickasawhay memb.* consists of 30 ft. of fossiliferous gray chalky marls, lss., and clays. Type section of Upper Chickasawhay memb. is in sec. 10–8 N.–7 W., Wayne Co., Miss., on W. bank of Chickasawhay River at locality CX. Type section of Lower Chickasawhay memb. is at locality LC, on highway No. 45, 3 mi. N. of Waynesboro, Wayne Co.

C. W. Cooke, 1935 (A. A. P. G. Bull., vol. 19, No. 8, pp. 1162–1172). *Chickasawhay marl* and *Bucatunna clay* of Blanpied are accepted as members of *Byram marl* (of Vicksburg group, Olig.), in which fm. the beds thus designated have heretofore always been included.

Chickasha formation.

Permian: Central southern and southwestern Oklahoma.

C. N. Gould, 1924 (A. A. P. G. Bull., vol. 8, pp. 324–341, map). *Chickasha fm.*—A series of ss. and shales varying in lithologic character from place to place. Thickness 175 to 295 ft. Near SE. end of Anadarko Basin it consists of 175± ft.

of variegated sss. and shales. Has been locally called "purple ss." Overlies Duncan ss. and underlies Blaine gyp. Named because city of Chickasha (Grady Co.) is built on the fm. According to C. Becker, 3 divisions can be recognized in the Chickasha—an upper purple ss. memb., 70 to 80 ft. thick; a middle pink sand memb., 50 ft. thick; and a lower purple ss. memb., 50 ft. thick.

Chickies quartzite.

Lower Cambrian: Southeastern Pennsylvania.

J. P. Lesley, 1876 (2d Pa. Geol. Surv. Rept. A, p. 60). *Chiques Rock,* in Susquehanna River above Columbia, may not be Potsdam ss. in northern N. Y. and at Bethlehem and Allentown. If Chiques Rock be not Potsdam, why then it remains simply *Chiques.*

J. P. Lesley, 1877 (2d Pa. Geol. Surv. Rept. CC, on York, Adams, and other counties, index). *"Chicques (or Chickies) quartzite, page 202."* [Page 202 describes the section at Wrightsville, York Co., and states that "a very thick bed of qtzite underlies the slates and schists of the Wrightsville section (Chicque's rock, etc.)."]

J. P. Lesley and P. Frazer, Jr., 1880 (2d Pa. Geol. Surv. Rept. C_3, map of Lancaster Co.). *Chikis qtzite (Potsdam?).* [Shown as older than hydromica schists and argillites and younger than Peach Bottom roofing slates.]

P. Frazer, Jr., 1880 (2d Pa. Geol. Surv. Rept. C_3, pp. 6–8, 19–20, 108). *Chikis qtzite.*—The qtzite of Chikis rock [Lancaster Co.] is representative of Primal ss. of Rogers. Is found in large mass only on northern half of composite hills known as "Chikis." The qtzite and quartz sl. which belong with it do not extend more than 115 paces (say 100 meters or yards) from the first bold, bare escarpment back of Prof. Haldeman's house to the point where the qtzite character appears to give place upwards to the somewhat chloritic hydromica schists so often spoken of. As a rule the schists which underlie the Chikis qtzite are much more chloritic than those which overlie it. The qtzite of Chikis rock can be followed out into and across the river, and it plays a part in the long ridge on the York Co. side. Chikis Ridge consists in the main of a qtzite replaced in portions by quartz sl. and chloritic schists.

J. P. Lesley, 1885 (2d Pa. Geol. Surv. Rept. X, map 35, of Lancaster Co., 1878). *Chikis qtzite (Potsdam?).* [Shown as younger than Peach Bottom roofing sl. and older than Lower calc. slates, hydromica schists, and argillites.]

P. Frazer, 1886 (Am. Phil. Soc. Proc., vol. 23, pp. 346, 398–400). *Hellam qtzite, Cambric.*—Same as Potsdam ss. and Formation No. 1. The base of the Paleozoic. A part of it composes Chickis Mtn. Contains *Scolithus linearis.* The *Hellam or Chickis qtzite* is a hard quartzose rock, generally white or gray, tinted by some other color, usually pink, brown, or blue. Is almost always crystalline. In Chester Co. it lies uncon. on Archean schists.

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 1, pp. 165–204). *Chiques ss.* is not only the oldest name for our fm. No. 1, but expresses the locality of its finest exposure. Is same as Hellam qtzite of York Co., North Valley Hill ss. of Chester Co., White Spot ss. at Reading, "Potsdam ss." of Repts. of Prog. (probably not same as Potsdam ss. of N. Y.) and Primal ss. Only fossil found in Chiques rock is *Scolithus,* but obscure shell-like forms have been seen in Hellam quarries. Is overlain by York County hydromica slates (on which rests the Great Valley ls.) and is underlain by South Valley Hill hydromica slates.

F. Bascom, 1904 (U. S. G. S. W. S. P. 106, p. 13). *Chickies qtzite* underlies Chester Valley ls. and overlies Baltimore gneiss in Phila. dist.

A. I. Jonas, 1905 (Am. Geol., vol. 36, pp. 301+). *Chickies qtzite.*—Thinly bedded crystalline rock full of sericite, which gives it a buff to green color and schistose character. Rests uncon. on pre-Camb. Baltimore gneiss in Phila. area.

F. Bascom, 1909 (U. S. G. S. Philadelphia folio, No. 162). *Chickies qtzite.*—Massive qtzite, with quartz cgl. at base [Hellam cgl. memb.] and quartz schist in upper part. Thickness 1,300± ft. Underlies Shenandoah ls. and uncon. overlies pre-Camb. Wissahickon mica gneiss.

G. W. Stose and A. I. Jonas, 1922 (Wash. Acad. Sci. Jour., vol. 12, pp. 360–362). *Chickies qtzite.*—Consists of (1) massive-bedded, *Scolithus*-bearing, light-colored vitreous qtzite, grainy qtzite with clear quartz grains, and some white clay beds in upper part, 400 ft. thick in Hellam-Chickies Hills and 400 ft. thick in Welsh Mtn; resting on (2) Hellam cgl. memb., 600 ft. thick in Hellam-Chickies Hills and 150 ft. thick in Welsh Mtn. The Chickies is overlain by Harpers phyllite and uncon. underlain by pre-Camb. greenstone and aporhyolite in Hellam Hills, and by gneiss and granitic rocks in Welsh Mtn. Lesley and Frazer did not apply name Chickies to Harpers phyllite [but the Chickies qtzite of many subsequent repts included the Harpers schist or phyllite and the overlying Antietam qtzite].

The definition of Chickies qtzite now followed by U. S. Geol. Survey and Pa. Geol. Survey restricts the name to beds beneath Harpers schist or phyllite. The Hellam cgl. is treated as basal memb. of the fm.

Chico formation (also **group**).

Upper Cretaceous: California and Oregon.

W. M. Gabb, 1869 (Calif. Geol. Surv. Pal., vol. 2, p. XIV, as reported by J. D. Whitney from unpublished paper by Gabb, and footnote by Gabb on p. 129). *Chico group.*—One of most extensive and important members of Pacific coast Cret. Is extensively represented in Shasta and Butte Counties; also in foothills of Sierra Nevada as far S. as Folsom; on E. face of Coast Ranges bordering Sacramento Valley; at Martinez; and in Oristamba Canyon, in Stanislaus Co. It includes all known Cret. of Oreg. and extreme N. part of Calif., and is the coal-bearing fm. of Vancouver's Island. It underlies Martinez group and overlies Shasta group, but Martinez group may eventually prove to be worthy of ranking only as a subdivision of Chico group. Typical localities are Chico Creek [Butte Co.], Pence's ranch, and Tuscan Springs.

The Chico rocks consist of sss., shales, and cgls. of marine origin, varying in thickness up to 21,000 ft. and characterized by an Upper Cret. fauna. In Diablo Range the Chico is of very great thickness and becomes a group, divided into Moreno fm. above and Panoche fm. below.

Chicontepec formation.

Eocene: Mexico (Tampico embayment, north end).

E. T. Dumble, 1918 (Calif. Acad. Sci. Proc., 4th ser., vol. 8, pp. 133, 134).

Chicopee shale. (In Newark group.)

Upper Triassic: Central Massachusetts and Connecticut.

B. K. Emerson, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 451–456). *Chicopee sh.*, or the calc. red sh. of the Triassic of Mass.

B. K. Emerson, 1898 (U. S. G. S. Holyoke folio, No. 50; see also U. S. G. S. Mon. 29). [See 1898 entry under *Longmeadow ss.*]

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 91–97). *Chicopee sh.*—A central band of Newark sediments, which begins at Holyoke, Mass., and is best exposed along railroad cut near Holyoke dam, where it consists of a thin dark-gray coaly calc. sh. or shaly ss., showing many impressions of raindrops, ripple marks, mud cracks, and angular markings. At mouth of Chicopee River and in bed of Conn. River at Mittineague the rock consists of red shales with many nodules and thin beds of concretionary ls. and casts of skeleton salt crystals in calcite. As the waters rose and attained greater width the central portion of the basin was occupied by a deposit of offshore sands, the Longmeadow ss., and when the max. width was reached the middle portion of the sss. decreased in size of grain to the fine-grained sand and mud beds which have become the central Chicopee sh. Immediately after the outflow of the sheet of Hampden diabase an explosive eruption took place locally, and blocks and pulverized dust of diabase were spread by the waters over a broad area, forming the Granby tuff. Then followed the uppermost layer of *rusty sands*, in which most of the tracks have been preserved. The whole was capped down the middle of basin by the thin Chicopee sh., in which only leaves and small tracks are found. From Holyoke to S. line of State the Holyoke diabase rests on Longmeadow ss. and Chicopee sh.

Chico Ridge limestone. (In Graford formation.)

Pennsylvanian: Central northern Texas (Wise County).

G. Scott and J. M. Armstrong, 1932 (Univ. Tex. Bull. 3224, p. 31). The name *Chico Ridge ls.* is here given to thick ls. mass the outcrop of which forms the extensive upland known as Chico Ridge, S. of Chico and N. of Lake Bridgeport Dam. The ls. N. of Trinity River interfingers laterally into the shales S. of that stream.

Two prominent tongues of the ls. (Rock Hill ls. at base and Devils Den ls. at top) are well developed S. of the river. They thin to SW., however, and lens out near Willow Point, Wise Co., and Joplin, Jack Co., respectively. To S. of river the interval btw. Rock Hill and Devils Den lss. is filled with more than 300 ft. of shales and sss., here named *Jasper Creek shales,* which are exact strat. equivalents of Chico Ridge ls. N. of river. Most of the ls. mass is white or gray, hard, and reeflike, but a small part of lower portion is dark and somewhat shaly.

†Chico-Tejon series.

A term introduced by C. A. White (U. S. G. S. Bull. 51, pp. 11–14, 1889) to include all Upper Cret. and Eocene rocks of Calif., because they were then believed to constitute an unbroken series of sediments without unconformities, but they are now known to contain several unconformities.

Chicotte formation.

Silurian: Quebec (Anticosti Island).

C. Schuchert and W. H. Twenhofel, 1910 (Geol. Soc. Am. Bull., vol. 21, p. 715).

Chief Consolidated limestone.

Ordovician: Central northern Utah (Tintic district).

G. W. Crane, 1915 (Am. Inst. Min. Engrs. Bull. 106, pp. 2149–2151). *Chief Consolidated ls.*—Lss., of different colors and characters, 617 ft. thick, underlying 542 ft. of Blue Fossiliferous ls. and overlying Gemini ls. [Detailed section given. Evidently named for Chief Consolidated mine.]

Crane's Chief Consolidated and Gemini lss. compose Bluebell dol.

Chieftain Hill volcanics.

Tertiary(?): Yukon Territory.

D. D. Cairnes, 1910 (Canada Geol. Survey Summ. Rept. 1909, p. 51).

Chignik formation.

Upper Cretaceous: Southwestern Alaska (Alaska Peninsula).

W. W. Atwood, 1911 (U. S. G. S. Bull. 467, pp. 24, 41–48, map). *Chignik fm.*—Cgl., ss., sh., and coal seams, 600+ ft. thick. Underlies Kenai fm. (Eo.) and overlies Herendeen ls. (Lower Cret.). Occurs on shores of Chignik and Herendeen Bays and near Douglas Village. Type section is in Whalers Creek, ½ mi. from shore of Chignik Lagoon. Fossils are Upper Cret.

Chikis quartzite.

See *Chickies qtzite*, the approved spelling.

Childers sand.

A subsurface sand, of Penn. age, in Childers field, Brown Co., north-central Tex., lying at 600 ft. depth.

Childress dolomite member (of Dog Creek shale).

Permian: Panhandle of Texas and central northern Texas (Childress to Nolan Counties).

A. M. Lloyd and W. C. Thompson, 1929 (A. A. P. G. Bull., vol. 13, p. 952, pl. 10). A gyp. and dol. bed, not more than 2 ft. thick, 150 ft. above Guthrie memb. of Blaine fm., is called *Childress dol.,* from outcrops in and around Childress, Childress Co. Can be followed southward to Nolan Co., the only extensive gaps being an area of windblown sand in northern Stonewall Co., and north-central Fisher Co. In central Stonewall Co. it forms escarpment W. of Aspermont, and is composed of a bed of blocky gyp. which changes laterally into dol. and farther S. is replaced by a gyp. bed which has been referrerd to locally as *Ideal gyp.* It has been considered best to use Childress dol. as dividing line btw. Blaine and overlying Whitehorse fm., as it is best marker near the strat. change. Is included in Blaine fm. [Authors use *Blaine* to include Dog Creek sh. (see chart, p. 948) and they show this dol.=top bed of Dog Creek sh.]

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 168). *Childress dol. and gyp.* is top memb. of Blaine fm., and lies 150± ft. above Guthrie dol. in Childress Co.; it is same as Ideal gyp., discarded.

The U. S. Geol. Survey treats this dol. as top memb. of Dog Creek sh.

Childress sand.

A subsurface sand, of Dev. age, in SW. W. Va. Considered as possibly of Genesee age. Named for Thomas Childress No. 1 well at Sarah, Cabell Co., W. Va.

Chilhowee group.

Lower Cambrian: Eastern Tennessee and western North Carolina.

J. M. Safford, 1856 (Geol. Reconn. Tenn., 1st Rept., pp. 149, 152–153). *Chilhowee sss. and shales.*—Great group of dark-gray, micaceous, sandy shales and sss., and grayish white quartzose layers, several thousand ft. thick, composing Chilhowee Mtn, in Sevier and Blount [Counties], Tenn. Near upper part of fm., more or less in all the Unaka Counties, heavy beds of grayish white quartzose ss. occur, generally freely pierced by peculiar rod-like fossil *Scolithus linearis*. Underlies Camb. (provisionally) Mag. ls. and sh. group (Calciferous ss.) and overlies Azoic Ocoee cgls. and slates.

J. M. Safford and J. B. Killebrew, 1874 (Resources of Tenn.) and 1876 (Elem. Geol. Tenn.), included in Chilhowee ss. all beds btw. †Knox ss. (Rome fm.) and †Ocoee group. This usage probably did not include the so-called "Beaver" ls., which was discriminated many years later.

A. Keith, 1895 (Phil. Soc. Wash. Bull., vol. 12, p. 75). *Chilhowee group* of Chilhowee Mtn consists of (descending): Sh., 300 ft.; fine white ss., 800 ft.; sh., 800 ft.; white ss., 500 ft.; sh., 1,000+ ft.; white ss., 700 ft.; and, at base, Chilhowee cgl., 700 ft.

A. Keith, 1895 (U. S. G. S. Knoxville folio, No. 16), mapped the rocks of Chilhowee Mtn as consisting of (descending) Hesse ss., Murray sh., Nebo ss., Nichols sh., Cochran cgl., and Sandsuck sh.

J. M. Safford and J. B. Killebrew, 1900 (Elem. Geol. Tenn.). *Chilhowee ss.* of Chilhowee Mtn includes (descending) Murray sh., Nebo ss., Nichols sh., Cochran cgl., Sandsuck sh., and Starr cgl.

The U. S. Geol. Survey draws base of Chilhowee group at base of Cochran cgl. and top at top of Hesse ss. According to C. Butts, *Olenellus* and brachiopods occur at top of Hesse qtzite and at top of Erwin qtzite and lowest fossils found occur in Murray sl., and consist of *Olenellus* and brachiopods.

†Chilhowee conglomerate.

Lower Cambrian: Southeastern Tennessee.

A. Keith, 1895 (Phil. Soc. Wash. Bull., vol. 12, p. 75, pl. 1). *Chilhowee cgl.*—Lower Camb. cgl., 700 ft. thick, forming base of Chilhowee Mtn and basal fm. of Chilhowee group.

Preoccupied. Same as Cochran cgl.

Chillicothe till.

A term that has been applied to a till sheet of Wisconsin stage extending from Ohio to northern Wis. and Minn. (See C. [R.] Keyes, Pan-Am. Geol., vol. 58, p. 203, 1932.)

Chilliwack series.

Carboniferous and older(?): Southern British Columbia and central northern Washington (121° 30′ to 122° 30′).

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, maps 15, 16, and 17). [Shows following blocks:]

Carboniferous:

1. *Chilliwack volcanic fm.* (Chiefly flows of augite and hornblende andesites with ash beds.) [Appears to correspond to part of No. 2.]
2. *Chilliwack series.* (Outcrops of fossiliferous ls.)

Carboniferous and older(?):

Chilliwack series. (Argillite, qtzitic ss., and ls., with interbeds of grit and cgl.)

Exposed along Chilliwack River, B. C.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 508). *Chilliwack series* is 6,780+ ft. thick. Neither top nor base found. Lower 4,600+ ft. consists of fossiliferous sediments, over which Chilliwack River flows. Little doubt as to Carbf. age. Overlying these fossiliferous sediments is the memb. here named *Chilliwack volcanic fm.* It is distinctly Upper Carbf., and consists of 2,000+ ft. of andesitic flows, tuffs, and aggls. The Chilliwack volcanic fm. is overlain by (ascending): Gray calc. qtzite and argillite 60± ft.; light-gray ls., 50 ft.; dark-gray argillite, 20 ft.; qtzitic ss., 50+ ft. Top of Chilliwack series not found.

Chilliwack volcanic formation.

See under *Chilliwack series*, of which it is a part.

Chilliwack granodiorite.

Miocene(?): Southern British Columbia and central northern Washington.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2). *Chilliwack granodiorite.*—Batholith intrusion in Chilliwack series. Forms bed of Chilliwack Lake and spreads far out on all sides. Extends into Wash. Assigned to Mio.(?).

Chilton sandstones. (In Kanawha formation.)

Pennsylvanian: West Virginia.

I. C. White, 1908 (W. Va. Geol. Surv. vol. 2A, p. 271). *Chilton ss.*—Dull gray or dove-colored, fine-grained, micaceous ss., often containing calcareo-siliceous layers. Thickness 30 to 50 ft. Underlies Lower Winifrede ss. and rests on Chilton coal. [Probably named for occurrence at Chilton, Kanawha Co.]

R. V. Hennen, 1914 (W. Va. Geol. Surv. Rept. Kanawha Co., pp. xxvi–xxviii). *Upper Chilton ss.*—Dull-gray, medium grained, micaceous ss., 20 to 40 ft. thick; underlies Winifrede ls. and overlies Chilton coal. *Lower Chilton ss.*—Dull gray, micaceous, 10 to 25 ft. thick; overlies Little Chilton coal and underlies fire clay beneath Chilton coal. [On another page he stated that *Chilton ss.* is name given to lower portion of Lower Winifrede ss. when it is, as sometimes happens, divided; and described it as consisting of 10 to 30 ft. of fine-grained, micaceous, dull gray or dove-colored ss., often containing limy layers, as resting on Chilton coal, and as included in Lower Winifrede ss.]

R. V. Hennen and D. B. Reger, 1914 (W. Va. Geol. Surv. Rept. Logan and Mingo Counties, pp. 52, 61, 68, 78, 102, 110, 147–151). *Upper Chilton ss.*—Grayish brown, massive, medium-grained, micaceous ss., 20 to 65 ft. thick; separated from overlying Chilton A coal by 8 to 18 ft. of fire clay and sh.; rests on Chilton rider coal (which lies 0 to 20 ft. above Chilton coal) or on Chilton coal; lies 11 to 27 ft. below Lower Winifrede ss. *Lower Chilton ss.*—Massive, bluish gray and light gray, micaceous, medium grained and aren., 0 to 50 ft. thick; lies 0 to 5 ft. below Chilton coal and overlies Little Chilton coal.

Chimneyhill limestone.

Silurian (Niagaran and earlier): Central southern Oklahoma.

C. A. Reeds, 1911 (Am. Jour. Sci., 4th, vol. 32, pp. 256–268). *Chimneyhill ls.*—Top memb., pink crinoidal ls. 0 to 39 ft. thick, averaging 15 ft.; middle memb., glauconitic ls. 0 to 25 ft. thick, averaging 15 ft.; lower memb., oolitic ls. 0 to 12 ft. thick, averaging 5 ft. Originally included as basal memb. of Hunton fm. Uncon. underlies Henryhouse sh. and uncon. overlies Sylvan sh. Corresponds to Ohio Clinton (Brassfield ls.). It is named after Chimneyhill Creek, which crosses the fm. in NE. corner of Arbuckle Mtns. The type loc. is at confluence of 3 small creeks, sec. 4, T. 2 N., R. 6 E. Since there were no geographic names in this region suitable for fm. names it was necessary to change "South Fork of Jack Fork" Creek to Chimneyhill Creek.

C. A. Reeds, 1926 (Am. Mus. Nat. Hist. Jour., vol. 26, pp. 470–474). Fossils of Chimneyhill ls. correspond to Ohio Clinton and Brassfield beds.

E. O. Ulrich, 1927 (Okla. Geol. Surv. Bull. 45, p. 30). Chimneyhill ls. is of early Niagaran and late Medina age.

E. O. Ulrich, 1930 (U. S. Nat. Mus. Proc., vol. 76, art. 21, p. 73). *Chimneyhill* corresponds to (descending) St. Clair ls., Brassfield ls., and Noix ls. (post-Richmond). It uncon. overlies Sylvan sh.

Chinati series.

Permian: Southwestern Texas (Shafter district, Presidio County).

J. A. Udden, 1904 (Univ. Tex. Min. Surv. Bull. 8, pp. 10–25). *Chinati series.*—Shales, cgls., and lss., 5,938 ft. thick, changing from conglomeratic rocks below, through aren. beds and clays to lss. above. Divided into (descending) Cibola lss., Alta beds, and Cieneguita beds. Fossiliferous. Uncon. underlies Lower Cret. Presidio beds and overlies granite.

Assigned to Perm. by C. L. Baker, 1929 (Univ. Tex. Bull. 2901, pp. 73+). Is a local name for all of Perm. in Chinati Mtns.

Chinitna shale.

Upper Jurassic: Central southern Alaska (Cook Inlet region).

G. C. Martin and F. J. Katz, 1912 (U. S. G. S. Bull. 485, p. 65, table opp. p. 30, map). *Chinitna sh.*—Sh., with subordinate amounts of ss. and ls. Thickness 1,300 to 2,400 ft. Rests with apparent conformity on Tuxedni ss. and is overlain by Chisik cgl. Well exposed on W. side of Chisik Island, on both shores of Chinitna and Oil Bays, and on E. shore of Iniskin Bay. Fauna, according to T. W. Stanton, indicates boreal facies of Callovian stage [of European classification], which belongs at top of Middle Jurassic or base of Upper Jurassic. [The fm. was in this rept assigned to Middle Jurassic, but the Callovian fauna has for many years been classified as Upper Jurassic.]

Chinle formation.

Upper Triassic: Northern Arizona, southern Utah, southeastern Nevada, southwestern Colorado, and northern New Mexico.

H. E. Gregory, 1915 (Am. Jour. Sci., 4th, vol. 40, p. 102). *Chinle fm.* overlies Shinarump cgl. and underlies La Plata group in Navajo Ind. Res., Ariz. Name adopted for forthcoming rept. [Not described.]

H. E. Gregory, 1916 (U. S. G. S. W. S. P. 380). *Chinle fm.*—In Navajo country consists of (descending): (1) Red sh. and shaly ss.; (2) lenses of ls. cgl. containing red sh.; (3) purple, lavender, green, and light-colored variegated shales with ls. cgl. lenses; (4) chocolate-colored aren. shales, at base. Thickness 400 to 1,000 ft. Overlain, uncon.(?), by Wingate ss. and underlain, uncon.(?), by Shinarump cgl. The Chinle contains the fossil forests. Named for Chinle Valley, NE. Ariz.

For distribution and further details see U. S. G. S. P. P. 93, 1917 (by H. E. Gregory); U. S. G. S. P. P. 129, 1922 (by J. B. Reeside, Jr., and H. Bassler); U. S. G. S. Bull. 726, 1922 (by N. H. Darton); U. S. G. S. P. P. 132, 1923 (by C. R. Longwell); U. S. G. S. Bull. 751, 1924 (by H. D. Miser); U. S. G. S. P. P. 150, 1928 (by J. Gilluly and J. B. Reeside, Jr.); and U. S. G. S. P. P. 183, 1936 (by A. A. Baker, C. H. Dane, and J. B. Reeside, Jr.). In all of the States listed above the fm. underlies Wingate ss. and overlies Shinarump cgl.

Chino Quarry quartzite.

Paleozoic(?): Southern California (Riverside County).

J. W. Daly, 1935 (Am. Min., vol. 20, No. 9, pp. 638–647, map). *Chino Quarry qtzite.*—Interstratified thin-bedded qtzite and fissile mica schists. Thickness 75+ ft. Contact with overlying Sky Blue Quarry ls. obscured by intrusives; may be uncon. Where contact with underlying Chino Quarry ls. is exposed it appears to be conformable, but is partly obscured by intrusives. Included in Jurupa series. Named for quarry at Crestmore.

Chino Quarry limestone.

Paleozoic(?): Southern California (Riverside County).

J. W. Daly, 1935 (Am. Min., vol. 20, No. 9, pp. 638–647, map). *Chino Quarry ls.*—White, medium- to thin-bedded and, medium to coarsely granular ls.; graphitic beds throughout, but more common near base. Thickness 470+ ft. Best exposed in Chino Quarry, at Crestmore. Included in *Jurupa series*. *Probably conformable* with overlying Chino Quarry qtzite, and possibly conformable with underlying undiff. complex of Jurupa series.

Chipmonk sand.

A subsurface sand, of probable Dev. age, in Chipmonk pool of Cattaraugus and Allegany Counties, SW. N. Y. (See N. Y. State Mus. Bull. 239, 240, map opp. p. 16, 1922.) Some repts spell this name *Chipmunk*.

†Chipola marl member (of Chipola formation).

Miocene (lower): Northern Florida and southeastern Alabama.

W. H. Dall, 1892 (U. S. G. S. Bull. 84, pp. 112–113, 120, 122, 157, 324). *Chipola marl.*—The lower bed (marl), 5 ft. thick, at Alum Bluff; characterized by *Orthaulax gabbi* Dall. At Baileys Ferry, on Chipola River, the Chattahoochee beds are overlain by a stratum of yellowish calc. sand containing well preserved fossils, identical with those at Alum Bluff, but in much better condition. Underlies Alum Bluff beds and overlies Chattahoochee ls.

G. C. Matson and F. G. Clapp, 1909 (Fla. Geol. Surv. 2d Ann. Rept., p. 102). *Chipola marl memb.* consists of a light gray to yellow marl, containing many shells and shell fragments. The matrix is composed of calc. clay containing a small percentage of fine sand. When weathered the marl becomes dark yellow or reddish yellow, from presence of hydrated iron oxide. Not known to have a thickness of more than 15 ft. and average is probably only a few ft. In some localities is represented by a very sandy marl. The Chipola marl memb. forms basal portion of Alum Bluff fm. and rests conformably on either the Chattahoochee or the Hawthorne fm. At type loc. of Alum Bluff fm. it constitutes basal div. of that fm., but farther N. it thins and permits the sandy beds of the Alum Bluff to overlap on the Chattahoochee.

Later studies by Julia Gardner resulted in finding the Chipola fauna in all beds stratigraphically btw. base of true Oak Grove sand and top of †Chattahoochee fm., and the name *Chipola fm.* was therefore adopted (U. S. G. S. P. P. 142, p. 2, 1926) to include not only †Chipola marl memb. of earlier repts but all overlying sands and clays up to horizon of Oak Grove sand.

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept.). Typical "Chipola marl" is a fine blue-gray to yellow sand loaded with shells. It is confined to vicinity of Chipola and Apalachicola Rivers, where it forms bottom memb. of Chipola fm. and is about 10 ft. thick.

Named for exposures on Chipola River, especially at McClelland farm, S. of Tenmile Creek, Jackson Co., Fla.

Chipola formation. (In Alum Bluff group.)

Miocene (lower): Northwestern Florida and southeastern Alabama.

Julia Gardner, 1926 (U. S. G. S. P. P. 142, pp. 1–2). *Chipola fm.*—Clays, marls, and sands overlying Chattahoochee fm. [Tampa ls.], and lying stratigraphically lower than Oak Grove sand. Characterized by distinctive fauna. Is basal fm. of Alum Bluff group. Includes "Chipola marl memb." of Matson and others and overlying sands and clays.

Named for exposures on Chipola River, Jackson Co., Fla. Type at McClelland's farm, near Bailey's ferry, N. part of Calhoun Co., Fla.

†Chipola beds.
†Chipola group.
†Chipola series.
†Chipola stage.
†Chipolan stage.

Terms used in early repts to include Miocene deposits (Alum Bluff group and Tampa ls.) of Fla., and now abandoned in favor of better-established and more useful name *Chipola fm.*, which is applied to basal fm. of Alum Bluff group.

Named for exposures on Chipola River, northern Fla.

Chippewa quartzite.

Pre-Cambrian (upper? Huronian): Central northern Wisconsin (Chippewa County).

E. T. Sweet, 1876 (Wis. Acad. Sci. Trans., vol. 3, pp. 40–55). On the Chippewa is a qtzite which has a layer the lowest stratum of which is a reddish metamorphic cgl. 300 ft. thick. The pebbles of this cgl. are either jasper or amorphous quartz. The cgl. and qtzite are distinctly and heavily bedded.

C. R. Van Hise, 1892 (U. S. G. S. Bull. 86, pp. 186–187, 195, and map, pl. 6). *Chippewa qtzites* assigned to upper Huronian. Younger than Baraboo qtzites. [On map they are called *Chippewa Valley qtzites.*]

R. D. Irving, 1892 (U. S. G. S. Mon. 19, pl. 1), mapped *Chippewa Valley qtzite.*

C. R. Van Hise and C. K. Leith, 1909 (U. S. G. S. Bull. 360, p. 388). Slight metamorphism and geographical relations suggest upper Huronian age for the qtzite on Chippewa River.

Named for exposures on Chippewa River, Chippewa Co.

†Chippewa felsite. (In Ashbed group.)

Pre-Cambrian (Keweenawan): Northern Michigan (Porcupine Mountains).

W. C. Gordon, 1905 (Mich. Acad. Sci. 7th Rept., pp. 188–195). Felsite, having a known thickness of 460 ft. and cannot exceed 1,400 ft. called *Chippewa felsite* for convenience. Outcrops only in Black River and on Chippewa Bluff [near Bessemer, Gogebic Co.].

See also A. C. Lane (Mich. Geol. and Biol. Surv. Pub. 6, geol. ser. 4, p. 560, 1911).

†Chippewa porphyry. (In Ashbed group.)

Pre-Cambrian (Keweenawan): Northern Michigan (Porcupine Mountains).

A name locally applied to a porphyritic facies of †Chippewa felsite. (See F. E. Wright and A. C. Lane, 1909, Mich. Geol. Surv. Rept. State Board for 1908, pl. 1.)

Chippewa granite.

Pre-Cambrian: Northwestern New York (Hammond quadrangle).

A. F. Buddington, 1934 (N. Y. State Mus. Bull. 296, p. 86). Differs from other fine-grained granite masses of region in that the potassic feldspar is almost wholly microcline instead of microperthite. Intrudes Grenville series. [Derivation of name not stated, but on p. 172 he speaks of granite exposed in valley of Chippewa Creek.]

†Chippewa Valley quartzite.

See under *Chippewa qtzite.*

Chiques quartzite.

See *Chickies qtzite.*

Chiquito sandstones.

Permian: Northern Arizona (Grand Canyon).

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, pp. 251, 336). *Chiquito sss.*—Sss. 50 ft. thick, underlying Huethawali lss. and composing basal fm. of Aubreyan series. Uncon. above [?] Coconino ss. Named for good exposures in lower valley of Rio Chiquito Colorado, Ariz.

Chiricahua limestone.

Permian: Southeastern Arizona (Chiricahua Mountains).

A. A. Stoyanow, April 30, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 532, 536). *Chiricahua ls.*—The youngest Perm. beds in SE. Ariz. which have same fauna as occurs in memb. B of Kaibab fm. of Grand Canyon. [Fossils listed.] [Objects to

R. E. King's proposal to use *Gym* for the Perm. of SE. Ariz., as present evidence does not warrant detailed and direct correlation.] Considered younger than Snyder Hill fm. Forms top of Carbf. sequence in Chiricahua Mtns near N. Mex. border.

Chiricahuan series.

A term introduced by C. [R.] Keyes to cover 300 ft. of qtzites (called *Lone* by him) of late Camb. age in N. Mex. and Ariz. Named for Chiricahua Range, N. Mex. (See his Conspectus of geol. fms. of N. Mex., 1915, pp. 4, 6.)

Chisholm shale.

Middle Cambrian: Eastern Nevada (near Pioche).

C. D. Walcott, 1916 (Smithsonian Misc. Coll., vol. 64, No. 5, Pub. 2420, pp. 409–410). *Chisholm shales.*—Pinkish, compact, argill. sh. with a few interbedded layers of ls. 3 to 15 inches thick. Thickness 100 to 125 ft. Type loc. is vicinity of Chisholm mine and Half Moon Gulch, 2 to 3 mi. NW. of Pioche. Contains Middle Camb. fossils [listed]. Lies about 1200 ft. above Lower Camb.

L. G. Westgate and A. Knopf, 1927 (Am. Inst. Min. and Met. Engrs. Trans., No. 1647, p. 5), and 1932 (U. S. G. S. P. P. 171). *Chisholm sh.* is 0 to 180 ft. thick in Pioche region, where it conformably underlies ls. here named *Highland Peak ls.* and conformably overlies ls. here named *Lyndon ls.* Is fine-grained, yellow brown to red, laminated, argill. sh. that weathers to small flat debris; contains interbedded lss. No mica. Fossils abundant (listed).

Chisik conglomerate member (of Naknek formation).

Upper Jurassic: Southern Alaska (Cook Inlet region).

G. C. Martin and F. J. Katz, 1912 (U. S. G. S. Bull. 485, pp. 68–69). *Chisik cgl.*—Predominantly coarse cgl. of well-rounded pebbles of granite and other crystalline rocks in andesitic tuffaceous matrix. Thickness 290 ft. at Iniskin Bay and probably somewhat thicker at Chisik Island. Overlies Chinitna sh. (Middle Jurassic) and underlies Naknek fm. (Upper Jurassic). Lithologically more closely related to Naknek fm., and therefore interpreted as basal cgl. of the Upper Jurassic.

G. C. Martin, 1926 (U. S. G. S. Bull. 776, pp. 170–171, 273–274, charts, etc.). *Chisik cgl.* at type loc., on Chisik Island, is 300–400 ft. thick, and is conformable with both Chinitna sh. and *Aucella*-bearing beds of Naknek fm. It was called Upper Jurassic "aggl." by Martin in 1905 (U. S. G. S. Bull. 250, p. 44), and was described by Martin and T. W. Stanton (Geol. Soc. Am. Bull., vol. 16, p. 406, 1905) as a local lens of coarse aggl. constituting basal part of Naknek fm. It has recently been considered best by U. S. Geol. Survey to classify it as a local basal memb. of Naknek fm.

Chisna formation.

Carboniferous: Southeastern Alaska (central Copper River region).

W. C. Mendenhall, 1905 (U. S. G. S. P. P. 41, p. 33, map). *Chisna fm.*—Tuffs, qtzites, and cgls. with associated igneous rocks consisting of porphyritic intrusives and their effusive representatives. At base qtzitic cgl. 75 ft. thick. Outcrops at head of Chisna River and in hills E. and W. of the Chisna. No fossils. Tentatively assigned to lower Carbf. or Dev.

A. H. Brooks, 1911 (U. S. G. S. P. P. 70, chart opp. p. 52, pp. 82–83), referred Chisna fm. to Carbf.

Chisos beds.

Upper Cretaceous (?): Western Texas.

J. A. Udden, 1907 (Univ. Tex. Bull. 93, pp. 17, 60–67). *Chisos beds.*—Tuffaceous sediments, stratified in thin and well-defined ledges and layers. Great bulk of strata bluish gray or white stratified rock in even, thoroughly consolidated ledges, with occasional layers of clay and ss. and even thin layers of cgl. Thickness at least 2,000 ft. Includes Crown cgl. at top. Grades into underlying Tornillo clays. Underlies Tert.

W. S. Adkins, 1933 (Univ. Tex. Bull. 3232, p. 513), did not include Chisos beds of Udden in the Cret., but considered the underlying Tornillo clay as probably the highest Cret. fm. of that region (see p. 508). He stated that no fossils are known from these beds.

Named for Chisos Mtns, Brewster Co.

Chispa andesite.

Tertiary: Southwestern Nevada (Goldfield district).

F. L. Ransome, 1909 (U. S. G. S. P. P. 66, pp. 28, 64, etc.). *Chispa andesite.*—One to five flows of brownish gray porous andesite interbedded in the dacite vitrophyre on Chispa Hills. Younger than Milltown andesite and older than Meda rhyolite.

Chispa Summit formation.

Upper Cretaceous (Gulf series): Southwestern Texas (Jeff Davis County).

W. S. Adkins, 1933 (Univ. Tex. Bull. 3232, pp. 239, 271, 426, 431). The Eagle Ford equivalent in Chispa Summit region, western Jeff Davis Co., has almost entirely the clay facies, with a subordinate amount of thin platy layers and bands of septaria and concretions. It is here called *Chispa Summit fm.* At Chispa Summit it overlies the Buda, apparently concordantly. Is overlain by Colquitt fm.

Chita sand member (of Catahoula formation).

Miocene ? (lower Mio ?): Eastern Texas (Trinity and Polk Counties).

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 715, 717). *Chita sand memb.* introduced to include the coarsely textured, and in places conglomeratic, basal sands of Catahoula fm. exposed at Chita [Trinity Co.] and Corrigan [Polk Co.]. Kennedy named this sand *Corrigan,* and Dumble referred to it as *Catahoula memb. of Corrigan fm.* Since Dumble, Udden, Baker, and others have used *Corrigan* for whole Catahoula fm., it is confusing to use the name again in its original restricted sense, and it seems best to drop the name. Chita sand is 10 to 80 ft. thick, has white, polished grains called "rice sands," and is in places solidly cemented to hard qtzite with siliceous cement.' In most places it forms a persistent cuesta. Underlies Onalaska tuff memb. of Catahoula fm., and rests on Fayette fm. Type loc., the exposures along north facing escarpment near Chita, Trinity Co.

Chitistone limestone.

Upper Triassic: Eastern Alaska (Nizina-Tanana region).

O. Rohn, 1900 (U. S. G. S. 21st Ann. Rept., pt. 2, p. 426). *Chitistone ls.*—Massive bed of dark-brown, dense, aphanitic ls. that weathers gray. Often brecciated. Overlies Nikolai greenstone and underlies McCarthy Creek sh. Thickness 500 ft. or more. Exposed at junction of Nizina and Chitistone Rivers, hence name. [On several pages (429, 431, 435, etc.) Rohn called this ls. *Nizina ls.*]

G. C. Martin, 1916 (Geol. Soc. Am. Bull., vol. 27, p. 690), introduced *Nizina ls.* for the thin-bedded lss., shaly toward top, forming upper, and conformable, part of Chitistone ls. as first defined, and restricted *Chitistone ls.* to the lower massive lss. This is present approved nomenclature of U. S. Geol. Survey. (See also G. C. Martin, U. S. G. S. Bull. 776, 1926.)

Chittenango member. (In Marcellus shale.)

Middle Devonian: Central New York.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 131, 219, etc.). *Chittenango memb. of Marcellus sh.*—Jet-black, fissile, non-calc. sh. overlying Cherry Valley ls. memb. of Marcellus from eastern N. Y. nearly to Cayuga Lake. Is separately designated because it is non-calc., nearly barren of fossils, and represents only part of time interval of Oatka Creek sh. of western N. Y. Type section is in a small gully 0.7 mi. N. of village of Chittenango Falls, where entire section, 120 ft. thick, is exposed. At top it interfingers with the blue-black Cardiff sh.

G. H. Chadwick, 1933 (16th Int. Geol. Cong. Guidebook 9A, p. 4), divided the Marcellus W. of Catskill region into (descending): Mount Marion ss., 800 ft., and *Chittenango black sh.,* 200 ft., and stated that the Chittenango of that region is probably=Union Springs, Cherry Valley, and *Chittenango members* of the Marcellus farther W. in N. Y.

B. Smith, 1935 (N. Y. State Mus. Bull. 300, p. 34). [See this entry under *Marcellus sh.*]

Chloride formation.

Devonian or Mississippian (?): Southwestern New Mexico (Sierra County).

C. R. Keyes, 1904 (Am. Jour. Sci., 4th, vol. 18, pp. 360–362). *Chloride fm.*—Dev. lss., 200 ft. thick. Underlie Lake Valley ls. and overlie Ord. lss.

Probably named for town in NW. part of Sierra Co., and probably refers to Dev. Percha sh. of present nomenclature or lower part of Lake Valley ls. (Miss.).

Chloridian series.

A term introduced by C. [R.] Keyes to cover 75 ft. of Upper Camb. lss. (called by him *Carrasco*) in N. Mex., and Abrigo ls. (700 ft. thick) of Ariz. (See his Conspectus of geol. fms. of N. Mex., 1915, pp. 4, 6.)

†*Choccolocco shale.*

Lower Cambrian: Alabama.

See explanation under †*Montevallo sh.*

†Chocolate limestone.

A name, based on color of the rock, applied by G. C. Swallow to a ls. in Kans. that is now known as *Tarkio ls.*, according to R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 229).

Chocorua granite.

Late Devonian or late Carboniferous: Northern New Hampshire (Mount Chocorua quadrangle, White Mountains).

C. H. Hitchcock, 1874 (Geol. N. H., pt. 1, btw. pp. 508 and 545). *Chocorua granite.*—Crystalline labradorite that gave rise to Chocorua Peak. Assigned to Labrador (pre-Huronian) period.

C. H. Hitchcock, 1877 (Geol. N. H., pt. 2, pp. 154, 230, pl. xi). A typical variety of *Chocorua granite* consists only of greenish feldspar, apparently orthoclase and amorphous smoky quartz. At E. base of Chocorua Mtn there is a similar rock of greenish gray color, very fine-grained, prevailing to exclusion of everything else. These 2 types of rock represent our Chocorua granite. I called them labradorite, perhaps erroneously, in pt. 1. [On p. 230 he *tentatively* divided his *Chocorua group* into 3 parts, the third part being the sienite, and said: Whether these 3 kinds really belong to different eruptive periods, or should properly be grouped as one, is a question for the future.] Is younger than Conway and Albany granites, all of which belong to Eozoic or early Paleozoic. They cut Eozoic rocks.

M. Billings, 1928 (Proc. Am. Acad. Arts and Sci., vol. 63, No. 3, pp. 67–137, map). *Chocorua group.*—Same as Chocorua group of Hitchcock. Divided into riebeckite granite, hastingsite granite, and nordmarkite. Is intrusive. Assigned to Dev. (?). Well exposed on Mount Chocorua. [On his map he placed his Chocorua group btw. his Albany group (below) and his Conway group (above). In 1935 he assigned all of these intrusives to late Dev. or late Carbf.]

M. Billings, 1935 (letter dated Aug. 27). *Chocorua granite* belongs to White Mtn magma series.

†Choctaw buhrstone. (In Claiborne group.)

Eocene (middle): Southern Alabama and Mississippi.

W J McGee, 1890 (Am. Jour. Sci., 3d, vol. 40, pp. 27, 30, 32). Over the ridge [in vicinity of Meridian, Miss.] formed by the peculiar siliceous rocks of Eocene age called by Smith [unpublished] *Choctaw buhrstone*, the Appomattox [fm.] is uncommonly obdurate. (Page 27.) Still farther S. lies the great siliceous deposit of the middle Eocene commonly known as Buhrstone—the Choctaw buhrstone of Smith [unpublished]. (Pages 29–30.)

In 1891 (U. S. G. S. 12th Ann. Rept., pt. 1, pp. 491, 493, 494) McGee introduced *Meridian fm.* to replace nongeographic term "Buhrstone," but other workers seem to have overlooked this name, as they continued to use "Buhrstone" until 1898, when W. H. Dall (U. S. G. S. 18th Ann. Rept., pt. 2, p. 344 and chart opp. p. 334) introduced *Tallahatta* (from Ala.) and *Orangeburg* (from S. C.) to replace "Buhrstone." *Tallahatta* soon gained currency as a name for the "Buhrstone" of Ala. and Miss.

"Orangeburg," however, was not adopted into the nomenclature of S. C., and more recent studies have shown that the beds to which the name presumably was intended to apply constitute the later discriminated McBean fm.

Name undoubtedly derived from the broad belt of the fm. across Choctaw Co., Ala.

†Choctaw limestone.

Lower Cretaceous (Comanche series): Northeastern Texas.

F. W. Cragin, 1894 (Colo. Coll. Studies, vol. 5, p. 41). *Choctaw ls.*—Fossiliferous quarry ls., 5 to 15 ft. thick, forming lower memb. of *Exogyra arietina* marl and Main Street ls. Underlies Grayson marls and overlies Pawpaw clays.

Same as Main Street ls. memb. as later restricted.

Named for Choctaw Creek, Grayson Co.

Choctawhatchee formation.

Miocene (upper and middle): Western Florida and St. Johns Valley, Florida.

G. C. Matson and F. G. Clapp, 1909 (Fla. Geol. Surv. 2d Ann. Rept., table opp. p. 50 and pp. 114–122). *Choctawhatchee marl.*—Greenish to light-gray sandy shell marl and greenish gray plastic sandy clay. Thickness 30 to 50 ft. Rests uncon. on Alum Bluff group and is overlain by Plio. beds. Is of marine origin.

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept.). Name changed to *Choctawhatchee fm.*, because the marl beds that contain the characteristic fossils of the Choctawhatchee make up only a part of fm. and are less persistent than the clay. Divided into (descending): (1) *Cancellaria* zone and (2) "aluminous clay," both upper Mio.; (3) *Ecphora* zone, (4) *Arca* zone, and (5) *Yoldia* zone, all middle Mio.

Named for exposure on Choctawhatchee River in Walton Co.

Chokecherry dolomite.

Lower Ordovician: Western Utah (Gold Hill district).

T. B. Nolan, 1930 (Wash. Acad. Sci. Jour., vol. 20, No. 17, Oct. 19, pp. 421–432). *Chokecherry dol.*—Characterized by considerable silica, which occurs both as nodules and bands of chert, usually of dark gray to black color, and as sandy laminæ btw. thin beds of dol. Lower beds as a rule are rather massively bedded chert-bearing dark-mottled dol., locally oolitic and cross bedded and containing thin lenses of dol. cgl. These beds are supplanted higher in fm. by thinner bedded dol. with sandy laminæ or, locally, by bands of chert. Lower Ord. fossils near top. Thickness 850 to 1,000+ ft. Absent in N. part of area, so that there must be pronounced uncon. above the fm. Lies uncon. on Hicks fm. and is overlain by Fish Haven dol. Named for exposures in Chokecherry Canyon, just S. of Gold Hill quad.

See also U. S. G. S. P. P. 177, 1934.

Chopaka schist.

Carboniferous(?): Central northern Washington.

R. A. Daly, 1906 (Geol. Soc. Am. Bull., vol. 17, pp. 329–376). *Chopaka schist.*—A large patch of schist that crowns Chopaka Mtn. Very similar to Kruger schist (Carbf.?), with which it may be contemp. May possibly be Triassic

Chopaka basic intrusives.

Carboniferous(?): Southern British Columbia and central northern Washington.

R. A. Daly, 1906 (Geol. Soc. Am. Bull., vol. 17, pp. 329–376). *Chopaka basic intrusives.*—A strong body of gabbro apparently transitional into pure olivine rock. Cuts Chopaka schist, which caps Chopaka Mtn, Wash. May be Carbf. or Triassic.

Choptank formation.

Miocene (middle): Eastern Maryland and Virginia.

G. B. Shattuck, 1902. [See under *St. Marys fm.*]

W. B. Clark, 1903 (Md. Geol. Surv. St. Marys Co. Atlas). *Choptank fm.*—Middle fm. of Chesapeake group. Thickness 112 ft. Consists (descending) of sandy clay, fossil bed, sandy clay, fossil bed, clay and sand. Underlies St. Marys fm. and overlies Calvert fm.

Named for exposures on Choptank River, Md., a short distance below Dover Bridge, Talbot Co.

Chorreras granite.

Age(?): Mexico.

R. H. Burrows, 1910 (Soc. geol. Mexicana Bol., t. 7, p. 100).

Choteau limestone.

Incorrect spelling of *Chouteau ls.*

Chouteau limestone. (Of Kinderhook group.)

Mississippian: Central and eastern Missouri and southwestern Illinois.

G. C. Swallow, 1855 (Mo. Geol. Surv. 2d Ann. Rept., pt. 1, p. 101 and sections opp. pp. 98, 103). *Chouteau ls.*—In Cooper Co. region upper part is thick-bedded, brownish gray, earthy, silico-mag. ls. 40 to 50 ft. thick; lower part compact, blue or drab, thin-bedded ls. 20 ft. thick. Underlies Encrinital [Burlington] ls. and overlies Vermicular ss. and shales [Hannibal sh.]. Included in Dev. Thins to E. and is only 10 to 30 ft. thick in Marion Co.

F. Springer, 1920 (Smithsonian Pub. 2501, p. 196). The upper part of what in Mo. is called the "Chouteau" is same thing as Lower Burlington beds in Iowa.

R. C. Moore, 1928 (Mo. Bur. Geol. and Mines vol. 21, 2d ser.), restricted Chouteau ls. to lower memb., which he correlated with upper part of Kinderhook group, and named the upper memb. *Sedalia ls.*, which he correlated with Fern Glen ls., and assigned both to Osage group. This is present generally accepted definition of Chouteau ls.

See also under *Kinderhook group.*

Named for Chouteau Springs, Cooper Co., Mo.

†Chouteau group.

Mississippian: Missouri.

G. C. Broadhead, 1874 (Mo. Geol. Surv. vol. 1, pp. 26–65). *Chouteau group* proposed *to replace "Chemung" of old Mo. repts. Includes (descending)* Chouteau ls., Vermicular ss. and shales [Hannibal sh.], and Lithographic [Louisiana] ls.

Replaced by Kinderhook group, older name.

Named "for chief member of the group" [Chouteau ls.].

†Chowan formation. (Of Columbia group.)

Pleistocene: Coastal Plain of North Carolina, Virginia, and Maryland.

W. B. Clark, 1910 (Geol. Soc. Am. Bull., vol. 20, p. 651). Name proposed by L. W. Stephenson in unpublished ms. In N. C. the Talbot terrace divides into two terraces, constituting Chowan and Pamlico fms.

L. W. Stephenson, 1912 (N. C. Geol. Surv. vol. 3, pp. 282–286). *Chowan fm.*—Sandy loams, more or less aren. clays, sands, and gravels; the coarser materials at base, and grading up into finer sands and loams at top. Thickness 15 or 20 ft. Surface of fm. forms a plain that slopes up from elevations of about 25 to 40 ft. above sea level along its E. edge to about 50 ft. along foot of escarpment separating it from Wicomico plain above. Where it passes up river valleys, however, it probably reaches max. elevations of 70 ft. at inland extremities of extensions. Older than Pamlico fm. (25-foot terrace) and younger than Wicomico fm. (50 to 100-foot levels). Included in Columbia group. Named for Chowan River, N. C., to S. of which, in Hertford Co., the plain forming the surface of the fm. is typically developed.

C. W. Cooke, 1931 (Wash. Acad. Sci. Jour., vol. 21, Dec. 19, 1931). The following reclassification of Pleist. terrace fms. of Md., Va., and N. C. is proposed:

Pamlico fm., 25-foot level.

Talbot fm. *restricted,* 40-foot level.

(Same as *typical* "Chowan", abandoned, but not same as "Chowan" *as defined,* which included the deposits on 25, 40, and 70-foot levels.)

Penholoway terrace (deposits not yet named), 70-foot level.

[These deposits have heretofore been included in Wicomico to N. and in † Chowan to S., and are now called *Penholoway fm.*]

Wicomico fm. *restricted,* 100-foot level.

See also under *Columbia group.*

Choza formation.

Permian: Central and central northern Texas.

J. W. Beede and V. V. Waite, 1918 (Univ. Tex. Bull. 1816, map, p. 49). *Choza fm.*—Includes rocks from top of Bullwagon dol. to [uncon. in later repts] base of San Angelo fm. Consists of a series of red shales separated by groups of thin dol. beds, some of which are fossiliferous. Highest dol. in fm. is Merkel dol., which lies 270 ft. below top of fm. Thickness of fm. 870 ft. Named for Choza Mtn, near Tennyson, Coke Co.

J. W. Beede and D. D. Christner, 1926 (Univ. Tex. Bull. 2607). Near Sagerton [Haskell Co.] San Angelo fm. cuts out underlying Merkel dol., but on Colorado River S. of Bronte, Coke Co., its base is 270 ft. above Merkel dol.

Christie member (of Dundas formation).

Ordovician: Ontario.

M. Fritz, 1926 (Roy. Soc. Canada Proc. and Trans., 3d ser., vol. 20, pt. 1, sec. 4, p. 89).

Chrysler waterlime.

Silurian (Cayugan): Central New York (Syracuse region).

G. H. Chadwick, 1930 (Geol. Soc. Am. Bull., vol. 41, p. 81). *Chrysler waterlime ("Rondout" of this region).*—Overlies Akron dol. and uncon. underlies Manlius group. Lies at top of Bertie (Tonoloway) group in central N. Y. Named for Chrysler's Glen [Syracuse quad.].

B. Smith, 1935 (N. Y. State Mus. Bull. 300, pp. 16–18), named the basal fm. of Manlius group in Skaneateles quad. the *Olney ls.;* stated that it rested on Chrysler fm. (as identified by him in this quad., on basis of strat. position and lithology); and that so far as he had been able to determine typical Chrysler is without fossils.

Chuar group.

Pre-Cambrian: Northern Arizona.

C. D. Walcott, 1883 (Am. Jour. Sci., vol. 26, pp. 439–442, 484). *Chuar group.*—Sandy and clay shales with interbedded sss. and lss., which are exposed in inner canyon valleys of Grand Canyon of the Colorado. Top group of Grand Canyon series. Overlies uncon. the Grand Canyon group [Unkar group].

C. D. Walcott, 1894 (U. S. G. S. 14th Ann. Rept., pt. 2, pl. 60, etc.). *Chuar terrane.*—Upper div. consists of 1,700 ft. of sss. and shales with some ls. beds, reddish, brown, black, gray, buff, etc. in color; base is massive bed of reddish brown ss. Lower div. consists of 3,420 ft. of shales and sss. with some ls. beds; of brown, gray, black, drab, and chocolate color; basal part consists of argill. shales resting on massive mag. ls. Uncon. underlies Tonto and overlies Unkar terrane.

Named for Chuar Valley, Grand Canyon region.

Chuarian series.

A name employed by C.[R.] Keyes instead of *Chuar group* of other geologists.

Chubb siltstone member (of Maroon formation).

Permian: Central Colorado (Park and Chaffee Counties).

D. B. Gould, 1935 (A. A. P. G. Bull., vol. 19, No. 7, pp. 971–1009). *Chubb siltstone memb. of Maroon fm.*—Gray to red brown siltstone, argill. and calc. near base, with sss. in upper part. Is 1,827 ft. thick on E. side of Chubb Gulch in sec. 16, T. 13 S., R. 77 W., for which it is named. Assigned to Perm. Conformably underlies Pony Spring siltstone memb. and conformably overlies Coffman cgl. memb., in Salt Creek area, Park and Chaffee Counties.

Chu Chua formation.

Eocene: British Columbia.

W. L. Uglow, 1922 (Canada Geol. Surv. Summ. Rept. 1921, pt. A, p. 82).

Chuckanut formation.

Eocene (lower): Northwestern Washington (San Juan Islands).

R. D. McLellan, 1927 (Univ. Wash. Pub. Geol., vol. 2, pp. 93, 136–138). *Chuckanut fm.*—Cross-bedded, arkosic sss. and cgls., with coal beds, occurring on N. part of Lummi Island and in vicinity of Bellingham Bay to E. They form lower part of White's Puget group. Thickness 500 ± ft. Contain leaves and plants identified by F. H. Knowlton as lower Eocene. Of brackish or fresh-water origin. Well exposed along Chuckanut Drive on Pacific Highway.

Chuctenunda.

Middle Ordovician: Eastern New York (Mohawk Valley).

R. Ruedemann and G. H. Chadwick, 1935 (Sci., n. s., vol. 81, No. 2104, p. 400). *Chuctenunda* introduced for upper middle Canajoharie or zone of *Lasiograptus eucharis* in Mohawk Valley.

Chugwater formation.

Triassic and Permian: Wyoming (rather widespread) and central southern Montana.

N. H. Darton, 1904 (Geol. Soc. Am. Bull. vol. 15, pp. 394–401). *Chugwater fm.* proposed for series of red beds extending along foot of Bighorn Range southward through Wyo. and Colo. In Black Hills region the red beds are divided near base by a ls. designated *Minnekahta,* and although there appears to be a continuous representative of this ls. in Bighorn uplift, a definite correlation cannot be ventured, so that a name is required for the undivided red beds. Thickness (1,250 ft.) is also greater than in Black Hills, but the fm. is believed to correlate with Spearfish, Minnekahta, and Opeche of that region. It uncon. underlies Sundance fm. (Jurassic), overlies Tensleep ss. (Carbf.), and is of Permian and Triassic(?) age. Named for Chugwater Creek near Iron Mtn, Wyo.

In 1908 (Geol. Soc. Am. Bull., vol. 19, pp. 403–463) Darton divided the red beds of SE. Wyo. (Laramie Basin region) into (descending) Chugwater fm. (Perm. or Triassic), Forelle ls. (Carbf.), and Satanka sh. (Carbf.). He stated that the Forelle was separated on account of its fossils; but for which the ls. and underlying Satanka sh. might be regarded as a portion of Chugwater fm.

Later it was found that in some areas the upper part of red beds included in Chugwater fm. contained an Upper Jurassic (Sundance) marine fauna; and these beds are now included in Sundance fm. Still later the upper part of the restricted Chugwater was removed and named *Popo Agie beds* by Williston and *Jelm fm.* by Knight, and this restricted definition is that now employed by U. S. Geol. Survey. The Chugwater is almost wholly nonmarine, and as now interpreted is of Triassic and Perm. age. It usually uncon. underlies Sundance fm., but in places is overlain by intervening Jelm fm. In Wind River Mtns the characteristic Chugwater redbeds rest on Dinwoody fm. In other parts of Wyo. the redbeds occupy a much larger strat. interval and rest on Tensleep ss. In SE. Wyo. the Chugwater has been described as resting on Forelle ls., which overlies the red Satanka sh.; but H. D. Thomas, 1934 (A. A. P. G. Bull., vol. 18, No. 12, pp. 1670, 1687), described Forelle ls. as an E. extension of middle part of Phosphoria fm., and Satanka sh. as basal part of Chugwater fm. as originally defined. He therefore applied *Satanka tongue of Chugwater fm.* to Satanka sh. of Darton, *Forelle tongue of Phosphoria fm.* to Forelle ls. of Darton, and the new name *Freezeout tongue of Chugwater fm.* to the red beds overlying the Forelle and underlying an E. extension of Dinwoody fm. which he named *Little Medicine tongue of Dinwoody fm.*

Chupadera formation.

Permian (lower): New Mexico.

E. H. Wells, 1919 [1920] (N. Mex. State School Mines Bull. 3, pp. 10–11, 17–18). *N. H. Darton's* plan of combining San Andreas and Yeso fms. under name of *Chupadera fm.* is followed in this rept. The plane of separation btw. Yeso and San Andreas is in many places difficult to locate, and plan of combining them under name of *Chupadera fm.* is especially appropriate in this (Puertecito) dist. The massive pink and light-yellow ss. 150 to 200 ft. thick, which is usual top memb. of old Yeso fm. of eastern Socorro Co., is absent near Puertecito, where upper part is entirely lss. and gyp. beds, with gyp. predominant; the colors of this part are cream, buff, and light bluish gray. Shaly strata are more abundant in lower part and decrease in amount toward top. Near base the colors are dark gray, yellowish brown, pink, and red. Thickness of fm. 1,000 to 1,200 ft. Rests on Abo ss., usually conformably. Uncon. overlain by Triassic. Is top fm. of Manzano group.

N. H. Darton, 1922 (U. S. G. S. Bull. 726 E, pp. 176–182). [The name *Chupadera fm.* was adopted by U. S. G. S. for this rept in July 1919, but rept was not published until March 31, 1922.] The name *Chupadera fm.* is here introduced for upper part of Manzano group, which Lee divided into Yeso fm. and San Andreas ls. In mapping these deposits it was found that while Lee's subdivisions were discernible in places, it was impracticable to separate them generally. Although ls. is conspicuous feature of San Andres ls. much of that subdivision consists of thick beds of gyp. and ss. which are not well exposed in the type localities. In future, wherever Lee's subdivisions can be recognized they will be treated as members of Chupadera fm., instead of as distinct fms. Named for Chupadera Mesa [E. part of Socorro Co.], a prominent topographic feature consisting of a very extensive capping of the fm., 1,500 or more ft. thick. Rests on Abo ss. Is overlain by Triassic.

A. G. Fiedler and S. S. Nye in 1933 (U. S. G. S. W. S. P. 639) divided the Perm. rocks of Roswell artesian basin of SE. N. Mex. into (descending): (1) Pecos fm., (2) Picacho ls. (considered to be same as San Andres ls. memb. of Chupadera fm. to W.), and (3) Nogal fm. (considered to be same as Yeso memb. of Chupadera fm. to W.).

W. B. Lang, 1935 (A. A. P. G. Bull., vol. 19, No. 2), abandoned Pecos fm., dividing it into (descending): Pierce Canyon redbeds, Rustler fm., Salado halite, and Castile anhydrite.

W. B. Lang, 1937 (A. A. P. G. Bull., vol. 21, No. 7), replaced *Picacho ls.* with San Andres ls. memb. of Chupadera fm. and replaced *Nogal fm.*, with Hondo ss. memb. of Chupadera fm. and Yeso memb. of Chupadera fm. (below). The recognition of Hondo ss. (new) involves a slight redefinition of both San Andres ls. and Yeso.

Church limestone. (In Howard limestone.)

Pennsylvanian: Southeastern Nebraska and eastern Kansas.

G. E. Condra 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 42, 54). *Church ls.*—Lower ls. of Howard ls. memb. of Wabaunsee fm. Bluish gray, dense, brittle, massive, quite fossiliferous, and in 1 or 2 beds forming large blocks. Thickness 2 to 6 ft. Underlies Kiewitz sh. and overlies Severy sh. memb., which contains Nodaway coal 4 ft. below top. Named for Church farm, on Turner Creek, SE. of Du Bois, Nebr.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3, pp. 20, 21, 94, 96), and R. C. Moore and G. E. Condra, 1932 (Oct. 1932 revised classification chart of Penn. rocks of Nebr. and Kans.), defined *Church ls.* as underlain by Aarde sh. (shown as a younger bed than Severy sh.) and overlain by Winzeler sh., and as belonging in middle of Howard ls.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 207–208). *Church ls.* is most persistent and important memb. of Howard ls. It overlies Aarde sh., or where Bachelor Creek ls. is absent and Aarde sh. is not differentiated, it forms basal unit of Howard ls. and rests on Severy sh. It underlies Winzeler sh. Thickness 1½ to 6 ft. Type loc., Church farm, on Turner Creek, SE. of Du Bois, Nebr.

Churchill arkose sandstone.

Cambrian: Hudson Bay region.

J. B. Tyrrell, 1898 (Canada Geol. Surv., n. s., vol. 9, p. 174 F).

Churchillian group.

Pre-Cambrian: Manitoba and Saskatchewan.

J. F. Wright, 1934 (Canada Geol. Surv., map 268A, The Pas Sheet, Manitoba and Saskatchewan, Pub. No. 2272).

Church Run conglomerate.

Term applied by J. F. Carll (2d Pa. Geol. Surv. Rept. I, pp. 38–40, 1875) to coarse cgl. in hill-tops at Church Run, Warren Co., NW. Pa. Probably same as Olean cgl. memb. of Pottsville fm.

Churn Creek member.

Mississippian: Southern Ohio.

J. E. Hyde, 1915 (Jour. Geol., vol. 23, pp. 656, 657, 763). *Churn Creek memb.*—Argill. sh. with an occasional thin ss. passing gradually into underlying Vanceburg ss. memb. Thickness 50 to 100 or more ft. Present only in SW. part of Scioto and eastern Adams Counties, and only in vicinity of Buena Vista is Logan fm. found overlying it. Is top memb. of Cuyahoga fm. in SW. part of Scioto Co. [Cuyahoga as used above includes lower part of Black Hand fm., to which these beds belong.]

Named for Churn Creek, SE. part of Adams Co.

Chusa tuff member (of Catahoula tuff).

Tertiary (lower Miocene or Oligocene): Southwestern Texas coastal plain.

T. L. Bailey, 1926 (Univ. Tex. Bull. 2645, pp. 65, 89–105, 178–179). *Chusa memb. of Gueydan fm.*—Primarily friable tuffaceous clays and impure bentonites which have evidently been formed by action of streams on underlying Soledad and Fant members of Gueydan fm. Thickness 160+ ft. Is top memb. of Gueydan fm. Grades into underlying Soledad memb. of Gueydan fm. and is uncon. or discon. overlain by Oakville fm. Traced to NW. it overlies, apparently conformably, typical Catahoula ss. of Gonzales and Lavaca Counties and occupies strat. position of Fleming clay. It is therefore quite possible it is of lower Mio. age. Named for exposures on slopes of La Chusa Mesa, in SE. McMullen Co.

The Gueydan fm. is now considered same as Catahoula tuff, and "Gueydan" has been abandoned by both Tex. Geol. Survey and U. S. Geol. Survey. The Chusa is therefore now treated as a memb. of Catahoula tuff.

Chushina formation.

Lower Ordovician: Alberta and British Columbia.

C. D. Walcott, 1923 (Smithsonian Misc. Coll., vol. 67, No. 8, p. 458). *Chushina fm.*—Bluish gray, thin-bedded lss., 1,500 ft. thick, occurring on N. slopes of Phillips and Lynx Mtns and Billings Butte, Robson Park, B. C. Fossils are Lower Ozarkian. Named for Chushina Glacier.

P. E. Raymond, 1930 (Am. Jour. Sci., 5th, vol. 20, p. 304), assigned this fm. to Lower Ord., and to B. C. and Alberta.

Chuska sandstone.

Tertiary (Eocene?): Northwestern New Mexico and northeastern Arizona.

H. E. Gregory, 1916 (U. S. G. S. W. S. P. 380). *Chuska ss.*—White and gray porous cross-bedded ss., 700 to 900 ft. thick. Overlies Tohachi sh., probably with uncon. Uncon. underlies basic lavas. Named for Chuska Peak, McKinley Co., NW. New Mex.

Cibao limestone.

Tertiary: Puerto Rico.

B. Hubbard, 1920 (Sci., n. s., vol. 51, p. 396).

Cibola limestone.

Silurian(?): Southwestern New Mexico (Silver City district).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257–259; Conspectus of geol. fms. of N. Mex., pp. 3, 6). *Cibola lss.*—Important mid-Siluric ls. memb. outcropping at Cibola mill, at Silver City. Thickness 175 ft. Underlies Naiad ls., and with it comprises Santa Ritan series. Assigned to Sil.

Cibolo formation.

Permian: Southwestern Texas (Shafter district, Presidio County).

J. A. Udden, 1904 (Univ. Tex. Min. Surv. Bull. 8, pp. 10–25). *Cibolo lss.*—Consist of (descending): Hard yellow dolomitic ls., 650 ft.; dark, even-bedded, compact ls., including some sandy strata, 470 ft.; thin-bedded ls. containing sponge spicules, 85 ft.; grayish white, heavy-bedded, brecciated ls., 133 ft.; gray marly sh., containing some lenticular ledges of organic and siliceous sand, forming basal transition beds, 100 ft. Fossiliferous. Top fm. of Chinati series. Uncon. underlie Lower Cret. Presidio beds and overlie Alta beds.

P. B. and R. E. King, 1929 (A. A. P. G. Bull., vol. 13, p. 908), state that underlying Cieneguita and Alta beds of Udden have been proved to be Perm.

Named for Cibolo Creek and Cibolo ranch, Presidio Co.

Cieneguita beds.

Permian: Southwestern Texas (Shafter district, Presidio County).

J. A. Udden, 1904 (Univ. Tex. Min. Surv. Bull. 8, pp. 10–25). *Cieneguita beds.*—Chiefly dark or almost black shales, but containing alternations of heavy lenticular masses of mortar rocks (indurated mixture of calc. mud and siliceous fragments of variable sizes and wear), cgls., dark lss., and mixtures of these materials. Thickness 1,000 ft. Fossiliferous. Basal fm. of Chinati series. Underlies Alta beds and overlies granite.

P. B. and R. E. King, 1929 (A. A. P. G. Bull., vol. 13, p. 908). Cieneguita and Alta beds, of Shafter region, formerly classed as Penn., have been proved to be of Leonard (Perm.) age.

Named for Cieneguita ranch, Presidio Co.

Cierbo sandstone. (In San Pablo group.)

Miocene (upper): Western California (Mount Diablo region).

B. L. Clark, 1921 (Jour. Geol., vol. 29, pp. 586–614). *Cierbo group.*—The use of *San Pablo* for upper Mio. series of deposits on West Coast makes it necessary to dispense with the use of that name for a part of the group. The name *Cierbo* is therefore used in this paper in referring to middle group of San Pablo series. Type section of the Cierbo is in S. side of Canada del Cierbo near Carquinez Straits. These marine beds are recognized only in general region of San Francisco Bay, where they lie discon. below Santa Margarita group and rest discon. on Briones group.

B. L. Clark and A. O. Woodford, 1927. (See 1927 entry under *San Pablo group.*)

B. L. Clark, 1930 (Geol. Soc. Am. Bull., vol. 41, pp. 751–770), included *Cierbo fm.* in San Pablo group, as explained under *San Pablo group*. This is present accepted definition of U. S. Geol. Survey.

Cimarron group.

Permian: Central southern Kansas.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, pp. 3, 18–48). *Cimarron series*—Upper part (1,100 to 1,250 ft. of prevailingly red unfossiliferous rocks) of Perm. of Kans. Overlies, probably uncon., the Big Blue or ls.-bearing series of Perm. and uncon. underlies Cret. deposits. Divided into ten fms. (descending): Big Basin ss., Hackberry shales, Day Creek dol., Red Bluff sss., Dog Creek shales, Cave Creek gypsums, Flower-pot shales, Cedar Hills sss., Salt Plain measures, and Harper sss.

Named for Cimarron River, Kans.

†Cimarron formation.

A term applied by C. R. Keyes (Am. Jour. Sci., 4th, vol. 18, pp. 360–362, 1904) to 1,000 ft. of sss. and sh. of N. Mex. uncon. underlying Comanche deposits, overlying the Carbf., and assigned by him to Triassic. In a later publication (Am. Jour. Sci., 4th, vol. 20, p. 425, 1905) he assigned these rocks to Perm.

Cimarron Creek latite.

Tertiary (Miocene or Pliocene): Southwestern Colorado (Ouray region).

W. Cross and E. Howe, 1907 (U. S. G. S. Ouray folio, No. 153). *Cimarron Creek latite.*—Quartz pyroxene latite. Intrusive into Potosi volcanic series. Especially common in drainage of Cimarron Creek in Ouray and Lake City quads.

Cimarronian series.

A term introduced by C. R. Keyes (Iowa Acad. Sci. Proc., vol. 16, pp. 159–163, 1909) for the post-Guadalupian Carbf. rocks of Rio Grande Valley, which he divided into (descending) Moencopie shales, unnamed sss., and Pecos shales. He also applied the name to supposedly equiv. deposits in other States, for example, to the Perm. (?) gyp. in Iowa that has been called "Fort Dodge gyp."

†Cincinnati group.

Originally proposed for the rocks now called *Cincinnatian series.* For definition see U. S. G. S. Bull. 769, p. 85.

†Cincinnati shale.

A name applied in early repts to Maquoketa sh. of Miss. Valley.

†Cincinnati limestone.

Upper Ordovician: Southwestern Ohio.

W. W. Mather, 1859 (Rept. State House Artesian Well at Columbus, Ohio, p. 6), applied incidentally, in one place, the term "Cincinnati ls." to the blue Ord. lss. [Cincinnatian series] of Cincinnati.

†Cincinnati beds proper.

Upper and Middle Ordovician: Southwestern Ohio and north-central Kentucky.

E. Orton, 1873 (Ohio Geol. Surv. vol. 1, pp. 370–387). *Cincinnati beds proper.*—Alternating beds of blue ls. and sh. 425 ft. thick, forming middle part of Cincinnati group, having for their inferior limit low water of the Ohio, and for an upper bdy the highest stratum found in Cincinnati hills. Divided into Hill Quarry beds (at top), Eden sh. (in middle), and River Quarry beds (at base). Overlain by Lebanon beds and underlain by Point Pleasant beds.

Includes Maysville and Eden groups.

Named because they compose all of †Cincinnati group visible at Cincinnati, Ohio.

Cincinnatian series (or **epoch**).

A provincial series of Upper Ord. rocks in the Eastern States, and the time covered by their formation. Includes Utica to Richmond, both inclusive, as defined by U. S. Geol. Survey and geologists generally, but some geologists exclude the Richmond. For definition see U. S. G. S. Bull. 769, pp. 85–86.

Cincinnatic system.

C. Schuchert and W. H. Twenhofel, 1910 (Geol. Soc. Am. Bull., vol. 21, p. 694). [Essentially same as Cincinnatian series of U. S. Geol. Survey.]

Cincinnatus sandstone.

Upper Devonian: Central New York.

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, p. 24 and chart). In typical section in Cortland Co. the Ithaca beds are divided into (descending): *Cincinnatus flags,* Otselic sands and shales, and Sherburne ss. [On chart Cincinnatus *ss.* is used.]

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 82 and chart). *Cincinnatus flags* (from Cincinnatus Twp, Cortland Co.) is applied to the later beds of the Ithaca specially characterized by *Spirifer mesastrialis.* Typical exposures are along Otselic River.

G. H. Chadwick, 1935 (Am. Mid. Nat., vol. 16, No. 6, p. 858). Oneonta red beds is=Cincinnatus ss. and probably underlying Otselic also.

Cinnamon.

Little Cinnamon of drillers of eastern Ohio has been identified as Sunbury sh., but W. Stout et al., 1935 (Geol. of nat. gas, A. A. P. G., p. 905), state it is now identified as Huron sh., and that the *Big Cinnamon* of the drillers is Cleveland sh.

Cinnemousun limestone.

Pre-Cambrian: British Columbia.

R. A. Daly, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 167).

Cinquefoil limestone.

Upper Devonian: Alberta (Interlaken to the Palisade).

P. E. Raymond, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 298, 300). *Cinquefoil ls.*—The western wholly calc. facies of upper part of Upper Dev. Thickness 2,500 ft. Well exposed on Cinquefoil Mtn. Corresponds to Upper Dev. Boule, Coronach, Fiddle, and Kiln fms. of area to E.

Cintura formation.

Lower Cretaceous (Comanche series): Southeastern Arizona (Bisbee region).

F. L. Ransome, 1904 (U. S. G. S. P. P. 21, pp. 56, 68). *Cintura fm.*—Strongly resembles underlying Morita fm., from which it is separated by Mural ls. Consists of (descending): (1) 600 ft. of reddish nodular sh. interbedded with flaggy cross-bedded sss., one of latter (about 200 ft. below present top of fm.) being of pale cream color; (2) 300 ft. of flaggy cross-bedded gray and buff sss. with occasional layers of red sh.; (3) 700 to 800 ft. of red nodular sh. with occasional beds (some 6 ft. thick) of buff ss., and very subordinate beds or lenses of impure, greenish nodular ls.; (4) 100 to 150 ft. of red sh., thin-bedded sss., and aren. gray or greenish lss., some of latter fossiliferous; and (5) 10 to 15 ft. of buff qtzite. Total thickness at least 1,800 ft. Rests conformably on Mural ls. Uncon. overlain by Quat. deposits. Is top fm. of Bisbee group, of Comanche age. Named for Cintura Hill, near N. edge of Bisbee quad.

Cinturan series.

Name proposed by C. [R.] Keyes (Pan-Am. Geol., vol. 64, No. 2, 1935, pp. 125–140) to cover the deposits named *Cintura fm.* by F. L. Ransome. Keyes divides these deposits into (descending) Dixie sh., Mexican ss., and Forrest sh.

Circle erosion cycle.

Pleistocene: Central western Wyoming.

E. Blackwelder, 1915 (Jour. Geol., vol. 23, pp. 310, 316–340). Interglacial erosion cycle following Buffalo stage of glaciation and preceding Bull Lake stage of glaciation in central western Wyo. A fine remnant of a prominent terrace of this cycle stands out just E. of Circle post-office, on Wind River.

Circle volcanics.

Mississippian (early): Northeastern Alaska (Eagle-Circle district).

J. B. Mertie, Jr., 1930 (U. S. G. S. Bull. 816, p. 85). *Circle volcanics.*—Essentially basaltic lavas of greenstone habit, but includes some interbedded sediments, chiefly argillite and chert, with some tuffs and flow breccias. Named for exposures along E. bank of Yukon River for about 15 mi. upstream from Circle. Assigned to early Miss. on basis of strat. position and correlation.

Cisco formation (also **Cisco group**).

Pennsylvanian: Central northern and central Texas.

E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, p. lxvii). *Waldrip-Cisco series.*—Alternating clays, shales, fire clays, and lss., with coal seams, overlying Brownwood-Ranger series and underlying Coleman-Albany series.

W. F. Cummins, 1891 (Tex. Geol. Surv. 2d Ann. Rept., pp. 361–398). *Cisco div.*—Cgls., sss., lss., clays, and sandy shales, 840 ft. thick, overlying Canyon div. and underlying Albany div. [Wichita fm.].

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31, etc.; Univ. Tex. Bull. 2132), divided Cisco group into (descending) Putnam, Moran, Pueblo, Harpersville, Thrifty, and Graham fms. E. H. Sellards, 1933 (Univ. Tex. Bull. 3232), excluded Putnam and Moran fms. from Cisco group and included them in Wichita group (Perm.), and this is present classification of U. S. Geol. Survey.

Named for Cisco, Eastland Co.

Cisco Branch facies.

Name applied by P. B. Stockdale (Ind. Dept. Cons., Div. Geol. Pub. 98, pp. 76, 197, 210, etc., 1931) to a lithologic development of his Floyds Knob fm. in a part of southern Ind.

Citadel series.

Ordovician: Quebec.

R. W. Ells, 1890 (Geol. Soc. Am. Bull., vol. 1, p. 467). Included in Quebec group.

Citico conglomerate.

Lower Cambrian: Eastern Tennessee and western North Carolina.

A. Keith, 1895 (U. S. G. S. Knoxville folio, No. 16, p. 2). *Citico cgl.*—Entirely siliceous, varying from fine white ss. to coarse quartz cgl., with a few thin beds of sandy sl. Changes from fine to coarse sediment very sudden and accompanied by changes in thickness from 50 to 800 ft., the coarse beds being thickest. Total thickness of fm. 50 to 800 ft. Overlies Wilhite sl. and underlies Pigeon sl. [Foregoing is original definition of fm. The name, however, was incidentally used by C. D. Walcott in 1894 (Geol. Soc. Am. Bull., vol. 5, pp. 196, 197), as "siliceous Citico cgl. (Keith)," which caps Wilhite sl. in Tenn.]

Named for Citico Creek, Monroe Co., Tenn.

Citronelle formation.

Pliocene (upper, middle, and lower): Gulf Coastal Plain from western Florida and southern Georgia to eastern Texas, inclusive.

G. C. Matson, 1916 (U. S. G. S. P. P. 98L and 98M, pp. 167–197). The name *Citronelle fm.* is applied to sediments of Plio. age, chiefly nonmarine, that occur near seaward margin of Gulf Coastal Plain, extending from short distance E. of W. bdy of Fla. westward to Tex. [Described on other pages as yellow and red sands and clays, locally gray where unweathered, with much gravel near landward margin.] Citronelle, a town on Mobile & Ohio R. R., in N. part of Mobile Co., Ala., was chosen as type loc. because of excellent exposures of fm. in its vicinity, especially to N. along the railroad for 3 or 4 mi. The best collection of fossils was obtained from a clay bed a few mi. S. of type loc., near a station called Lamberts, where a flora sufficiently well preserved to permit correlation of the beds with the Plio. was found. The Citronelle fm. is=part of deposits formerly classified as "Drift," "Orange sand," and "Lafayette." The name can not be regarded as a synonym for any of the older terms because in all earlier descriptions the old names were made to include not only Citronelle fm., but overlying alluvial and colluvial sands and gravels and extensive areas of sand and gravel lying farther inland and belonging to a number of different terranes. In addition, the earlier application of the old names were such as to include beds of Pleist. age, forming a fringe btw. the Plio. beds and the coast and extending into the river valleys. It uncon. overlies Pascagoula clay and uncon. underlies Pleist. terrace deposits. Thickness 50 to 400 ft.

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept., pp. 180–181). No fossils from Citronelle fm. in Fla. Fossil plants from the fm. in Ala. are assigned by Berry to later half of Plio., but writers believe the fm. may represent all or any part of Plio.

F. B. Plummer, 1933 (Tex. Univ. Bull. 3232), applied *Citronelle group* to Plio. deposits of Tex. coastal plain, as explained under *Goliad sand.* In this group he included Goliad fm. and overlying "unnamed Pliocene? sand," and stated that it rested uncon. on Lagarto fm. (as restricted by him) and that it was overlain by Lissie fm. The U. S. Geol. Survey has not yet adopted this definition of *Citronelle.*

Named for exposures around Citronelle, Mobile Co., Ala.

City Bluffs shale. (In Shawnee formation.)

Pennsylvanian: Southwestern Iowa and northwestern Missouri.

G. L. Smith, 1909 (Iowa Geol. Surv. vol. 19, pp. 613, 615, 617, 622, 631). *City Bluffs shales.*—Gray and yellow shales, 210 ft. thick, with three thin beds of ls. Forms middle part of Atchison shales. Underlain by cap rock of Nodaway coal [on p. 628 Nodaway coal is included in City Bluffs shales] and overlain by Tarkio ls. Included in Missouri stage.

G. E. Condra and N. A. Bengston, 1915 (Nebr. Acad. Sci. Pub., vol. 9, No. 2), stated City Bluffs sh.=Scranton sh.

Named for City Bluffs (now known as Burlington Junction), Nodaway Co., Mo.

City Lake sandstone member (of Springer formation).

Pennsylvanian: Central southern Oklahoma (Carter County).

R. Roth, 1928 (Econ. Geol., vol. 23, p. 45). [See under *Overbrook ss. memb.* Derivation of name not stated.]

†City Ledge sandstone. (In Cuyahoga formation.)

Mississippian: Ohio and northeastern Kentucky.

E. B. Andrews, 1870 (Ohio Geol. Surv. Rept. Prog. 1869, pp. 66, 67, 68). *City Ledge.*—Famous stratum of ss., 3 ft. 5 in. to 4 ft. 6 in. thick, called "city ledge." Separated from Waverly black sl. below by 5 ft. 4 in. of clay and sh. Overlain by 5½ ft. of soft bluish sh. Quarried at Rockville and Buena Vista, Ohio.

Nongeographic name. The bed belongs in Buena Vista ss. memb. of Cuyahoga fm.

Claggett formation. (Of Montana group.)

Upper Cretaceous: Central northern, eastern, and central southern Montana and Elk Basin region of central northern Wyoming.

J. B. Hatcher and T. W. Stanton, 1903 (Sci., n. s., vol. 18, pp. 211–212). *Claggett fm.*—Marine shales and sss., 400 ft. thick, overlying Eagle fm. and underlying Judith River beds. Named for old Fort Claggett [now called Judith], at mouth of Judith River, in neighborhood of which the fm. is well developed.

T. W. Stanton and J. B. Hatcher, 1905 (U. S. G. S. Bull. 257, p. 13). The beds to which name *Claggett fm.* has been given lie above Eagle fm. and below Judith River beds. In neighborhood of Judith (old Fort Claggett), where they are well exposed, they have total thickness of 400± ft. and consist largely of dark clay shales with variable intercalated bands and beds of ss., especially in upper half. The dark shales of lower part of fm. contain many calc. concretions containing fossils [listed]. The yellowish ss. beds higher in fm., especially one 200± ft. from top and another near summit, are often locally very fossiliferous [fossils listed].

Claiborne group.

Eocene (middle): Gulf Coastal Plain from Georgia to southern Texas.

T. A. Conrad, 1847 (Phila. Acad. Nat. Sci. Proc., vol. 3, pp. 280–282). [Described 105 new fossil species from Eocene of vicinity of Vicksburg, Miss. Divided the Eocene into "Upper or Newer Eocene," and "Lower or Older Eocene," and stated that *Vicksburg group* belongs to former and *Claiborne sands* to latter. Neither Vicksburg group nor Claiborne sands was described.]

T. A. Conrad, 1856 (Phila. Acad. Nat. Sci. Proc., vol. 7, pp. 257–258). [See 1856 entry under *Vicksburg group.*]

E. W. Hilgard, 1860 (Rept. Geol. and Agric. Miss., pp. 108, 123–128), described *Claiborne group* as consisting of:

"*Calcareous Claiborne group* (marls and limestone, white, sometimes indurate, and blue).

Lignitic clays and sands of North Clarke County.

Siliceous Claiborne group (siliceous sandstones and claystones)."

E. W. Hilgard, 1867 (Am. Jour. Sci., 2d, vol. 43, p. 33). *Claiborne group proper.*—The blue marl and white marlstone which I designate "Calcareous Claiborne" group in my Rept are strictly=the typical fossiliferous sand at Claiborne with the underlying ls. bed. Underlies Jackson group and overlies Siliceous Claiborne or Buhrstone group. [This restricted definition of *Claiborne group* was used for many years.]

In 1894 (Am. Jour. Sci., 3d, vol. 47, pp. 303–304) G. D. Harris included the †Buhrstone (Tallahatta fm.) in his *Lower Claiborne stage*, but other writers continued for several years to exclude it from Claiborne group. In 1900 T. W. Vaughan (U. S. G. S. Mon. 39) included it in his *Claibornian stage*, but E. A. Smith of Ala. Geol. Survey, continued to exclude it. In 1920, however, J. E. Brantly (Ala. Geol. Surv. Bull. 22) included Tallahatta fm. in Claiborne group. The U. S. Geol. Survey has since 1906 included Tallahatta in Claiborne group. The Claiborne group as now understood is characterized by a distinctive fauna, is overlain by Jackson fm. and underlain by Wilcox group. It is chiefly of marine origin and in Miss. is divided into following fms. (descending):

Yegua (†Cockfield) fm.=Gosport sand of Ala. and includes †Claiborne sand and †*Ostrea sellaeformis* beds of earlier repts.

Lisbon fm. (type in Ala). } =St. Maurice fm. of La.
Tallahatta fm. (†Buhrstone); (type in Ala.). }

In Tex. it is divided into (descending) Yegua, Cook Mtn, and Mount Selman fms. and Carrizo sand.

Named for exposures at Claiborne Bluff and Claiborne Landing, on Alabama River, Monroe Co., Ala. (The Tallahatta fm. is not there exposed, but is exposed a few mi. up the river.)

†Claiborne sand. (In Claiborne group.)

Eocene (middle): Southern Alabama and Mississippi.

T. A. Conrad, 1847 (Phila. Acad. Nat. Sci. Proc., vol. 3, pp. 280–281), described new fossils from Vicksburg group, divided the Eocene into *Upper or Newer Eocene* and *Lower or Older Eocene,* and stated that *Vicksburg group* belongs to former and *Claiborne sands* to latter. Neither Vicksburg group nor Claiborne sands is described, but Conrad stated he refers to the sand at Claiborne, Ala.; also that his "Lower or Older Eocene" is characterized by *Ostrea sellaeformis,* which occurs abundantly beneath the fossiliferous sands at Claiborne.

In 1887 (U. S. G. S. Bull. 43, pp. 29–30) E. A. Smith and L. C. Johnson published a detailed section of Claiborne bluff, in which *Claiborne sand* is defined as consisting of 15 to 17 ft. of ferruginous sand, holding vast numbers of comminuted as well as well-preserved shells, with thin bands of lignite near center and laminated gray clays with leaf impressions forming upper part along the ferry road. Their section shows it resting on †Ostrea sellaeformis beds and underlying 6 ft. of coarse ferruginous sand, with glauconite, fossiliferous, passing below into more calc. material, which is indurated and projects from the face of the bluff.

Is a bed in upper part of Gosport sand, top fm. of Claiborne group in Ala. and in upper part of Yegua fm. of Miss. The use of Claiborne in this narrow sense has been abandoned for the name in the broader or group sense.

Named for exposures at Claiborne Bluff, on Alabama River, in Monroe Co., Ala.

Claibornian.

Time term used by some authors to cover the interval of Claiborne group (middle Eocene).

Clallam formation.

Miocene and Oligocene: Northwestern Washington.

R. Arnold, 1906 (Geol. Soc. Am. Bull., vol. 17, pp. 451–468, map). *Clallam fm.*—Cgl. and breccia alternating with ss. and sh., also much clayey sh. and coal. Thickness 15,000 ft. Uncon. underlies Quinaielt fm. and uncon. overlies Crescent fm. Upper part Mio. and lower part Olig. Well exposed in region btw. Clallam Bay and Pillar Point.

C. E. Weaver, 1916 (Wash. Geol. Surv. Bull. 13, p. 202, map), restricted Clallam fm. to the Olig. marine deposits, and stated there is probably an uncon. btw. the Mio. (*Arca montereyensis* zone) and Olig. parts of the fm. as previously defined. "Lower two-thirds of area mapped as *Clallam* is of Olig. age."

L. G. Hertlein and C. H. Crickmay, 1925 (Am. Phil. Soc. Proc., vol. 64, No. 2, pp. 245, 261–264). If name *Clallam* is to be used it should be restricted to the Mio.

beds, as its founder (Arnold) in 1913 limited it to the beds of Monterey-Temblor age in the NW. Arnold and Hannibal considered Clallam to be=Monterey-Temblor fm. of Calif. It seems advisable to retain name *Clallam fm.* at present. Weaver's so-called Clallam fm. appears to be identical with Astoria series as used by Arnold and Hannibal.

Clam Bank series.

Lower Devonian: Newfoundland.

C. Schuchert and C. O. Dunbar, 1934 (Geol. Soc. Am. Mem. 1, p. 104).

Clansayes beds.

Cretaceous: Mexico.

E. Böse and O. A. Cavins, 1927 (Univ. Tex. Bull. 2748, p. 85).

Claremont shale. (In Monterey group.)

Miocene (middle): Western California (San Francisco region).

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). *Claremont sh.*—Bituminous sh. In Sobrante anticline it is in part soft and distinctly shaly or chalky and in places contains a large admixture of fine detrital material, but in Berkeley Hills it is notably cherty, consisting of beds of hard flinty chert alternating at regular intervals with partings of sh. Thickness 250 to 1,000 ft. A fm. of Monterey group. Underlies Oursan ss. and overlies Sobrante ss. Named for exposures on Claremont Creek, Concord quad.

†Claremore formation.

Pennsylvanian: Northeastern and central eastern Oklahoma.

C. N. Gould, D. W. Ohern, and L. L. Hutchison, 1910 (Okla. State Univ. Research Bull. 3, pp. 6, 7, 10). *Claremore fm.*—Approx.=Fort Scott. ls. of Kans., which is correlated with Calvin ss. of Coalgate folio. Includes three lss. and two sh. beds, the lower ls. coming in below Fort Scott ls. of Kans., which consists of two ls. beds and one sh. bed. Basal fm. of Tulsa group.

D. W. Ohern, 1910 (Okla. State Univ. Research Bull. 4, p. 15). *Claremore fm.*—Shales and lss., one prominent ss., and 2 or more coals. Thickness 50 to 135 ft. Underlies Labette sh. and overlies Vinita fm. Includes Fort Scott ls. and uppermost part of Cherokee sh. Named for Claremore, Rogers Co.

Clarendon beds.

Pliocene: Panhandle of Texas.

J. W. Gidley, 1903 (Am. Mus. Nat. Hist. Bull., vol. 19, pp. 632–635). *Clarendon beds.*—Local name proposed for deposits heretofore called Loup Fork in this region. Chiefly cross-bedded sands and sss. intermixed and cross-bedded with yellow and bluish sandy clays. Thickness 400 ft. Upper Mio. fossils. Beds identical with Goodnight (Paloduro) beds, which name as a distinct horizon should be abandoned.

H. F. Osborn, 1918 (Am. Mus. Nat. Hist. Mem, n. s., vol. 2, pt. 1, pp. 25, 26). *Clarendon beds* are Upper Mio. or Lower Plio.

H. F. Osborn, 1918 (Geol. Soc. Am. Bull., vol. 32, p. 330), cited a sub-family of mastodon as appearing in "the Lower Pliocene of the Clarendon beds of Tex."

G. G. Simpson, 1933 (Am. Mus. Nat. Hist. Bull., vol. 67, p. 98). Clarendon and Goodnight-Hemphill are both distinctly older than Blanco.

There seems to now be unanimity of opinion that there is no Mio. in this part of Tex. All of these beds are mapped as *Ogallala fm.* (*Plio.*) on 1937 geol. map of Tex.

Named for Clarendon, Donley Co.

Clarendon gravel.

Pleistocene: Northwestern Pennsylvania (Warren County).

E. H. Williams, Jr., 1920 (Am. Phil. Soc. Proc., vol. 59, pp. 62, 73). The following glacial outwashes were dropped during the discharge of Conewango Ponding at Barnes [Warren Co.]: (1) *Clarendon gravels* (coarse gravel with interbedded quicksand); (2) *Upper Indian Hollow sands*, which underlie Clarendon gravels; (3) *Lower Indian Hollow sands*, 0 to 125 ft. thick, along the Conewango, which rest in the (4) blued sticky *Conewango clay* (sometimes over 200 ft. thick, and carrying wood fragments and logs). All referred to Kansan stage.

Named for Clarendon, Warren Co.

Clarendon sand.

Drillers' term. Western Pa. Of Chemung age. Younger than Cherry Grove sand. Lies 125 to 175 ft. higher than Clarendon gas sand, according to J. F. Carll, 2d Pa. Geol. Surv. Rept. I_4, 1883. Named for Clarendon, Warren Co., Pa.

Clarendon Springs dolomite.

Lower (?) Cambrian: Southwestern Vermont (Rutland County).

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 397). *Clarendon Springs dol.*—Fine-grained dol. of light gray or dove color. Differs from the older Wallingford dol. mainly by absence of ss. and qtzite. Grades up into Shelburne marble, without interbedding or other notable features. Thickness 100 to 200 ft. Type loc., Clarendon Springs [Castleton quad.]. Correlates with Milton dol. (*Lower Camb.*), which underlies St. Albans sl.

C. Schuchert, 1933 (Am. Jour. Sci., 5th, vol. 25, pp. 353–381), stated that the fm. that underlies St. Albans sl. is not true Milton dol., which is Upper Camb., but a local basal cgl., 0 to 20 ft. thick, which he named *Rugg Brook dol. cgl.* and assigned to Middle Camb. Keith correlated his Clarendon Springs dol. with so-called Milton dol. (Rugg Brook cgl. of Schuchert). If this correlation is correct the nonfossiliferous Rugg Brook of Schuchert may be Lower Camb., or the unfossiliferous Clarendon Springs dol. may be Middle Camb.

Clarenville series.

Lower Ordovician: Newfoundland.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4). *Clarenville series.*—Basal part of Lower Ord. Discon. overlain by Bell Island series and underlain by Upper Camb. Divided into (descending) Riders Brook, Maidment, Apsey, and Brown Mead fms. Correlated with Tremadoc of Europe. [Derivation of name not stated.]

Clarion coal group. (In Allegheny formation.)

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

H. D. Rogers, 1858 (Geol. Pa., vol. 2, pt. 1, pp. 474–477). *Clarion group,* 100 to 200 ft. thick. Underlies Freeport or contorted ss. and overlies Tionesta ss. Includes Kittanning coal (75 ft. below top), Ferriferous ls., Clarion coal, and Brookville coal (0 to 15 ft. above base).

J. P. Lesley, 1877 (2d Pa. Geol. Surv. Rept. H_3, p. xxiii). Lower Productive Coal Measures [Allegheny fm.] divided into (descending) Freeport coal group, Kittanning coal group, and *Clarion coal group.*

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q). *Clarion group* extends from top of Buhrstone iron ore that overlies Ferriferous (Vanport) ls. to base of fire clay that underlies Brookville coal.

G. H. Ashley, 1926 (Pa. Topog. and Geol. Atlas No. 65, Punxsutawney quad., pl. 4, p. 29). *Clarion fm.* extends from top of Vanport ls. to top of Homewood fm.

Clarion coal group is treated by U. S. Geol. Survey as an economic memb. in lower part of Allegheny fm., extending from top of Vanport ls. memb. to top of Pottsville fm., of which Homewood ss. is top memb.

Clarion sandstone member (of Allegheny formation).

Pennsylvanian: Western Pennsylvania and Maryland and eastern Ohio.

J. J. Stevenson, 1878 (2d Pa. Geol. Surv. Rept. K_3). *Clarion ss.,* 35 ft. thick, lies 10 ft. below Clarion coal and 30 ft. above Brookville coal in Fayette and Westmoreland Counties.

H. M. Chance, 1884 (2d Pa. Geol. Surv. Rept. H_7, p. 26). In some localities (in Clearfield Co.) the whole interval from Kittanning Lower coal down to Brookville coal is occupied by *Clarion ss.* This ss. singularly resembles Homewood ss., being often massive and conglomeratic and in some places a true cgl., but it is more commonly a rather friable yellowish ss.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, pl. 6), applied *Clarion ss.* to a ss. *overlying* the Clarion coal in Pa., W. Va., and Md., and did not apply any name to the ss. beneath the Clarion coal.

Clarion clay. (In Allegheny formation.)

Pennsylvanian: Western Pennsylvania.

W. G. Platt, 1880 (2d Pa. Geol. Surv. Rept. H_5). *Clarion fire clay*, 2 to 7 ft. thick, underlies Clarion coal and overlies Clarion ss. in Armstrong Co.

Clarion formation.

See under *Clarion coal group*, G. H. Ashley, 1926.

Clark formation.

Pennsylvanian: Southern West Virginia and southwestern Virginia.

M. R. Campbell, 1896 (U. S. G. S. Pocahontas folio, No. 26, p. 3). *Clark fm.*—Alternating sss., shales, and coals, with heavy ss. at bottom and top. Limited below by top of Pocahontas (No. 3) coal and above by base of Quinnimont coal. Thickness 430 to 440 ft.

Overlies Pocahontas fm. and underlies Quinnimont sh.

Named for Clark Gap, in Flat Top Mtn, Mercer Co., W. Va.

†Clark County littorals.

Upper Cretaceous (Gulf series): Southwestern Arkansas.

R. T. Hill, 1888 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 2, pp. 79–83). The deposits spoken of here as "*Clark County littorals*," namely, "the second blue dirt," "Koster joint clays," and "Big De Gray beds," are purely local, and have therefore been given no place in synoptical table of widespread fms. of SW. Ark. Are probably littoral or near shore beds deposited at time when Big Deciper fm., High Bluff blue sands, Washington or High Bluff greensands, Marlbrook-Columbus chalk marls, Brownstown marls, and White Cliffs chalk were being deposited in deeper waters.

Now differentiated into several fms. Probably include Nacatoch sand, Saratoga chalk, Marlbrook marl restricted and Annona chalk.

Named for exposures in Clark Co.

Clarke interglacial.

Pleistocene: Ontario.

A. P. Coleman, 1909 (Ontario Bur. Mines Ann. Rept., vol. 18, pt. 1, p. 297).

Clarke oil zone.

Subsurface beds, of Plio. age, encountered in wells in Santa Fe oil field, Los Angeles Co., Calif., that lie lower than O'Connell oil zone and higher than Hathaway zone.

†Clark Fork beds.

Eocene (basal): North-central Wyoming (Bighorn Basin region).

W. Granger, 1914 (Am. Mus. Nat. Hist. Bull., vol. 33, p. 204). *Clark Fork beds.*—Low-lying gray shales, sparingly fossiliferous and 500 ft. thick, occurring at SW. base of McCulloch Peak and in vicinity of low divide btw. Clark Fork and Bighorn basins N. of Ralston. Underlie Sand Coulee beds (lower Eo.), perhaps with angular uncon., and rest on beds of undet. age, perhaps Fort Union, or perhaps Cret. Perhaps belong to Paleocene series. Named for Clark Fork basin.

According to H. F. Osborn (U. S. G. S. Mon. 55, 1929) these beds are a mammal faunal zone in basal part of Wasatch fm.

Clark Peak schist.

Paleozoic and infolded Triassic(?): Southeastern Alaska (Juneau region).

G. C. Martin, 1926 (U. S. G. S. Bull. 776, pp. 93, 94, 247). *Clark Peak schist.*—Schistose rocks derived from sl., ss., ls., and cgl. Oldest fm. exposed in Juneau dist. Underlies Perseverance sl. (Triassic or older). Writer believes it is Paleozoic, but may include some infolded Triassic beds.

Named for Clark Peak, Juneau dist.

Clark Reservation limestone.

Silurian(?): Central New York (Onondaga County).

B. Smith, 1929 (N. Y. State Mus. Bull. 281, pp. 26, 27, 30–35). *Clark Reservation ls.*—Compact blue ls., usually sharply separated from overlying Jamesville ls. and underlying Elmwood beds, all included in Manlius group. Undoubtedly included in Vanuxem's Manlius. Some authors have included this ls. and overlying Jamesville ls. in Helderbergian. Thickness 0 to 3 ft. 8 in. Named for Clark Reservation State Park, slightly over 1 mi. W. of Jamesville. Type section, in cliff S. of the lake which is included in the park.

B. Smith, 1935 (N. Y. State Mus. Bull. 300, p. 18). [See 1935 entry under *Manlius ls.*]

Clarksburg limestone member (of Conemaugh formation).

Pennsylvanian: Southwestern Pennsylvania, western Maryland, West Virginia, and eastern Ohio.

I. C. White, 1891 (U. S. G. S. Bull. 65, p. 88). *Clarksburg ls.*—Upper part rather slaty; beneath this the layers are very compact and come out in rhomboidal blocks; some layers are very ferruginous. Thickness 20 to 30 ft. Directly underlies Little Clarksburg coal and is separated from underlying Morgantown ss. by 25 to 40 ft. of soft shales. Finely exposed in vicinity of Clarksburg [Harrison Co., W. Va.], along bed of Elk and the West Fork River.

See also *Little Clarksburg ls.*

Clarksburg volcanics.

Pre-Cambrian (upper Huronian): Northwestern Michigan (Marquette district).

C. R. Van Hise and W. S. Bayley, 1895 (U. S. G. S. 15th Ann. Rept., p. 604). *Clarksburg fm.*—Greenstones and volcanic cgls. Replaces upper part of Ishpeming fm. and lower part of Michigamme fm. in part of Marquette dist. Extends E. and W. from Clarksburg.

W. S. Bayley, 1897 (U. S. G. S. Mon. 28, pp. 461, 484). *Clarksburg fm.* is a set of interbedded tuffs, lavas, sedimentary and volcanic cgls. and breccias and other sediments, cut through and through by dikes and bosses of altered diabase or basalt. Contemp. with closing stages of Ishpeming time and opening stages of Michigamme time. Overlies Goodrich qtzite. In places rests on Negaunee fm. Is overlain by sl. of Michigamme fm.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184). *Clarksburg volcanics* (upper Huronian) underlie Michigamme sl. and overlie Greenwood iron-fm., which rests on Goodrich qtzite. [The Greenwood iron-fm. appears to have been included in Goodrich qtzite or Clarksburg volcanics of previous repts.]

Clarksburg red shale. (In Conemaugh formation.)

Pennsylvanian: West Virginia and southwestern Pennsylvania.

R. V. Hennen, 1912 (W. Va. Geol. Surv. Rept. Doddridge and Harrison Counties, p. 240). *Clarksburg red sh.*—Red and variegated sh. 25 to 40 ft. thick. Underlies Clarksburg ls. and overlies Morgantown ss. [Named for Clarksburg, Harrison Co.]

Clarksburg fire clay shale. (In Conemaugh formation.)

Pennsylvanian: Northern West Virginia.

R. V. Hennen, 1912 (W. Va. Geol. Surv. Rept. Doddridge and Harrison Counties, p. 236). *Clarksburg fire clay sh.*—Fairly pure fire clay sh., 0 to 5 ft. thick, underlying Little Clarksburg coal and overlying Clarksburg ls. Named because of its association with Little Clarksburg coal.

Clark's Mill beds.

Lower Devonian: Central Pennsylvania (Perry County).

E. W. Claypole, 1885 (2d Pa. Geol. Surv. Rept. F_2, pp. 59–62, 181–184). ***Clark's Mill beds.***—Thin-bedded lss. and calc. shales, 100 to 150 ft. thick. Exposed at Clark's Mill, Centre Twp, Perry Co. Divided into 9 fossiliferous zones. Rests on Lewistown (Bossardville) ls. Overlain by 8 ft. of black cherty ls. Included in Lower Helderberg.

†Clarksville.

Upper Cretaceous: Southern Arkansas and northeastern Texas. See *†sub-Clarksville sand.*

Clarksville division. (In Richmond group.)

Upper Ordovician: Southwestern Ohio and north-central Kentucky.

A. F. Foerste, 1909 (Denison Univ. Sci. Lab. Bull. 14, p. 292). ***Clarksville div.***—Includes all of Waynesville bed of Richmond fm. btw. base of *Orthoceras fosteri* horizon below and base of lower *Hebertella insculpta* layer above. Is overlain by Blanchester div. and underlain by Fort Ancient div.

Named for Clarksville, Clinton Co., Ohio.

Clarksville oil sand.

Name applied in some early repts to sand lying about 75 ft. below Richburg or Allegany oil sand in Allegany Co., N. Y. According to C. R. Fettke (Geol. Soc. Am. Bull., vol. 44, No. 3, p. 626, 1933) this sand is 6 ft. thick, of Chemung age, and occupies interval btw. 1,268 and 1,274 ft. in Gilbert No. 1 well, on Gilbert farm, 2 mi. N. of Richburg, Allegany Co., N. Y.

Clarno formation.

Oligocene (lower) and Eocene (upper): Central northern Oregon (John Day Basin).

J. C. Merriam, 1901 (Geol. Soc. Am. Bull., vol. 12, pp. 496–497, and Univ. Calif. Pub., Bull. Dept. Geol., vol. 2, No. 9, p. 285). *Clarno fm.*—Made up entirely of tuffs, ashes, and andesitic and rhyolitic lavas. Thickness 400+ ft. Many fossil plants. Presumably Eo. The beds at Bridge Creek are considered to be upper Eo.; those on Cherry Creek are held to be earlier. Typically exposed at Clarnos ferry, on the John Day, E. of Antelope. Underlies (probably uncon.) John Day fm. and overlies Chico fm. (Upper Cret.).

F. H. Knowlton, 1902 (U. S. G. S. Bull. 204, p. 113), assigned flora from beds at Bridge Creek (upper Clarno) to upper Eo., and flora from Cherry Creek (lower Clarno) to lower Eo.

J. C. Merriam and W. J. Sinclair, 1907 (Univ. Calif. Pub., Bull. Dept. Geol., vol. 5, No. 11, p. 173). *Clarno fm.* has yielded an abundant flora but no vertebrates. The upper beds are upper Eo. and the lower Clarno is lower Eo.

W. D. Smith and E. L. Packard, 1919 (Univ. Oreg. Bull., vol. 16, No. 7, p. 105, and Jour. Geol., vol. 27, p. 105), assigned Clarno fm. to lower Eo.; M. R. Thorpe, 1921 (Am. Jour. Sci., 5th, vol. 1, pp. 217–219), assigned it to upper Eo.; R. W. Chaney, 1922 (Am. Jour. Sci., 5th, vol. 4, p. 220) assigned upper part of Clarno to Olig.; W. D. Smith, 1924 (Commonwealth Review Univ. Oreg., vol. 6, No. 4, p. 74) assigned it to lower Eo.; J. P. Buwalda, 1927 (Geol. Soc. Am. Bull., vol. 38, p. 155), and 1928 (Geol. Soc. Am. Bull., vol. 39, p. 270), stated that Clarno is probably Olig.

F. H. Knowlton, 1926 (U. S. G. S. P. P. 140, p. 23), after comparing flora from Bridge Creek (upper Clarno) with Latah and other floras, stated that flora from Bridge Creek is probably lower Mio.; and E. W. Berry also considered that this flora "might be as young as Mio."

R. W. Chaney, 1927 (Carnegie Inst. Wash. Pub. 346). Knowlton has referred lower Clarno flora of John Day Basin to Lower Eo., on basis of occurrence of a considerable number of Fort Union sp. Writer is not prepared to question seriously this reference, but wishes to point out several reasons for supposing that this flora may be as young as Lower Olig. The so-called upper Clarno, which includes *Bridge Creek leaf shales* of John Day Basin, and which is also represented in Crooked River Basin, is here referred to lower div. of John Day series (Olig.).

R. W. Chaney, 1927 (Carnegie Inst. Wash. Pub. 349, pp. 1–22), included his *Bridge Creek shales* in John Day fm. (See under *Bridge Creek shales.*)

R. W. Chaney, 1932 (16th Int. Geol. Cong. Guidebook 21, p. 4), assigned Clarno fm. (probably exclusive of the beds on Bridge Creek) to upper or middle Eo.

The U. S. Geol. Survey now assigns Clarno fm. as originally defined to lower Olig. and upper Eo. R. W. Brown classifies the flora from Bridge Creek as lower Mio.

Claron limestone.

Eocene: Southwestern Utah (Iron Springs region).

C. K. Leith and E. C. Harder, 1908 (U. S. G. S. Bull. 338, p. 41). *Claron ls.*—Includes some ss. and cgl. Thickness 800 ft. Overlies (uncon.) Pinto ss. (Cret.) and underlies late Mio. igneous rocks. Occurs at and around Mount Claron.

Corresponds to Wasatch fm.

Clarysville sandstone. (In Conemaugh formation.)

Pennsylvanian: Western Maryland (Allegany and Garrett Counties) and northeastern West Virginia.

C. K. Swartz, W. A. Price, and H. Bassler, 1919 (Geol. Soc. Am. Bull., vol. 30, p. 573). *Clarysville ss.*—Underlies Lower Hoffman coal and overlies Clarksburg ls.; all included in Conemaugh fm.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, p. 67, pl. 6). *Clarysville ss.*—Thick ss., usually thin-bedded and somewhat argill. Locally replaced by sh. Exposed above the Clarysville coals in Hoffman Drainage Tunnel at Clarysville, Allegany Co.

Clay Creek limestone. (In Kanwaka shale.)

Pennsylvanian: Eastern Kansas and southeastern Nebraska.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 94, 96). A very persistent ls. in upper Kanwaka sh. is named *Clay Creek ls.* and the portions of the Kanwaka above and below are given the names *Stull sh.* and *Jackson Park sh.*, respectively. [On p. 52 *Clay Creek ls.* is described as consisting of 2 ft. of hard bluish ls. that weathers brown; shelly. Derivation of name not stated.]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 171), more fully described this ls. and gave type loc. as Clay Creek, about 1 mi. W. of Atchison, Kans.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Claypool formation.

Pennsylvanian: Central southern Oklahoma (Jefferson County).

J. R. Bunn, 1930 (Okla. Geol. Surv. Bull. 40PP, pp. 9+). *Claypool fm.*—Predominantly sh. and sandy sh. (of brown, gray, and yellow colors, chiefly brown with irregular gray and blue mottling), with one or more uniform ss. members. The sss. are thin bedded, gray to buff in color, soft and friable. Is quite different in lithologic appearance from overlying Addington fm. (Perm.), with which it may not be entirely conformable. Thickness several hundred ft. Covers large area to S. and E. of Claypool, Jefferson Co. Overlies Asphaltum ss. Is top fm. of Penn. in Jefferson Co.

Claypool sand.

A subsurface sand in Carbondale fm. (Penn.) of Clark Co., Ill. (See Ill. Geol. Surv. Bull. 54, index.)

Clay Spur bentonite bed. (In Mowry siliceous shale member.)

Upper Cretaceous: Northeastern Wyoming and southeastern Montana.

W. W. Rubey, 1930 (U. S. G. S. P. P. 165, p. 4). *Clay Spur bentonite bed,* 1 to 4 ft. thick, lies at top of Mowry siliceous sh. memb. of Graneros sh. over entire area discussed [in NE. Wyo. and SE. Mont.]. Named for exposures near Clay Spur, sec. 30, T. 47 N., R. 63 W., Weston Co., Wyo.

Claysville limestone member (of Greene formation).

Permian: Western Pennsylvania (Washington County).

W. T. Griswold and M. J. Munn, 1907 (U. S. G. S. Bull. 318, p. 78). From 205 to 225 ft. above base of Greene fm. in S. and W. parts of Claysville quad., is a ls.

separated into 2 layers by 6 to 8 ft. of yellow sh. Top layer is 6 to 8 inches thick, bluish white, and dark brown on fresh fracture. Bottom layer (in places 18" thick) is dark gray on fresh fracture and weathers with rough surface to reddish or yellow. In N. part of East and West Finley and Morris Twps the ls. is a rather compact bed, 6 to 8 ft. thick, the top layers being heaviest and all of dark-gray color. Can not be correlated with any bed previously named and is among most prominent lss. in Greene fm. Is therefore named *Claysville ls.*, from town in Donegal Twp, Washington Co.

Clayton formation. (In Midway group.)

Eocene (lower): Southern Alabama, southwestern Georgia, northeastern Mississippi, southern Tennessee, and southeastern Missouri.

D. W. Langdon, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 589–605). *Midway or Clayton group.*—Consists of (descending): (1) 200 ft. of white calc. sand containing few casts of *Ostrea*(?); sometimes irregularly indurated; in upper 10 ft. pockets of white sand enclosed in black clay; (2) light-yellow siliceous ls., large *Ostrea* and many obscure casts, 10 ft.; (3) massive coarse-grained ss., almost a cgl., 8 ft. Underlies Black Bluff group [Sucarnoochee (Porters Creek) clay] and overlies Ripley group.

Is now treated as basal fm. of Midway group, the foregoing narrow use of *Midway* having been discontinued. (See under *Midway group, broad sense*, and under *†Midway series, narrow sense.*) It is a marine deposit. Named for exposures near Clayton, Barbour Co., Ala.

Clayton sandstone. (In Bluefield formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Giles County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 298, 383). *Clayton ss.*—Usually reddish brown, fine-grained, smooth-textured, medium hard, thick-bedded. Thickness 20 to 40 ft. Underlies Coney sh. and overlies Clayton sh.; all members of Bluefield group [fm.]. Type loc. on waters of Griffith Creek, on road that descends into this valley 1.2 mi. NE. of Clayton, Summers Co. Also occurs in Mercer and Monroe Counties, W. Va., and in Giles Co., Va.

Clayton shale. (In Bluefield formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 298, 384). *Clayton sh.*—Red and variegated or greenish; streaks of ss. and marine fossils. Thickness 50 to 95 ft. Underlies Clayton ss. and overlies Graham ss.; all members of Bluefield group [fm.]. Type loc. same as Clayton ss.

Clayton clay.

Name applied by R. F. Flint (Geol. Soc. Am. Bull., vol. 44, No. 5, pp. 965–987, 1933) to a late Pleist. clay exposed at Clayton, Hartford Co., Conn.

†Clayton Peak quartz diorite.

A name that has been applied to the stock of diorite (of late Cret. or early Tert. age) in Park City and adjacent dists. of northern central Utah. (See S. F. Emmons, 1903, Am. Jour. Sci., 4th, vol. 16, pp. 141–147, and F. F. Hintze, Jr., 1913, N. Y. Acad. Sci. Annals, vol. 23, pp. 85–143.) As there is only one diorite in the dists., the U. S. Geol. Survey has not adopted a geographic name for the rock, but uses the term *Clayton Peak stock* for the structural feature which it forms.

Claytonville dolomite.

Permian: Central northern Texas (Nolan and Fisher Counties).

M. G. Cheney, 1929 (Univ. Tex. Bull. No. 2913, p. 26, pl. 1). *Claytonville dol.*—White to gray dol., 1 to 3 ft. thick. Usually underlain by red ss. and followed by red sh. and gyp. Caps escarpment 2 mi. W. of Sweetwater, Nolan Co., also at town of Claytonville, Fisher Co. The name *Sweetwater*, formerly used for this dol., is preoccupied. Lies near top of Double Mtn group.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 166). *Claytonville dol.* of Cheney lies 50± ft. below Quartermaster fm. in Fisher Co. It replaces "Sweetwater," preoccupied.

Claytonville gypsum. (In Double Mountain group.)

Permian: Central northern Texas (Fisher County).

H. T. Morley, 1929 (Tex. Bur. Econ. Geol., geol. map of Fisher Co.). *Claytonville gyp.* lies 325± ft. above Eskota dol. and 320± ft. below Sweetwater dol.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 167). *Claytonville dol.* (Cheney, 1929) replaced "Sweetwater dol.," which is preoccupied. *Claytonville gyp.* is therefore preoccupied and is discarded. It lies 300± ft. below Claytonville (Sweetwater) dol.

Clear Branch sandstone.

Lower Devonian: Northern central Alabama (Birmingham Valley).

C. Butts, 1927 (Am. Jour. Sci., 5th, vol. 14, pp. 366, 367; U. S. G. S. Bessemer-Vandiver folio, No. 221). *Clear Branch ss.*—Ss., containing fossils of Oriskany age, heretofore included in Frog Mtn ss. At Clear Branch Gap the fm. contains an Oriskany fauna, and consists of (descending): (1) A quartz lens, 4 inches thick, crowded with brachiopod shells stained with manganese oxide; (2) a 4-inch lens of black chert; and (3) 5 ft. of ss. with fine pebbles of quartz. It is there overlain by 1½ ft. of green sh. (Chattanooga? sh.) and underlain by beds that probably belong to Red Mtn fm. Believed to extend northward to Birmingham, but no fossils were found in the ss. of that area which occupies strat. position of Clear Branch ss. The 50 ft. of ss. in cuts of Alabama Great Southern R. R. a mi. or 2 W. of Vance, Tuscaloosa Co., is also believed to be of Oriskany age and to belong to Clear Branch ss. So far as present knowledge goes, the beds of Oriskany age in Ala. are confined to SW. end of Appalachian Valley from Tuscaloosa to Chilton Co. and do not extend NE. of present margin of Coastal Plain.

Named for exposures at Clear Branch Gap through Red Mtn, in Jefferson Co., 5 mi. S.-SW. of Bessemer.

Clear Creek limestone.

Middle and Lower Devonian (Onondaga and Oriskany): Southwestern Illinois and southeastern Missouri.

A. H. Worthen, 1866 (Ill. Geol. Surv. vol. 1, pp. 126-129). *Clear Creek ls.*—Fossiliferous lss., 250 to 350 ft. thick, of Lower Helderberg and Oriskany age, in Jackson, Union, and Alexander Counties, Ill. Consists of 300 ft. of yellowish gray thin-bedded siliceous lss., underlain by 10 to 25 ft. of mottled lss. with, locally, at base, 4 ft. of fossiliferous coarse-textured dark bluish gray lss. Overlies Niagara ls. and underlies Oriskany ss.

A. H. Worthen, 1868 (Ill. Geol. Surv. vol. 3), assigned *Clear Creek lss.*, 200-250 ft. thick, to Oriskany.

In some subsequent repts *Clear Creek ls.* was assigned to Oriskany and Lower Helderberg.

A. H. Worthen, 1882 (Econ. Geol. Ill., vol. 1), assigned *Clear Creek lss.* (200 to 250 ft. thick in Jackson and Union Counties, Ill.) to Oriskany.

C. Schuchert, 1900 (Geol. Soc. Am. Bull., vol. 11, pp. 272, 319), assigned lower 200 ft. of Clear Creek ls. of Ill. to Helderberg and rest of it to lower Oriskany.

E. O. Ulrich, 1904 (Mo. Bur. Geol. and Mines vol. 2, 2d ser., p. 110), restricted *Clear Creek ls.* to beds said to be of Oriskany age, and named the beds of New Scotland (Helderberg) age *Bailey ls.* As he defined it, it was said to be overlain by Grand Tower ls.

S. Weller, 1906 (Ill. Geol. Surv. Bull. 1, map), assigned *Clear Creek ls.* of southern Ill., 200-250 ft. thick, to Oriskany. In 1907 (Ill. Geol. Surv. Bull. 6) Weller stated that fauna of Clear Creek fm., 300 ft. thick in Ill., suggests Oriskany, although some fossils resemble Onondaga sp.

T. E. Savage, 1908 (Am. Jour. Sci., 4th, vol. 25, pp. 431-443, and Ill. Geol. Surv. Bull. 8, pp. 104-116). *Clear Creek fm.* (*or chert*) of SW. Ill., 237 ft. thick, corresponds in age to Camden chert of Tenn., and is Upper Oriskany. Is underlain, with short break, by New Scotland ls. (Helderbergian) and conformably overlain by Onondaga.

T. E. Savage, 1910 (Ill. State Acad. Sci. Trans., vol. 3, pp. 116+). Grand Tower fm. of Keyes in Mo. is here divided into Grand Tower (Onondaga) fm. (restricted) and Clear Creek fm. (of upper Oriskany age). [The 1912 geol. map of Ill.

(F. W. DeWolf, Director) restricted *Clear Creek* to 200 to 240 ft. of chert and ls. of upper Oriskany age, overlain by Grand Tower ls. (of Onondaga age), and uncon. underlain by New Scotland ls. (of Helderberg age). This classification was followed by E. F. Lines, 1912 (Ill. Geol. Surv. Bull. 17, pp. 59–76); R. S. Blatchley, 1913 (Ill. Geol. Surv. Bull. 22, pp. 26–32), and 1914 (Ill. Geol. Surv. Bull. 28, pp. 14–15), and the 1917 geol. map of Ill.]

C. O. Dunbar, 1919 (Tenn. Geol. Surv. Bull. 21, pp. 68–69, 89, 91, etc.). *Clear Creek chert* of southern Ill. is northward extension of Camden chert of Tenn. They have heretofore been regarded as of upper Oriskany age, but they belong with the Onondaga instead. They may be partially at least time equiv. of Esopus and Schoharie grits of N. Y.

T. E. Savage, 1920 (Am. Jour. Sci., 4th, vol. 49, pp. 169–178). *Clear Creek chert* [restricted] of SW. Ill. and SE. Mo. is in large part a succession, 300+ ft. thick, of chert and ls. layers 3 to 8 inches thick. Uppermost layers are in places interbedded with ss. layers containing Onondaga fossils. Where present in Mo. it uncon. overlies Little Saline River ls.; in SW. Ill. it is uncon. on Backbone ls., of Helderbergian age. Is almost everywhere overlain by Dutch Creek ss. In previous rept by writer the chert was thought to be of upper Oriskany age, but Dunbar has shown that Camden chert of W. Tenn., which is = in age to Clear Creek fm., occurs uncon. above the typical upper Oriskany strata. There is lack of any hiatus btw. Clear Creek chert and undoubted Onondaga strata, and it is now referred to basal part of Ulsterian (Onondaga) series. [On his chart on pp. 170–171, however, *Clear Creek chert* stands opposite "Possibly Esopus and Schoharie," which are pre-Onondaga.]

T. E. Savage, 1925 (Jour. Geol., vol. 33, pp. 550–558), assigned *Clear Creek chert* of SW. Ill. to Onondaga; called overlying fm. (also of Onondaga age) *Dutch Creek ss.*, and called underlying fm. (of Oriskany age) *Little Saline ls.*

C. F. Bassett, 1925 (Ill. Acad. Sci. Trans., vol. 18, pp. 360–368). *Clear Creek chert* of SW. Ill., 300 ft. thick, is assigned to basal Onondaga by Savage, on basis of fossils. It is overlain by Dutch Creek ss. and uncon. underlain by Backbone ls. (of Oriskany age). In Mo. it is underlain by Little Saline ls. (= lower part of Backbone ls.) and overlain by Dutch Creek ss.

E. R. Pohl, 1930 (Tenn. Acad. Sci. Jour., vol. 5, pp. 54–63), assigned Clear Creek of Ill. and Mo. to Schoharie.

The U. S. Geol. Survey at present classifies Clear Creek ls. as of Oriskany and Onondaga age.

Named for exposures on Clear Creek, Union Co., Ill.

†Clear Creek sandstone. (In Cherokee shale.)

Pennsylvanian: Western Missouri.

G. C. Broadhead, 1874 (Mo. Geol. Surv. vol. 1, pp. 57–61, 69, 100). *Clear Creek ss.*—Rather fine-grained ss., 50 ft. thick, containing some micaceous beds, forming basal part of Coal Measures in Bates Co. and E. and N. parts of Vernon Co. In Barton Co. underlain by 99 ft. of cgl. and iron ore belonging to Coal Measures.

F. C. Greene and W. F. Pond, 1926 (Mo. Bur. Geol. and Mines vol. 19, 2d ser.). *Clear Creek ss. memb. of Cherokee fm.*, 82 to 130 ft. thick, is = Graydon ss. and cgl. of Shepard. Overlies Dederick sh. memb. of Cherokee with sharp contact.

Named for exposures on Clear Creek, Vernon Co.

†Clear Creek limestone member (of Graford formation).

Pennsylvanian: Central Texas (Colorado River region).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 387, 392). *Clear Creek bed.*—To S. practically all ls.; to N. contains considerable clay and in places is divided by 20 to 50 ft. of clay. Upper ls. 5 to 15 ft. thick; lower ls. 25 to 75 ft. thick. Fossiliferous. Total thickness 20 to 140 ft. Memb. of Canyon div. Underlies bed No. 7 (25 to 100 ft. of clay) and overlies Cedarton bed.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31, 35; Univ. Tex. Bull. 2132, pp. 109, 111, 113, 115). *Clear Creek ls.*, 10 to 25 ft. thick, is a memb. of Brad fm. in Colorado River Valley. Underlies Placid sh. and overlies Cedarton sh. and ss.; all members of Brad fm. West of Brownwood and along its outcrop across Brown Co. it is a yellow-brown ls. made up of several more or less discontinuous layers which in places combine to form a solid ledge, but in other places are separated by thin beds of sh. In places it can be distinguished by its dark yellow-brown color; in other places it is light gray and massively bedded.

E. H. Sellards, 1931 (News Letter from Bur. Econ. Geol. Univ. Tex., dated Sept. 1931). Clear Creek ls. is same as Adams Branch ls. W. of Graford.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 104, 111), extended Graford fm. up to base of Placid sh. and restricted Brad fm. to Placid sh. and Ranger ls. members. He also discarded *Clear Creek ls.*, stating that it is preoccupied and "may be replaced by *Merriman*, a term applied originally to a part of the Clear Creek."

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501), divided Brad fm. of McCulloch Co., Colorado River region, into following members (descending): Ranger ls., Placid sh., Clear Creek ls., and Cedarton sh., and stated (p. 205): Clear Creek ls. is also known as Merriman ls.

Named for Clear Creek, Brown Co.

According to Wallace Lee (ms. soon to be published by Tex. Geol. Survey), Merriman ls. of Brazos River region as originally defined by Reeves corresponds to only the upper (3 to 4 ft. thick) of the 2 lss. that were included in Clear Creek ls. of Drake and of Plummer and Moore in Colorado River region. The beds called "Clear Creek ls." (preoccupied) in Colorado River region are now included, without a name, in upper part of Graford fm. This is present definition of U. S. Geol. Survey.

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, p. 24) showed *Clear Creek ls.* as much younger than Merriman ls., and included both in Brad fm., drawing base of Brad considerably lower than Merriman ls., and at top of Staff ls. of Brown Co., Colorado River Valley.

Clear Creek greenstone.

Mississippian (?): Northwestern California (Klamath Mountains region).

O. H. Hershey, 1901 (Am. Geol., vol. 27, pp. 226, 233, 238). *Clear Creek greenstone.*—The foundation rock of basin of Trinity River btw. Trinity Center and Lewiston, the Trinity Mtns and the ridges eastward to Sacramento River. Provisionally assigned to Jurassic. Is made up of a variety of deposits of a volcanic nature, but all having something in common, so that it appears over wide areas as a massive, fine-grained, dull-green rock. Much of it is of a detrital character, chiefly diabasic tuffs and ashes, although in places it is brecciated and occasionally it has a cgl. structure. In large part is extrusive. Was deposited on land. Thickness more than 1,000 ft. Is associated with Bragdon slates [Miss.]. Rests uncon. on Devono-Carbf. rocks.

Probably named for exposures on or near Clear Creek, Shasta Co.

Clear Creek series.

Mississippian (?): Northwestern California (southern part of Klamath Mountains).

O. H. Hershey, 1903 (Am. Geol., vol. 31, pp. 231–245). *Clear Creek series.*—Volcanic materials, such as andesite and rhyolite lavas and tuffs, intruded by dikes of diorite, diabase, and rhyolite porphyry, all altered. Thickness 200 to 2,000 ft. Associated with Bragdon fm. [Miss.].

Clear Creek volcanic series.

Triassic (?): Northwestern California (Trinity and Shasta Counties).

O. H. Hershey, 1904 (Am. Geol., vol. 33, pp. 248–256, 347–360). *Clear Creek volcanic series.*—Lavas and tuffs, which grade into overlying Pit shales by interstratification. Assigned to Triassic.

According to J. S. Diller (Am. Jour. Sci., 4th, vol. 19, pp. 380–385, 1905) the Clear Creek volcanics of Hershey are pre-Bragdon and in part at least pre-Middle Dev.

Clear Creek gneiss.

Pre-Cambrian: Central northern Colorado (Jefferson and Clear Creek Counties).

J. Underhill, 1906 (Univ. Colo. Studies, vol. 3, No. 4, p. 270; also Colo. Sci. Soc. Proc., vol. 8, pp. 103–122). *Clear Creek gneiss.*—Characterized by quartz, feldspar, and mica. Not so plicated as older Fundamental gneiss, into which it grades. Occurs along Clear Creek [Jefferson and Clear Creek Counties].

†Clear Fork group.

Pennsylvanian: Western Missouri.

G. C. Broadhead, 1873 (Mo. Geol. Surv. Prel. Rept. on Iron Ores, pt. 2, pp. 169, 170). *Clear Fork group.*—Shales and clays, with 2 or 3 coal seams; 84 ft. thick; includes beds Nos. 1 to 10 of detailed section of lower Coal Measures from Sedalia to Kansas City. Overlies lower Carbf.

Is a part of Cherokee sh.

Named for exposures on Clear Fork, 6 mi. SW. of Kansas City.

Clear Fork formation (also **group**).

Permian: Central and central northern Texas and western Oklahoma.

E. T. Dumble and W. F. Cummins, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. lxix, 188). *Clear Fork beds.*—Fossiliferous mag. and earthy lss., calc. clays and sss., with small quantities of gyp. and cgl. Overlie Wichita beds and conformably underlie Double Mtn beds.

Some geologists include Arroyo fm. of Beede and Waite in Clear Fork group, but Beede, Waite, and Wrather include it in Wichita group. The U. S. Geol. Survey includes it in Clear Fork group.

Probably named for Clear Fork of Brazos River, Jones and Shackelford Counties, Tex.

Clear Lake sediments.

Pleistocene: Northern California (Lake County).

W. H. Dall and G. D. Harris, 1892 (U. S. G. S. Bull. 84, pp. 201-202). The body of water in which these Cache Lake beds were laid down overlapped area at present occupied by Clear Lake, with which Dr. G. F. Becker shows its geol. history has been continuous. The later andesite overlies the Cache Lake deposits and also underlies the *Clear Lake sediments.*

Clearwater shale.

Cretaceous: Alberta, Canada.

R. G. McConnell, 1893 (Canada Geol. Surv., n. s., vol. 5, pt. 1, pp. 30D-32D, 55D-58D). [Assigned to Colorado epoch of Upper Cret. Some recent repts by other geologists assign this fm. to Lower Cret.]

Clem Creek sandstone member (of Ochelata formation).

Pennsylvanian: Central northern Oklahoma (Osage County).

W. B. Emery, 1918 (U. S. G. S. Bull. 686B, pp. 2, 3). *Clem Creek ss.*—A series of massive medium-grained sss. and thin lenticular shales aggregating 60 to 65 ft., exposed along Clem Creek in NW. part of T. 23 N., R. 11 E. Rests on red ls. and its upper limit is top of a massive ss. 18 ft. thick, which is marked by a line of woods at base of a grass-covered prairie, developed on the overlying sh. Top lies 195± ft. above top of Avant ls. and 175± ft. below Bigheart ss.

Clemville formation. (In Chaleur series.)

Silurian (Niagaran): Quebec (Gaspe Peninsula).

C. Schuchert and J. D. Dart, 1926 (Canada Geol. Surv. Bull. 44, p. 44).

S. A. Northrop, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, p. 271). Clemville and LaVieille fms. of middle Sil. Chaleur series are correlated by faunas with Clinton.

Cleopatra quartz porphyry.

A sill of pre-Camb. rock intrusive into greenstone complex of Jerome dist., Ariz., and said to be younger than Deception quartz porphyry. (See L. E. Reber, Jr., Am. Inst. Min. Engrs. Trans., 1920, and J. L. Fearing, Jr., Econ. Geol., vol. 21, pp. 757-773, 1926.)

Clepsydrops shale.

A paleontologic name (listed in U. S. G. S. Bull. 191) applied by E. D. Cope, 1879 (U. S. Geol. and Geog. Surv. Terr. Bull. 5, pp. 51-52), to a thin stratum of black and rarely reddish carbonaceous shales and clays in SE. Ill. and SW. Ind., "which appear to lie conformably on the Coal Measures, to which they have been referred by previous geologists, but Collett, Gibson, and others have shown that it is uncon. over considerable areas. It does not belong to Coal Measures."

Clermont limestone. (In Allegheny formation.)

Pennsylvanian: Central northern Pennsylvania (McKean County).

C. A. Ashburner, 1880 (2d Pa. Geol. Surv. Rept. R, pp. 46, 128). *Clermont (Ferriferous) ls.*—Bluish gray siliceous ls., 4 to 8 ft. thick. First studied in vicinity of Clermont, McKean Co. Has been traced through and identified as Ferriferous ls. Lies 30 ft. above Clermont (Clarion) coal and 8 to 32 ft. below Lower Kittanning coal.

Same as Vanport ls. memb., the older name.

Clermont group. (In Allegheny formation.)

Pennsylvanian: Central northern Pennsylvania (Elk County).

C. A. Ashburner, 1882 (Am. Phil. Soc. Proc., vol. 19, btw. pp. 337 and 348). *Clermont group.*—Includes Clermont or Ferriferous ls. at top and Clermont (Clarion) coal at base in Elk Co. Rests on Homewood ss. (top of Pottsville cgl.).

Clermont shale. (In Maquoketa group.)

Upper Ordovician (Richmond): Northeastern Iowa.

S. Calvin, 1906 (Iowa Geol. Surv. vol. 16, pp. 60, 98). *Clermont sh.*—Bluish, plastic, fine-grained sh., 15 ft. thick, in lower part of Maquoketa stage. Overlain by Fort Atkinson ls., of Maquoketa stage [group], and underlain by Elgin shaly ls., also of Maquoketa stage.

Named for exposures at Clermont, Fayette Co.

Cleveland shale.

Upper Devonian or Mississippian: Northern Ohio.

J. S. Newberry, 1870 (Ohio Geol. Surv. Rept. Prog. 1869, pp. 19, 21). *Cleveland sh.*—Black bituminous sh., 20 to 60 ft. thick, underlying Bedford sh. and forming basal fm. of Waverly group in northern Ohio. Overlies Erie [Chagrin] sh. Is Carbf.

Named for exposures at Cleveland.

For many years this fm. was placed in Carbf. by Ohio geologists. About 1875 geologists began to assign it to Dev. E. Orton followed latter classification from 1880 on. In 1911 (Geol. Soc. Am. Bull., vol. 22) E. O. Ulrich assigned this sh. to Miss., and since then much has been written on the subject. Most geologists (Prosser, Kindle, Claypole, Cushing, Burroughs, VerWiebe, Decker, Stout, and others) continued to assign the Cleveland to Dev., and the U. S. Geol. Survey classified it as Dev. until 1927, when they changed to *Dev. or Carbf.*

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 154). *Cleveland sh.* does not contain, so far as known at present, a single invertebrate fossil whose presence would unquestionably indicate a Miss. age. Yet it would be premature to pass judgment, for at present very little is known about Miss. black sh. fossils. The facies aspects seem to indicate Dev. age.

Cleveland sandstone. (In Kanawha formation.)

Pennsylvanian: Northern West Virginia.

D. B. Reger, 1916 (W. Va. Geol. Surv. Rept. Lewis and Gilmer Counties, pp. 75, 172). *Cleveland ss.*—Massive gray ss. and sandy sh. 45 to 55 ft. thick, outcropping along N. bank of Little Kanawha River at Cleveland, Webster Co. Underlies Winifrede coal and overlies Chilton (?) coal. Is lowest outcropping fm. recognized in either Lewis or Gilmer Co. May be same as Upper Chilton ss.

Cleveland moraine.

Pleistocene (Wisconsin stage): Northeastern Ohio and northwestern Pennsylvania. Shown on moraine map (fig. 8) in U. S. G. S. Columbus folio (No. 197), p. 12. Named for Cleveland, Ohio.

Cleveland sand.

A subsurface sand, of Penn. age and 0 to 160± ft. thick, in Okla., that originally was correlated with a part of Nowata sh. Named for early production in it on townsite of Cleveland, Pawnee Co. According to N. W. Bass (U. S. Dept. Int. Press Rept. 105,368 [1936], map, pl. 1) this sand belongs in Coffeyville fm., instead of in Nowata sh.

Cleveland magnafacies.

Upper Devonian or Mississippian: Northwestern Pennsylvania.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, pp. 28–29). The next western [than Chagrin] magnafacies is a black fissile sh. which seems to have been the typical "open sea" deposit in Neodevonian time. For this westernmost magnafacies the name *Cleveland* is tentatively selected. The Cleveland sh. is also a terrane embracing several stages, and the use of the name in this manner is clarifying.

Cleveland County red lands.

Eocene: Southeastern Arkansas.

R. T. Hill, 1888 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 2, pp. 58–59, 61, 188). The "red lands" of Cleveland Co. constitute a fossiliferous horizon at or near top of Camden series [which included Jackson fm., Claiborne, Wilcox, and Midway groups, and Upper Cret. fms.]. This fm. consists of the characteristic sediments of that series, but is accompanied by extensive deposits of marine shells and greensand which bring into these strata an ingredient of lime, which is conspicuously lacking in underlying beds. This lime renders the otherwise almost sterile micaceous sands and clays a fertile calc. marl. Fossils are all characteristic of Claiborne fm. of Ala. and Miss.

The 1929 geol. map of Ark., by G. C. Branner, maps the rocks of Cleveland Co. as Claiborne and Jackson.

Named for exposures at O. H. Mark's place, Red Land Twp, Cleveland Co.

†Click series.

Pre-Cambrian (Llano series): Central Texas.

T. B. Comstock and E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. lvii, 274). *Click series.*—Metamorphosed calc. rock or dolomitic marble, overlying Iron Mtn series and forming top div. of Fernandan system.

Part of Packsaddle schist of modern nomenclature.

Probably named for Click, Llano Co.

†Cliff limestone.

Silurian and Devonian: Southwestern Ohio, southeastern Indiana, and north-central Kentucky.

John Locke, 1838 (Ohio Geol. Surv. 2d Ann. Rept., pl. opp. p. 205, pp. 206, 211). *Cliff ls.*—Generally compact, often soft and friable, sometimes porous and spongy ls., also aren. ls.; fossiliferous in places; of yellowish, reddish, gray, or nearly white color. Thickness 89 ft. Overlies the blue ls., from which it is separated by marls and by a siliceous fm. which in Adams Co., Ohio, is 50 ft. thick but elsewhere is reduced to few inches or is absent.

Nongeographic name. Rocks now divided into several fms.

Named because it forms cliffs in banks of Ohio River and tributaries.

Cliff House sandstone. (In Mesaverde group.)

Upper Cretaceous: Southwestern Colorado and northwestern New Mexico.

A. J. Collier, 1919 (U. S. G. S. Bull. 691K). *Cliff House ss.*—Upper fm. of Mesaverde group. Is "Upper Escarpment" of W. H. Holmes's subdivision of the Mesaverde on SW. side of Mesa Verde [Montezuma Co., Colo.], where it consists of hard ss. In area S. of Mancos it is too friable to form cliffs, tho it still contains many thin beds of ss., and it is there nowhere covered by overlying fms., being partly eroded. At Echo Cliff it occurs as a sheer face of ss. more than 400 ft. thick. As it is most strikingly exposed in the canyons above the cliff houses of

Mesa Verde National Park, which were built along a shaly parting in it, it is here named Cliff House ss. Overlies Menefee fm.

J. B. Reeside, Jr., 1924 (U. S. G. S. P. P. 134). [See under *Mesaverde group*, 1924 entry.]

Cliff Lake granite porphyry.

Pre-Cambrian: Manitoba.

A. T. Bruce, 1918 (Canada Geol. Surv. Summ. Rept. 1917, pt. D, p. 5).

†Cliffwood clays.

Upper Cretaceous: Northeastern New Jersey.

H. B. Kümmel and G. N. Knapp, 1904 (N. J. Geol. Surv. vol. 6, p. 166). *Cliffwood lignitic sands and clays.*—White sand, with seams of black lignite and thin beds of black clay. Its many ss. concretions have yielded numerous plant remains. Thickness 15 to 20 ft. Top memb. of Raritan clay series. Underlies Merchantville clay and rests on No. 4 sand (laminated sand 40 to 75 ft. thick). Exposed in clay pits about Cliffwood [and at Cliffwood Point, on S. shore of Raritan Bay].

W. B. Clark, 1904 (Am. Jour. Sci., 4th, vol. 18, pp. 435–440), restricted Raritan fm. as explained under *Raritan fm.*, and correlated (Johns Hopkins Univ. Circ. vol. 23, No. 7, 1904) Cliffwood clays with Magothy fm. of current nomenclature.

Clifton formation.

Silurian (Niagaran): Western central Tennessee.

J. M. Safford and J. B. Killebrew, 1876 (Elements of geol. of Tenn., pp. 108, 142–146). *Clifton ls.*—Chiefly thick-bedded, gray, fossiliferous ls., sometimes containing clayey layers and weathering into sh. Thickness 0 to 200 ft. In western valley, the region of its greatest development, it is equally divided into a lower variegated ls. and marble and an upper gray ls., each 100 ft. thick. Clifton [Wayne Co.] is located on lower part of fm. Same as Meniscus ls. Underlies Linden ls. [Dev.], and overlies Dyestone group.

Clifton formation.

Pennsylvanian: New Brunswick.

F. J. Alcock, 1935 (Canada Dept. Mines Geol. Surv. Bur. Econ. Geol. Mem. 183, p. 95).

Clifton Forge sandstone member (of Keyser limestone).

Lower Devonian (Helderberg): Central western Virginia.

F. M. Swartz, 1930 (U. S. G. S. P. P. 158 C). *Clifton Forge ss. memb.*—Calc. sss. and shaly sss., with some aren. sh., composing middle memb. of Keyser ls. at Clifton Forge, Hot Springs, Gala, and other places in western Va. Thickness 66 to 102 ft. (66 ft. thick at Clifton Forge). Intertongues with and finally replaces the upper ls. and Big Mtn sh. members of Keyser ls. Rests on lower ls. memb. of the Keyser.

Clifty limestone.

Middle Devonian: Northwestern Arkansas (Eureka Springs-Harrison region).

H. D. Miser, 1916 (U. S. G. S. Eureka Springs–Harrison folio, No. 202). *Clifty ls.*—A bed of ls. nowhere more than 2½ ft. thick. Named for East Fork of Little Clifty Creek, Eureka Springs quad., where, within an area not exceeding ½ sq. mi., all its known exposures occur. Lower 1½ ft. is gray, compact, laminated, cross-bedded ls. with few fossils and large amount of quartz sand, the grains of which are rounded and translucent. Upper 12 inches is compact, light bluish-gray ls., with conchoidal fracture and small amount of sand like that in underlying bed. Uncon. underlies Sylamore ss. memb. of Chattanooga sh. and uncon. overlies Kings River ss. memb. of Everton ls. Contains Hamilton fossils in lower 18 inches.

†Clifty conglomerate lentil.

Pennsylvanian: Eastern Tennessee (White County).

L. C. Glenn, 1925 (Tenn. Geol. Surv. Bull. 33B, pp. 370–371). [See quotation under †*Clifty sh.*, which contains all of definition.]

†Clifty shale.

Pennsylvanian: Eastern Tennessee (White County).

L. C. Glenn, 1925 (Tenn. Geol. Surv. Bull. 33B, pp. 370–371). About Clifty and Bon Air in White Co. the Lee fm. consists of following, in descending order: Rockcastle cgl., in remnants on hilltops; Vandever sh.; Clifty cgl. lentil (upper part of Bonair cgl.); Clifty sh., with Clifty coal in top part; Bonair cgl. (lower part); Whitwell sh., with Bon Air coals; Sewanee cgl.; and Gizzard sh. The Clifty cgl. merges, when traced W. toward De Rossett [White Co.] with upper part of Bonair cgl. by lensing out of Clifty sh. and coal. It is here assumed that Clifty sh. lentil also disappears to N. and that Clifty cgl. either disappears or more probably unites with and forms top part of Bonair or Monterey cgl., thus losing its identity as a separate memb.

Clinch sandstone.

Silurian (early): Eastern Tennessee, southwestern Virginia, and southern West Virginia.

J. M. Safford, 1856 (Geol. Reconn. Tenn. 1st Rept., p. 157). *Clinch Mtn ss.*—Light-gray, generally thick-bedded ss., at many points abounding in fucoids; sometimes contains layers of cgl. with pebbles the size of small peas. In some places upper [lower?] part is red and highly ferruginous. [If *upper* was meant, the red beds are part of Rockwood fm.; if *lower* was meant, as in all of Safford's later repts, the red beds are the Ord. Sequatchie fm. In some of Safford's later repts this lower red sh. was called *Clinch Mtn red sh.* and *Clinch sh.*] Thickness several hundred ft. Is the great protecting rock of many high ridges in NE. Tenn. Underlies 200 or 300 ft. of shales with thin fine sss. and iron ore. Overlies Nashville or top memb. of Hudson River group.

J. M. Safford, 1869 (Geol. Tenn., pp. 151, 161, 292, 297). *Clinch Mtn ss.* (*Medina*) [also called Clinch group].—Hard ss., mostly white or grayish-white, 400 or more ft. thick [called *Clinch ss.* on pp. 295, 298, etc.], overlying 400 ft. of red calc. shales, provisionally included in fm. [and called *Clinch red sh.*, on pp. 295, 298, etc.]. Confined to E. Tenn. Included in Niagara group. Underlies White Oak Mtn sss. and overlies Nashville or Nash group.

In 1895 (U. S. G. S. Knoxville folio, No. 16) and 1896 (U. S. G. S. Loudon folio, No. 25, and Morristown folio, No. 27) A. Keith restricted Clinch ss. to upper massive white ss. of Safford's Clinch Mtn ss. and applied new name *Bays ss.* to underlying red sss. and shales. He defined Bays ss. as underlying white Clinch ss. and overlying Sevier sh., and as 300 to 1,100 ft. thick. Later work by several geologists indicated that the red sss. of Bays Mtn (type loc. of Bays ss.) are older than the red sss. underlying Clinch ss. on Clinch Mtn. (See under *Bays ss.*) The fm. underlying Clinch ss. is now called *Juniata fm.* in eastern belt and *Sequatchie fm.* in western belt. The overlying fm. is of Clinton age. E. O. Ulrich and C. Butts correlate Clinch ss. with Albion ss. of N. Y.

Named for exposures on Clinch Mtn, Hancock and Hawkins Counties, Tenn., and Scott Co., Va.

†Clinch red shale.

Upper Ordovician: Eastern Tennessee.

See 1869 entry under *Clinch ss.* Is same as Sequatchie fm. of present nomenclature.

†Clinch Mountain sandstone.

Silurian and Upper Ordovician: Eastern Tennessee and western Virginia.

See explanation under *Clinch ss.* Included Clinch ss. and Sequatchie fm. of present nomenclature.

†Clinch Mountain red shale.

Upper Ordovician: Eastern Tennessee.

See explanation under *Clinch ss.* Is same as Sequatchie fm. of present nomenclature.

†Cline.

Upper Cretaceous (Gulf series): Southern Texas.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, p. 114), used *Cline*, in table only, for beds btw. Austin chalk and Anacacho fm. in Uvalde section.

Probably named for Cline, Uvalde Co.

Clingman conglomerate. (In Chilhowee group.)

Lower Cambrian: Eastern Tennessee and western North Carolina.

A. Keith, 1895 (U. S. G. S. Knoxville folio, No. 16, p. 3). *Clingman cgl.*—Of precisely same composition as Thunderhead cgl., and none of its beds can be distinguished from the Thunderhead. Only noticeable difference is smaller development of sl. beds in Clingman cgl. Thickness 1,000 ft. Overlies Hazel sl.

Named for Clingmans Dome (spelled thus on the map), Swain Co., N. C.

Clinton formation. (In Niagara group.)

Silurian: New York to northeastern Tennessee; also Michigan.

T. A. Conrad, 1839 (Phila. Acad. Nat. Sci. Jour., vol. 8, pt. 1, pp. 228–235), applied *Clinton group* to beds underlying Niagara sh. [Rochester sh. memb. of Clinton fm.] and overlying Niagara ss. [Albion ss.].

L. Vanuxem, 1842 (Geol. N. Y., pt. 3), defined *Clinton group* of Third Dist. of N. Y. as consisting of green and black-blue sh., greenish and gray ss., red ss. often laminated, calc. ss., encrinal ss., and red fossiliferous iron ore beds, the most prominent memb. being the sh., the next most prominent memb. the greenish ss., and the third persistent memb. the iron ore beds. He stated that characteristic masses of these rocks occur around Clinton, Oneida Co., N. Y.; that overlying fm. is *Niagara group=Lockport group;* and that underlying fm. is *Oneida or Shawangunk cgl.*

The application of the names *Clinton group* and *Clinton fm.* to the beds btw. so-called *Niagara sh.* (or Rochester sh.) above and Medina ss. [=Albion ss.] below was universally followed until 1908, when A. W. Grabau (Sci., n. s., vol. 27, pp. 622–623) included the *Upper Medina* [Albion ss.] in the Clinton, and repeated this classification in 1909 (Jour. Geol., vol. 17, pp. 234–237). This proposed change was not, however, adopted by other geologists.

In 1910 (N. Y. State Mus. Bull. 140, pp. 21–23) J. M. Clarke stated that as originally described the upper limit of *Clinton fm.* was not defined; "or in other words the entire section exposed at Clinton village above the Medina ss. was left as the exponent of the Clinton fm.;" but that "with the progress of knowledge it is satisfactorily determined that at the Clinton section at Clinton there is a weak development of the Rochester sh., and this was included by inference in Vanuxem's definition of the Clinton fm." "In the Clinton section no entirely satisfactory division of the strata has yet been made. How far the division of the Rochester section can be correlated with or applied to the Clinton section is still to be determined, but they now seem to have little in common. The fauna indicates the presence of species of the Rochester member well down in the strata, and in paleontology it may be unwise to separate the Rochester member and its fauna from the series with which it is so intimately bound in this typical section."

In 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 28, etc.) E. O. Ulrich redefined *Clinton group* to include Rochester sh. at top and Brassfield ls. of Ky. ("the oldest Clinton known") at base, defining the Brassfield as lying strat. btw. Sodus sh. (above) and Medina ss. (below), but as not present in N. Y. He stated: It being now conceded that the Rochester sh. zone is included in and forms the top div. of the typical Clinton, and as the part beneath the Rochester is locally divisible into several lithologically and faunally distinct members or fms., the composite Clinton unit manifestly has become a group. He also showed a hiatus of considerable magnitude btw. Rochester sh. and overlying Lockport dol.

In 1912 (N. Y. State Mus. Hdb. 19) C. A. Hartnagel included Rochester sh. in the Clinton.

In 1913 (Geol. Soc. Am. Bull., vol. 24) A. W. Grabau stated: The hiatus which Ulrich places btw. the Rochester and Lockport, in order to make room for some southern fms., is absolutely nonexistent; the Rochester sh. by becoming more calc. passes without a break upward into the Lockport dol.

In 1913 the U. S. Geol. Survey adopted *Rochester sh. memb. of Clinton fm.* (See Niagara folio, No. 190.)

In Canada Geol. Surv. Guidebook No. 4, 1913, F. B. Taylor and W. A. Parks excluded Rochester from Clinton, thus following the old classification, as did M. Y. Williams in 1914 (Geol. Soc. Am. Bull., vol. 25, pp. 40–41, and Canada Geol. Surv. Summ. Rept. for 1913); also 1919 (Canada Dept. Mines, Geol. Surv. Mem. 111); E. M. Kindle (Sci., n. s., vol. 39, p. 918, 1914), who stated that "there is no excuse for including Rochester in the Clinton;" and C. Schuchert (Geol. Soc. Am. Bull., vol. 25, pp. 277–320, 1914), who stated that from Rochester, N. Y., westward into Ontario there is an easily discerned discon. or time break of considerable length btw. Lockport dol. and Rochester sh., the latter pinching out along Niagara escarpment.

In 1915 (U. S. Nat. Mus. Bull. 92, vol. 2, pl. 4) R. S. Bassler included Rochester in Clinton.

In 1918 (Geol. Soc. Am. Bull., vol. 29, p. 82) E. O. Ulrich introduced, without definition, *Kirkland fm.* for *Lower Clinton* of Pa. and Md. [The name *Kirkland* was suggested to U. S. Geol. Survey as a name for the pre-Rochester part of Clinton fm. in a letter from J. M. Clarke dated April 24, 1916.] In same vol. (pp. 327–368) G. H. Chadwick subdivided Clinton fm. into many minor units [see N. Y. chart] and (pp. 349, 359, 364) applied, in heading, the name *Kirkland iron ore* to what he described as "really a ferriferous ls., conspicuously crinoidal, and known locally as the 'red-flux bed,'" its "finest exposures being across the town of Kirkland, in which lies Clinton village." On many pages he used *Kirkland ls. and ore.* He defined his Kirkland as 0 to 6 ft. thick, and as located in upper part of Clinton fm., underlying his Phoenix sh. memb. and overlying his Brewerton sh. memb. He suggested dropping Clinton, and substituting a new name for each half, and stated: "Stratigraphically the Rochester sh. is excluded from the type section of the Clinton." He also restricted Rochester sh., by removing from it (under name *Gates ls.*) the upper 20 ft. of calc. beds ("really a ls.") heretofore included in the Rochester.

In 1923 (Md. Geol. Surv. Sil. vol., see index) C. K. Swartz introduced *Rose Hill fm.* for the pre-Rochester part of *Clinton group* of Md., and stated that "the close relationship of the Rose Hill and the pre-Rochester Clinton of central N. Y. in fauna, lithology, stratigraphic position, and geographic variation justify their correlation." He also expressed the opinion that Clinton might still fittingly be retained for the beds beneath the strata containing the Rochester fauna, although some at least of the iron ores occur in the beds assigned to the Rochester by Ulrich. In same vol.

(pp. 244, 267, etc.) Ulrich again redefined the Clinton by including in it, at base, the Thorold ss. [memb. of Albion ss.], but he still treated the Rochester as top memb. of Clinton. He also stated that in paper read by him before Geol. Soc. Am. in 1917 [published in 1918] the term *Kirkland* was proposed for *Middle* Clinton [published *Lower* Clinton], and suggested that Chadwick's name *Sauquoit* may be the one finally adopted for *Middle* Clinton, which he showed (p. 347) as present in only the Clinton and Crugers Mill sections of N. Y., its horizon being btw. Williamson sh. and Wolcott ls. On pp. 349–362 of same vol. Ulrich and R. S. Bassler divided the Clinton of *Appalachian Valley region* (p. 349) into *Upper Clinton or Lakemont fm.*, Middle Clinton, and Lower Clinton. On p. 359 they stated: "The term *Lakemont ls. or fm.* is proposed for the Upper Clinton as developed in *central Pa.* The type section is at Lakemont Park along the highway between Hollidaysburg and Altoona, Pa. The advantage of using this new name for the Upper Clinton in Md. seems assured, but in southwestern Va., where the corresponding beds consist entirely of ss. and sandy sh., some other designation probably is desirable. The propriety of its use for N. Y. deposits of similar age also is questionable." In correlation chart on p. 244 Ulrich showed Lakemont=Rochester sh., Irondequoit ls., and Williamson sh. of N. Y. subdivisions of Clinton.

The thickness of the Clinton at Clinton, N. Y., is stated by Ulrich (1923) to exceed 86 ft. In central Pa. it is 890 ft. thick.

The U. S. Geol. Survey treats *Clinton fm.* as basal div. of Niagara group, and includes Rochester sh. memb. in the Clinton, at top, but does not include Thorold ss. at base. In N. Y. the Clinton is overlain by Lockport dol. and underlain by Albion ss. In central Pa. the Lockport is absent and Cayuga group rests on the Clinton, which is in turn underlain by Tuscarora qtzite (correlated with Albion ss.). In eastern Tenn. the deposits of Clinton and Albion age are included in Rockwood fm.; in Ala. they are included in Red Mountain fm., where, according to E. O. Ulrich, they possess a different facies from the deposits of similar age in Tenn.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10), included Rochester sh. and Thorold ss. ("=Oneida cgl.") in the Clinton.

C. Schuchert and C. R. Longwell, 1932 (Am. Jour. Sci., 5th, vol. 23, pp. 305–311), excluded Oneida cgl. from the Clinton.

J. T. Sanford, 1936 (Jour. Geol., vol. 44, p. 811), excluded Oneida cgl. from the Clinton.

The U. S. Geol. Survey does not include Oneida cgl. in Clinton fm.

Clinton quartzites.

A name tentatively applied (N. Y. State Mus. Bull. 80) to Binnewater ss. of eastern N. Y., because the beds are in some respects similar to Clinton fm. of western N. Y.

Clinton sand.

A subsurface sand in basal part of Sil. of Ohio.

Clintonville oil sand.

Drillers' term for a sand in basal part of Venango oil sand group of NW. Pa.

Clipper Gap formation.

Mississippian (probably): Northern California (Colfax quadrangle).

W. Lindgren, 1900 (U. S. G. S. Colfax folio, No. 66). *Clipper Gap fm.*—A highly compressed sequence of black clay slates and dark argill. sss. Bodies of ls. abundant but usually lenticular. Bluish or grayish chert is also common, and so closely connected with the ls. as to strongly suggest its derivation from that rock by a process of silicification. Contains lower Carbf. fossils. Corresponds to upper part of Calaveras fm. Overlies Delhi fm. Is top fm. of Carbf. age in area. Named for exposures at village of Clipper Gap, Placer Co.

Cloche Island beds.

Middle Ordovician: Ontario (Manitoulin Island).

A. F. Foerste, 1921 (Ohio Nat., vol. 13, p. 39). *Cloche Island beds.*—Darker lss. [than underlying Swift Current beds] probably reaching thickness of 150 ft. Are of post-Leray Black River age. In lower part fine-grained lss. alternate with coarser grained layers for vertical distance of about 30 ft.; these are overlain by coarser grained lss. in which finer grained layers are not conspicuous and which reach thickness of about 50 ft. Form almost entire surface of Cloche Island. Overlain by lss. of Trenton age. Fauna discussed.

†Cloquet slate.

Pre-Cambrian (upper Huronian): Northeastern Minnesota (Carlton County). See under †*Thomson sl.*

Cloquet moraine.

Pleistocene (Wisconsin stage): Northeastern Minnesota.

F. Leverett, 1928 (U. S. G. S. P. P. 154). Named for Cloquet, Carlton Co.

Clore limestone. (Of Chester group.)

Mississippian: Southwestern Illinois and western Kentucky.

S. Weller, 1913 (Ill. Acad. Sci. Trans., vol. 6, pp. 120, 129). *Clore fm.*—Variable lss., more than 30 ft. thick, some beds thin-bedded and shaly, other beds hard and similar to Menard ls., and still other beds more granular or crystalline; passage beds at base, in places 25 ft. thick, consist of aren. and calc. shales with some ls. beds. Topmost fm. of Chester group. Overlies Palestine ss.

S. Weller, 1920 (Jour. Geol., vol. 28, Nos. 4 and 5), named topmost fms. of Chester group in southern and western Ill., Kinkaid ls. (above) and Degonia ss. (below), and stated that the Degonia rested on Clore ls. [restricted] (0 to 40 ft. thick) and that both Kinkaid and Degonia had been included in Penn. in earlier repts.

S. Weller, 1920 (Ill. Geol. Surv. Bull. 41, pp. 212 to 222), stated that *Clore fm.* of earlier *mapping* included Kinkaid ls. and Degonia ss.

Named for Clore School, Randolph Co., Ill. Typically exposed in heads of ravines along SW. side of high ridge extending from Clore School to Randolph County Farm.

Cloud Chief gypsum.

Permian: Southwestern Oklahoma.

C. N. Gould, 1924 (A. A. P. G. Bull., vol. 8, pp. 324–341, map). *Cloud Chief fm.*—Two or more ledges of massive gyp. interbedded in red clay sh.; the gypsums vary much in number and thickness. Includes what was originally described as "eastern area" of the Greer. The name "Cyril" was used for this gyp. in Cement area by Clapp, who erroneously considered it to be = the Blaine. Reeves recognized Clapp's error in correlation, but himself falls into error when he states that "only the basal part of the Greer is present in this area, where it is represented by Cyril memb." In point of fact, so far as can be determined, the entire Greer is present at Cement. Because of fact that both geologists who have used the name Cyril have fallen into error in use of the term, in order to avoid additional confusion, it appears wise to introduce an entirely new name. Therefore the name *Cloud Chief* is proposed for this fm. Typically exposed near town of Cloud Chief in eastern Washita Co. Rests on Day Creek dol. and is overlain by Quartermaster fm., with erosion uncon. according to Beede.

C. N. Gould, 1924 (Okla. Geol. Surv. Bull. 35, p. 95), stated that this fm. varies in thickness up to 115 ft.

H. D. Miser, 1926 (geol. map of Okla.), placed Cloud Chief gyp. below Quartermaster fm. and above Day Creek dol.

C. N. Gould and F. E. Lewis, 1926 (Okla. Geol. Surv. Circ. No. 13), suggested that "it might be well to consider the Day Creek the basal part of Cloud Chief gyp."

J. W. Beede and D. D. Christner, 1926 (Univ. Tex. Bull. 2607, pp. 14–15), recognized no fm. btw. Cloud Chief gyp. and Whitehorse ss. in Okla.

R. W. Sawyer, 1929 (Okla. Geol. Surv. Bull. 40HH). In Kiowa and Washita Counties *Cloud Chief fm.* overlies Whitehorse ss. and underlies Quartermaster fm. The term "Day Creek dol." of Cragin has been applied to Weatherford dol., Greenfield dol. and Quartermaster dol. It is believed its continued use will only serve to confuse. Writer does not know what bed, if any, in SW. Okla., corresponds to Day Creek dol. of Kans.

R. L. Clifton, 1930 (A. A. P. G. Bull., vol. 14, pp. 161–172). Evidences in field suggest *Cloud Chief* is not a geologic unit, but rather that it represents a group of more or less continuous strat. units. Writer believes Cloud Chief as a fm. name should be dropped and that another fm. name should be adopted to include the beds from *base* of Day Creek up to base of Quartermaster. [See further details under *Quartermaster fm.*]

N. Evans, 1931 (A. A. P. G. Bull., vol. 15, No. 4, pp. 408–432). Day Creek dol. *overlies* Cloud Chief gyp., and Cloud Chief should be made a memb. of Whitehorse fm. [See under *Quartermaster fm.*]

S. Buckstaff, 1931 (A. A. P. G. Bull., vol. 15, No. 4, pp. 434–437), does not regard Evans' interpretation of strat. relations of the various fms. as proved.

R. Roth, 1932 (Jour. Geol., vol. 40, No. 8, p. 700), believes there is no way of retaining *Cloud Chief* as a formational name; if used at all it should be as a zone name.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 146), placed Cloud Chief below Quartermaster and above Whitehorse. On p. 184 he stated that the Cloud Chief and Whitehorse fms. are not separable in Tex. either on the surface or underground.

D. A. Green, 1936 (A. A. P. G. Bull., vol. 20, No. 11, pp. 1454, 1458, 1473). Quartermaster fm. is here divided into (descending): (1) Elk City ss. memb.; (2) Doxey sh. memb.; and (3) *Cloud Chief memb.* (consisting of ss., gyp., and dol. facies). The strat. section in which the gypsums at Cloud Chief are developed is predominantly a ss. section, when considered in a large area, in which the gyp. facies occur as lenses, and has max. thickness of 300 ft., as shown by sample log of well S. of Cordell, in sec. 23, T. 9 N., R. 17 W. At type loc. the basal 100 ft. is solid gyp. and next 50 ft. lenticular gypsums in ss. To NW. of Clinton the contact of the Cloud Chief with Doxey memb. is irregular gradation. Greatest problem in Cloud Chief memb. is occurrence of Quartermaster dolomites, which in many places suggest chemical alteration from gyp. to dol. Many exposures indicate that Cloud Chief gyp. facies and Quartermaster dolomites are in same strat. horizon. Which of these dolomites, if any, is = Day Creek dol. of NW. Okla. is open question.

Cloud Mountain series.

Cambrian or pre-Cambrian: Newfoundland.

C. Schuchert and C. O. Dunbar, 1934 (Geol. Soc. Am. Mem. 1, p. 32).

Clough conglomerate.

Silurian (middle or lower): Northwestern New Hampshire (Ammonoosuc River region).

M. Billings, 1934 (Sci., vol. 79, No. 2038, pp. 55–56, Jan. 19). *Clough cgl.* (*lower Sil.*).—Qtz cgl. and qtzite, 0 to 200 ft. thick. Underlies Fitch fm. (middle Sil.) and uncon. overlies Partridge sl. (Upper Ord.?).

M. Billings, 1934 (Am. Jour. Sci., 5th, vol. 28, pp. 413–415, Dec.). *Clough cgl.* is absent from most of Littleton quad., by overlap, but is well developed in Moosilauke quad. No fossils, but it is uncon. on underlying pre-Sil. rocks, and grades into overlying Fitch fm. (middle Sil.), and is therefore believed to be middle or lower Sil. Named for Clough Hill dist. [Moosilauke quad.].

See also M. P. Billings, 1935 (Geology of Littleton and Moosilauke quads., N. H., maps and text).

M. Billings, 1935 (letter dated Aug. 27). Coos qtzite of Hitchcock is our Clough cgl.

Clover quartzites.

Clover Canyon quartzites.

Pre-Cambrian: Northwestern Nevada.

C. King, 1878 (U. S. Geol. Expl. 40th Par., vol. 1, p. 69), in his description of the "Archean rocks" of Humboldt Range, Nev., mentioned *Clover Canyon qtzites* and *Clover qtzites.*

Clover Creek limestone. (In Chester group.)

Mississippian: Western central Kentucky (Breckinridge County).

A. F. Foerste, 1910 (Ky. Geol. Surv. Rept. Prog. 1908 and 1909, pp. 83, 85). *Clover Creek ls.*—Ls., 11 and perhaps 15 ft. thick, underlying Garfield ss. and overlying Big Clifty ss. in Meade and Breckenridge Counties.

Named for exposures at mouth of Clover Creek, Breckinridge Co.

Clover Creek greenstone.

Permian: Northeastern Oregon (Baker quadrangle).

J. Gilluly, 1937 (U. S. G. S. Bull. 879). *Clover Creek greenstone.*—Altered volcanic flows and pyroclastic rocks, with subordinate ls. and chert. Thickness 4,000+ ft. Uncon. underlies pre-Mio. gravels. Relation to Elkhorn Ridge argillite (Penn.?) unknown. Named for exposures along Clover Creek, secs. 24, 25, 26, and 35, T. 7 S., R. 42 E.

Cloverly formation.

Lower Cretaceous: Central, eastern, and northern Wyoming and central southern Montana (Stillwater-Rosebud Counties region).

N. H. Darton, 1904 (Geol. Soc. Am. Bull., vol. 15, pp. 394–401). *Cloverly fm.*—Gray to reddish purple clay, 30 to 40 ft. thick, resembling Fuson fm., underlain by 10 to 60 ft. of coarse-grained buff or dirty gray cross-bedded massive ss., with some very thin deposits of coal or coaly sh., and believed to represent the Lakota of the Black Hills. Owing to lack of definite evidence as to equivalency of these beds on E. side of Bighorn Mtns to the Fuson and Lakota, and especially in consideration of apparent absence of deposits representing the Dakota ss., it has been thought best to give the series a separate designation. Underlies Benton fm., the lower part of which as here discriminated may possibly include beds representing Dakota ss. Rests on Morrison fm. Named for Cloverly, a post office on E. side of Bighorn Basin, Wyo.

C. T. Lupton, 1916 (U. S. G. S. Bull. 621, table opp. p. 166, pp. 167, 168). At type loc. of Cloverly fm., near Cloverly, Wyo., about 15 mi. NE. of Basin, Bighorn Co., Wyo., the Cloverly fm., according to N. H. Darton (U. S. G. S. P. P. 51, p. 52, 1906), consists of 113 ft. of strata, a detailed section of which is here given. Upper 20 ft. (light-buff or tan-colored ss.) of this fm. constitutes Greybull sand, which carries oil and gas in Greybull field and water in Lamb anticline and Torchlight dome. The Greybull sand is overlain by Thermopolis sh.

D. F. Hewett and C. T. Lupton, 1917 (U. S. G. S. Bull. 656, p. 19), defined base of Thermopolis sh. and top of Cloverly fm. as top of Greybull ss. memb., and stated that the Thermopolis includes the "rusty beds" [20 to 100 ft. thick] described by Washburne (in U. S. G. S. Bull. 340, p. 350, 1908) as basal memb. of Colorado fm. in Bighorn Basin, Wyo.

W. T. Lee, 1927 (U. S. G. S. P. P. 149, p. 64), included the "rusty beds" in his Greybull ss. memb. of Cloverly fm.

R. S. Knappen and G. F. Moulton, 1931 (U. S. G. S. Bull. 822, pp. 23–28), included the "rusty beds" in Thermopolis sh. [of Colorado age] and treated Greybull ss. as top memb. of Cloverly fm. This is present approved definition of Cloverly fm. The Greybull ss. is tentatively classified as Lower (?) Cret.

Cloverport "sand."

Drillers' name for 15± ft. of gray *ls.* in Keokuk ls. (Miss.) of NW. Ky. It is source of oil at Cloverport, Breckinridge Co.

Clugston limestone.

Paleozoic (?): Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 71; map). *Clugston ls.*—Varies from pure white, dense, fine-grained, massive, crystalline rock to bluish gray and dark-gray banded ls. that becomes somewhat argill. The pure white varieties often show well-defined banding or stratification. In some cases the purer types are interstratified with less pure phases, and in other cases they grade over into the other impurer types. Medium-grained bluish gray to very light-gray tints prevail. Rocks commonly shattered and squeezed. Thickness 1,200±ft. Overlies Colville qtzite and underlies Mission argillite. [Mapped around headwaters of Clugston Creek.]

Clyburn formation.

Pre-Cambrian (?): Canada (Cape Breton Island).

W. J. Wright, 1914 (Canada Geol. Surv. Summ. Rept. 1913, p. 273).

Clyde formation. (In Wichita group.)

Permian: Central and central northern Texas.

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, pp. 192, 197–198 and charts). *Clyde fm.*—Included in Wichita group, and includes all strata btw. top of Bead Mtn ls. memb. of underlying Belle Plains fm. and top of Talpa ls. bed of Drake. Thickness averages 475 ft. In Colorado Valley is overlain by higher ls. strata that outcrop 2 mi. E. of Talpa, on Santa Fe R. R. Named for town of Clyde, 8 mi. W. of Baird, Callahan Co. It is a poor name because in vicinity of the town the Perm. is covered by Cret. sand and it is necessary to go several mi. S. of town to get good exposures. But it is only locality along its outcrop available as a name.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 169). *Talpa ls. of Drake* is top bed of Clyde fm.

Coachella fanglomerate.

Miocene (middle or upper): Southern California (San Bernardino Mountains).

F. E. Vaughan, 1922 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 13, No. 9, pp. 344, 386–387, 391, and map). *Coachella fangl.*—A clastic rock having all characteristics of a fangl. For most part the fragments are angular and show little sorting, but material varies somewhat throughout the mass. Greater part of mass is light-gray and dark purplish gray, rather persistent coarse gravel and subangular polygenetic pebbles 2 inches to a foot in diam., probably derived from the old rocks to N. In places it consists mostly of sharply angular fragments varying in size up to 3 ft. across. The fragments are of porphyry, granite, and, largely, basalt. To E. this fangl. dips beneath more recent (Cabezon) fangl., which differs from it in being more uniform and massive, of yellowish color, and in lying nearly horizontal. The Coachella fangl. rests on old schists and gneisses. Is younger than Deep Canyon fangls.

Named for Coachella Valley, Riverside Co., near which it occurs.

Coahuila silt.

Pleistocene: Southern California (Imperial County).

G. D. Hanna, 1926 (Calif. Acad. Sci. Proc., 4th ser., vol. 14, No. 18, p. 435). The Yuha Reefs are followed by an enormous thickness of silt deposited in fresh waters of ancient Lake Coahuila, an appropriate name for which is *"Coahuila silt."* It is exposed where San Diego-El Centro highway crosses New River about 1 mi. W. of El Centro. Total thickness of these silts is not known but they contain fresh-water fossils to base of exposure indicated.

†Coal Bluff series. } (In Wilcox group.)
†Coal Bluff beds. }

Eocene (lower): Southern Alabama.

D. W. Langdon, Jr., 1894 (Ala. Geol. Surv. Rept. on Coastal Plain, p. 421). *Coal Bluff series of sands and lignites.*—Cross-bedded sands and sandy clays, 0 to 70 ft. thick, including Coal Bluff lignite, 5 ft. thick, at base. Is that portion of the Tert. below Nanafalia group and above Coal Bluff lignite, inclusive.

This term, as above defined, restricted Nanafalia fm. by separation, from its basal part, of these beds as well as the underlying lignite. The 1886 and 1892 uses of *Nanafalia* by E. A. Smith were *Nanafalia and Coal Bluff section,* in which these beds were included. The term "Coal Bluff" fell into disuse until 1920, when J. E. Brantly (Ala. Geol. Surv. Bull. 22, pp. 148–152) revived it, applying "Coal Bluff beds" to 42 to 77 ft. of strata forming basal memb. of Nanafalia fm. in Ala. and calling the rest of the Nanafalia the "Gullette Bluff beds." In 1932 C. W. Cooke extended Ackerman fm. of Miss. into Ala. to replace *Coal Bluff beds* and restricted Nanafalia fm. to the beds above the †Coal Bluff. This is present approved definition of Nanafalia fm.

Named for exposures on Alabama River at Coal Bluff, Wilcox Co.

Coalburg sandstones. (In Kanawha formation.)

Pennsylvanian: West Virginia.

I. C. White, 1908 (W. Va. Geol. Surv. vol. 2A, pp. 271, 468). *Coalburg ss.*—Coarse, massive, bluish gray ss., often weathering into "chimney rock" columns on summits. Thickness 40 to 80 ft. Lies 5 to 10 ft. above Coalburg coal and 6 to 52 ft. below Kanawha black flint. [Probably named for occurrence at Coalburg, Kanawha Co.]

R. V. Hennen and D. B. Reger, 1914 (W. Va. Geol. Surv. Rept. Logan and Mingo Counties, pp. 137–141). *Upper Coalburg ss.*—Massive, coarse, bluish gray and brown rock, often weathering into "chimney towers" and "table rocks" when exposed near summits; thickness 50 to 80 ft.; lies 25 to 50 ft. below Stockton coal and 0 to 10 ft. above Coalburg coal. *Lower Coalburg ss.*—Massive, gray and brown, medium-grained and aren. stratum, 20 to 50 ft. thick, lying 22 ft. below Little Coalburg coal and 5 to 9 ft. above Buffalo Creek coal.

Coalburg shale. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

D. B. Reger, 1921 (W. Va. Geol. Surv. Rept. Nicholas Co., p. 243). *Coalburg sh.*—Dark-gray or black, argill. deposit, coming just above Coalburg coal at Mollie Frame Farm Mine, 0.3 mi. W. of Birch River village, where it is only 3 inches thick, but it is 5 ft. thick at S. end of Powell Mtn, on Brushy Fork of Muddlety Creek. Contains plant and brackish water or possibly marine fossils. It is not quite clear whether Coalburg sh. belongs above or below Coalburg A coal, as the two members were not noted in conjunction, but indications are that the sh. underlies that coal.

Coal Creek formation.

Pennsylvanian: New Brunswick.

W. S. Dyer, 1926 (Canada Geol. Surv. Mem. 151, p. 7).

Coal Creek formation.

Silurian to Mississippian: New Brunswick (Queens and Sunbury Counties).

W. J. Wright, 1935 (Canadian Inst. Min. Metallurgy Trans., vol. 38, p. 211).

Coal Creek limestone. (In Topeka limestone.)

Pennsylvanian: Southeastern Nebraska, southwestern Iowa, northeastern Kansas, and northwestern Missouri.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 42, 52, 53). The upper unit of Topeka ls. was named *Union ls.* by Condra and Bengston in 1915. That name being preoccupied the div. is here named *Coal Creek ls.*, from exposures on Coal Creek, N. of Union, Nebr. The ls. is dark blue, dense, brittle, and quite fossiliferous. At places it is split into 2 or 3 beds. Overlies Holt sh.

Coal Creek quartzite.

Pre-Cambrian: Central northern Colorado (Boulder region).

M. F. and C. M. Boos, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 2, p. 306), mentioned the pre-Camb. *Coal Creek qtzite* and *Ralston fm.*, both of sed. origin, of Boulder region, but did not define them, and stated that they were taken from unpublished thesis of J. Adler, Univ. Chicago, 1930. Both are intruded by Boulder Creek granite gneiss.

Coaledo formation. (In Arago group.)

Eocene: Southwestern Oregon.

J. S. Diller, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, pp. 319–320). *Coaledo fm.*—The coal-bearing strata of Arago fm. of Coos Bay coal field. In lower part sss. predominate. Then comes the part where the workable coal beds occur, and the associated rocks are about equal quantities of sss. and rather dark-colored shales. In upper part light-colored shales are abundant and characteristic. Distinguished from Pulaski fm. (the main body of Arago fm.) by presence of coal beds and relatively large proportions of beds containing brackish water fossils. Well exposed in vicinity of Coaledo. [Arago fm. as defined by Diller included all beds in Coos Bay dist. btw. Empire fm. (Mio.) and †Pulaski fm.]

J. S. Diller, 1901 (U. S. G. S. Coos Bay folio, No. 73). [Repeated above description and stated that Coaledo fm. rests on Pulaski fm.]

W. H. Dall, 1909 (U. S. G. S. P. P. 59), assigned the beds at Tunnel Point to Olig., and stated that they uncon. overlie Arago fm., which includes Coaledo and Pulaski fms. The separation of the beds at Tunnel Point from Coaledo fm. constituted a restriction of Coaledo.

Harrison & Eaton (firm), 1920 (Min. Res. Oreg., Oreg. Bur. Min. and Geol., vol. 3, No. 1). *Coaledo fm.*—A series of fresh, brackish, and marine beds of ss. and muddy sh. In Coos Bay region there are a number of coal seams. Thickness 4,000 ft. [In table they placed Coaledo above Tyee ss., but stated that Tyee of Florence and Newport doubtless includes same horizon as Coaledo of Coos Bay.]

W. D. Smith, 1924 (Econ. Geol., vol. 19, p. 458), placed Coaledo above Tyee ss.

H. G. Schenck, 1927 (Univ. Calif. Pub. Bull. Dept. Geol. Sci., vol. 16, No. 12) and 1928 (Univ. Calif. Pub. Bull. Dept. Geol. Sci., vol. 18, No. 1). Tunnel Point ss. of Coos Bay dist. is middle Olig. and overlies Bassendorf sh. (lower Olig.), which rests on Coaledo fm. [*restricted*], upper Eocene. [Tunnel Point ss. and Bassendorf sh. of Schenck must have been included in Coaledo fm. of Diller, and Schenck's Bassendorf sh.—judging by thicknesses given—appears to have been partly included in Tunnel Point beds of Dall and partly in Coaledo fm. of Dall. This restricted definition has not been considered by U. S. Geol. Survey.]

†Coalinga beds.

Pliocene and Miocene: Southern California (Fresno and Kings Counties).

F. M. Anderson, 1905 (Calif. Acad. Sci. Proc., 3d ser., vol. 2, pp. 174–185). *Coalinga beds.*—The series of beds uncon. underlying Etchegoin fm. and resting uncon. on all underlying fms., the youngest of which is Monterey sh. Includes (descending):

Sands, etc., 1,300 ft.
Tamiosoma bed (oyster bed), 20 ft.
Sands and shales, 600+ ft. (Includes *"Rainbow beds."*) [See p. 177 of book cited above.]
Reef bed, 15–50 ft.
Basal sands and gravels, 120–250 ft.

F. M. Anderson, 1908 (Calif. Acad. Sci. Proc., 4th ser., vol. 3, pp. 1–40). It is now proposed to restrict Coalinga beds to lower part of a series that is uncon. related to older members of the Mio. The Santa Margarita beds of San Luis folio are clearly related to Coalinga beds. Overlain, generally conformably, by Etchegoin fm., and underlain, in places uncon., by Monterey shales. The "Reef bed" of former rept is properly a part of Temblor beds.

The "Coalinga beds" as originally described included rocks belonging to Jacalitos fm., Santa Margarita (?) fm., †Maricopa sh., and Vaqueros ss. of subsequent repts. The restricted definition applied to essentially same rocks that were called *Santa Margarita (?) fm.* in U. S. G. S. Bull. 398, descriptive of Coalinga dist.

Named for exposures N., NW., and W. of Coalinga, Fresno Co.

†Coal Measure conglomerate.

A term formerly applied to basal cgl. of Penn. series. In Pa. it was applied to Pottsville fm. of present terminology.

†Coal Measures.

A term commonly applied in early repts to the Perm. and Penn. rocks of present terminology. (See U. S. G. S. Bull. 769, 1925, pp. 65–70.)

Coalmont formation.

Eocene: North Park, Colorado.

A. L. Beekly, 1915 (U. S. G. S. Bull. 596, pp. 20, 49–71). *Coalmont fm.*—By evidence now available the 4,000 to 5,000 ft. of fresh-water beds lying btw. the marine Cret. and North Park fm. (Tert.) can be no more definitely assigned than to "Cret. or Tert." Lithologic differences in these rocks indicate they are made up of two more or less distinct members. The 3,000 to 4,000 ft. of dark-colored coal-bearing beds that immediately overlie the marine Cret. on E. side of North Park field and outcrop in various localities in W. and SW. parts appear to be the older and to be uncon. overlain by about 2,000 ft. of lighter colored ss. and cgl., which outcrop over a large part of park floor, and in many localities appear to overlap the lower beds. No definite line of demarcation btw. the coal-bearing and sandy members can be drawn, for no unmistakable contact btw. them is exposed at any locality in the field. The sandy memb. may be a separate and distinct fm., resting uncon. on the dark-colored coal-bearing rocks; or the two sets of beds may belong to an unbroken fm., and lithologic differences represent varying phases of contemp. deposition. Meanwhile, in default of a decisive solution of problem, all strata resting uncon. on marine Cret. and overlain by North Park (Tert.) fm. are here treated as a single fm., to which name *Coalmont* is applied. The fm. is better exposed along North Platte River than in vicinity of Coalmont, but *Coalmont* is used as the most acceptable name not preoccupied or otherwise unsuitable. [See also 1915 entry under *North Park fm.*]

The fm. is now regarded as unquestionably of Eocene age.

Coamo tuff limestone.

Cretaceous: Puerto Rico.

C. P. Berkey, 1915 (N. Y. Acad. Sci. Annals, vol. 26, pp. 19, 61).

Coamo Springs limestone series.

Eocene: Puerto Rico.

E. T. Hodge, 1920 (Scientific survey of Porto Rico and Virgin Islands, vol. 1, pt. 2, p. 153, N. Y. Acad. Sci.).

†Coast clays.

†Coast formation.

†Coast Pliocene.

†Coastal clays.

Descriptive terms used in early repts on Gulf Coastal Plain. In part replaced by Port Hudson fm. (Pleist.), and in part by Beaumont clay (Pleist.).

Coast complex.

Pre-Franciscan (possibly pre-Cambrian): Southern California (northwestern part of Monterey County).

B. Willis, 1900 (Geol. Soc. Am. Bull., vol. 11, p. 419). *Coast complex.*—Crystalline rocks, chiefly metamorphic, including marble, qtzitic schists, mica schists, gneisses, and intrusive granite. The marbles and schists are of sed. origin. The gneisses may be partly or wholly igneous. Occurs at base of geologic column in Coast Ranges. Is long pre-Cret. May be Paleozoic. Is "basement complex" of Fairbanks.

Same as Santa Lucia series of Willis.

†Coast group.

†Coastal series.

†Coastal group.

Pre-Cambrian: New Brunswick.

G. F. Matthew and L. W. Bailey, 1872 (Canada Geol. Surv. Rept. Prog. 1870–71).

See also C. R. Van Hise and C. K. Leith, 1909 (U. S. G. S. Bull. 360, index).

Coastal series.

Pleistocene: Jamaica.

R. T. Hill, 1899 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 34, pp. 82–99).

Coastal limestone.

Quaternary: Sierra Maestra of Cuba.

S. Taber, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 4, p. 589).

Coasters Harbor Island arkose.

Carboniferous: Southern Rhode Island.

A. F. Foerste, 1899 (U. S. G. S. Mon. 33, p. 380). *Coasters Harbor Island arkose.*—Occurs at S. end of Coasters Harbor Island. May be contemp. with some part of Aquidneck sh. series. May be younger than Conanicut arkose. Not so thick as Conanicut arkose.

A part of Wamsutta fm. as mapped by B. K. Emerson, U. S. G. S. Bull. 597, 1917.

Coast Range complex.

A name that has been applied to the pre-Franciscan rocks of Coast Ranges of southern Calif.

Coast Range intrusives.

Jurassic or Cretaceous: Southeastern Alaska, Yukon Territory, and British Columbia.

Name applied to the intrusive rocks of the Coast Range. Locally divided into many map units. In Hyder dist. of SE. Alaska includes (descending) Hyder quartz monzonite, Boundary granodiorite, and Texas Creek granodiorite, also many dikes of different lithology. (See U. S. G. S. Bull. 807, 1929.)

Coast Range diorite.

Age (?): Alaska.

A. C. Spencer, 1906 (U. S. G. S. Bull. 287, map opp. p. 12).

†Coata sandstone member (of Atoka formation).

See *Coody ss. memb.*

Coatzacoalcos formation.

Miocene: Mexico.

J. W. W. Spencer, 1897 (Geol. Soc. Am. Bull., vol. 9, pp. 13, 23).

Cobalt series.

Pre-Cambrian (late Huronian): Quebec and Ontario.

R. Harvie, Jr., 1911 (Quebec Dept. Colonization, Mines, and Fisheries, Mines Branch, pp. 9, 17).

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), assigned these rocks to late Huronian.

Cobb coal group.

A group of coal beds, in Pottsville fm. (Penn.) of Warrior coal field, central Ala., lying above Camp Branch ss. memb., and including the Cobb upper and Cobb lower coals.

Cobblestone Hill moraine.

Pleistocene (Wisconsin stage): Northeastern New York. Same as Cannon Corners moraine. See Geol. Soc. Am. Bull., vol. 35, pp. 669–676, and Jour. Geol., vol. 32, p. 665, 1924. Named for hill 3 mi. NW. of West Chazy, Clinton Co.

Cobequid series.

Silurian: Nova Scotia.

G. M. Dawson, 1880 (Canadian Nat., 2d ser., vol. 9, p. 332).

Cobham conglomerate member.

Devonian or Carboniferous: Northwestern Pennsylvania (Warren County).

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61, pp. 61, 112, 116, 117). *Cobham cgl. memb.*—The upper and most persistent cgl. of Knapp formational suite. Is a typical flat-pebble cgl. of varying texture. Thickness 75 to 100 ft. on Cobham Hill, where it is exposed along SE. and SW. faces of the hill, at Glade, Warren Co. This name replaces *Glade cgl.* (preoccupied) of writer's 1933 rept. Underlies Tidioute sh. memb. and overlies East Kane sh. memb. [According to C. Butts (personal communication, Jan. 1936) the above named cgl. is true Knapp and all of true Knapp present in area cited, and it contains fossils of Kinderhook age.]

Cobleskill limestone (also dolomite). (In Cayuga group.)

Silurian (late): New York and Ontario.

See first three paragraphs under *Rondout ls.*

In 1903 (N. Y. State Mus. Mem. 5, pp. 136–137) C. A. Hartnagel described the Cobleskill in its typical development at Schoharie and Howes Cave, Schoharie Co., N. Y., as consisting of a massive layer of dark-gray somewhat mag. ls. averaging 6 ft. in thickness, underlying the Rondout and overlying green argill. shales "which doubtless pertain to the Salina stage." In 1905 (N. Y. State Mus. Bull. 82) J. M. Clarke and D. D. Luther described it as consisting, in Tully quad., N. Y., of very hard, rather fine-grained, dark-gray ls. little altered, underlying Rondout dol. or waterlime and overlying Bertie dol., top fm. of Salina group.

In 1913 (Md. Geol. Surv. Lower Dev. vol., pp. 115–116) E. O. Ulrich stated the beds heretofore called *Manlius ls.* occur at much higher horizon than the ls. at Manlius, and gave following as correct strat. succession (descending): Coeymans ls.; Keyser ls ("Manlius of the literature"); Rondout ls.; and Decker Ferry ls. (all Lower Dev.); *typical* Manlius ls., and Cobleskill ls., the latter two Sil. In same volume C. K. Swartz, C. Schuchert, and C. S. Prosser classified the Cobleskill of N. Y. as Lower Dev., but Schuchert's 1924 Textbook of geol. assigned it to Sil. (Cayugan).

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10), placed *Cobleskill ls.* beneath Rondout ls. and above Salina, and included all in Sil.

See also under †*Akron dol.*

In western N. Y. the Cobleskill consists of dol. and is called *Cobleskill dol.;* it has also been called "Akron dol.," "Bullhead rock," "Bullhead ls.," and "Greenfield ls.," the latter an Ohio name.

Named for exposures on Cobleskill Creek, Schoharie Co., N. Y.

Coboconk limestone.

Ordovician: Ontario.

W. A. Johnston, 1911 (Canada Geol. Surv. Summ. Rept. 1910, p. 191).

Cobourg limestone.

Ordovician: Ontario.

P. E. Raymond, 1921 (Canada Geol. Surv. Mus. Bull. No. 31, geol. ser. No. 38, Feb. 17, 1921, p. 1). *Picton* having been used by Prof. Cushing in 1910 for a granite, the name *Cobourg* is here used in its stead, the upper Trenton being fossiliferous in vicinity of that town. The Utica is here considered as a shaly phase of Trenton group. The Cobourg underlies Collingwood of Ont., which is = Utica of northern N. Y. The *Upper Cobourg* (Upper Picton of former papers) corresponds to lower part of "Utica" of Quebec, or *Hormotoma* zone. The *Lower Cobourg*

(Lower Picton of former papers) corresponds to *Rafinesquina deltoidea* zone of the Trenton, and rests on Trenton restricted.

A. F. Foerste, 1924 (Canada Dept. Mines, Geol. Surv. Mem. 138, chart opp. p. 58), assigned Cobourg ls. to upper Trenton and placed overlying Collingwood and Gloucester in Utica.

R. Ruedemann, 1925 (N. Y. State Mus. Bull. 258, pp. 51, 62, 63, 149), assigned *Cobourg ls.* to Utica.

G. M. Kay, 1933 (Am. Jour. Sci., 5th, vol. 26, No. 151, pp. 2, 6), applied *Cobourg ls.* in N. Y., to beds beneath Collingwood and above Sherman Fall, and included them *all in Trenton group. He stated type loc. is in Northumberland Co., Ont.,* and divided the rocks into *Upper Cobourg ls.*, 75+ ft. thick, and *Lower Cobourg ls.*, 175 ft. thick. Fossils listed. In 1935 (Geol. Soc. Am. Bull., vol. 46, pp. 227–228) he also assigned all 3 fms. to Trenton.

Cobre.

Tertiary: Jamaica.

R. T. Hill, 1899 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 34, p. 78).

†Cobscook series.

Silurian and Devonian: Southeastern Maine.

N. S. Shaler, 1886 (Am. Jour. Sci., 3d, vol. 32, pp. 44–60). Greater part of sed. rocks of *Cobscook series* consist of very fine-grained sss. and dark-blue and blackish shales, which at certain points contain a good deal of lime, but rarely are pure lss. The fossiliferous rocks are mostly thin bedded, even the impure lss. At many points there are strata that contain small scattered fragments of hypogene rocks, presumably of volcanic origin. Believed to have been formed at some distance from shore. Thickness not less than 4,000 ft. Underlies Perry beds. Rests on Campobello series, with undoubted uncon., although contact has not been seen. Devonian fossils in upper beds. Includes, at top, Moose Island shales [which are a sed. facies of Eastport fm. (Sil.)]. Also includes Leighton's Cove series. Carries fossils related to Clinton, Niagara, lower Helderberg, and Dev. faunas.

Includes five fms. of Sil. age. (See Maine table.)

Named for development in Cobscook Bay dist., east coast of Washington Co.

Cobscook Bay series.

Silurian and Devonian: Southeastern Maine.

H. S. Williams, 1900 (U. S. G. S. Bull., 165, pp. 34–35). *Cobscook Bay series.*—Prof. Shaler (A. J. S., vol. 32) has described an interesting series of Sil. deposits on extreme SE. coast of Me., which contain faunas similar to those of Ashland and Sheridan series of Aroostook Co. [Lists the fossils and assigns them to Lower Helderberg, Lockport, and Clinton. Some fossils from Moose Island "probably belong to horizon of Ohio sh. (Dev.)."]

Coburn formation.

Middle Ordovician: Central and central southern Pennsylvania.

R. M. Field, 1919 (Am. Jour. Sci., 4th, vol. 48, pp. 404, 420). *Coburn fm.*—Top fm. of Trenton group. Upper beds become increasingly shaly and finally merge into overlying Reedsville sh. The middle and lower beds consist of alternations of crystalline, highly fossiliferous ls., and black shaly ls. At base, wherever exposed, is *Parastrophia hemiplicata* zone. Thickness 400 ft. Is faunally and lithologically distinct from underlying Salona fm. Named for town [in Center Co.].

Cocalico shale.

Ordovician: Southeastern Pennsylvania (Lancaster County).

G. W. Stose and A. I. Jonas, 1922 (Wash. Acad. Sci. Jour., vol. 12, pp. 359, 365). *Cocalico sh.*—Dark gray sh. containing graptolites of Normanskill type and thin crinoidal ls. at base; gray, green, and purple slates and green impure ss. above. Thickness 1,000± ft. Rests on Beekmantown ls. NE. of Lancaster.

G. W. Stose and A. I. Jonas, 1927 (Wash. Acad. Sci. Jour., vol. 17, No. 9). The Ord. sh., generally called *Martinsburg* but locally named *Cocalico* in area N. of Lancaster, occurs in a broad belt NW. of Appalachian Valley and in several smaller areas S. of the main belt.

The U. S. Geol. Survey at present uses *Cocalico sh.* to S. of main Triassic belt and *Martinsburg sh.* to N. of main Triassic belt, the Cocalico being regarded as in part=Martinsburg sh., but E. O. Ulrich is still of opinion that basal part of Cocalico sh. is older than Martinsburg, which is considered to be of Upper and Middle Ord. age.

Named for fact it is exposed on Cocalico Creek.

Cochahee sandstone member (of Nelagoney formation).

Pennsylvanian: Central northern Oklahoma (Osage County).

D. E. Winchester, K. C. Heald et al., 1918 (U. S. G. S. Bull. 686G, p. 60). *Cochahee ss.*—Flaggy bed, massive, hard, fossiliferous, having a peculiar weathered surface suggesting turkey tracks. *Fusulina* abundant. Thickness 3 to 25 ft. Lies 45± ft. above Labadie ls. and 125 ft. below Oread ls. Named for good exposures on headwaters of Cochahee Creek, in SW. part of T. 25 N., R. 10 E.

Cochise limestones.

Lower Cretaceous (Comanche series): Southeastern Arizona.

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, pp. 250, 336). *Cochise sandy ls.*—Lower part of Fredericksburg section of Tex., finely exposed in SE. part of Ariz. Thickness 300 ft.

Probably named for exposures at or near Cochise, Cochise Co.

Cochise formation.

Middle Cambrian: Southeastern Arizona (Whetstone Mountains and Bisbee region).

A. A. Stoyanow, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 466, 479, 480, 482). *Cochise fm.*—At type loc., in Whetstone Mtns, it is 311 ft. thick, and consists of (descending): (1) Upper div. characterized by blue ls., which at base is rather grayish, brownish, and mottled, and alternates with sh., and in upper part contains some thin-bedded, calc., micaceous ss. layers with *Neolenus intermedius pugio* Walcott; (2) yellow, pink, gray, white, purple, buff, and red shales, in upper part alternating with calc. sh. and thin rubbly ls., the pink and gray sh. containing *Obolus* (*Westonia*) *chuarensis* (Walcott) and *Agraulos* n. sp., 116 ft.; (3) pink and reddish, thin-bedded sss., 30 ft. Rests on Pima ss. and underlies Abrigo fm. [restricted to middle part of Abrigo ls. of previous repts, or to 420 to 430 ft. of thin-bedded, cherty, dolomitic gray ls. containing listed fossils]. Is Middle Camb. [Derivation of name not stated.]

Cochran conglomerate. (In Chilhowee group.)

Lower Cambrian: Eastern Tennessee and western North Carolina.

A. Keith, 1895 (U. S. G. S., Knoxville folio, No. 16, p. 3). *Cochran cgl.*—Ss., 600 to 900 ft. thick, underlain by bluish-gray sh. 0 to 100 ft. thick, in turn underlain by 500 to 700 ft. of coarse greenish-white cgl. The ss. is composed of round grains of white quartz; the sh. is argill., micaceous, and slightly sandy; the cgl. is composed of quartz and feldspar embedded in a matrix of argill. sand. A small bed of reddish brown ss. occurs near base of the white ss. Overlies Sandsuck sh. Underlies Nichols sh.

Is basal fm. of Chilhowee group.

Named for Cochran Creek, Sevier Co., Tenn., on S. slope of Chilhowee Mtn.

Cockeysville marble.

Pre-Cambrian (Glenarm series): Maryland, southeastern Pennsylvania, and northeastern Virginia.

G. H. Williams and N. H. Darton, 1892 (U. S. G. S. map of Baltimore and vicinity, to accompany "Guide to Baltimore," prepared for Baltimore meeting Am. Inst. Min. Engrs., Feb. 1892). *Cockeysville marble.*—Highly crystalline dol. with all its original impurities separated in form of well-defined minerals. Extensively quarried at Cockeysville, Md. Overlies Setters quartz schist and underlies gneiss [Wissahickon fm.].

E. B. Mathews, 1904 (Am. Jour. Sci., 4th, vol. 17, pp. 141–159), gave thickness of Cockeysville marble as 0 to 2,000 ft., and in 1909 (Md. Geol. Surv. vol. 8, pp. 334–338) as 2,300 ft.

E. B. Knopf and A. I. Jonas, 1922 (Am. Jour. Sci., 5th, vol. 5, pp. 45–49, 61–62). *Cockeysville marble* included in Glenarm series. Underlies Wissahickon fm. and overlaps Setters fm. Thickness 400± ft.

The Glenarm series was formerly classified by U. S. Geol. Survey as of Algonkian age, but that term having been discarded it is now classified as pre-Camb.

Cockeysville volcanics.

Pre-Cambrian: Maryland.

E. B. Mathews, 1933 (Md. Geol. Surv. geol. map of Md.). *Cockeysville volcanics.*—Volcanics interbedded with Cockeysville marble.

†Cockfield formation. (In Claiborne group.)

Eocene (middle): Northwestern Louisiana, eastern Texas, and Mississippi.

T. W. Vaughan, 1895 (Am. Geol., vol. 15, p. 220). *Cocksfield Ferry beds.*—Lignitiferous sands and clays, which in a general way represent the Claiborne sands of Ala. Underlie Jackson stage and overlie Lower Claiborne stage [=St. Maurice fm. of present nomenclature].

The term "Cocksfield Ferry beds" was later changed to *Cockfield memb. of Claiborne fm.* Afterward the Claiborne was elevated to a group and Cockfield to a fm. In 1912 the equivalency of Cockfield fm. of La. with Yegua fm. of Tex. was established, and "Cockfield" was dropped for the earlier name, Yegua fm. It was later revived, and again dropped, as explained under *Yegua fm.*

Named for Cockfield Ferry (correct spelling), on Red River, near Petite Ecore, Winn Co., La.

†Cockfield lignite.

Eocene (middle): Mississippi.

E. N. Lowe, 1915 (Miss. Geol. Surv. Bull. 12, p. 77). *Cockfield lignite.*—Lignitic clays and lignites, with abundant impressions of leaves of land and marsh plants. Thickness 30 to 40 ft. Named for Cockfield Ferry [Winn Co.], La. Top memb. of Lisbon fm. in Miss.

According to C. W. Cooke (personal communication Dec. 1936) the beds described above are same as Cockfield fm. of other authors, now replaced by Yegua fm. The Yegua overlies Lisbon fm.

†Cocksfield Ferry beds.

See †*Cockfield fm.*

Cockpit limestone group.

Oligocene: Jamaica.

C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 422). The ***White or Cockpit ls. group,*** about 1,500 ft. thick, was divided by [R. T.] Hill into 3 members (descending): Cobre chalky-white ls., 1,000 ft.; Moneague ls., no great thickness; and Montpelier ls., 500± ft.

†Cock-tail grit.

A descriptive term applied in early repts to Esopus grit, the rock being characterized by the fossil *Fucoides caudagalli*, which resembles in appearance the tail of a chicken cock.

Cocoa sand member (of Jackson formation).

Eocene (upper): Southwestern Alabama.

J. A. Cushman, 1925 (Cushman Lab. Foram. Research Contr., vol. 1, pt. 3, pp. 65–69), described foraminifera "from the Cocoa sand of Ala., which is of upper Eocene (Jackson) age and occurs at Cocoa Post Office, Ala."

C. W. Cooke, 1933 (A. A. P. G. Bull., vol. 17, No. 11, pp. 1387–1388). *Cocoa sand memb. of Jackson fm.*—Fine yellow sand with soft white calc. lumps and large irregular lumps of hard yellow sandy marl. Thickness 6 ft. Grades up into *Zeuglodon*-bearing bed (which consists of gray or drab sandy and argill. marl with harder ledges and irregular calc. concretions, very argill. in upper part, and 11 ft. thick). Separated from underlying *Periarchus*-bearing bed (so-called *Scutella* bed) by 30 to 50 ft. of light-green plastic calc. clay with shells, in part micaceous and sandy. Named for an abandoned country postoffice called Cocoa, which many years ago stood in SW¼ sec. 13, T. 11 N., R. 5 W., Choctaw Co., Ala., about 2½ mi. E. of Melvin, on road to Gilbertown. Probably represents part of Yazoo clay of Miss. [Cooke now regards this sand as represented in lower part of Yazoo clay of Miss. (Personal communication, Feb. 1935.)]

Coconino sandstone. (Of Aubrey group.)

Permian: Northern Arizona, southern Utah, and southeastern Nevada.

N. H. Darton, 1910 (U. S. G. S. Bull. 435, pp. 21, 27). *Coconino ss.* is proposed for the cross-bedded gray to white ss. of Aubrey group, which is so conspicuous in walls of Grand Canyon. It underlies entire Coconino Plateau, as well as the extensive plateau country N. of Grand Canyon. Thickness 50 to 610± ft. Underlies Kaibab ("Aubrey") ls. and overlies Supai fm. It is upper part of "Aubrey ss. series" of early writers. [Subsequently the upper part of Supai fm. of Ariz. was separated from the Supai and named *Hermit sh.*, so that according to present definition the Coconino ss. rests on Hermit sh.]

Later repts have shown that Coconino ss. in parts of southern Utah greatly thickens and occupies the time interval of Kaibab ls. and part at least of Supai fm. See R. C. Moore and H. E. Gregory, 1931 (U. S. G. S. P. P. 164) and A. A. Baker and J. B. Reeside, Jr., 1929 (A. A. P. G. Bull., vol. 13, No. 11, pp. 1413–1448).

Codell sandstone member (of Carlile shale).

Upper Cretaceous: Western Kansas and eastern Colorado.

N. W. Bass, 1926 (Kans. Geol. Surv. Bull. 11, pp. 28, 64). *Codell ss. bed.*—A sandy zone forming topmost 20 to 25 ft. of Blue Hill sh. memb. of Carlile sh. in western Kans. (Russell to Hamilton Counties). Named for excellent exposures in bluffs along Saline Valley in Ellis Co., Kans., 5 mi. S. and a little W. of Codell.

K. F. Mather, J. Gilluly, and R. G. Lusk, 1928 (U. S. G. S. Bull. 796B), applied *Codell ss. memb.* to topmost 3 to 20 ft. of Benton sh. in eastern Larimer Co., Colo., or to ss. called "Niobenton sand" by drillers.

C. H. Dane and W. G. Pierce, 1933 (U. S. G. S. Press Notice, June 8, "Geol. and oil and gas prospects in part of eastern Colo."), elevated *Codell ss.* to rank of a memb. at top of Carlile sh. and restricted Blue Hill sh. memb. to underlying part of the Blue Hill sh. of previous repts.

Codorus limestone.

Ordovician and Cambrian: Southeastern Pennsylvania (York County).

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 1, p. 454). The trap cuts *Codorus ls.* beds its whole visible length and throws a short branch SW., also in the ls. [On p. 167 mention is made of Codorus Creek, in York Co. On p. 473 he speaks of the white and blue lss. of Codorus Valley.]

Cody shale.

Upper Cretaceous: Northern Wyoming (Bighorn Basin).

C. T. Lupton, Jan. 21, 1916 (U. S. G. S. Bull. 621, pp. 166, 171, table, etc.). *Cody sh.*—Gray and dark sh., with 1 bed of ss. near base and several thin fossiliferous sss. near top. Thickness 3,360± ft. Includes Basin (Niobrara) sh. and overlying Pierre sh. of Hintze 1915 classification. Underlies Mesaverde fm. and overlies Frontier fm. Town of Cody is located on outcrop of this sh. near Shoshone River, where it is 2,150 ft. thick. [Detailed section of fm. given, and fossils listed.]

Coetas formation.

Pliocene: Panhandle of Texas.

L. T. Patton, 1923 (Univ. Tex. Bull. 2330, pp. 80–86). *Coetas fm.*—Slightly consolidated sand of gray to buff color, with 2 to 20 ft. of bedded somewhat sandy, flaggy ls. near top, which are known by their fossil content to be Plio. The fm. is quite calc. and contains many tabular calc. concretions. Thickness 150 to 200± ft. Overlies Potter fm. Is uncon. overlain by Quat. Contains Plio. vertebrate fossils. Well exposed on Coetas Creek, in E. part of Potter Co.

Is a part or all of Ogallala fm. (Plio.) of Texas Panhandle.

Coeur d'Alene series.

Pre-Cambrian (Belt series): Northeastern Idaho (Coeur d'Alene district) and central western Montana.

D. F. MacDonald, 1906 (U. S. G. S. Bull. 285, pp. 42–43). *Coeur d'Alene series.*—All Algonkian rocks of Coeur d'Alene Mtns region, including (descending): Striped Peak fm. 1,000+ft.; Wallace fm. 4,000 ft.; St. Regis fm. 1,000 ft.; Revett qtzite 1,200 ft.; Burke fm. 2,000 ft.; Prichard sl. 8,000+ft.; a total of 17,200 ft. of rocks, overlying the Archean.

Is a local name for Belt series of present terminology.

oeymans limestone. (In Helderberg group.)

Lower Devonian: Eastern New York and Pennsylvania, western Maryland and Virginia, and northern West Virginia.

J. M. Clarke and C. Schuchert, 1899 (Sci., n. s., vol. 10, pp. 874–878). *Coeymans ls.*, the Lower Pentamerus (Helderberg and Pentamerus lss.) of N. Y. geologists. Exposed at Coeymans, Albany Co. N. Y. Underlies New Scotland ls. and overlies Manlius ls. Basal fm. of Helderbergian group.

In subsequent N. Y. State repts this fm. was described as consisting of hard, massive, bluish gray ls., vertically jointed (see N. H. Darton, N. Y. State Mus. 47th Ann. Rept., 1894), and ranging in thickness from 30 to 100 ft.

In 1908 (Sci., n. s., vol. 28, pp. 346-348) G. H. Chadwick introduced *Kalkberg ls.* "to cover certain layers heretofore included variously by writers with the beds above (New Scotland) or below (Coeymans)," and carrying a mixed fauna, highly developed and excellently silicified on Catskill Creek [Greene Co., N. Y.], where the beds show numerous thin parallel seams of black flint nodules.

Chadwick's restricted definition of Coeymans ls. is generally accepted. Included in Helderberg group.

In central Pa. the Helderberg is treated as a fm. and these beds are designated *Coeymans ls. memb.* of Helderberg ls.

offee sand.

Upper Cretaceous: Western Tennessee and northeastern Mississippi.

J. M. Safford, 1864 (Am. Jour. Sci., 2d, vol. 37, pp. 361, 362–363). *Coffee sand.*—Mostly stratified sands, usually containing mica scales. Thin leaves of dark clay often interstratified with the sand, the clay leaves occasionally predominating. Sometimes beds of dark laminated or slaty clay 1 to 20 or more ft. thick are included. Thickness probably 200 ft. Northern extension of Tombigbee sand of Hilgard, which most likely ought to be included in his Eutaw group. Underlies Cret. Green sand or shell bed [Selma chalk of later repts.]. Is lowest Cret. fm. in western Tenn.

Above definition continued to be followed until 1911, when L. W. Stephenson (Ga. Geol. Surv. Bull. 26, pl. 5) divided the sands that had previously been called *Coffee sand* in Tenn. and *Tombigbee sand* in Miss. into 2 members, the upper being called *Coffee sand memb. of Eutaw fm.* and the lower being called *Tombigbee sand memb. of the Eutaw*, and he showed a considerable thickness of Eutaw deposits below the Tombigbee sand in Miss. He showed *Coffee sand memb.* as grading laterally into lower part of Selma chalk in Miss. and as also overlain by Selma chalk, but stated it is lithologically like Eutaw deposits and should therefore be treated as a memb. of Eutaw fm. (See L. W.

Stephenson, Wash. Acad. Sci. Jour., vol. 7, No. 9, 1917.) This sand is not present in Ala. The Coffee sand of early Ala. repts included Tombigbee sand memb. and underlying beds of Eutaw fm.

Further work led Stephenson (in March 1936) to belief *Coffee sand* should be treated as a distinct fm., instead of as a memb. of Eutaw fm. or a memb. of Selma chalk, into the lower part of which it grades laterally. The present classification of U. S. Geol. Survey treats Coffee sand as a distinct fm. and restricts Eutaw fm. to beds btw. top of Tombigbee sand memb. and top of underlying Tuscaloosa fm.

Named for exposures at Coffee Landing, Hardin Co., Tenn.

Coffee shale.

A color term applied by drillers to the Sunbury sh. of W. Va. oil fields.

†Coffee Mill Hammock marl.

Pleistocene: Southern Florida (De Soto County).

E. H. Sellards, 1919 (Fla. Geol. Surv. 12th Ann. Rept., pp. 73, 74). *Coffee Mill Hammock marl.*—Shell marl, 2 ft. max. thickness. Rests on fresh-water ls. at top of Fort Thompson beds. Although removed by erosion at the rapids this marl is very persistent. Is seen in place at Goodno's Landing, Fort Thompson, and at Coffee Mill Hammock [De Soto Co.], 12 mi. above Labelle. Predominating fossil is *Chione cancellata,* shells of which have been thrown out in great profusion by the dredge.

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept.). Deposits named "Coffee Mill Hammock marl" by Sellards are included in Fort Thompson fm., and name is considered unnecessary.

Coffee Ranch.

Pliocene: Texas Panhandle.

R. D. Reed, 1933 (Geol. of Calif., p. 303), listed, in his "standard section," the name *Coffee Ranch,* and placed it below Blanco beds, above Clarendon, and opp. Middle Etchegoin.

R. D. Reed, 1936 (letter dated May 18). The "Coffee Ranch" locality is in Hemphill Co., Tex., and has been described by Matthew and Stirton in papers of Univ. Calif. geol. series; also in a bull. on Hemphill Co. put out by Tex. Bur. Econ. Geol.

The compiler finds that Matthew and Stirton (in Univ. Calif. Dept. Geol. Sci. Bull., vol. 19, No. 7, 1930, pp. 171–216) described species of Plio. fossil mammals from Coffee Ranch, near town of Miami, Hemphill Co., Tex., but did not name the beds containing them. Also that Univ. Tex. Bull. 3231, 1932, describing the geol. of Hemphill Co., Tex., did not describe the Coffee Ranch locality, and named the Plio. deposits (all *lower* Plio.) of that Co. *Hemphill beds.* Therefore, *Coffee Ranch* as a geologic name appears to have no standing.

Coffeyville formation.

Pennsylvanian: Southeastern Kansas and northeastern and central Oklahoma.

F. C. Schrader and E. Haworth, 1905 (U. S. G. S. Bull. 260, p. 448). *Coffeyville fm.*—Series of lss. and shales, 250 ft. thick, underlying Drum fm. and overlying Parsons fm. Includes Cherryvale sh., Dennis [Winterset] ls., Galesburg sh., Mound Valley [Bethany Falls] ls., and Ladore-Dudley sh.

In NE. Okla. overlies Lenapah ls. and underlies Hogshooter ls.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 67). *Coffeyville fm.* of Schrader and Haworth includes beds btw. top of Lenapah ls. and base of true Drum ls.

Named for exposures at Coffeyville, Montgomery Co., Kans.

†Coffeyville limestone.

Pennsylvanian: Southeastern Kansas.

E. Haworth and J. Bennett, 1908 (Kans. Acad. Sci. Trans., vol. 21, pt. 1, p. 74). *Coffeyville ls.*—Overlies Walnut sh. and underlies Pleasanton shales.

Preoccupied. Same as Lenapah ls.

Named for Coffeyville, Montgomery Co.

Coffman conglomerate member (of Maroon formation).

Pennsylvanian (?): Central Colorado (Park and Chaffee Counties).

D. B. Gould, 1935 (A. A. P. G. Bull., vol. 19, No. 7, pp. 971–1009). *Coffman cgl. memb. of Maroon fm.*—Arkosic cgl. with interbedded sh. and ss. Conformably underlies Chubb siltstone memb. and conformably overlies Weber (?) fm. in Salt Creek area, Park and Chaffee Counties. Thickness 20 to 1,000 ft. Named for Coffman Park, in SE. part of area. Type section is in unnamed valley in sec. 24, T. 13 S., R. 77 W., about 2 mi. N. of Coffman Park, where it is 615 ft. thick. Is 1,000 ft. thick about 1 mi. E. of type section, and only 20 ft. thick in Chubb Gulch. Assigned to Penn.(?).

Coggon limestone.

Middle Devonian: Central eastern Iowa.

W. H. Norton, 1894 (Iowa Acad. Sci. Proc., vol. 1, pt. 4, pp. 23, 24). *Coggon beds.*—Heavy-bedded dolomitic lss., probably of Sil. age. Underlie Otis beds.

In 1901 (Iowa Geol. Surv. vol. 11) Norton transferred his Coggon beds to Dev. and to Wapsipinicon ls., and they have since been included in that fm.

W. H. Norton, 1921 (Iowa Geol. Surv. vol. 27, p. 374). *Coggon phase of Otis ls.*—Soft mag. ls., finely crystalline, granular, in some places earthy, varying in color from light-cream yellow to rather dark buff. Fossils prove it to be simply mag. basal portion of the Otis. Present in Linn, Scott, and Cedar Counties. Type exposures at Coggon, Linn Co., at crossing of Buffalo River by Illinois Central Ry., where Ashby's quarry shows 14 ft. of it. In Linn Co. the Coggon phase rests on Bertram beds; in N. part of county on Hopkinton ls.; in Cedar Co. it is in places uncon. on Leclaire beds of the Gower, and in places conformable on Anamosa beds.

M. A. Stainbrook, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 249–251), included Bertram beds in Otis and placed Coggon below Otis, as did the "Conf. classification," fig. 1.

Cohansey sand.

Tertiary (Miocene?): New Jersey.

H. B. Kümmel and G. N. Knapp, 1904 (N. J. Geol. Surv. vol. 6, p. 137). *Cohansey sand.*—Coarse quartz sand with occasional small pebbles; locally cemented into ss. Contains clay lenses 8 to 24 ft. thick. Rests on Shiloh marl [memb. of Kirkwood fm.]. Underlies Beacon Hill gravel. Was included in Beacon Hill of Salisbury.

Later repts give thickness as 0 to 450± ft.

Named for exposures along Cohansey Creek, Cumberland Co., N. J.

Coharie formation. (Of Columbia group.)

Pleistocene: Atlantic Coastal Plain from Delaware to Florida.

L. W. Stephenson, 1912 (N. C. Geol. Surv. vol. 3, pp. 273–277). *Coharie fm.*—Sandy clays, sands, more or less argill. or arkosic, and gravels. Almost everywhere gravels or coarse sands constitute basal beds; these are irregularly bedded, and in many places exhibit cross bedding. In almost all sections the coarser materials at base grade up into unstratified argill. sands or sandy clays; and these in turn into a soil of gray sand or sandy or clayey loam. Over large areas the immediate surface materials, from a few inches to 2 or 3 ft. thick, consist of loose gray sands. Thickness of deposits 25 to 50 ft. Upper surface of Coharie deposits forms a terrace plain, more or less dissected, which slopes up from elevations of about 160 or 170 ft. along its SE. edge to about 230 or 235 ft. along foot of escarpment which separates it from the Lafayette belt. Oldest fm. of Columbia group in N. C. Named for Great Coharie Creek, a tributary of Black River in N. C. The terrace plain formed by surface of the fm. has a widespread development on either side of the narrow valley of this creek in N. half of Sampson Co.

C. W. Cooke, 1931 (Wash. Acad. Sci. Jour., vol. 21, pp. 503–513), proposed to restrict Coharie fm. to the 215-foot level. The terrace fms. of Columbia group (including the Coharie) now recognized by Cooke from Del. to southern Ga. and probably into Fla., are enumerated herein under *Columbia group.*

Cohulta conglomerate.

Misprint (on p. 123 of U. S. G. S. Bull. 191) for *Cohutta cgl.*

Cohutta conglomerate.

Probably Lower Cambrian: Northwestern Georgia.

C. W. Hayes, 1891 (Geol. Soc. Am. Bull., vol. 3, pl. 3, p. 4). [Name appears in this rept at top of Hayes' Holly Creek section, in NW. Ga., but is not defined. The cgl. referred to is regarded by A. Keith as probably lower part of Great Smoky fm.]

Probably named for Cohutta Mtn, Gilmer and Fannin Counties.

Cojimar formation.

Oligocene or Miocene: Cuba.

R. H. Palmer, 1934 (Jour. Geol., vol. 42, No. 2, p. 134).

Colbert porphyry.

Pre-Cambrian: Central southern Oklahoma (Arbuckle Mountains).

C. A. Reeds, 1926 (Am. Mus. Nat. Hist. Jour., vol. 26, pp. 470–474, map). *Colbert porphyry.*—Pink porphyry dikes of pre-Camb. age.

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z, pp. 9–10). *Colbert porphyry.*—A mass rising in East Timbered Hills to highest point in Arbuckle Mtns, 1400± ft. altitude. Is largely pink feldspar phenocrysts in a reddish to gray groundmass, cut by numerous diabase dikes. Probably formed at less depth than Tishomingo granite. Lack of metamorphism in Colbert porphyry and Tishomingo granite suggests they are not older than Algonkian; may be as recent as Keweenawan or even Camb.

Derivation of name not stated.

Colbert sand.

A subsurface sand, of Penn. age, in Colbert pool, Okla. (T. 19 N., R. 12 E., W. part of Tulsa Co.), which according to F. Aurin (Okla. Geol. Surv. Bull. 19, pt. 2, chart opp. p. 526, 1917) correlates with Dutcher sand.

†Colchester formation.

Lower Cambrian: Northwestern Vermont (Chittenden County).

A. Keith, 1923 (Am. Jour. Sci., 5th, vol. 5, pp. 110, 129). *Colchester fm.*—Differs from underlying fms. in that it contains numerous shaly and slaty beds; is interbedded with sss. and dolomites. Greater portion of fm. in northern sections is sh., which decreases to S., and beds of calc. ss. and sandy dol. become more numerous. The shales are usually dark or black, distinctly banded and much speckled with little scales of mica. The ss. is gray, in thin layers, locally argill., but in places calc. In Highgate and Swanton the fm. contains many non-banded massive layers, which weather light gray or white, and many very strongly bedded layers that are used for flagstones. A few layers of sandy dol. are present here and there. A notable feature of fm. is a peculiar tough, dark-gray dol. that weathers brick red, and which forms lenses as much as 5 ft. thick and 50 ft. long near base of fm. In Swanton they are numerous and prominent and closely associated with a peculiar cgl. of irregular dol. bowlders in a sl. matrix. The fm. also contains another set of lenses of massive blue marbleized ls., sharply separated from the sl. These are best shown 2 mi. SE. of Swanton, where 2 of them are surrounded by gray sl. The lenses measure 100 by 60 ft. and 105 by 75 ft. The fm. is uncon. overlain by Milton dol. and grades into underlying Mallett dol. Thickness 200 to 250 ft. to S. and 500± ft. at N. Named for good exposures 1 to 2 mi. N. of Colchester village in town of Colchester [Milton quad.], which borders Burlington on N. Extends from Canada to Monkton, where it is cut off by a thrust fault. South of Monkton its position in eastern sequence is taken by a fm. of similar aspect but with less sh. and more dol. The Colchester has furnished a large part of the Lower Camb. fossils from Vt., and most of them have come from Parker quarry (now Howard quarry), 2¼ mi. N. 60° W. of Georgia. May include some Middle Camb.

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 371), renamed this fm. *Parker sl.,* and abandoned Colchester fm., because of poor exposures at that place.

Coldbrook group.

Pre-Cambrian or Cambrian: New Brunswick.

G. F. Matthew, 1863 (Canadian Nat., vol. 8, pp. 244, 246–247).

Cold Spring horizon.

Miocene or Pliocene: Eastern Texas (San Jacinto County).

E. T. Dumble, 1915 (Geol. Soc. Am. Bull., vol. 26, pp. 468, 470, 472, 473, 476). Cold Springs, W. of Trinity River [San Jacinto Co.], is in midst of an important outcrop of the Fleming. In this region the Fleming brown and gray clay has a considerable portion of brown, buff, and white sand. Locally there are large boulders of grayish-brown soft ss., some of which are 10 to 12 ft. long. There are also a fine-grained, hard, brown claystone and numerous calc. nodules; locally crystals of selenite; also pure white sand with only a minor amount of clay. Vertebrates [listed by W. D. Matthew] were secured from *Cold Springs horizon,* which is above center of the series of deposits in Trinity drainage here referred to the Fleming. Matthew says they are not earlier than Middle Mio. nor younger than Lower Plio. The *Cold Springs horizon* is in upper half of Fleming. [In chart on p. 476 the *Cold Springs* is placed below the Burkville. On map (p. 448) the town is spelled *Cold Spring,* which is spelling given in latest P. O. Guide.]

E. T. Dumble, 1920 (Univ. Tex. Bull. 1869, p. 237). *Cold Springs horizon* is much higher than the Burkeville, and is in upper half of Fleming clay.

Cold Springs granite.

Pre-Cambrian: Southwestern Oklahoma (Kiowa County).

C. H. Taylor, 1915 (Okla. Geol. Surv. Bull. 20). Finest-grained of Okla. granites. Is near a quartz monzonite. The only granite of commercial importance in Cold Springs area. Age relations to other granites of Wichita Mtns dist. cannot be stated with certainty. Appears to be older than Lugert granite.

Coldwater shale.

Mississippian: Michigan (Lower Peninsula).

A. C. Lane, as reported by M. E. Wadsworth, 1893 (Mich. Geol. Surv. Rept. 1891 and 1892, p. 66). *Coldwater shales,* 667 to 1,000+ ft. thick, underlie Marshall ss. and overlie Richmondville or Berea ss.

A. C. Lane, 1899 (U. S. G. S. W. S. P. 30, pp. 84–85). *Coldwater shales.*—In general composed of fine-grained, micaceous, bluish shales. Thickness 896 ft. Underlie Lower Marshall and overlie Berea black sh., 130 ft. thick.

C. H. Gordon, 1900 (Mich. Geol. Surv. vol. 7, pt. 3, pp. 1–20), divided *Coldwater shales* of Sanilac Co. into (descending): (1) Forestville shales, 100 to 200 ft.; (2) Richmondville ss., 50 to 80 ft.; (3) blue shales, 200 to 250 ft. Underlie Lower Marshall ss. and overlie Berea grit sh. (black shales 50 to 150 ft. thick).

A. C. Lane, 1902 (Mich. Geol. Surv. vol. 8, pt. 2, map at end), also 1909 (Mich. Geol. Surv. Rept. 1908) and later repts applied *Coldwater sh.* to all beds btw. Marshall ss. above and Berea grit below, including at base 25 to 55 ft. of black sh. called Sunbury or Berea sh.

This basal black sh. was included in Coldwater sh. in most subsequent repts, including: U. S. G. S. Ann Arbor folio, No. 155, 1908; W. H. Sherzer, 1913 (Mich. Geol. and Biol. Surv. Pub. 12); R. A. Smith, 1914 (Mich. Geol. and Biol. Surv. Pub. 14); C. W. Cook, 1914 (Mich. Geol. and Biol. Surv. Pub. 15); the 1916 geol. map of Mich. (by R. C. Allen, R. A. Smith, and L. P. Barrett); R. A. Smith, 1916 (Mich. Geol. Surv. Pub. 21, map opp. p. 148); C. G. Carlson, 1927 (A. A. P. G. Bull., vol. 11, p. 959+). The following repts treated Sunbury sh. as a distinct fm., underlying Coldwater sh. (restricted): W. F. Cooper, 1909 (Mich. Miner, vol. 11, No. 6, p. 13); W. M. Gregory, 1912 (Mich. Geol. and Biol. Surv. Pub. 11); and R. B. Newcombe, 1933 (Mich. Geol. Surv. Pub. 38).

In 1932 the U. S. Geol. Survey adopted for its publications the restricted definition of Coldwater sh. and treated the subsurface Sunbury sh. as a distinct fm.

In some repts the so-called Huron gritstone has been included in overlying Marshall ss. and in other repts in Coldwater sh.

Named for exposures on Coldwater River, in Branch and Hillsdale Counties.

Coldwater group.

Oligocene: British Columbia.

G. M. Dawson, 1896 (Canada Geol. Surv., n. s., vol. 7, pp. 26B, 65B–66B, 68B–71B, 160B–164B). [Assigned to Olig. Most later Canada repts assign this group to Olig., but a few have assigned it to Eo. and some to *Tert.*]

Coldwater sandstone member. (In Tejon formation.)

Eocene: Southern California (Los Angeles and Ventura Counties).

W. S. W. Kew, 1924 (U. S. G. S. Bull. 753). The top ss. of Tejon fm. in parts of Los Angeles Co. is locally known as "*Coldwater ss.*"

N. L. Taliaferro, 1924 (A. A. P. G. Bull., vol. 8, pp. 789–802). *Coldwater memb. of Tejon fm.*—West of Sespe Canyon, in heart of an anticline along Coldwater Creek, and again to N. along S. flank of Topatopa Mtns, there are 400 to 500 ft. of hard white sss. with intercalations of light-pink, pale-green, and grayish shales. The sss. carry a dwarfed estuarine fauna of Eocene age. These beds have heretofore been included with the Sespe, but since they are fossiliferous, and also differ lithologically from typical Sespe, they should be included in Tejon as *Coldwater memb.*

P. F. Kerr and H. G. Schenck, 1928 (Geol. Soc. Am. Bull., vol. 39, p. 1091). *Coldwater ss.*, top memb. of Tejon fm., is about 2,500 ft. thick near Matilija, Ventura Co. Is characterized by white friable arkose ss. interbedded with reddish sandy sh. and massive hard ledges composed of numerous shells of *Ostrea idriaensis* Gabb. Has been traced more than 40 mi. along Santa Ynez Range westward from type loc. in Coldwater Canyon.

Cole sand.

A subsurface producing sand in Fayette ss. (Eocene) of Driscoll pool, Duval Co., Tex. Lies higher than Mirando City sand.

Colebrooke schist.

Pre-Cretaceous: Southwestern Oregon (Port Orford quadrangle).

J. S. Diller, 1903 (U. S. G. S. Port Orford folio, No. 89). *Colebrooke schist.*—Completely metamorphosed sed. rocks, in part mica schists intermingled with slates in which cleavage is highly developed but without definite crystalline structure visible to unaided eye. Rocks always fine-grained, with decided schistose structure. Pre-Cret.; possibly pre-Dev. [Type loc. not stated, but Colebrooke Butte and surrounding country in Port Orford quad. are mapped as in this fm.]

G. M. Butler and G. J. Mitchell (1916) assigned this fm. to pre-Jurassic; W. D. Smith and E. L. Packard (1919) assigned it to pre-Camb.

†Cole Camp sandstone. (In Van Buren formation.)

Lower Ordovician (Beekmantown): Central Missouri.

A. Winslow, 1894 (Mo. Geol. Surv. vol. 6, pp. 331, 364–369). *Cole Camp ss.*—White saccharoidal ss., 6 to 25 ft. thick, underlying Osage ls. and overlying Proctor ls.

E. M. Shepard, 1904 (Bradley Geol. Field Sta. Drury Coll. Bull., vol. 1, pt. 1, p. 42). *Cole Camp ss.* is same as Gunter ss. [memb. of Van Buren fm.].

E. R. Buckley, 1905 (Mo. Bur. Geol. and Mines vol. 3, 2d ser., pp. 3–9). The *ss. at Cole Camp* is not Gunter ss. but a ss. bed in St. Elizabeth [Roubidoux] fm.

H. F. Bain and E. O. Ulrich, 1905 (U. S. G. S. Bull. 260, p. 234, and Bull. 267, p. 12). *Cole Camp ss.* of Winslow belongs in Gasconade ls., which underlies St. Elizabeth fm. [Gasconade has been restricted to upper part of Gasconade of early repts, and lower part has been named *Van Buren fm.* Gunter ss. is basal memb. of the Van Buren.]

Named for outcrops on Cole Camp Creek, Cole Co.

Cole Canyon dolomite.

Cambrian (Middle?): Central northern Utah (Tintic district).

G. F. Loughlin, 1919 (U. S. G. S. P. P. 107). *Cole Canyon dol.*—Alternating beds, 10 to 25 ft. thick, with nearly white and dark-gray weathered surfaces; some beds dense and finely banded, others finely crystalline. Thickness 500 to 510 ft. Underlies Opex dol. and overlies Bluebird dol. Scattered exposures occur along upper W. slope of Cole Canyon. Top and bottom drawn arbitrarily at lowest and highest light-colored bed.

Coleman limestone. (In Conemaugh formation.)

Pennsylvanian: Southwestern Pennsylvania (Somerset County).

F. and W. G. Platt, 1877 (2d Pa. Geol. Surv. Rept. H_3, pp. 286, 292). *Coleman ls.* underlies Coleman coal, from which it is separated by 6 inches of slate, and lies 40 ft. above Philson or Rose coal in Somerset Co. [Probably same as Cambridge ls. memb.]

Probably named for exposures at or near Coleman, Somerset Co.

†Coleman division.

Permian: Central Texas.

E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, p. lxvii). *Coleman-Albany series.*—Shales, clays, and lss., barren of coal, overlying Waldrip-Cisco series and underlying Wichita beds.

R. S. Tarr, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pp. 210–213). *Coleman div.*—Alternating lss., clays, shales, and sss. overlying Waldrip coal div. The ls. forming basal bed of Coleman div. is 25 to 100 ft. thick and not more than 100 ft. above the coal in Waldrip div.

Approx. same as Wichita fm.

Named for Coleman Co. and for occurrence near town of Coleman.

Coleman bed.
Coleman clay. } (In Admiral formation.)
Coleman limestone.

Permian: Central Texas (Colorado River region).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 421, 424). *Coleman bed.*—To S. mostly marly yellowish clay with some thin beds of ls. To N. chiefly black or dark-gray sandy clay sh. with many white specks scattered through it. Thickness 50 to 100 ft. Memb. of Albany div. [Wichita group]. Overlies bed No. 5 (25 to 60 ft. of ls. with some marly clay) and underlies Elm Creek bed.

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, p. 193, pl. 11), divided their Admiral fm. (basal fm. of Wichita group) into (descending): Elm Creek ls., 20 to 50 ft.; "Coleman clay" (Drake), 148 ft.; *Coleman ls.*, 12 ft.; "Bed No. 5" of Drake, 3 ft.; Indian Creek sh., 105 ft.; Hordes Creek ls., 2 ft.; Lost Creek sh., 46 ft. They defined "Coleman clay" as consisting of (descending), grayish yellow sh. 22 ft.; yellow-gray ls. 2 ft.; black sh. 34 ft.; muddy brown ls. 1 ft.; dark gray sh. 17 ft.; gray ls. 1 ft.; sh. 11 ft.; sandy sh. 3 ft.; sh. 58 ft.; and defined *Coleman ls.* as consisting of 3 ft. of yellow gray ls. underlain by 9 ft. of yellow sh.

Named for Coleman, Coleman Co.

Coleman Junction limestone member (of Putnam formation).

Permian: Central and central northern Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, p. 421). *Coleman Junction bed.*—In descending order: Yellowish friable ls., 8 to 10 ft.; clay, 10 ft.; massive, hard, brittle, yellowish brown, slightly cherty ls., 20 ft. Basal memb. of Albany div. Overlies Santa Anna Branch bed of Cisco div.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, p. 40). *Coleman Junction ls. memb.*—Upper memb. of Putnam fm., which is top fm. of Cisco group. Assigned to Penn. Overlies Santa Anna Branch sh. (lower memb. of the Putnam). Named for Coleman Junction, Coleman Co.

Putnam fm. was transferred to Perm. Wichita group in 1933.

Coles Brook limestone.

Pre-Cambrian: Western Massachusetts (Berkshire County).

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, pp. 27–28). *Coles Brook ls.*—More or less crystalline, white, impure mag. ls. Exposed at mouth of Coles Brook and 1 mi. to E.

B. K. Emerson, 1899 (U. S. G. S. Bull. 159, pp. 41–43). *Coles Brook ls.*—A remarkable linear outcrop of Hinsdale ls. 7 mi. long, which has cut through the Camb. gneisses like a knife, from Factory Hollow, in Middlefield, to S. part of Becket. Best exposed a mi. NW. of Bancroft Station, in Middlefield, where Boston and Albany R. R. cuts off a loop of Westfield River and Coles Brook enters this loop from N. South from Coles Brook the ls. rises in a great hill S. of Middlefield R. R. station, where it is 330 ft. thick.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 20–22 and map). *Coles Brook ls.*—Coarse, highly crystalline, mag. ls., locally white and pure, generally graphitic and greatly changed to a mass of silicates—chondrodite, wollastonite, wernerite, hypersthene, pyroxene, amphibole, titanite, adularia, pericline, and others. In southern part of State is largely changed to pyrrhotite. Thickness 600 ft. max. Lies in upper part of Hinsdale gneiss.

Colesburg dolomite.

Silurian (Niagaran): Central eastern Iowa.

C. [R.] Keyes, 1912 (Iowa Acad. Sci. Proc., vol. 19, pp. 149, 150). *Colesburg terrane.*—Dol., 30 ft. thick, comprising next to bottom fm. of Niagaran series. Overlies Sabula dol., of Niagaran, and underlies Hartwick dol., also of Niagaran. Separated from Hartwick and Sabula by fauna.

C. [R.] Keyes, 1932 (Pan-Am. Geol., vol. 58, No. 5, p. 377). Is same as Waucoma ls. and has priority.

Named for Colesburg, Delaware Co.

Colfax formation.

Upper Jurassic: Northern California (Gold Belt region).

J. P. Smith, 1910 (Jour. Geol., vol. 18, charts opp. pp. 217, 221). *Colfax fm.*—Tuffs and shales of Gold Belt with *Perisphinctes colfaxi*. Of Portland (Upper Jurassic) age. Overlies Mariposa fm. [restriction of Mariposa] and is older than Knoxville fm.

R. W. Goranson, 1924 (Am. Jour. Sci., 5th, vol. 8, p. 162). Mariposa fm. (of Auriferous slates) of Sierra Nevada is divided into two parts, the lower part being Mariposa sl., and the upper the *Colfax series* of the Gold Belt. The tuff beds of Colfax contain *Perisphinctes colfaxi*, and the same beds near Nashville, Amador Co., contain *Simbirskites* sp.

Is upper part of Mariposa sl. as used by U. S. Geol. Survey.

Colgate member (of Fox Hills sandstone).

Upper Cretaceous: Eastern Montana (Dawson County) and southwestern North Dakota.

W. R. Calvert, 1912 (U. S. G. S. Bull. 471, pp. 189–198). *Colgate ss. memb. of Lance fm.*—White and yellowish ss., 185 ft. thick, forming basal memb. of Lance fm. as here interpreted. Exposed on both sides of Cedar Creek anticline. In vicinity of Iron Bluff, in NE. part of T. 14 N., R. 55 E., it consists of following beds (descending): (1) Massive white ss., most prominent stratum in region, 35 ft.; (2) brown ss. 75 ft.; fossil leaves in bottom part; forms summit of Iron Bluff; (3) sh. and ss., 75 ft., fossil leaves in upper 20 ft. Overlies Pierre sh. and underlies, with only local unconformities, 500±ft. of somber colored clay and lenticular sss. containing a few lignite beds, which compose upper part of Lance. Although in Iron Bluff section there is an appearance of transition btw. Colgate ss. and Pierre sh., which suggests the ss. occupies the strat. position of the Fox Hills, the evidence of fossil leaves indicates that much if not all of it is of later age. Lower part may be Fox Hills, but if flora collected 70 ft. above base is found to continue to base of Colgate, then it should be considered merely as a memb. of Lance fm. Named for prominent development in vicinity of Colgate station, on Northern Pacific Railway.

W. T. Thom, Jr., and C. E. Dobbin, 1924 (Geol. Soc. Am. Bull., vol. 35, pp. 484–497). *Colgate ss. memb.* is here redefined and name is applied to the conspicuous white upper ss. of the Fox Hills, typically developed btw. Colgate station and

Glendive, Mont., and extensively exposed along Cedar Creek anticline and elsewhere in eastern Mont. The 35-foot white ss. is the upper (Colgate) memb. of the Fox Hills and forms top part of the lower 75-foot ss. of Iron Bluff, its white color being masked in the Iron Bluff exposure by ferruginous matter leached from the overlying brown ss. of the Lance. In addition to fossil leaves the Colgate ss. as here redefined contains abundant casts of *Halymenites major* in exposure along Cedar Creek anticline, and is gradational into underlying marine strata on Little Beaver Creek, S. of Baker. The Colgate is strikingly developed along the Missouri btw. Hell Creek and Musselshell River, consisting of 15 to 50 ft. of white ss. resembling its type development. That the fluviatile basal ss. of Lance in central Mont. is=Colgate ss. and upper white ss. of type Fox Hills the writers feel confident, although this has not been conclusively demonstrated by continuous tracing.

C. J. Hares, 1928 (U. S. G. S. Bull. 775), identified 17 to 40 ft. of Colgate ss. memb. in top of Fox Hills ss. of Marmouth lignite field, N. Dak.

Colgate member. (In Skaneateles shale.)

Middle Devonian: Central New York.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th. vol. 19, pp. 219, 221, etc.). *Colgate memb. of Skaneateles fm.*—Fine-grained, thin-bedded, cross-bedded ss. and bluish gray aren. sh. exposed on campus of Colgate Univ., Hamilton. Stratigraphically it lies at top of Berwyn memb. and is transitional with it. Upper part consists of 20 ft. of coarse aren. sh. capped by 1½ ft. of crinoidal ls. containing *Spirifer divaricatus*, which is characteristic of Centerfield ls., basal memb. of overlying Ludlowville fm. Best exposures of this upper sh. are at top of Univ. Quarry and in falls and quarry behind the buildings of Hatch's Red Gate stock farm. The Colgate is not known W. of E. margin of Cazenovia quad., and E. of type section it was but imperfectly identified in upper part of Gould's gully, Unadilla Valley, where the upper sh. has disappeared. But the memb. is prominent in Chenango Valley and is noted for its fine fossils. [Although this memb. is included in Skaneateles fm., diagram on p. 219 shows it to be E. equiv. of Centerfield ls. memb. of Ludlowville fm.]

Collazo shale.

Tertiary: Puerto Rico.

C. A. Reeds, 1916 (N. Y. Acad. Sci. Annals, vol. 26, p. 437).

College Hill limestone.

Upper Ordovician: Central Tennessee.

J. M. Safford, 1869 (Geol. Tenn., p. 276). *College Hill ls.*—Dark blue, highly fossiliferous, coarsely crystalline and roughly stratified ls., with more or less of its laminae shaly. Generally weathers into rough, flaggy lss., and shaly matter interstratified, often liberating multitudes of fossils, especially small corals; some of ls. layers are made up wholly of corals and shells. Thickness 120 ft. Well exposed on College Hill, Nashville. Lowest layers are at top of bluff at Wire Bridge. Top div. of Nashville fm. Overlies *Cyrtodonta* bed, a remarkable bed of coarsely crystalline, ashen-gray or light yellowish gray ls., in great part made up of valves of several species [enumerated] of fossils.

College Point stage.

Pleistocene: Southeastern New York (Long Island).

J. B. Woodworth, 1901 (N. Y. State Mus. Bull. 48, pp. 621-663). *College Point delta* and *College Point stage* included in Wisconsin epoch of Nassau Co. and Borough of Queens, Long Island.

Collier shale.

Cambrian: Southwestern Arkansas and southeastern Oklahoma (McCurtain County).

A. H. Purdue, 1909 (Geol. Soc. Am. Bull., vol. 19, p. 557; Slates of Arkansas, Ark. Geol. Surv., pp. 30, 31). *Collier sh.*—Dark, soft, graphitic, clay sh., containing widely separated thin beds of dense, black, and intensely fractured chert. As result of squeezing and shearing practically all traces of bedding have disappeared. In places slaty cleavage is visible. Upper 100 ft. or more is calc.; ls. occurring in dark-colored crystalline lenses and layers and in beds several ft. thick.

Upper part of ls. is conglomeratic. Thickness several hundred ft.; only upper 200 ft. exposed. Age unknown. Underlies, probably uncon., Crystal Mtn ss.

Named for Collier Creek, Montgomery Co., Ark.

Collingsworth gypsum member (of Blaine gypsum).

Permian: Central northern Texas, Texas Panhandle, and southwestern Oklahoma.

F. W. Cragin, 1897 (Am. Geol., vol. 19, p. 356, footnote). *Collingsworth gyp. fm.*—A higher gyp. than Quanah gyp. May represent Cave Creek fm.

C. N. Gould, 1902 (Okla. Geol. Surv. 2d Bien. Rept., p. 56). *Collingsworth gyp.*—Massive white gyp., 0 to 20 ft. thick, composing upper gyp. ledge of Greer div. In Okla. separated from overlying Delphi dol. [now known as Mangum dol.] by 20 ft. of red clay, and from underlying Cedartop gyp. by red clay sh. Named for exposures in Collingsworth Co., Tex.

C. N. Gould, 1924 (A. A. P. G. Bull., vol. 8, No. 3, pp. 324–341). Collingsworth gyp. memb. is provisionally considered = Shimer gyp. memb.

On 1926 geol. map of Okla (by H. D. Miser) this gyp. was included in *Blaine gyp.*, and the equiv. Greer fm. was abandoned.

Collingwood formation.

Middle Ordovician: Ontario (Manitoulin Island) and Michigan.

P. E. Raymond, 1912 (Canada Geol. Surv. Summ. Rept. for 1911, p. 354). *Lower Utica* (*Collingwood fm.*).—A thin fm. of layers of fine-grained rather pure blue ls. alternating with thick beds of soft brown sh. Thickness not known but appears to be less than 50 ft. Fauna, which is well developed at Collingwood, Ont., differs from that of typical Utica in many respects. Overlain by darker shales containing typical Utica fauna, and underlain by Trenton ls.

E. O. Ulrich, 1913 (12th Int. Geol. Cong. chart), placed *Collingwood sh.* in upper Trenton.

C. Schuchert, 1915 (Textbook geol., p. 629 and index). [*Collingwood fm.* is shown in table as top of Middle Ord., as overlying Trenton, and as underlying Utica and Eden.]

R. Bassler, 1915 (U. S. Nat. Mus. Bull. 92, vol. 2, pl. 2), placed *Collingwood* in upper Trenton.

W. Malcolm, 1915 (Canada Geol. Surv. Mem. 81, p. 23), included this fm. in Utica.

R. Ruedemann and G. M. Ehlers, 1924 (Geol. Soc. Am. Bull., vol. 35, p. 186), identified it in Mich. and assigned it to upper Utica, as did A. F. Foerste, 1924 (Canada Geol. Surv. Mem. 138, table opp. p. 58).

R. Ruedemann, 1925 (N. Y. State Mus. Bull. 258, pp. 62, 64, 149), placed *Collingwood sh.* below Gloucester sh. and above Cobourg ls. and assigned all 3 to Utica. He stated the deposits reached N. Y. "only in traces."

W. A. Parks, 1927 (Geol. Soc. Am. Bull., vol. 38, p. 229). If *Collingwood black sh.* is to be defined by presence of *Ogygites canadensis* it must include not only the black sh. with ls. beds but also many ft. of upper Trenton.

G. M. Kay, 1933 (Am. Jour. Sci., 5th, vol. 26, No. 151, p. 2), and 1935 (Geol. Soc. Am. Bull., vol. 46, pp. 227–228) included *Collingwood* in Trenton group.

Collinsville limestone.

Pennsylvanian: Southwestern Illinois (Madison County).

A. H. Worthen, 1873 (Ill. Geol. Surv., vol. 5, p. 315). *Collinsville ls.*—Fossiliferous ls., in upper div. of Coal Measures near Collinsville, Madison Co., lying about 115 ft. above the coal seam mined at that point, which is probably No. 5. Regarded same as Rock Creek ls. [Later studies by E. W. Shaw indicate that this ls. is probably older than Carlinville ls. and is the ls. in lower part of McLeansboro fm. that is known among mining men as the "top ls.," which lies 100 to 130 ft. above Herrin or No. 6 coal.]

Collinsville granite gneiss.

Ordovician (?): Northern central Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 105–107 and map). *Collinsville granite gneiss.*—Two types appear intermingled without order: (1) a light-gray, heavy-bedded, finely crystalline rock, grading into massive granite; and (2) a very dark gray to black variety which grades by imperceptible stages into even-banded hornblende gneiss and, rarely, into schistose phases. The darker varieties are produced by greater development of biotite in bands and patches, and the rock splits readily into even slabs from 1 inch to 10 inches thick. Dikes and veins of fine-grained granite and coarser pegmatite occur in Collinsville granite gneiss. Hornblende and plagioclase are so abundant in parts of the Collinsville that the whole fm. might be called a granodiorite gneiss. Well exposed at Collinsville.

H. E. Gregory and H. H. Robinson, 1907 (Conn. Geol. and Nat. Hist. Surv. Bull. 7, p. 34). The *Collinsville granite gneiss* was originally granite and diorite intruded into Hartland [Hoosac] schist.

Collores limestone.

Age (?): Puerto Rico.

C. R. Fettke, 1924 (N. Y. Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, vol. 2, pt. 2, p. 149).

†Collozoic age.

A time term that has been applied to all post-Keewatin pre-Camb. time. For definition see U. S. G. S. Bull. 769, pp. 26–27.

Colmar shales.

Upper Ordovician: Iowa.

C. [R.] Keyes, 1931 (Pan-Am. Geol., vol. 55, pp. 217-222), introduced this name to replace Clermont of Calvin.

†Colob sandstone.

Jurassic (?): Southwestern Utah (Washington County).

E. Huntington and J. W. Goldthwait, 1903 (Jour. Geol., vol. 11, pp. 46–63). *Colob ss.*—White ss. (Jurassic of Dutton) underlying Cretaceous sss. and sh. and overlying Kanab ss. (Triassic of Dutton). [*In* 1904 (Harvard Coll. Mus. Comp. Zool. Bull., geol. ser., vol. 6, p. 203, pl. 7) they called the rocks Colob fm., and described them as hard, white, cross-bedded ss. Name apparently derived from Colob Creek on Colob Plateau (spelled Kolob on some maps), Washington Co.]

According to A. A. Baker, C. H. Dane, and J. B. Reeside, Jr. (U. S. G. S. P. P. 183, chart opp. p. 33), Colob ss. of Huntington and Goldthwait's 1904 rept. is=upper part of Navajo ss.

Colony sand.

A prolific subsurface gas sand, 100 ft. thick, opened at Colony, T. 19 S., R. 23 E., Kans., and traced 15+ mi.

Coloradan series.

A term employed by C. R. Keyes instead of *Colorado group.*

†Colorado conglomerate.

Term applied by J. F. Carll (2d Pa. Geol. Surv. Rept. I, pp. 38–40, 48, 1875) to the coarse cgl. in hill-tops at Colorado, Warren Co., NW. Pa. Probably same as Olean cgl. memb. of Pottsville fm. (Penn.).

Colorado group. (**Colorado shale** or **Colorado formation** where undivided.)

Upper Cretaceous: Colorado, Wyoming, Montana, Idaho, North Dakota, South Dakota, northeastern New Mexico, Nebraska, Iowa.

F. V. Hayden, 1876 (U. S. Geol. and Geog. Surv. Terr. 8th Ann. Rept., p. 45). Numbers 2, 3, and 4 of the Cret., or the Fort Benton, Niobrara, and Fort Pierre divisions, may be regarded as one group, under the name of *Colorado group*, as adopted on Clarence King's beautiful geol. map of Green River basin. Underlain by Dakota group and overlain by Fox Hills group. *Exposed along E. base of Front or Colorado Range.*

C. King, 1876 (U. S. Geol. Expl. 40th Par., Atlas, map 1). *Colorado* includes [descending] Fort Pierre, Niobrara, and Fort Benton. Overlies Dakota and underlies Fox Hill.

C. King, 1878 (U. S. Geol. Expl. 40th Par., vol. 1, pp. 298, 305). The name *Colorado group was suggested by Hayden at my request, for the marine deposits* conformably underlying Fox Hills group and conformably overlying the Dakota.

C. A. White, 1878 (U. S. Geol. and Geog. Surv. Terr. 10th Ann. Rept., pp. 21, 22, 30). While adopting the name *Colorado group* of Mr. King, I, for paleontological reasons chiefly, so restrict its application as to include only what I understand to be equiv. with Nos. 2 (Fort Benton) and 3 (Niobrara) of Meek and Hayden's original section, leaving the equiv. of No. 4 (or Fort Pierre group) to be included with the strata of Fox Hills group, instead of with Colorado group, as Mr. King has done. Mr. Meek, who studied the paleontology of these groups so carefully, has shown in his works that while the paleontological affinities btw. the Fort Benton and Niobrara groups, and the Fort Pierre and Fox Hills groups, respectively, are very close, they are comparatively very slight btw. the two former and two latter groups, respectively.

The generally accepted definition of Colorado group includes only Benton and Niobrara and their equivalents.

Named for exposures at E. base of Colorado or Front Range, Colo.

†Colorado series.

Upper Cretaceous.

Name proposed by G. H. Ashley (Eng. and Min. Jour.-Press, vol. 115, No. 25, pp. 1106–1108, 1923) to include Colorado group and underlying Dakota ss.

Colquitt formation.

Upper Cretaceous (Gulf series): Southwestern Texas (Brewster County).

W. S. Adkins, 1933 (Univ. Tex. Bull. 3232, pp. 239, 271, 441, 452). From Val Verde to Terrell Counties westward to beyond Terlingua, the Austin consists of thin ls. flags, chalkier to E., more crystalline to W. Near Terlingua these are thin and are interbedded with much marly material, so as to weather down to flats. To NW. the fm. becomes more marly, until at Chispa Summit it consists of marl with thin subordinate amounts of marly and platy ls. flags. This facies is here called *Colquitt fm.* Thickness 1,200± ft. Overlies Chispa Summit fm. (Eagle Ford) and underlies Taylor clays. Type loc. is on Colquitt ranch below Chispa Summit, western Jeff Davis Co.

Colquitz gneiss.

Jurassic: British Columbia.

C. H. Clapp, 1913 (Canada Geol. Surv. Mem. 36, p. 57).

Columbia group.

Pleistocene: Atlantic Coastal Plain from Delaware to **Florida.**

W J McGee, 1886 (Rept. Health Office D. C. for 1885, p. 20; also Am. Jour. Sci., 3d, vol. 31, p. 473). Washington is located in a depression, or amphitheater, rising 20 to 80 ft. above tide, bounded on E., N., and SW. by bluffs rising 150 to 300 ft. in altitude and traversed by Potomac River and Eastern Branch. Within this amphitheater, and rising above its periphery to an altitude of something over 100 ft., is a well-defined Quat. deposit to which the name *Columbia fm.* is applied by U. S. Geol. Survey. It consists of loam or brick clay above, and sand, gravel, or both combined, below. Thickness varies considerably, the upper memb. ranging from almost nothing to perhaps 20 to 30 ft., and the lower from perhaps 1 to 20 ft. The fm. is more or less distinctly stratified throughout, particularly in its lower div., and at base it often becomes a simple bed of bowlders and gravel without considerable admixture of finely comminuted materials. In some places it rests on gneissoid, schistose, and greenstone rocks. The entire fm. appears to represent a subaqueous delta of Potomac River, formed when the sea rose far above its present level and fashioned the marine terraces exhibited in the bluffs. Overlies Potomac fm. In places rests on gneiss.

W J McGee, 1888 (Am. Jour. Sci. 3d, vol. 35, pp. 126–143, 367–388, 448–466; also Am. Ass. Adv. Sci. Proc., vol. 36, pp. 221–222). *Columbia fm.* consists of a series of subestuarine and submarine deltas and associated littoral deposits, occupying entire Coastal Plain of Middle Atlantic slope up to altitudes ranging from about 100 ft. to S. to over 400 ft. to N. Occurs from Long Island to Ga. Rests uncon. on the various known Tert. and Quat. deposits of the region, and has therefore been inferred to be Quat. The fm. was named for District of Columbia.

W J McGee, 1893 (Cong. Géol. Int. Compte rendu, 5th sess., pp. 231–239). The *Columbia fm.* has been traced throughout greater part of Coastal Plain from mouth of Hudson to beyond the Mississippi, or over an area of more than 200,000 sq. mi., its thickness and composition varying from place to place with the volumes of rivers and with character of sediments transported by them. Traced northward the fm. is found to pass under the terminal moraine and the drift sheet it fringes.

In N. J. the *Columbia group*, as the deposits are now called, is divided into (descending) Cape May, Pensauken, and Bridgeton fms. In the Atlantic Coastal Plain from Del. to Fla. it is now divided by C. W. Cooke into following terrace fms. (youngest to oldest): Pamlico fm. (at 25 ft. elev.), Talbot fm., restricted (at 42 ft. elev.), Penholoway fm. (at 70 ft. elev.), Wicomico fm. (at 100 ft. elev.), Sunderland fm. (at 170 ft. elev.), Coharie fm. (at 215 ft. elev.), and Brandywine fm. (at 270 ft. elev.). (See Int. Geol. Cong., 16th, Guidebooks Nos. 5 and 12, 1933.) Cooke stated (Guidebook No. 12, p. 8): The division into fms. is based chiefly upon geomorphology, the fill corresponding to each Pleist. terrace being considered a separate fm. and bearing the same name as the terrace. Cooke regards all of the fms. as chiefly or wholly marine, but some geologists—especially M. R. Campbell (Geol. Soc. Am. Bull., vol. 42, pp. 825–832, 1931) and C. K. Wentworth (Va. Geol. Surv. Bull. 32, 1930)—do not recognize any marine terraces above the 100-foot Wicomico terrace. All of the fms. enumerated above are present in Dist. of Columbia, the type loc. of the group. Cooke does not recognize the Princess Anne terrace (and fm.), which has been assigned to 12-foot elev.

†Columbia granite.

Pre-Cambrian: Central Virginia.

A. I. Jonas, 1928 (Va. Geol. Surv. prel. ed. of geol. map of Va.). *Columbia granite.*—Biotite quartz monzonite. Intrusive into Glenarm series. Mapped at and around Columbia, Fluvanna Co. Is pre-Camb.

A. I. Jonas, 1932 (Va. Geol. Surv. Bull. 38, pp. 18–23, map). *Columbia granite* (pre-Camb.) ranges in composition from quartz monzonite to granodiorite. It was named for its occurrence at Columbia, on Fluvanna-Goochland Co. line, N. of James River. Intrudes Wissahickon fm. and the hornblende gneiss. Mylonitized granite, the *Shelton granite gneiss facies of Columbia granite,* occurs in 2 zones [described]. The freshest and largest exposures of Columbia granite are in Cowherd quarries at Columbia, on N. side of James River, near highway 60.

This name conflicts with Columbia group (Pleist.) of same State.

†Columbia lava.

See *Columbia River basalt.*

Columbia Ford limestone.

Pennsylvanian: Eastern Kansas.

L. C. Wooster, 1905 (The Carbf. rock system of eastern Kans.). [No definition except that it is included in Humphrey shale. Derivation of name not stated. If it occurs in Humphrey sh. it is probably Wakarusa ls.]

Columbia Hill oil rock.

Drillers' term for a bed in basal part of Venango oil sand group of NW. Pa.

Columbian marble.

Trade name for a marble of Ord. age in western Vt. Derivation of name not known.

Columbia River basalt.

Tertiary (Eocene, Miocene, and Pliocene?): Oregon, Washington, and northern Idaho.

I. C. Russell, 1893 (U. S. G. S. Bull. 108, map. and pp. 20–22). Resting uncon. on Kittitas system and overlapping it to N., there is a great series of lava sheets, composed principally of basaltic rocks, which extend with unbroken continuity, not only over whole of Douglas Co., but larger part of Yakima and Kittitas Counties, Wash., and besides are known to pass southward beyond boundaries of Wash. Although this great series of lava sheets is irregular in many ways and of an entirely different origin from the sediments above and below it, yet it forms the most important geological series in the Northwest. As region it occupies is drained almost entirely by Columbia River, I venture to name it *Columbia lava*. So far as known this is most extensive fm. of its kind in the world. It is known to occupy large portions of Oregon and Idaho and to extend into northern Calif. Its estimated area is 200,000± sq. mi. It is traversed by Snake River throughout its entire course, and by the Columbia from near mouth of Spokane River to where the Columbia breaks through Cascade Mtns, a distance of 800 mi. The streams tributary to the Columbia from the S., below mouth of the Snake, also drain the same great lava field. The Columbia lava is not one vast flow, but is composed of many separate flows, sometimes separated by land surfaces, which frequently contain the stumps of large trees, or by sheets of lapilli. The sheets of which it is composed overlap and supplement each other, so as to form one continuous but highly compound system. No single sheet can be traced over entire field, but in sides of deep canyons that have been eroded in its surface individual flows may be followed continuously for a score or more of miles. The entire series varies in thickness from 300 or 400 ft. or less along rim of canyon of Columbia, on NW. border of Douglas Co., to 3,700 ft., according to Le Conte, in Cascade Mtns at the Dalles. Its average thickness is probably about 2,000 ft. In the best sections of Columbia lava exposed in coulees or canyons is Douglas Co. and the remarkable gates eroded by Yakima River through ridges of same material there are frequently 6 or 8 distinct layers of basalt exposed, from 50 to 150 ft. thick. The rock is usually a compact bluish black basalt, with frequently a well-defined columnar structure, but it is also at times vesicular and scoriaceous, especially on surfaces of the sheets. Near upper surface of Columbia lava in Yakima region there is a thin layer of clay formed as a sediment in a Tert. lake and later covered by a lava flow 100 ft. thick. Above this bed of basalt and resting evenly on its surface are gravels and fine, evenly bedded lacustral sediments 125 ft. thick. Then comes a sheet of columnar basalt 40 to 100 ft. thick, which can be traced from the hills about Ellensburg eastward to Columbia River and appears again in E. part of Saddle Mtn. Above this layer are the lacustral deposits of John Day system. The presence of Mio. lake beds on the surface of Columbia lava and the occurrence of Kittitas system of probable Eocene age below it, show that the volcanic outbursts belong somewhere near middle of Tert. [The map accompanying this rept. covers Yakima, Kittitas, Okanogan, and Douglas Counties and parts of counties adjacent on the E.]

I. C. Russell, 1900 (U. S. G. S. 20th Ann. Rept., pt. 2, pl. 9), mapped the Tert. rocks of Mount Stuart quad., Wash., and to N. and E., as follows (descending): Ellensburg ss., Columbia lava, Roslyn ss., Swauk ss., and andesite, and made the following statements (pp. 118–134): In U. S. G. S. Bull. 108 the author proposed term *"Kittitas system"* for the fms. here named *Roslyn* and *Swauk sss.* It has been thought best to abandon the provisional name first used. [p. 118, footnote.] The Columbia lava, in common with Swauk and Roslyn sss., has been upraised, and removal of upper part of these elevations has left exposed the edges of 4 distinct lava sheets. The lowest sheet in Mount Stuart quad. lies conformably on Swauk ss. (which contains Eocene plants) and is separated from second or Table Mtn sheet (which is of very wide extent) by Roslyn ss. (which also contains Eocene plants and is 200 to 3,500 or more ft. thick), with which it also appears to be conformable. The second sheet is of very wide extent. The third sheet is 300 to 350 ft. thick. The Ellensburg ss. contains plants identified by Knowlton as upper Mio. The Roslyn ss. is separated from Ellensburg ss., which occurs stratigraphically above it, by the several later sheets of Columbia lava and their associated tuffs. The number of separate overflows in entire Columbia system is not known, but is certainly a score or more. They are sometimes separated by sediments. The best exposures of Columbia lava occur in Snake River Canyon, where a vertical thickness of 4,000 ft. can be seen in a single escarpment.

I. C. Russell, 1901 (U. S. G. S. W. S. P. 53, p. 28, footnote). *Columbia River lava.*—In previous repts this fm. has been termed *Columbia lava*, but to avoid confusion with Columbia fm. of Atlantic States it has been thought best to change name to *Columbia River lava*.

J. C. Merriam, 1901 (Univ. Calif. Pub., Bull. Dept. Geol., vol. 2, No. 9). *Columbia lava.*—The name given to the lava fm. above the John Day was first used by Russell (U. S. G. S. Bull. 108, p. 20), who applied it to the series of eruptives which forms such a prominent feature of geology of area drained by Columbia River. In region discussed by Russell there are several distinct horizons of Columbia lava, separated by important fms. belonging to different geological periods. Obviously only one of them can retain the name, if it is to be used as a series or fm. name in geological classification. This one should be the horizon which is most prominent along Columbia River, as it was this fm. which suggested the name. In John Day basin it is found that the lavas of the Columbia form a well-defined series which lies btw. the John Day [upper and middle Olig. and Mio.] and Mascall [middle Mio.] fms. This series is the one of the several to which the name is applied which has the greatest lateral extent, forming probably the largest lava field in world and one of most important fms. on continent. It would seem advisable to restrict the name *Columbia* to this horizon. The lava series is composed of a large number of basalt flows which are sometimes separated by beds of tuff. At Turtle Cove 23 flows were counted in the bluff.

G. O. Smith, 1901 (U. S. G. S. W. S. P. 55), applied *Yakima basalt* to the Mio. part of Columbia River basalt, which he stated included basalts of Eocene, Mio., and post-Tert. age.

G. O. Smith (U. S. G. S. Ellensburg folio, No. 86, 1903, and Mount Stuart folio, No. 106, 1904) applied the name *Teanaway basalt* to the pre-Roslyn (Eocene) basalt flow, and the name *Yakima basalt* to the Mio. (pre-Ellensburg) basalt flow (2,000± ft. thick), and stated: In the reconn. surveys of central and SE. Wash. by Russell and others the names *Columbia lava* and *Columbia River lava* have been used, including not only basalts of Eocene, Mio., and possibly Plio. age, but also hypersthene andesite of Pleist. age. In detailed areal mapping igneous rocks of different ages must necessarily be separated, and therefore the name *Teanaway* has been applied to this fm., which includes only the basalt flows and interbedded basaltic pyroclastics of Eocene age, and which constitutes a series that can be taken as a unit. [He also applied the name *Wenas basalt* to a younger flow, 20 to 200 ft. thick, interbedded in the Ellensburg fm. (Mio.).]

J. P. Buwalda, 1923 (Idaho Bur. Mines and Geol. Pam. No. 5). *Columbia River basalts* are generally assigned to Mio. In SW. Idaho they lie on granite or on early phases of Payette fm. and are intercalated with it. They appear to be continuous with the great Columbia River basalt flows of Wash., Oreg., and central Idaho.

V. R. D. Kirkham, 1931 (Jour. Geol., vol. 39, No. 3, pp. 201–239). *Columbia River basalt* (Mio.) discon. underlies Idaho fm. in Idaho, and includes, 300 to 1,000 ft. below its top, the 1,000± ft. of terrestrial deposits and lake beds known as Payette fm., which carry a Mio. flora.

The U. S. Geol. Survey at present recognizes *Columbia River basalt* as a convenient blanket term, covering basalts of Eo., Mio., and Plio.(?) age in the broad region described by Russell. Some geologists restrict the name to the Mio. basalt (Yakima basalt).

See also *Snake River basalt* and *Yakima basalt*.

Columbus limestone.

Middle Devonian: Ohio.

W. W. Mather, 1859 (Rept. State House Artesian Well at Columbus, Ohio, p. 25). *Columbus ls.*, 138½ ft. thick, underlies 15 ft. of Dev. sl. and overlies 2 ft. of gritty hard rocks. [As thus defined included at top Delaware ls.]

J. S. Newberry, 1873 (Ohio Geol. Surv. vol. 1, pt. 1, p. 89). *Columbus ls.*—Very light-colored ls., containing balls of chert. Forms lower part of Corniferous ls., while Sandusky ls. forms upper part of Corniferous.

E. Orton, 1878 (Ohio Geol. Surv. vol. 3). *Columbus ls.*—White and buff lss., 45 ft. thick, underlying the bone bed [6 to 8 ft. thick] or basal bed of Delaware ls., and overlying Waterlime group or Lower Helderberg ls. Includes "Delhi stone" near top. Is lower part of Corniferous ls., the Delaware ls. being upper part of Corniferous.

E. Orton, 1890 (Ohio Geol. Surv., 3d ser., 1st Ann. Rept.), included the "bone bed" in Columbus ls., and it has been thus included in subsequent repts of all other geologists.

J. A. Bownocker, 1915 (Ohio Geol. Surv., 4th ser., Bull. 18), describes lower part of Columbus ls. as gray and upper part as usually buff.

Named for exposures at Columbus.

†Columbus sandstone. (In Cherokee shale.)

Pennsylvanian: Southeastern Kansas.

E. Haworth and M. Z. Kirk, 1894 (Kans. Univ. Quart., vol. 2, p. 106). *Columbus ss.*—The most extensive ss. system in Cherokee shales. Lies more than 200 ft. above base of Cherokee and in places divides it into two parts. Named for outcrops along Brush Creek, E. of Columbus, Cherokee Co.

W. G. Pierce and W. H. Courtier (unpublished mss.). The term "Columbus ss." was proposed by Haworth and Kirk for the ss. exposed SE. of Columbus, but was rather loosely defined and would probably include both Little Cabin and Bluejacket ss. members of Cherokee sh.

†Columbus sand.

Upper Cretaceous: New Jersey.

G. N. Knapp, as reported by R. D. Salisbury, 1899 (N. J. Geol. Surv. Ann. Rept. State Geol. 1898, pp. 35, 36). *Columbus bed.*—Sand underlying Marshalltown bed and overlying Woodbury bed. All included in Clay marl series [Matawan group].

H. B. Kümmel and G. N. Knapp, 1904 (N. J. Geol. Surv. vol. 6, p. 156). *Columbus sand.*—White or yellow quartz sand marked by delicate lines of red. Thickness 20 to 100 ft. Overlies Woodbury clay and underlies Marshalltown clay marl.

Preoccupied. Replaced by Englishtown sand.

Named for occurrence at Columbus, Burlington Co.

†Columbus marl.

Upper Cretaceous (Gulf series): Southwestern Arkansas.

See explanation under *Marlbrook marl.*

Named for Columbus, Hempstead Co.

Columbus quartzite.

Pennsylvanian: Central northern Utah (central Wasatch Mountains).

L. A. Palmer, 1906 (Mines and Min., vol. 26, pp. 438–439), in a description of rocks of Alta, divided the Carbf. rocks into: (1) upper lss., 1,000+ ft.; (2) *Columbus qtzite* (or upper qtzite), some hundreds of ft. ("corresponds in geologic age to Ontario qtzite of Park City"); (3) lower lime. The qtzite appears to be named for Columbus Consolidated Mine.

Same as Weber qtzite.

†Colville series.

Upper Cretaceous and Pliocene: Northern Alaska.

F. C. Schrader, 1902 (Geol. Soc. Am. Bull., vol. 13, p. 248). *Colville series.*—Chiefly heavy-bedded, partly consolidated silts or mud rock, with intercalated harder layers of soft ss., ls., sh., lignite, and unconsolidated silts. Thickness 500 to 600 ft. Of Plio. and Olig. age. The supposed Olig. part is best exposed along Colville River near mouth of the Anaktoovuk, where it comprises lower 150 ft. of section.

Later work proved Upper Cret. age of lower part of this "series" and Plio. age of upper part.

Colville granite.

Colville granodiorite.

Mesozoic (probably Cretaceous): Northeastern Washington.

J. T. Pardee, 1918 (U. S. G. S. Bull. 677). [The granite and granodiorite that compose Colville batholith, in Colville Indian Res., are, for brevity, called *Colville granite* and *Colville granodiorite* in this rept. They intrude Covada group.]

Colville quartzite.

Paleozoic: Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 68; map). *Colville qtzite.*—More homogeneous than Addy qtzite. Ranges from a pure light-colored massive rock, composed almost entirely of quartz grains, to a fine-grained pebbly or cgl. qtzite, pebbles usually less than ⅛-inch diam. Locally the belts become schistose and even argill. South of Kettle Falls along Columbia River they grade into schists and argillites and are difficult to distinguish from the younger Mission argillite. Thickness 5,000± ft. Rests with apparent conformity on Old Dominion ls. and underlies Mission argillite and Clugston ls. [Mapped close to town of Colville.]

Colvin limestone member (of Washington formation).

Permian: Southwestern Pennsylvania (Greene County) and northern West Virginia.

I. C. White, 1891 (U. S. G. S. Bull. 65, pp. 23, 39). *Colvin's Run ls.*—Buffish ls., 0 to 10 ft. thick. Named for Colvin's Run, Greene Co. Lies 0 to 1 ft. above Waynesburg "A" coal and 30 to 35 ft. below Waynesburg "B" coal. Included in Dunkard Creek series [Dunkard group]. Seldom seen S. of Pa. line.

In several subsequent repts by Pa. Geol. Survey this ls. was called *Calvin Run ls.*, upon the misapprehension that the stream for which it was named (in Greene Co.) was correctly spelled *Calvin*, as on the topog. maps. Later the Pa. Geol. Survey changed the name of the ls. to *Colvin Run*. In explanation, G. H. Ashley, State Geol., stated (letter dated Sept. 4, 1931) that according to the postmasters at Mount Morris and Kirby the name is correctly spelled *Colvin Run*.

In 1910 the U. S. Geol. Survey adopted *Colvin ls. memb.* (of Washington fm.) as the name of this ls.

Colvin sand.

A subsurface sand of late Chester (Miss.) age in Ind. that has been correlated with Tar Springs ss.

†Colvins Run limestone member.

See *Colvin ls. memb.*

Colwood sands and gravels.

Pleistocene: British Columbia.

C. H. Clapp, 1913 (12th Int. Geol. Cong. Guidebook 8, p. 294; Canada Geol. Surv. Mem. 36, p. 112); 1914 (Canada Geol. Surv. Mem. 51, p. 85; Canada Geol. Surv. Summ. Rept. 1912, p. 51); and 1917 (Canada Geol. Surv. Mem. 96, p. 345). *Colwood sands and gravels*, Pleistocene, British Columbia.

Colwood formation.

Recent: Northwestern Washington (San Juan Islands).

R. D. McLellan, 1927 (Univ. Wash. Pub. Geol., vol. 2). *Colwood fm.*, post-Vashon alluvium, deposited since retreat of last glacier. Thickness 0 to 50 ft. [Assigned to Recent.]

Comanchan series.

Comanchan system.

Terms applied by some geologists to *Comanche series* of U. S. Geol. Survey and other geologists.

Comanche series (or **epoch**).

The provincial series of marine Lower Cretaceous rocks present in Southwestern States and the time during which they were deposited. **For definition see U. S. G. S. Bull. 769, pp. 59–61.**

†Comanchean system.

Name introduced by T. C. Chamberlin and R. D. Salisbury in 1906 (Geology, vol. 3, pp. 107–137), for major part of Comanche series, but excluding at top the rocks of Albian and Cenomanian age, which they included in overlying "system," to which they restricted the name *Cretaceous*. See U. S. G. S. Bull. 769, p. 60.

Comanche Creek bed. (In Strawn formation.)

Pennsylvanian: Central Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 374, 385). *Comanche Creek bed.*—Clays, 300 ft. thick, divided into three parts by 8 to 10 ft. of hard, massive ss. associated with 10 to 15 ft. of shaly friable ss. and clay. Memb. of Strawn div. Underlies Antelope Creek bed and overlies Wilbarger Creek bed.

Named for Comanche Creek, Mills Co.

†Comanche Peak group.

Lower Cretaceous (Comanche series): Central Texas.

B. F. Shumard, 1860 (St. Louis Acad. Sci. Trans., vol. 1, pp. 583, 584). *Comanche Peak group.*—Fossiliferous, soft, yellowish and whitish chalky ls. and buff and cream-colored lss. of greater or less compactness. Thickness 300 to 400 ft. Underlies Caprina ls. [Shumard's section of this "group" at Shovel Mtn, Burnet Co., shows it included Comanche Peak ls., Walnut clay, and at least larger part of Trinity fm. Name was later used by R. T. Hill in same sense as Fredericksburg group.]

Named for Comanche Peak, Hood Co.

Comanche Peak limestone. (In Fredericksburg group.)

Lower Cretaceous (Comanche series): Eastern Texas.

R. T. Hill, 1889 (Tex. Geol. Surv. Bull. 4, pp. xiv, xvii–xix). *Comanche Peak chalk bed.*—Persistent, fossiliferous, white chalky ls., composing middle fm. of Fredericksburg div. [group]. Conformably underlies Caprina chalk and chalky ls. [Edwards ls.] and overlies *Exogyra texana* beds [Walnut clay].

Named for Comanche Peak, Hood Co.

See also under *Fredericksburg group.*

Comanchian series.

Comanchian system.

Terms applied by some geologists to Comanche series.

†Combahee shale.

Miocene (lower and upper): Southern South Carolina (Colleton County).

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 12, 18, name only, not defined); and 1908 (S. C. Geol. Surv., ser. 4, Bull 2, pp. 435, 464, 465). *Combahee phase.*—Poorly stratified gray and yellow sh. with occasional pockets of glauconite, and enclosing casts and moulds of shells and, along its littoral margin, impressions of the dwarf palmetto. Overlain by Parachucla marl.

According to C. W. Cooke (personal communication, 1935) Combahee sh. of Sloan included Hawthorn fm. (lower Mio.) and Raysor marl (upper Mio.).

Appears to be named for exposures on Combahee River.

Combe sandstone.

Upper Jurassic: Northern California (Mount Jura).

C. H. Crickmay, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 81), divided the Jurassic rocks of Mount Jura into following fms. (descending), but did not define any of them:

Upper Jurassic: *Combe ss.*, Trail tuffs and cgls., Lucky S argillite, Cooks Canyon aggl., Forman argillite, North Ridge aggl., Hinchman arkose.

Middle Jurassic: Hull aggl., Moonshine cgl., Mormon ss., Thompson red sh., Fant volcanics, Hardgrave tuff.

Lower Jurassic: Lilac argillite.

C. H. Crickmay, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 5, pp. 896, 903). *Combe fm.*—Calc. marine ss. and cgl. containing cobbles from the mid Upper Jurassic quartz porphyry and from granitic plutonics. Thickness 550 ft. Rich but ill-preserved fauna. Of late Upper Jurassic age. Overlies Trail tuff and cgl. Type loc., Combe Canyon, N. of Mount Jura.

Combined Metals bed.

A name locally applied to 40 or 50 ft. of ls. in Pioche sh. of Pioche dist., Nev., which is the productive horizon (silver, lead, and zinc) of the Combined Metals mine. (See U. S. G. S. P. P. 171, pp. 54–55, 1932.)

Combs limestone.

Upper Devonian: Eureka district, Nevada.

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 52, 78). *Combs lss.*—1,200 ft. thick, form top fm. of Nevadan series [Nevada ls.] in Nev. Named for Combs Peak, in neighborhood of Eureka.

Comerio beds.

Early Cretaceous (?): Puerto Rico.

C. P. Berkey, 1915 (N. Y. Acad. Sci. Annals, vol. 26, p. 61).

Comet Creek bed.

Lower Cretaceous: Western Oklahoma (Custer County).

R. T. Hill, 1895 (Am. Jour. Sci., 3d, vol. 50, p. 228). *Comet Creek bed.*—Isolated remnant of Cret. at Comet Creek, G Co., Okla., described by Prof. Jules Marcou as a single stratum of Gryphaeate ls., 5 ft. thick, containing one fossil speciès, the *G. pitcheri* of Marcou. Probably part of same general fm. as those nearby at Camp Supply and Belvidere. [Marcou located Comet Creek at lat. 35°32′21″ and long. 99°14′40″.]

Commerce sandstone.

Tertiary: Southeastern Missouri (Scott County).

C. L. Dake, 1918 (Mo. Bur. Geol. and Mines, vol. 15, 2d ser., p. 191). *Commerce ss.*—Prominent ss. that outcrops at and near Commerce, Scott Co. Best exposures in cuts of St. Louis & San Francisco R. R. in and just N. of Commerce. Rock moderately fine-grained, buff to pink, and varies from loose friable ss. to vitreous qtzite. About 20 to 30 ft. is exposed in R. R. cuts. Has been referred to Cret. by some of earlier writers, but Marbut classifies it as a more indurated phase of the Tert. Similar sands and qtzites of Tert. age, underlain by unconsolidated Tert. clays, are reported from many points on Crowley's Ridge, Ark.

Commercial limestone member (of Bingham quartzite).

Pennsylvanian: Central northern Utah (Bingham district).

A. Keith, 1905 (U. S. G. S. P. P. 38, p. 40, map, sections). *Commercial ls. memb. of Bingham qtzite.*—Most extensive ls. body of Bingham region. Commonest strata are blue lss. and altered white marbles, with here and there beds of light-blue, gray, dark-blue, and black ls.—precisely the same kinds of rock as in Jordan ls., which lies a considerable distance below it. Thickness 0 to 200 ft. May possibly be same as Yampa ls. lentil and Jordan ls. may possibly be same as Highland Boy ls. memb. [Evidently named for Commercial mine.]

Commonwealth ore formation.

Age (?): Northern Michigan.

C. L. Rominger, 1881 (Geol. Surv. Mich., vol. 4, pt. 2, p. 223). *Commonwealth ore fm.*—The ore fm. of Commonwealth Mine, Menominee iron region, which I place below Quinnesec ore fm. of Quinnesec mining dist.

†Como beds.

Name applied by W. B. Scott in 1897 (Introduction to geol., pp. 477, 491) to the beds in southern Wyo. and Colo. which were named *Morrison fm.* by G. H. Eldridge in 1896. In 1907 Scott adopted *Morrison fm.*, and

Como beds (from Como, Wyo.) is no longer used. W. C. Knight, 1900 (Geol. Soc. Am. Bull., vol. 11, pp. 377–388), called these beds *Como stage*. They have also been called "*Atlantosaurus* beds" (paleontologic name). The Morrison fm. is now classified as Upper Jurassic.

Comondu formation.

Tertiary: Mexico (Lower California).

A. Heim, 1922 (Geol. Mag., vol. 59, p. 542).

Comox formation.

Cretaceous: British Columbia.

C. H. Clapp, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 105). [Age not assigned; but MacKenzie, 1922 (Can. Inst. Min. and Met., Mon. Bull. No. 122, p. 674), assigned it to Cret.]

Compton limestone.

Mississippian (Kinderhook): Southwestern Missouri.

R. C. Moore, 1928 (Mo. Bur. Geol. and Mines vol. 21, 2d ser., pp. 60, 108–109, 111, 118–122, 131, 158). *Compton ls.*—Light bluish-drab or grayish-blue compact ls., very fine grained and breaking with conchoidal fracture; occurs in beds averaging 6 to 8 inches in thickness but in places as much as 2 ft. thick. Thickness 0 to 25 ft. Conformably overlain by (merges with) Northview fm. Rests uncon. on Sylamore ss. in some places, but usually lies on Ord. Contains a typical Chouteau fauna, and it seems best to regard it as a thin extension of a part of Chouteau ls. of central Mo. It is certainly not=Louisiana ls., although in most previous repts it has been called Louisiana. In some repts it has been included as a calc. facies of Northview fm. Cannot be correlated directly with previously recognized strat. units, and therefore the name *Compton ls.* is proposed. Named for exposures along James River in vicinity of Compton, near W. line of Webster Co., where 22 ft. is exposed.

Compton formation.

Ordovician: Southeastern Quebec (Mount Megantic region).

H. W. McGerrigle, 1935 (Quebec Bur. Mines Ann. Rept. 1934, French ed., pt. B, p. 78).

H. W. McGerrigle, 1935 (Quebec Bur. Mines, Rept. Minister Mines 1934–35, pt. D, pp. 71–73). Sss. and slates, granitic and gabbroic sills at base. Widely developed in Compton Co.

†Conanicut granite.

A name that has been casually applied in some repts (for example, L. V. Pirsson, Am. Jour. Sci., 3d, vol. 46, p. 363, 1893) to the granite described as *granite of Conanicut Island*, southern Rhode Island, which is now considered to be same as Sterling granite gneiss. (See B. K. Emerson, U. S. G. S. Bull. 597, p. 171 and map, 1917.)

Conanicut arkose.

Carboniferous: Southern Rhode Island (Conanicut Island).

A. F. Foerste, 1899 (U. S. G. S. Mon. 33, p. 380). *Conanicut arkose.*—Evidently composed of detrital material derived from the granite. Occurs on E. side of Mackerel Cove, Conanicut. Thickness may reach 100 ft. Possibly contemp. with part of Aquidneck shales.

A part of either Rhode Island fm. or Wamsutta fm. as mapped by B. K. Emerson, U. S. G. S. Bull. 597, 1917.

Conasauga shale, also **Conasauga limestone.**

Upper and Middle Cambrian: Northwestern Georgia, northern Alabama, and eastern Tennessee.

C. W. Hayes, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 143, 144–148). *Conasauga sh.*—Alternating beds of ls. and calc. sh., 1,600 to 2,000 ft. thick. Underlies Knox dol. and overlies Rome ss. Same as Knox sh. of E. A. Smith and J. M. Safford.

C. W. Hayes, 1891 (U. S. G. S. Bull. 81, p. 304). In section from Rome, Ga., to Gadsden, Ala., *Connasauga sh.* is 1,600 to 2,000 ft. thick, and consists of (descending): Thin-bedded seamy ls., sometimes blue and massive; yellow calc. shales grading into seamy ls.; earthy ls. interbedded with shales, often wanting and locally carrying nodules of chert; yellow shales; oolitic ls. and thin beds of light-green or yellow shales; variegated sandy shales, purple, green, brown, etc. Overlies Rome ss.

C. W. Hayes, 1894 (U. S. G. S. Ringgold folio, No. 2). *Connasauga sh.*—At base thin lss., in part oolitic, interbedded with shales; in middle yellow or greenish clay shales; at top blue seamy ls. or calc. shales. Where the oolitic ls. is absent bdy btw. Connasauga and underlying Rome fm. becomes very indefinite. The same is true when upper part of the Rome contains lss. Thickness probably 1,500 to 2,500 ft.

C. W. Hayes, 1902 (U. S. G. S. Rome folio, No. 78). *Conasauga fm.* presents several widely different phases in this quad. At type loc. (in Dalton quad., to NE.) it consists of great thickness of fine clay sh. with occasional beds of rather pure blue ls. from a few inches to several hundred ft. thick. Near Rome and to NE. it consists at base of several hundred ft. of fine olive clay sh., then beds of oolitic ls., and finally of 1,000 ft. or more of calc. shales interbedded toward top with blue lss. To S. of Rome the lss. increase. In Coosa Valley the fm. can be divided into 3 rather distinct phases: The upper part consisting of characteristic greenish siliceous shales, in some places replaced by greenish micaceous ss. To NW. the siliceous beds are replaced by fine olive-green shales, and throughout central part of valley this division is represented by olive shales containing many flat concretions of gray siliceous rock intermediate btw. qtzite and chert. The intermediate div. of the Conasauga in Coosa Valley is clay sh. containing varying amounts of ls. The lower part of fm. is wholly fine clay or slightly sandy sh.

C. Butts, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14, p. 69, etc.). *Conasauga ("Coosa") fm.*—Made up of ls., dol., and sh. of varying proportions in different areas; in places it is chiefly ls., in other places chiefly sh. Thickness ranges from 500 to possibly 3,600 ft. Overlies Rome fm. and underlies Brierfield dol. and younger fms. into which Knox dol. has been divided in this region.

Named for exposures in Conasauga Valley, Dalton quad., NW. Ga.

Conception slate.

Pre-Cambrian: Newfoundland.

C. D. Walcott, 1899 (Geol. Soc. Am. Bull., vol. 10, p. 220).

Conchos gravels.

Age(?): Mexico.

R. H. Burrows, 1909 (Min. and Sci. Press, vol. 99, p. 327).

Concord granite.

Late Paleozoic(?): Central southern New Hampshire.

C. H. Hitchcock, 1873 (Rept. Geol. Surv. N. H. 1872, pp. 9, 12). Of the specific members of White Mtn series that known as "*Concord granite*" has been traced irregularly from Concord to Fitzwilliam. [p. 12. On p. 9 he calls it the *celebrated Concord granite.*]

C. H. Hitchcock, 1877 (Geol. N. H. pt. 2). A not less important variety of Montalban group is a granitic gneiss with very different degrees of crystalline coarseness. The finer grained rock often displays no visible marks of stratification, though there is no reason to doubt its sed. origin, and, for convenience, this is designated *Concord granite.* It is usually incoherent, tender, and quite friable after decomposition has commenced, and is distinguished from Lake granitic gneiss by its fineness of texture.

G. W. Hawes, 1881 (Am. Jour. Sci., 3d, vol. 21). Origin of *Concord granite* is open to question. [He mapped it.]

C. H. Hitchcock, 1884 (Bull. Am. Mus. Nat. Hist., vol. 1, No. 5, pl. 16, pp. 178–179), placed *Concord granite* below Montalban.

W. O. Crosby and M. L. Fuller, 1896 (Tech. Quart., vol. 9, p. 330). Montalban gneiss seems to be merely a more gneissoid phase of *Concord granite.* They are youngest and most acidic of entire granite series of the region. Intrusions of normal Concord granite occur chiefly in more massive fms. (Winnipesaukee gneiss, porphyritic gneiss, etc.).

M. Billings, 1935 (letter dated Aug. 27). I have never studied *Concord granite* in the field, but would tentatively assign it to New Hampshire magma series [late Dev. or late Carbf.] from description I have read.

Concord formation.

Oligocene: Western California (San Francisco Bay region).

B. L. Clark, 1918 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 11, pp. 54-111). *Concord fm.*—Chiefly fine grayish ss., becoming finer and more shaly near top, and including at base a thin layer (6 inches) of cgl. the boulders of which are composed mainly if not entirely of tuff, ss., and sh. apparently derived from immediately underlying Olig. beds. Thickness about 250 ft. On S. side of Sobrante anticline, in Concord quad., it discon. overlies Kirker tuff and uncon. underlies Sobrante ss. [restricted definition, and only upper part of Lawson's Sobrante ss.] of Monterey group. Included in San Lorenzo series. Is lower part of Sobrante ss. as defined by Lawson, the name *Sobrante* being restricted by author to upper 80 to 100 ft. of Lawson's Sobrante.

Concreto shale.

Pennsylvanian: Southeastern Kansas.

G. I. Adams, 1904 (U. S. G. S. Bull. 238, p. 20). *Concreto sh.*—Clay sh., 75 ft. thick, overlying Iola ls. and underlying Allen [Plattsburg] ls.

According to H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines vol. 13), this is same as Lane sh., but according to N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, p. 56), and R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), it includes true Lane sh. and 2 overlying fms. (Wyandotte ls. and Bonner Springs sh. of present Kans. Geol. Surv.) up to base of Plattsburg ls. (See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.) Newell says (p. 56 cited above): Concreto may properly be used for beds btw. top of Iola ls. and base of Plattsburg ls.; but it seems preferable to indicate the combined Lane and Bonner Springs sh. by hyphenated term *Lane-Bonner Springs sh.*, where intervening Wyandotte ls. disappears, thus avoiding using a geographic name that gives no indication of its strat. relation to correlative units, and the introduction of a different name where separating lss. thin out.

Named for Concreto, Allen Co.

Condon erosion surface (Oregon).

See under *Ochoco erosion surface*.

Conecuh sands.

Pleistocene: Southeastern Alabama.

See under †*Ozark sands*.

Probably named for Conecuh River.

Conejo volcanics.

Miocene: Southern California (western end of Santa Monica Mountains).

N. L. Taliaferro, 1924 (A. A. P. G. Bull., vol. 8, pp. 800-801). One of most important centers of Mio. volcanism in the State lies in W. end of Santa Monica Mtns. This region is often referred to as Conejo Mtns, and name *Conejo volcanics* is here applied to all volcanic and intrusive rocks occurring in that region. These volcanic rocks and the interbedded Mio. sediments probably aggregate 15,000 ft in thickness.

Conejos andesite. (Of Potosi volcanic series.)

Miocene: Southwestern Colorado.

E. S. Larsen, 1917 (Colo. Geol. Surv. Bull. 13, pp. 20, 38-39). *Conejos fm.*—Dark-colored andesite of compact texture and similar in appearance to Summitville andesite. Presumably an augite andesite. Basal fm. of Potosi volcanic series ih Platoro-Summitville quad. Underlies Treasure Mtn latite. In field we called this fm. *Palisade andesite*. [Palisade is preoccupied.]

W. H. Emmons and E. S. Larsen, 1923 (U. S. G. S. Bull. 718). *Conejos fm.* is 0 to 3,000+ ft. thick in Platoro-Summitville dist. Named for exposures along Conejos River.

W. W. Atwood and K. F. Mather, 1932 (U. S. G. S. P. P. 166). *Conejos fm.* is an extremely variable volcanic aggl. with intervening flows of andesite. In places in Summitville quad. a considerable thickness of it consists of stream-laid gravels and bowlders.

E. S. Larsen, 1935 (U. S. G. S. Bull. 843). *Conejos andesite.*—In nearly all large exposures of this fm. tuff breccia is in greater amount than massive rock. In central and thickest part of the Conejos volcanic pile, in Summitville, Conejos, and Del Norte quads., massive rock makes up considerable part of fm., but near borders, to W., in San Cristobal quad., and to N., in N. part of Del Norte quad. and S. part of Cochetopa and Saguache quads., massive rock is very subordinate and tuff breccia, much of it rather well bedded, makes up most of fm. To S., in Tusas quad., N. Mex., beginning not far S. of State line, the fm. is made up mostly of several hundred ft. of sands and gravels, composed chiefly of volcanic rocks, with some layers of pyroclastic beds or flows. Farther S. the fm. becomes thinner and grades into sands and gravels composed chiefly of pre-Camb. rocks. In S. slopes of the mtns a variable thickness of soft bedded sands and gravels made up of volcanic material underlies the normal Conejos andesite. It has been included in the Conejos although it may be older. It is commonly very poorly exposed. Is well developed in drainage of Chama River in SE. part of Summitville quad. and N. and E. of Quien Sabe Mtn, in NW. part of Summitville quad. and adjoining part of Pagosa Springs quad., where it overlies Blanco Basin fm. The greater part of the rocks of Conejos fm. are andesitic.

Conemaugh formation.

Pennsylvanian: Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

F. Platt, 1875 (2d Pa. Geol. Surv. Rept. H, p. 8). *Conemaugh series* underlies Pittsburg coal bed, basal bed of Monongahela series, and overlies Allegheny series, which includes Upper Freeport coal at top. The Conemaugh includes Middle Barren Measures and underlying Mahoning ss. [This definition accords with current definition of Conemaugh fm. except that the thin clay underlying the Pittsburg coal has for many years been included in Monongahela fm.]

The present Pa. Geol. Survey classifies the Conemaugh as a *group*.

Named for exposures along Conemaugh River, Pa.

Conestoga limestone.

Ordovician (Lower) and Cambrian(?): Southeastern Pennsylvania.

G. W. Stose and A. I. Jonas, 1922 (Wash. Acad. Sci. Jour., vol. 12, pp. 359, 365–366). *Conestoga ls.*—Dark slaty ls., coarse ls. and marble cgl., thin-bedded granular blue ls. and thin graphitic sl. Overlaps southeastward on all fms. from Ledger dol. to Harpers schist. Probably older than or in part=Cocalico sh. and probably of Chazy age.

E. B. Knopf and A. I. Jonas, 1923 (Am. Jour. Sci., 5th, vol. 5, p. 55). *Conestoga ls.*—Strongly crumpled, gray to blue, crystalline ls. with partings of black graphitic sl. Is gashed by numerous veinlets of coarsely crystalline white calcite. To S. around Mine Ridge Hill it is gray or blue, micaceous, banded ls. In some places it comprises massive beds of white marble speckled with phlogopite. Near base are lentils of coarse ls. cgl., which are now regarded as basal cgls. in a transgressive series of probably Chazy age. Edgewise cgls. occur near base in some places. Named for outcrops along Conestoga Creek S. of Lancaster.

G. W. Stose and A. I. Jonas, 1923 (Geol. Soc. Am. Bull., vol. 34, pp. 507–524). [Detailed description.]

G. W. Stose and A. I. Jonas, 1927 (Geol. Soc. Am. Bull., vol. 38, pp. 524–526). *Conestoga ls.*—Extends from NE. of Phila. along Chester and Quarryville valleys to Lancaster, thence across Lancaster, York, and Hanover valleys to Md. line. Rests uncon. on fms. from Beekmantown ls. to Harpers schist (Lower Camb.). Probably of Chazy or Black River age.

This fm. is now classified by U. S. Geol. Survey as of Beekmantown age in Chester Valley and as Lower Ord. or Camb. at type loc. It has yielded very few fossils.

Conewago group.

Upper Triassic: Central southern Pennsylvania (Dauphin and York Counties).

G. H. Ashley, 1931 (Topog. and Geol. Surv. Pa. Bull. G_1, p. 77). *Conewago group*.—Alternating hard, purplish, or pinkish red ss. and red sh., 8,000 ft. thick, underlying Lewisburg group and overlying Manchester group, all Upper Tr. [Credited to [M. H.] Bissell. When the Triassic of New Cumberland quad. (in which occur the geographic features indicated) was differentiated for 1931 geol. map of Pa., these rocks were included in Gettysburg sh., and the underlying "Manchester group" was mapped as New Oxford fm., of which it is a westward continuation.]

Conewango formation.

Devonian or Carboniferous: Northwestern Pennsylvania (Warren County).

C. Butts, 1908 (Pa. Topog. and Geol. Surv. Rept. 1906–08, pp. 191, 198) and 1910 (U. S. G. S. Warren folio, No. 172). *Conewango fm*.—Greenish sandy sh. with thin layers of very fine-grained greenish, micaceous, and argill. sss. and cgls. Thickness 550 ft. Underlies Knapp fm. and overlies Chemung fm. Includes Salamanca cgl. memb. near middle. Marked change in fossils at Conewango-Chemung bdy. Assigned to Devono-Carboniferous. Is=Oswayo and Cattaraugus fms. of Olean and Salamanca quads., N. Y., which can not be differentiated in Warren Co. because of absence of red beds above Salamanca cgl. Represents upper part of Catskill fm. but differs from it in lithologic and paleontologic character. At base of the Conewango in Olean region, N. Y., is Wolf Creek cgl., which appears to lie at about same horizon as Panama cgl. The fm. is named for fact the beds make most of valley walls and uplands bordering Conewango Creek S. of N. Y. bdy.

G. H. Chadwick, 1924 (N. Y. State Mus. Bull. 251, p. 157), correlated Conewango fm. with Riceville sh. and underlying beds, called Venango, shown as extending to base of LeBoeuf ss. (Panama cgl.). He repeated this correlation in 1933 (Pan-Am. Geol., vol. 60, No. 3, p. 195). Chadwick classified the beds as post-Chautauquan and assigned them to "Bradfordian" (Upper Dev.). On p. 10 of this Pan-Am. paper he stated that what has been called Oswayo in Tioga Co., Pa., is Cattaraugus or older.

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 203), assigned ***Oswayo sh. memb.*** to his Riceville fm. (restricted to lower part of Riceville of previous repts), and named the upper part of the Riceville of previous repts the ***Smethport sh. memb. of Knapp fm.*** He assigned his Smethport to Miss. and Oswayo to Upper Dev.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71), applied *"Conewango series"* to beds extending from top of Riceville restricted down to base of Panama cgl. He included typical Oswayo sh. of Olean quad., N. Y., in his Riceville stage (Riceville monothem), assigned the Conewango to Dev. and discarded "Bradfordian," which he stated included definitely Miss. and definitely Dev. beds. On p. 47 he restricted Riceville to "Dev. part" of Riceville of previous usage, and named the "Miss. part" ***Kushequa sh.*** (to replace his Smethport sh.).

G. H. Chadwick, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, p. 332). If, and writer is not averse to this, to succeeding Cussewago or Knapp group is transferred top 40 ft. of original Conewango at Warren, Pa., the Smethport (subsequently Kushequa) sh. of Caster, carrying therewith the corresponding upper part of the Riceville, and also the Devil's Den (Leptodesma) ss. near Smethport, then some of the Miss. element (so called) is subtracted and the case for Dev. age of the Conewango is by thus much strengthened. [Fossils listed and discussed pp. 328–333.]

The U. S. Geol. Survey at present classifies Conewango fm. as *Dev. or Carbf.*

Conewango clay.

Pleistocene: Northwestern Pennsylvania (Warren County).

See under *Clarendon gravel.*

Named for Conewango Creek, Warren Co.

Conewango series.

See 1934 entry under *Conewango fm.*

Coney limestone. (In Bluefield formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 298, 379). *Coney ls.*—Greenish yellow, shaly; occasional marine fossils. Thickness 0 to 4 ft. Top memb. of Bluefield group [fm.]. Overlies Coney sh. and underlies Stony Gap ss. Type loc. in vicinity of Avis, just opposite Coney Island, Summers Co.

Coney shale. (In Bluefield formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 298, 380). *Coney sh.*—Red, variegated, and sandy; marine fossils, also a persistent plant zone; streaks of ss. or ls.; 40 to 95 ft. thick. Underlies Coney ls. and overlies Clayton ss.; all members of Bluefield group [fm.]. Type loc. on E. side of New River, just E. of Avis and just opposite Coney Island, Summers Co. Also exposed in Mercer and Monroe Counties, W. Va., and in Giles and Tazewell Counties, Va.

Confederate limestone member (of Hoxbar formation).

Pennsylvanian: Central southern Oklahoma (Carter County).

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z, p. 15). *Confederate ls. memb.*, basal memb. of Hoxbar fm., reaches max. thickness of 60± ft. at its westernmost outcrop, NW. of Ardmore. Elsewhere it contains cgl. streaks, with chert and ls. pebbles.

C. W. Tomlinson, 1929 (Okla. Geol. Surv. Bull. 46, pp. 39–40). *Confederate ls. memb.*, basal memb. of Hoxbar fm.; consists of two resistant ledges, each 15–20 ft. thick, of coarsely granular, semi-crystalline gray to buff ls., sparingly fossiliferous, separated by a 30-foot interval of weaker material, part of which is also ls. Thins in general to SE. and thickens to NW. Lies 400± ft. below Union Dairy memb. of Hoxbar. Named because well exposed and has been quarried a short distance back (W.) of Oklahoma Confederate Veterans' Home, in SE¼ sec. 36, T. 4 S., R. 1 E., on SW. outskirts of Ardmore.

C. W. Tomlinson, 1934 (A. A. P. G. Bull., vol. 18, No. 8, p. 1085). According to revised mapping *Confederate ls. memb.* has been traced SE. *into*, instead of *below*, Westheimer memb. as mapped W. of Hoxbar, near S. line of Carter Co. *Westheimer ls.* can now be dropped and *Confederate*, geographically preferable, be substituted. This places base of Hoxbar fm. slightly higher than base as originally mapped by Goldston (1922). However, as this memb. is in that area the lowest of the conspicuous lss. which here constitute the most essential distinguishing characteristic of Hoxbar fm. as compared to the fms. above and below it, and also includes the lowest ls. cgl. (possibly intraformational) above Bostwick memb. of Dornick Hills fm., it appears most appropriate to continue to regard base of Hoxbar as coincident with base of Confederate ls. memb.

†Congaree shales (also †Congaree phase).

Eocene (lower and middle): Central South Carolina.

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 12, 16). *Congaree shales.*—The *Congaree phase* exhibits its littoral line in Aiken Co. along Hollow Creek, near Savannah River, and extends easterly with occasional tongues forming shore line indicated for Tertiary. It is delimited on S. by a line extending from mouth of Hollow Creek (Aiken Co.) along Tinkers Creek N. of Kennedy's Bluff by Binnaker's Bridge (South Fork Edisto River), by Springfield, by Orangeburg, by Jenkins Hill, by Warley Hill, and by Fullers Earth Creek. From this point the fm. apparently constitutes narrow bands whose respective lines around the Carolina Ridge and by Catchall and Naked Creek probably follow the littoral line indicated for the Tert. in general description. The Congaree shales in some localities grade upward to a pea-green marl (Kennedy's Bluff on Tinkers Creek; Binnakers Bridge on Edisto River; Wannamakers Kiln on Caw Caw Swamp; and to a limited extent at Warleys Hill). The materials consist of buhrstone and sands, shales, and marl. Named for exposures on western scarp of Congaree River and the embayments of its tributaries to Lang Syne and Warley Hill, Orangeburg Co. [On p. 449 of Bull. 2 cited above Sloan showed *Congaree* as consisting of (descending) buhrstone, sands, and shales, underlying Caw Caw shales and marls (basal part of his Warley Hill phase) and overlying Black Mingo "phase."]

C. W. Cooke and H. K. Shearer, 1918. (See 1918 entry under †*Congaree clay memb.*)

C. W. Cooke, 1936 (U. S. G. S. Bull. 867). Fossils from Congaree phase of Sloan show that it included part of Black Mingo fm. (of Wilcox age) and lower part of McBean fm. (of Claiborne age), and it is abandoned. Its type loc. appears to be on Elmore Williams' place at head of First Creek, 0.8 mi. W. of Gaston, Lexington Co.

†Congaree clay member.

Eocene (upper): Eastern Georgia.

J. O. Veatch and L. W. Stephenson, 1911 (Ga. Geol. Surv. Bull, 26, p. 267), and 1915 (U. S. G. S. W. S. P. 341, pp. 77, 268). *Congaree clay memb. of McBean fm.*—Principally fullers' earth and drab or greenish sandy clays. Fossiliferous. Its name is adopted from S. C., where Sloan has described its distribution [under name *Congaree shales*]. In Ga. it lies at base of Claiborne group and of McBean fm., resting uncon. on Lower Cret. Thickness at least 100 ft. [Named for Congaree, Richland Co., S. C.]

C. W. Cooke and H. K. Shearer, 1918 (U. S. G. S. P. P. 120C). The beds called *Congaree clay memb. of McBean fm.* by Veatch and Stephenson are of Jackson age and much younger than "Congaree shales" of Sloan, which are of Wilcox age. The rest of McBean fm. contains Claiborne fossils. McBean fm. is therefore here restricted to beds of Claiborne age, and the "Congaree" clay memb., which is of Jackson age, is here transferred to Barnwell sand and renamed *Twiggs clay memb. of Barnwell fm.* Twiggs clay memb. thins out in Ga., near Savannah River and is absent in S. C. [See also C. W. Cooke, 1936 (U. S. G. S. Bull. 867, on S. C.).]

Congdon Hill moraine.

Pleistocene (Wisconsin stage): Rhode Island (Narragansett Bay region).

J. B. Woodworth, 1896 (U. S. G. S. 17th Ann. Rept., pt. 1, table opp. p. 988).

Conglomerate series.

Conglomerate group.

Conglomerate measures.

Names applied in early repts to Pottsville group of Appalachian region.

Connasauga shale.

See *Conasauga sh.*

Connaughtic.

A term introduced by C. [R.] Keyes for a pre-Camb. epoch, separating his Anianic from his Nisconlithic. (See Pan-Am. Geol., vol. 55, pl. 8, p. 132, 1931.)

Conneaut group.

Upper Devonian: Northwestern Pennsylvania and northeastern Ohio.

Am. Jour. Sci., 5th, vol. 27, p. 471, June, 1934. *Note. A new stratigraphic name.*—In a paper by George H. Chadwick accepted for publication in this Journal, the new name *"Conneaut group"* (footnote: Caster, K. E., Bulls. Am. Pal., No. 71, now issuing) is employed to embrace the Upper Dev. Girard and Chadakoin shales of NW. Pa., or lower Chagrin of Ohio.

K. E. Caster, June 9, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 136, footnote). The substitution of *French Creek ls.* for *Conneaut ls.*, proposed in earlier parts of this paper for same memb., is at request of G. H. Chadwick, so that *Conneaut* may be used as a group name in his forthcoming revision of the "Portage" and "Chemung." The name *Conneaut* is especially fitting for the unit to which he is applying it, and "French Creek" is equally appropriate for the Miss. ls. of this paper. The name *Conneaut* is introduced to embrace Girard and Chadakoin stages of Upper Dev. in NW. Pa. and also the underlying Cuba ss. farther east. The wording in Chadwick's ms. is as follows: To these pseudo-Chemung beds, from base of the Dunkirk to base of Cuba ss., I am proposing to apply the substitute and distinctive name *Canadaway group,* and to those from base of Cuba ss.

to base of Wolf Creek (Panama) cgl., in which the fauna has been modified by loss of *Delthyris mesacostalis* and accession of *Camarotoechia(?) duplicata,* the name *Conneaut group.*

G. H. Chadwick, Feb. 28, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, p. 351). [See this entry under *Canadaway group.*]

G. H. Chadwick, Nov., 1935 (Am. Mid. Nat., vol. 16, No. 6, pp. 860, 862). *Conneaut group* (or lower Chagrin) named for exposures on Conneaut Creek, in O. and Pa., which crosses the 2 members of the group present on Lake Erie, viz, Girard sh. below and Chadakoin beds (I. C. White's "Chemung") above.

†Conneaut limestone member.

Mississippian: Northwestern Pennsylvania.

K. E. Caster, June 9, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61), proposed *Conneaut ls. memb.* to replace *upper Meadville ls.* of early repts on NW. Pa. On p. 136 of same book he substituted *French Creek ls.,* for his proposed Conneaut ls. memb., at request of G. H. Chadwick, who desired to apply "Conneaut" to a Dev. unit in the same region.

†Connecticut shales, sandstone, and conglomerate.

†Connecticut sandstone group.

†Connecticut River sandstone.

Names applied in early Conn. and Mass. repts to sed. part of Newark group as developed in valley of Connecticut River. The interbedded igneous *flows* are treated as part of Newark group, the name now universally applied to these rocks. Has also been called *"Otozoum beds,"* because the rocks contain footprints of *Otozoum moodii,* a sp. of batrachian.

Connellsville sandstone member (of Conemaugh formation).

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

F. Platt, 1876 (2d Pa. Geol. Surv. Rept. L) *Connellsville ss.*—Coarse, gray, diagonally bedded ss., 65 ft. thick. [Called also *Ligonier ss.* on pp. 17, 19, 20.] Caps highest hills in Ligonier Valley, SW. Pa., and town of Connellsville, Pa., is built on it. Lies about 25 ft. below Pittsburg ls. and about 40 ft. above Pittsburg (Morgantown?) ss. [The Pittsburgh ss. is a much younger bed than Morgantown or Connellsville sss. The Morgantown is considerably older than the Connellsville, according to generally accepted classifications.]

Connellsville red bed. (In Conemaugh formation.)

Pennsylvanian: Southeastern Ohio, western Pennsylvania, and northern West Virginia.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, pl. 6), applied name *Connellsville red bed* to beds immediately underlying Summerfield ls. in Muskingum Co., Ohio; to beds lying a short distance below Lower Pittsburgh ss. at Wheeling, W. Va.; to beds overlying Little Clarksburg coal and = Connellsville ss. at Pittsburgh, Pa.; to beds overlying Connellsville ss. and underlying Little Pittsburgh coal in Preston Co., W. Va.; and to a red bed in midst of Connellsville ss. at Latrobe, Pa.

Connellsville member. (In Conemaugh formation.)

A term employed by Pa. Geol. Surv. (M. E. Johnson, Topog. and Geol. Atlas Pa., No. 27, Pittsburgh quad., p. 31, 1929) to include Connellsville ss. and Franklin coal.

Connelly conglomerate. (In Oriskany group.)

Lower Devonian: Southeastern New York.

G. H. Chadwick, 1908 (Sci., n. s., vol. 28, pp. 346–348). *Connelly cgl.*—Pebble beds, 18 to 20 ft. thick, typically exposed on hill above South Rondout (Connelly P. O.) [Ulster Co.] and in creek bank opposite. Included in Oriskanian. Underlies Glenerie ls. and overlies Port Ewen ("Kingston").

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 370), assigned this cgl. to Oriskany.

Connoquenessing sandstone member (of Pottsville formation).

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q). *Connoquenessing ss. (Lower Homewood).*—Consists of (descending): Very massive, hard white ss. 40 to 50 ft.; darkish sandy shales, generally containing iron ore at top and in some places a thin coal below, 40 to 50 ft.; hard, massive, grayish brown ss. 20 to 25 ft. Overlies Sharon shales. Lies 20 to 80 ft. below Upper Homewood [Homewood] ss.

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q_2), applied following names in Lawrence Co, Pa. (descending): Lower Mercer iron shales, 5–10 ft.; *Upper Connoquenessing ss.*, 45 ft.; Quakertown coal, 0 to 3 ft.; Quakertown iron shales, 40 ft.; *Lower Connoquenessing ss.*, 25 to 50 ft.; Sharon iron shales, 0 to 25 ft.; Sharon coal, 0 to 3 ft. The *Upper Connoquenessing ss.* forms upper cliff along Connoquenessing Creek btw. its mouth and Slippery Rock, and *Lower Connoquenessing ss.* is frequently seen along bed of Connoquenessing Creek [Lawrence Co., Pa.].

H. M. Chance, 1879 (2d Pa. Geol. Surv. Rept. V, pp. 221–226). *Connoquenessing ss. group.*—Underlies Mercer group and overlies Sharon group in western Pa. Thickness 140–180 ft. Divided by Mr. White into an Upper and a Lower Connoquenessing ss., but it could be readily subdivided into Upper, Middle, and Lower, or even into 4 divisions. As these rocks are very variable in thickness and character, being often nearly or wholly replaced by sh. and sl., they may be called the "*Connoquenessing ss. group.*"

Conococheague limestone.

Cambrian (Upper): Central southern Pennsylvania, western Maryland, and northwestern Virginia.

G. W. Stose, 1908 (Jour. Geol., vol. 16, p. 701). *Conococheague ls.*—Closely banded dark-blue ls., characterized by beds containing thin sandy laminae and quartz grains that weather into hard sh. fragments and thin slabby sss. Base marked by siliceous beds and cgls. of two kinds.

G. W. Stose, 1909 (U. S. G. S. Mercersburg-Chambersburg folio, No. 170), gave 1,635 ft. as thickness of Conococheague ls.

Named for Conococheague Creek in Scotland, Franklin Co., Pa. Underlies Beekmantown ls. and overlies Elbrook fm.

Conover slate.

Pre-Cambrian (upper Huronian): Northeastern Wisconsin (Vilas County).

R. C. Allen and L. P. Barrett, 1915 (Mich. Geol. and Biol. Surv. Pub. 18, geol. ser. 15, pp. 123–129). *Conover slates.*—Soft red, gray, or black slates containing seams of ferruginous chert and abundant iron carbonate. Probably continuous eastward with sl.-iron fm. series of Iron River dist., Mich., of which it is regarded as a tongue. Underlie eastern three-fourths of Conover dist.

Conroe sand.

A subsurface sand, 250 ft. thick, in Montgomery Co., Tex. According to A. Deussen and E. W. K. Andrau (A. A. P. G. Bull. vol. 20, No. 5, 1936, p. 540) it lies in upper part of Yegua fm. in Conroe dist. (5 mi. SE. of Conroe, Montgomery Co.), at about horizon of Tuleta sand of Pettus dist. (See F. W. Michaux, Jr., and E. O. Buck, A. A. P. G. Bull., vol. 20, No. 6, pp. 736–779, for description of Conroe oil field.)

Conshohocken clay.

Cretaceous? or Ordovician?: Southeastern Pennsylvania (Montgomery County).

T. C. Hopkins, 1899 (Am. Geol., vol. 23, p. 102; and Sci. n. s., vol. 9, p. 139) and 1900 (Geol. Soc. Am. Bull., vol. 10, pp 480–482; also Pa. State Coll. Ann. Rept. 1899–1900). *Conshohocken clays.*—Tough, plastic, refractory clays, 30 to 60 ft. thick. Rest on blue ls. (in places white and blue) of supposed Trenton age. No fossils except lignite. Occur on hill N. of Conshohocken. Resemble plastic clays of N. J., Long Island, and Marthas Vineyard.

Contention series.

Mesozoic (Lower Cretaceous?) : Southeastern Arizona (Tombstone district).

W. P. Blake, 1902 (Tombstone and its mines). *Contention and Toughnut series, of* Tombstone dist., consists of (descending) shales, blue ls., and qtzite. It overlies, uncon. (?), the Manganiferous or Luck-Sure series of massive, thick-bedded lss. [Derivation of name not stated.]

J. A. Church, 1903 (Am. Inst. Min. Engrs. Trans., vol. 33, pp. 3–37). *Contention sh. series.*—Contains a heavy bed of qtzite, many thin lss. and thin qtzites. Regarded as a single composite memb. Thickness 700 ft. Top div. of Toughnut series. Overlies Blue lime.

F. L. Ransome, 1920 (U. S. G. S. Bull. 710D). Contention sh. series of Church is Mesozoic, probably Comanche (Lower Cret.).

†Contra Costa lake bed.

Pliocene: Western California (San Francisco Bay region).

J. G. Cooper, 1894 (Calif. Acad. Sci. Proc., 2d ser., vol. 4, p. 169). *Contra Costa lake bed.*—Lies chiefly on NE. slope of hills W. of San Pablo Creek, forming bdy btw. Contra Costa and Alameda Counties in that part of its course about 4½ mi. NE. of State University.

Contra Costa County Miocene.

A term applied in earlier literature to the Mio. deposits of Contra Costa Co., Calif., which are now divided into several named fms.

Conway granite.

Late Devonian or late Carboniferous: White Mountains and northwestern New Hampshire.

C. H. Hitchcock, 1874 (Geol. N. H. pt. 1, btw. pp. 508 and 545). *Granite of Conway,* so called since most of town is underlaid by it. Carries much quartz. Is pre-Camb.

C. H. Hitchcock, 1877 (Geol. N. H. pt. 2, many pp.). *Conway granite.*—Contains quartz, feldspar, and mica. Thickness 600 ft. The typical rock known as the "Conway" is best example of a real granite in N. H. Older than Albany granite. [Assigned to pre-Camb. in this and subsequent repts of Hitchcock and others.]

M. Billings, 1928 (Proc. Am. Acad. Arts and Sci., vol. 63, No. 3, map and pp. 67–137). *Conway group (Dev. ?).*—Chiefly biotite granite. Is=Conway granite of Hitchcock. At least 6 distinct phases in North Conway quad., some of which are segregation phases and others distinct intrusives: (1) Red phase (coarse biotite granite); (2) Green phase (relatively coarse hastingsite granite); (3) *Baldface phase* (medium-textured biotite granite low in dark minerals); (4) *Diana phase* (porphyritic biotite granite); (5) *Black Cap phase* (fine-grained pink biotite granite typically exposed on SE. slope of Black Cap, where it is shattered by Conway granite; is of either Conway or pre-Conway age); (6) contact phases.

M. P. Billings and C. R. Williams, 1935 (Geology of Franconia quad., N. H., map), assigned *Conway granite* to late Dev. or late Carbf., and to their White Mtn magma series.

Conway schist.

Silurian(?): Western Massachusetts, southeastern Vermont, and southwestern New Hampshire.

B. K. Emerson, 1892 (U. S. G. S. Hawley sheet, i. e., proof sheets of geol. maps and text intended for a geol. folio, but never completed and published in that form, although cited in U. S. G. S. Bull. 191, 1902). *Conway schist.*—Rusty, contorted, muscovite schist. Underlies Leyden phyllite and overlies Goshen schist. The Conway and Goshen comprise Calciferous mica schist of Hitchcock.

B. K. Emerson, 1898 (U. S. G. S. Holyoke folio, No. 50; also U. S. G. S. Mon. 29, pp. 183–225). *Conway schist.*—Dark graphitic mica schist, with biotite, garnet, staurolite, zoisite, and many beds of dark impure ls. and sandy qtzite. Thickness 5,000 (?) ft. Probably=Amherst schist to E. Underlies Leyden argillite [in Mass. and Vt.; absent in N. H.] and overlies Goshen schist. [See also B. K. Emerson, U. S. G. S. Bull. 597, 1917, pp. 46–47, and map, in which Amherst schist is assigned to Carbf. and Conway schist to Sil.(?).]

Named for development along the rivers in Conway and Deerfield, Franklin Co., Mass.

Coody sandstone member (of Atoka formation).

Pennsylvanian: Eastern Oklahoma (Muskogee and McIntosh Counties).

C. W. Wilson, Jr., 1935 (A. A. P. G. Bull., vol. 19, No. 4, pp. 503–520). *Coata ss. memb.*—Massive ss., medium to coarse-grained; large pebbles of quartz and chert near base; light to dark brown; fossiliferous. Thickness 40 ft. Basal memb. of Atoka fm. in Muskogee-Porum dist. Separated from overlying Pope Chapel ss. memb. by 150 to 220 ft. of sh. Named for exposure along Coata Creek in secs. 34 and 35, T. 15 N., R. 19 E.

R. H. Dott, 1936 (letter dated June 12). One mi. S. of Muskogee is a stream called *Coody Creek,* named for one of the old families in the area. An oil field has been named for it, and this name is universally applied. The topog. map shows it as "Coata." Since "Coata" is meaningless to anyone living or working in the area, I believe this usage should be corrected to *Coody*.

Cook sand.

A subsurface sand, of Penn. age, in Cook and Engle fields, Shackelford Co., north-central Tex., lying at 1,170 to 1,200 ft. depth.

Cooke granite.

Pre-Cambrian: Central southern Montana (Park County).

T. S. Lovering, 1930 (U. S. G. S. Bull. 811A, p. 17). Medium-grained pink granite, chiefly quartz and pink orthoclase. Cuts Goose Creek granite. Well exposed near Cooke [in SE. corner of Park Co.].

Cook Inlet gravels.

Pleistocene: Central southern Alaska (Cook Inlet region).

J. E. Spurr, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 174–175). *Cook Inlet gravels.*—Pleist. marine gravels, extending from Cook Inlet along drainage basin of Skwentna River as far as Tordrillo Mtns. Thickness 40 to 100 ft.

Cook Mountain formation. (In Claiborne group.)

Eocene (middle): Southern and eastern Texas and northwestern Louisiana.

W. Kennedy, 1892 (Tex. Geol. Surv. 3rd Ann. Rept., pp. 54–57). *Cook's Mtn series.*—Extensive series of marine beds, prevailingly greensands, but including greensand marls, altered greensand with thin strata of carbonate of iron, indurated altered fossiliferous greensand, green fossiliferous clays, glauconitic sss. and clays, stratified black and gray sandy clays, brown fossiliferous sands, black or yellow clays with limy concretions, and occasionally local deposits of black sand with gyp. crystals. Thickness 390 ft. Underlies Yegua div. and overlies Mount Selman div.

Sparta sand was for many years treated as basal memb. of Cook Mtn fm., but it is now treated as a distinct fm.

Named for Cook Mtn, Houston Co., Tex.

Cook Ranch formation.

Oligocene (middle): Southwestern Montana (Beaverhead County).

A. E. Wood, 1933 (Jour. Mammalogy, vol. 14, No. 2, May 1933, pp. 134–135). A small collection of Middle Olig. fossils [listed] was found by A. E., F. D., and H. E. Wood, and R. Dowden in a butte immediately W. of road opposite (W. of) front entrance to buildings of Cook Sheep Co. Home Ranch, 8.1 mi. by road N. and E. of Dell railroad station, T. 12 S., R. 33 E., secs. 27 and 34. This butte forms W. (right) wall of valley of Sage Creek, in that part of its course which flows S. The fossils were in 3 small pockets, at essentially same strat. level, either just above, or just below, a prominent ss. lens. As these beds are definitely of a different age from those described by Douglass as the Sage Creek beds, a new fm. name is required, and *Cook Ranch* is elsewhere proposed (H. E. Wood, Bull. Am. Mus. Nat. Hist., in press). Sage Creek fauna is middle and upper Eocene, according to determinations by H. E. Wood and others. The Cook Ranch resembles Brule of Big Badlands in composition and erosion forms. Most of exposure is gray clay, but there are intercalated sss., a foot or less thick, resembling the *Metamynodon* sss. Thickness exposed estimated at 125 ft. At top of bluff is a coarse gravel (age undet.) lying horizontally and uncon. above Cook Ranch beds. Similar gravels occur at a considerably lower altitude a short distance to N. [See also H. E. Wood, 2nd, 1934 (Am. Mus. Nat. Hist. Bull., vol. 67, art. 5, pp. 250–255, 277), where practically same description as above is given, and where he stated *Cook Ranch fm.* (Middle Olig [illegible] rests uncon. on *Sage Creek fm.* (Eocene), and is overlain uncon. by [illegible] of upper Olig. (?) or Mio. (?) age.]

Cooks Canyon agglomerate.

Upper Jurassic: Northern California (Monni Jura).

C. H. Crickmay, 1933 (Geol. Soc. Am. Bull., vol. 44, No. [illegible]: 81. [See under *Combe ss.*]

C. H. Crickmay, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 5, pp. 896, [illegible]). *Cooks Canyon fm.*—At type loc. (ridge btw. Cooks Canyon and Lights Creek) mostly red aggls. containing here and there fossil charcoal of coniferous wood and angular fragments from the mid Upper Jurassic intrusive quartz porphyry. In Forman Ravine and neighborhood it is mostly coarse, water-laid, clastic sediment of volcanic origin, gray to green color, containing here and there fossil charcoal of coniferous wood. Thickness 1,900 ft. at Cooks Canyon, 900 ft. at Forman Ravine. No fossils. Of middle Upper Jurassic age. Underlies Lucky S argillite and overlies Forman argillite.

Cool Creek formation.

Ordovician: Southern Oklahoma.

E. O. Ulrich, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 105). The upper part of Simpson group of Okla. includes a widely distributed and clearly distinguishable strat. unit of formational rank, previously neglected. The name *Cool Creek fm.* is applied to this unit. [All of definition. The fm. seems to overlie Tulip Creek fm. and to underlie Criner fm., but he does not say so.]

C. E. Decker, 1933. See *this entry under Simpson fm.*

Above are only recorded uses of this name.

Cooledge chalk.

Upper Cretaceous: Eastern Texas (Leon, Freestone, and Limestone Counties).

J. A. Waters and W. A. Reiter, 1930 (A. A. P. G. Bull., vol. 14, pp. 322–323). The highest chalk in Taylor fm. in wells and outcrops in Leon, Limestone, and Freestone Counties. Well exposed 3 mi. NW. of Cooledge, on main road to Hubbard, Limestone Co., where it consists of white marl. Lies at top of Taylor fm.

W. S. Adkins, 1933 (Univ. Tex. Bull. 3232, p. 466). *Cooledge chalk* is a higher Taylor chalk than Marlin chalk.

L. W. Stephenson, 1934 (letter dated Feb. 3), stated that this bed is not chalk and that it is merely a part of Neylandville marl, the basal fm. of Navarro group.

Coombs limestone member (of Islesboro formation).

Cambrian (?): Central southern Maine. (Penobscot Bay quadrangle).

G. O. Smith, E. S. Bastin, and C. W. Brown, 1907 (U. S. G. S. Penobscot Bay folio, No. 149, pp. 2–3). *Coombs ls. memb.*—Chiefly shaly or qtzitic ls., but in three localities it is represented by fairly pure ls. Thickness 7 to 100 ft. Top memb. of Islesboro fm. Underlies Battie qtzite. Is assigned to Camb(?). Named for exposures near Coombs Point, on NE. shore of Islesboro, Waldo Co.

On 1933 geol. map of Maine, by A. Keith, the Islesboro fm. is included in the Camb. and Ord. block.

Coon Creek tongue (of Ripley formation).

Upper Cretaceous: Western Tennessee, southern Kentucky (?), southern Illinois (?), and northern Mississippi (?).

B. Wade, 1917 (Johns Hopkins Univ. Circ., n. s., No. 3, Whole No. 293, pp. 74, 101). *Coon Creek horizon or memb.*—Variable sediments, ranging from local lenses of impure ls. through very fossiliferous marls to glauconitic sands and gypsiferous clays poor in fossils. The sediments containing Coon Creek fauna are dark bluish green and gray clayey sands at base of Ripley fm., a thickness of more than 30 ft. of which is exposed along banks of Coon Creek, McNairy Co., Tenn. Overlies Selma chalk and is separated from overlying McNairy sand memb. of Ripley by 100 ft. of sparsely fossiliferous ferruginous clay.

B. Wade, 1926 (U. S. G. S. P. P. 137), defined *Coon Creek tongue of Ripley fm.* as underlying McNairy sand memb. and overlying Selma fm., and included in it at top the 100 ft. of ferruginous clay which was originally excluded from it. This is present approved definition of Coon Creek.

Cooney quartz latite.

Tertiary: Mogollon district, New Mexico.

H. G. Ferguson, 1927 (U. S. G. S. Bull. 787). Alternating brick-red quartz latite flows and beds of tuff, with a few lenses of red, purple, and, more rarely, green ss. Thickness 700 to 1,400 ft. Older than Pacific quartz latite and younger than Whitewater Creek rhyolite.

Named for exposures in canyon of Mineral Creek near old mining camp of Cooney.

Coon Mountain sandstone member (of Pueblo formation).

Pennsylvanian: Central Texas (Colorado River region).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 387, 417). *Coon Mtn bed.*—Ss. and cgl., 0 to 75 ft. thick. Memb. of Cisco div. Underlies Stockwether bed and overlies Camp Creek bed.

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, footnote on p. 172 and charts). Detailed mapping of W. part of Brown Co. has shown that Coon Mtn ss. bed (No. 11 of Drake's section) is largely Cret. sands overlapping several Penn. beds. Named for Coon Mtn, Brown Co.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 103), recognized Coon Mtn ss. of Drake as underlying Stockwether ls. and overlying Camp Creek sh.

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501), ignored Coon Mtn ss., and redefined Camp Creek sh. memb. to include all beds in McCulloch Co. beneath Stockwether ls. and above Saddle Creek sh.

C. O. Nickell (Univ. Tex. Bull. soon to be published). *Coon Mtn ss. memb.* of Pueblo fm. underlies Stockwether ls. and overlies Camp Creek sh. memb. [This is adopted definition of U. S. Geol. Survey.]

Cooper marl.

Eocene (Jackson): Southern South Carolina (west of Santee River).

M. Tuomey, 1848 (Agr. Surv. S. C. 1st Rept., pp. 162–169, 190, 211). *Ashley and Cooper beds, the newest Eocene beds of the State.*—The marl of these beds is characterized by its dark gray color and granular texture, while the remains of fishes and Mammalia give its fossil remains a peculiar character, and leave no doubt of position assigned it, at the top of the Eocene series. These, together with the Santee beds, must amount, at least, to a thickness of 600 or 700 ft. Overlie Coralline marl (Eocene) and uncon. underlie Plio. [Mio.]. Exposed along Ashley and Cooper Rivers, S. C. [In text of above rept the beds along Ashley River are called *Ashley marl* and *Ashley beds* (pp. 162, 164), and the beds along Cooper River are called *Ashley and Cooper beds* and (p. 139) *Cooper River marls.* Page 165 states that many of the fossils of the Ashley are found on the Cooper.]

E. Sloan, 1908 (S. C. Geol. Surv., ser. 4, Bull. 2), defined Cooper marl as underlying †Ashley marl.

T. W. Vaughan, 1912 (U. S. G. S. P. P. 71, p. 739). The beds called *Ashley-Cooper marl* by Sloan are referable to Jackson group.

G. S. Rogers, 1914 (U. S. G. S. Bull. 580, pp. 186–187). *Cooper marl* consists of over 100 ft. of grayish-green marl. The lower part (Cooper marl of Sloan) is greenish drab, somewhat plastic when wet, but lighter-colored and fairly hard when dry. The upper part (Ashley marl of Sloan) is dull olive green and semi-plastic when wet and drab when dry. Uncon. underlies Edisto marl and conformably overlies Barnwell sand.

C. W. Cooke, 1936 (U. S. G. S. Bull. 867). Small phosphatic lumps are locally abundant in Cooper marl. The extent of phosphatization the rock has undergone was used by Sloan as principal criterion in distinguishing btw. his Ashley marl and his Cooper marl, the greater amount of phosphate being characteristic of his Ashley. His Ashley marl included in part Hawthorn fm. (lower Mio.).

Cooper limestone.

Middle Devonian (Onondaga): Central Missouri.

G. C. Swallow, 1855 (Mo. Geol. Surv. 2d Ann. Rept., pt. 1, pp. 108, 196). *Cooper marble.*—Upper part bluish drab compact ls. containing cavities filled with yellowish green substance which gives rock a fine mottled appearance; lower part bluish compact beds containing numerous small crystals of calc spar. Thickness 20 to 60 ft. in Cooper Co. No fossils, but on lithology and strat. position referred to Onondaga.

E. B. Branson, 1918 (Univ. Mo. Bull., vol. 19, No. 15). *Cooper ls.* is discon. overlain by Callaway ls. Contemp. with Grand Tower ls., but deposited in separate sea, which came from Arctic ocean and did not connect with Grand Tower sea.

E. B. Branson, 1920 (Am. Jour. Sci., 4th, vol. 49, pp. 267–276). *Cooper ls.* occurs in patches. Is contemp. with Mineola ls. Rests uncon. on Jefferson City dol. in most places, but in a few places on St. Peter ss.

D. K. Greger, 1920 (Am. Jour. Sci., 4th, vol. 50, pp. 20–24). *Cooper ls.* of Moniteau, Cooper, and Pettis Counties contains at base a sandy cgl. 2 to 14 ft. thick. Fossils found are chiefly new and undescribed sp. In all exposures studied in Marion Co. the Cooper is uncon. overlain by Saverton sh.

E. B. Branson, 1921 (Geol. Soc. Am. Bull., vol. 32, p. 35). The Cooper and Mineola seas were in part contemp., but Cooper sea withdrew before close of Mineola time, and Mineola spread so as to overlap part of Cooper.

The 1922 geol map of Mo. by Mo. Geol. Surv. placed *Cooper* above Grand Tower and below Beauvais ss.

E. B. Branson, 1923 (Mo. Geol. and Nat. Hist. Surv. vol. 17, 2d ser., pp 8-24). *Cooper ls.* is contemp. with Mineola ls., but deposited in separate sea or bay, and faunas, although related, are distinct.

Named for exposures in Cooper Co.

Cooper sand.

Drillers' term for sand in Bradford oil sand group (Upper Dev.) of NW. Pa. The name has also been applied to a Miss. sand in Wayne Co., Ky.

†Cooper-Ashley beds.
†Cooper River beds.
†Cooper River marl.

Eocene (upper): Southern South Carolina.

Terms used in early repts on geology of S. C. Now replaced by *Cooper marl* (of Jackson age), which is exposed along Ashley and Cooper Rivers.

Coopers Lake limestone member.

Middle Devonian: Northwestern Montana.

C. F. Deiss, 1933 (Mont. Bur. Mines and Geol. Mem. 6, pp. 43 and passim). *Coopers Lake ls. memb.*—Underlies Lone Butte ls. and overlies Glen Creek sh., all members of Jefferson ls. Thickest (508 ft.) in Dearborn section and thinnest (225 ft.) in Wall Creek-Juliet Creek Ridge section. Probably most striking feature is great number of organisms it contains. One of best exposures is in SW. part of White Ridge, where it consists of (descending): (1) Thick-bedded, massive, chocolate to tan, fine-grained ls. containing numerous Jefferson fossils, 132 ft.; (2) thick-bedded to shaly tan-gray ls. carrying rich Jefferson fauna, 157 ft.; (3) massive, friable, brown, thick-bedded, aren. ls. which in some beds becomes essentially a calc. ss., interbedded with thin bands of buff sh., 48 ft. Named for fact it forms a large part of Jefferson ls. over NE. part of Coopers Lake quad., especially in Powell Co., Mont. Type loc. on SE. slope of SW. peak of White Ridge, in SW¼ sec. 16, T. 22 N., R. 11 W.

Coos group.

Paleozoic (?): Northern New Hampshire (Coos County).

C. H. Hitchcock, 1870 (2d Ann. Rept. Geol. and Min. N. H., map and p. 34). *Coos group.*—Under this appellation are included the argill. schists, whetstone mica schists, grits, etc. of northern Coos Co., as explored by J. H. Huntington, the similar and associated rocks in Barford, Hereford, Auckland, etc., P. Q., and Essex Co., Vt., the qtzites, staurolite rocks, micaceous schists, hornblende schists, perhaps green, protogene and other rocks W. of White Mtn series and E. of Conn. River, along whole of western N. H., but excluding the calciferous mica schist. The unity of the series, its age, thickness, and relations to Quebec group, calciferous mica schist, and the clay slates remain to be defined. It appears clearly to overlie White Mtn series uncon. [Mapped over large part of Coos Co. and southwestward across W. part of N. H. to Mass. line. On 1932 geol. map of U. S. these rocks are mapped as pre-Camb.]

C. H. Hitchcock, 1870 (Am. Nat., vol. 4, p. 568). *Coos group.*—Qtzite and ls. with staurolite slates and schists. Characterized by presence of silicates of alumina destitute of alkalies; minerals are staurolite, andalusite, and kyanite. Is Sil. or older. Thickness 10,000 ft. in White Mtns. Younger than White Mtn series.

C. H. Hitchcock, 1871 (Geol. Surv. N. H. Rept. for 1870). Sections of *Coos group* measured at Hanover, Lyme, Orford, and Lisbon give following composite section: Hornblende schist, 2,300 ft.; gneiss; clay slates, 1,500 ft.; green schists, 4,200 ft.; clay slates, 2,400 to 4,500 ft.; staurolite schist or mica schist, 1,500 to 2,100 ft.; granitic gneiss, 1,700 ft.; qtzite and ls., 800 to 2,200 ft.; gneiss. Uncon. overlies White Mtn series. Named for northern part of Coos Co.

C. H. Hitchcock, 1873 (Boston Soc. Nat. Hist. Proc., vol. 15, pp. 304–309). *Coos group.*—Embraces "calciferous mica schist" of eastern Vt., the hard mica schist of Essex Co., Vt., the softer slates of northern Coos Co., N. H., together with the various slates and schists holding staurolite as far as Mass. and adjoining Conn. River, and various patches of andalusite sl. on Mount Washington, Mount Monadnock, Mount Kearsarge, in Warner, Rochester, etc. Older than the clay slates and younger than Merrimac group of qtzites and fine-grained mica schist. [All included under "mostly Cambrian (?)."]

C. H. Hitchcock, 1874 (Geol. N. H., pt. 1, pp. 508–545). *Coos group* of N. H. consists of qtzite, mica schist, slates full of staurolite and garnet. Overlies clay slates (Camb.) and Merrimack group, and is older than lss. of Helderberg age.

C. H. Hitchcock, 1874 (Am. Jour. Sci., 3d, vol. 7, pp. 468–476). *Coos group.*—Qtzites, mica schist, argill. schist, clay slates, possibly phyllite, calc. mica schist, hornblende rocks, and various sss. Thickness 10,000 ft. The ls. and gneiss heretofore included in this group must be eliminated; they underlie Coos group. The group may embrace "calciferous mica schist" of Vt. The original definition of this group expressely excluded latter rock. The Coos group has been erroneously confounded with White Mtn series in Swiftwater-Littleton area. The White Mtn series may be pre-Camb. Coos group can not be older than Camb. and Dana thinks it is all of Helderberg age. T. Sterry Hunt included both Coos group and White Mtn series in his Montalban, and originally he included them in his Terranovan.

C. H. Hitchcock, 1877 (Geol. N. H., pt. 2, pp. 348–408), divided rocks of Conn. Valley into: Calciferous mica schist, *Coos slates and schists, Coos qtzite,* Camb. clay sl. and older rocks, and stated: I am sometimes disposed to maintain that the two [calciferous mica schist and Coos slates and schists] were synchronous. Also: The Coos qtzite is grouped with Coos slates on account of their proximity and intimate association. On pp. 658 to 675 he divided the Paleozoic rocks of N. H. into: Upper Helderberg (Vermont), 200 ft.; Lower Helderberg, 500 ft.; calciferous mica schist, 4,800 ft.; *Coos group,* consisting of staurolite sl., 3,000 ft.; mica schist, often stauroliferous, 3,300 ft.; and qtzite, 1,000 ft., overlying Camb. slates of Conn. Valley.

C. H. Hitchcock, 1884 (Am. Mus. Nat. Hist. Bull., vol. 1, No. 5, pp. 178–179, pls. 16, 17). Calciferous mica schist and *Coos group* are essentially same series, and underlie Niagara group and overlie Kearsarge group.

C. H. Hitchcock, 1896 (Jour. Geol., vol. 4, pp. 44–62), divided Paleozoic rocks of northern N. H. into: Argillite (perhaps Dev.); Lower Helderberg; Niagara lss., slates, and sss.; calciferous mica-schist with Trenton to Utica graptolites; *Coos group* (several thousand ft. of slates, staurolite mica schists, hornblende schists, mica schists, and basal qtzite); and Camb. slates.

C. H. Hitchcock, 1905 (Geol. of Littleton, N. H.), assigned *Coos group* (mica schist and qtzite) of Littleton area to Sil., and placed these rocks below his Swiftwater schist series (Sil.) and above his hydro-mica schist group (Lower Sil. or Camb.).

C. H. Hitchcock, 1912 (Vt. State Geol. 8th Ann. Rept., pl. 46, pp. 139–145), assigned the rocks that he called *Coos group* in Hanover and Lebanon region, N. H., to Dev., and stated that they are=Bernardston fm.

M. Billings, 1934 (Sci., vol. 79, No. 2038, pp. 55–56), divided the rocks of Littleton and Ammonoosuc region, N. H., into: Littleton fm. (Lower Dev.); Fitch fm. (middle Sil.); Clough cgl. (lower ? Sil.); and Partridge sl., Ammonoosuc volcanics, and Albee qtzite, all of Upper Ord. (?) age.

The age and strat. position of the typical Coos group of Hitchcock (which he stated is in N. part of Coos Co.) appears to be undet. On 1932 geol. map of U. S. these typical rocks are mapped as pre-Camb., but Billings (1934) suggests the possibility that there are no pre-Camb. rocks in N. H.

M. Billings, 1935 (letter dated Aug. 27). *Coos qtzite* of Hitchcock is our *Clough cgl.*

Coos quartzite.

See 1877 entry under *Coos group* and 1935 entry under *Clough cgl.*

Coos conglomerate.

Pliocene: Southwestern Oregon (Coos Bay region).

W. H. Dall, 1897 (U. S. G. S. 18th Ann. Rept., pt. 2, pp. 336–343). *Coos cgl.*—A singular fm. at Fossil Point, Coos Bay, Oreg. Consists of Mio. fossils, small water-worn chert pebbles, sand, and a few fossil forms still living in vicinity, cemented into hard cgl. Rests on eroded surface of Empire fm. Only fragments of original deposit remain, the rest having been eroded, though originally some 10 ft. thick. The Mio. fossils are from Empire beds; source of chert unknown. The only part of the cgl. that may be regarded as strictly contemp. with its deposition comprises the rather small proportion of Pleist. fossils and sand which is intermixed with the rehandled older material.

J. S. Diller, 1901 (U. S. G. S. Coos Bay folio, No. 73). *Coos cgl.*, named by Dr. Dall, consists of 30 ft. of consolidated cgl., cross-bedded, generally known as "Fossil Rock," on account of large number of conspicuous fossil shells it contains, some of which represent living species, but larger part were derived by erosion directly from underlying fossiliferous Empire beds. Dall says probably Pleist. Exposed extent covers about 1 acre.

Harrison & Eaton (firm), 1920 (Min. Res. Oreg., vol. 3, No. 1, pp. 6–7), assigned *Coos cgl.* to upper Plio., and stated that it contains a mixed fauna of living, Plio., and Mio. fossils. H. V. Howe, 1921 (Geol. Soc. Am. Bull., vol. 32, p. 147), also assigned the cgl. to Plio.

H. V. Howe, 1922 (Univ. Calif. Pub., Bull. Dept. Geol. Sci., vol. 14, No. 3, pp. 86–91). *Coos cgl.* is an integral part of Plio. series of South Slough syncline. That it represents a time break is evident from its composition, but that this break is not great enough to bridge remainder of Plio. is seen both by its fauna and strat. position. The fauna listed by Dall contains only 3 sp. not contained in beds below. To Merriam and Lawson should go credit of first correctly determining Plio. age of Coos cgl. It is not Pleist., as assigned by Dall. Uncon. overlies Empire fm. and uncon. underlies massive unfossiliferous sss. of Pleist. age.

W. D. Smith, 1924 (Univ. Oreg. Commonwealth Rev., vol. 6, No. 4, p. 73), assigned Coos cgl. to Plio., as did L. G. Hertlein and C. H. Crickmay, 1924 (Am. Phil. Soc. Proc., vol. 64, No. 2).

L. G. Hertlein and C. H. Crickmay, 1925 (Am. Phil. Soc. Proc., vol. 64, No. 2, pp. 264–270). *Coos cgl.* appears to be without doubt Plio. [Gives résumé of literature.]

†Coosa shale.

Upper and Middle Cambrian: Western Georgia and eastern Alabama.

E. A. Smith, 1890 (Ala. Geol. Surv. Rept. on Cahaba coal field, p. 148, map, and structure section opp. p. 162). *Coosa shales* on p. 148, *Flatwoods shales* on map legend, and *Coosa Valley or Flatwoods shaly lss.* on structure section.—Shaly lss. which give rise to the "Flatwoods." Underlie Montevallo shales.

Owing to faulting in dist., for many years the relations of †Coosa sh. to Conasauga sh. and Rome fm. were misunderstood. The †Coosa sh. is now, however, known to be same as Conasauga sh. and to overlie Rome fm., now known to be same as †Montevallo shale. *Coosa sh.* is now replaced by *Conasauga sh.*, better established name. Underlies Knox dol., or Brierfield dol., or Ketona dol., and overlies Rome fm.

Named for Coosa Valley, btw. Rome, Ga., and Gadsden, Ala.

†Coosa Valley.

Upper, Middle, and Lower Cambrian: Eastern Alabama.

E. A. Smith, 1888 (Ala. Geol. Surv. Rept. Prog. 1884–88, geographic map of Ala.). *Coosa Valley* (*Knox*).—Sh. above; ss. below. Underlies Knox dol. and overlies Ladiga (Potsdam) ss. [Only definition is on map legend. See also under †*Coosa sh.*]

Probably includes Conasauga (†Coosa) sh., Rome (†Montevallo) fm. and Shady (†Beaver) ls.

Named for Coosa Valley.

Copake limestone.

Lower Ordovician (Beekmantown): Southeastern New York (Dutchess County).

J. D. Dana, 1879 (Am. Jour. Sci., 3d, vol. 1, pp. 376–383), described the ls. of Copake, in two places on p. 382 called it *Copake ls.*, and stated that "the Wappinger Valley ls. is not the only southern extension of the Copake ls."

E. B. Knopf, 1927 (Am. Jour. Sci., 5th, vol. 14, pp. 429–458). *Copake ls.*—Mainly mottled gray and white ls. carrying *Ophileta* sp., with some white ls. and a gray aren. dol. that weathers to a deep sandy surface, which is riddled with *Scolithus* borings and contains a large *Ophileta*. Thickness 0 to 400 ft. Overlies, probably conformably, Rochdale ls., of Beekmantown age. Ulrich considers Copake fauna to be=upper part (divisions D and E) of Beekmantown of Lake Champlain dist. Named for extensive development in neighborhood of Copake, N. Y. Overlain by lss. of early Trenton and Black River age. [This fm. was included in Rochdale group of Dwight, 1887.]

Copan formation.

Pennsylvanian: Northeastern and central Oklahoma.

D. W. Ohern, 1910 (Okla. State Univ. Research Bull. 4, p. 29). *Copan memb.*—Shales, heavy-bedded sss., and ls. lentils, 250 ft. thick, forming middle memb. of Wann fm. Underlies Stanton ls. memb. and overlies Hogshooter ls. memb. Includes Avant and Dewey ls. lentils.

A. E. Fath, 1925 (U. S. G. S. Bull. 759, pp. 13, 16). *Copan fm.* (*restricted*).—The Copan as defined by Ohern in 1910 included all beds btw. base of Stanton ls. above and top of Hogshooter ls. below. The Stanton ls. thins out a few mi. S. of Kans. line, and the next logical fm. bdy is base of Tiger Creek ss., which persists from Nowata quad. through Bristow quad. The adoption of that bdy line, however, throws into Bristow fm. some rocks included in Copan fm. as originally defined by Ohern, but this slight restriction of Copan is believed to be justified, as it will make the Copan a map unit over a large area and prevent the introduction of a new name for rocks=major part of Ohern's Copan. The Hogshooter ls. is thought by writer to be same as "Layton lime" of Bristow quad. Thickness of Copan fm. in Bristow quad. 600–700 ft.; divided into (descending): (1) Upper sh., 150 ft.; (2) upper ss. and interbedded sh., including a lenticular ls. and Dewey ls. memb., 85–250 ft.; (3) middle sh. 100 to 125 ft.; (4) lower ss. with interbedded sh., 100 to 150 ft.; (5) lower sh., 100 to 200 ft.

C. N. Gould, 1925 (Okla. Geol. Surv. Bull. 35, p. 76). *Copan fm.*—Named by D. W. Ohern, 1910. Consists of ss. and gray sh., and in its upper part includes Dewey [Avant] ls. memb. Thickness 600 to 700 ft. Includes lower part of Ochelata fm., the underlying Dewey ls., and the Nellie Bly fm. Named for Copan, Washington Co.

Copeland moraine.

Pleistocene (Wisconsin stage): Northern Colorado.

W. T. Lee, 1917 (The geol. story of Rocky Mtn Nat. Park, p. 82).

Coplay limestone.

Lower Ordovician: Southeastern Pennsylvania (Lehigh Valley district).

E. T. Wherry, 1909 (Sci., n. s., vol. 30, p. 416). *Coplay ls.* (*Beekmantown*).—Dark gray, shaly, with mottled crystalline layers and many fossils; 1,500 ft. thick. Uncon. underlies Nisky fm. and overlies Allentown ls.

Probably named for occurrence at or near Coplay, Lehigh Co.

Btw. 1910 and 1927 this name was used in several Pa. Geol. Survey and other repts. In 1928 (letter dated March 26) B. L. Miller stated: "The names Nisky, Nazareth, and Coplay were tentatively used in this region by us some years ago. We finally dropped the term *Coplay* when we were convinced that this limestone was the same as the Beekmantown. For Nisky and Nazareth combined, we have accepted the term *Jacksonburg;* the Nisky representing the high calcareous layers at the base and the Nazareth the upper and major portion of the formation. We are not now separating the Jacksonburg, inasmuch as in many localities the distinction between the lower and upper portions cannot be definitely recognized."

Copley meta-andesite.

Devonian or older: Northern California (Redding quadrangle).

J. S. Diller, 1906 (U. S. G. S. Redding folio, No. 138). *Copley meta-andesite.*—Includes a great mass of lava made up of many separate volcanic flows of considerable variety and sheets of tuffs more or less distinctly bedded but generally so compressed as to develop slaty cleavage. Is generally pale green on weathered surface, but darker green and compact on fresh, somewhat shaly fracture. Thickness 1,000± ft. Is overlain by Kennett ls. (Middle Dev.), and is oldest fm. exposed in Redding quad. In places Bragdom fm. rests on it. Named for occurrence in vicinity of Copley.

Copperas Creek. (In McLeansboro formation.)

Pennsylvanian: Central western Illinois (Fulton County).

T. E. Savage, 1927 (Am. Jour. Sci., 5th, vol. 14, pp. 307–316), applied *Copperas Creek sh. and ss.* to that part of McLeansboro fm. in Fulton Co. lying beneath his Rolls Ford sh. and above his Brereton ls. Thickness and derivation of name not stated, but probably is Copperas Creek, NE. of Canton, Fulton Co., which flows across Edington quad.

Copper Cliff arkose.

Pre-Cambrian: Ontario.

A. P. Coleman, 1913 (12th Int. Geol. Cong. Guidebook 7, p. 13).

Copper Creek beds.

Pre-Cambrian (upper Keweenawan): Northwestern Wisconsin (Douglas County).

F. T. Thwaites, 1912 (Wis. Geol. Nat. Hist. Surv. Bull. 25, pp. 42, 43, 44, 67). *Copper Creek beds.*—White and pink fine-grained ss., with magnetite and mica grains and a few ripple marks. Thickness 75 to 100 ft. Included in Orienta ss., which see for overlying and underlying beds. Named for exposures on Copper Creek, Douglas Co.

Copper Harbor group.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. C. Lane and A. E. Seaman, 1907 (Jour. Geol., vol. 15, pp. 680, 690). *Copper Harbor cgls.*—The cgls. N. of Eagle River group were grouped together by Douglass Houghton, who considered the Lake Shore traps as intrusive dikes. When these were understood to be interbedded flows the cgl. was divided into the Great and Outer, respectively, below and above the Lake Shore traps. Hubbard's studies around Copper Harbor have shown that there are at least three heavy cgls. It is not probable that the lines btw. the Great Cgl., Lake Shore Trap, and Outer Cgl. can be drawn at all consistently. Together they cover the period of decadent vulcanism, and it is not at all likely that the flows from these last expiring throes filled the whole basin, but more likely they occur irregularly in the cgl. series. It therefore seems fitting to give a local term to whole assemblage, treating the Lake Shore traps as a lentil or lentils in the same. Underlies Nonesuch sh. and overlies Eagle River group. Thickness 1,740 to 7,500 ft.

Named for exposures around Copper Harbor, Keweenaw Co.

Coppermine series.

Age (?): Canada.

A. Sandberg, 1914 (In Lands Forlorn, by G. M. Douglas, p. 280, N. Y.).

Coppermine River series.

Pre-Cambrian: Arctic Canada.

J. J. O'Neill, 1924 (Canadian Arctic Expedition, 1913–18, Rept., vol. 11, pt. A, pp. 23, 57).

†Copper Mountain porphyry.

Eocene: Colorado (Tenmile district).

S. F. Emmons, 1898 (U. S. G. S. Tenmile Special folio, No. 48), applied *Copper Mountain porphyry* to the mass of Elk Mtn porphyry on Copper Mtn.

Copper Mountain greenstone or amphibolite schist.

Age (?): Alaska (Prince William Sound region).

F. C. Schrader, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 414–415). *Copper Mtn greenstone or amphibolite schist.*—Constitutes almost entire mass of Copper Mtn. Is totally different from either Orca or Valdez series, and seems to be much older.

Copper Queen intrusion.

Age (?): Mexico.

J. E. Spurr and G. H. Garrey, 1908 (Econ. Geol., vol. 3, p. 694).

Copper Queen limestone.

Upper Cambrian: Southeastern Arizona (Bisbee-Tucson region).

A. A. Stoyanow, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 469–471, 480–482). *Copper Queen ls.*—White-gray granular and algal ls. with *Idahoia, Irvingella,* and *Maladia;* cliff-forming in lower part; at top Parting qtzite memb., 8 ft. thick; at base thinner bedded gray ls. with *Billingsella coloradoensis.* Thickness 81 ft. Overlies Abrigo fm. [here restricted to middle part of Abrigo ls. of previous repts] and underlies Martin ls. (Dev.). Is youngest Camb. fm. in Bisbee dist., and is Upper Camb. Named for Copper Queen mining area of Bisbee, where it is good horizon. Correlated with Rincon ls. (new) of Whetstone Mtns, and with Peppersauce Canyon ss. of Santa Catalina Mtns. [See last sentence under *Peppersauce Canyon ss.*]

Copper Ridge dolomite.

Upper Cambrian: Eastern Tennessee, southwestern Virginia, and Alabama.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pp. 548, 635–636, pl. 27). In Knox Co., Tenn., where the fm. was first studied and from which it was named, the Knox consists mainly of a characteristically and profusely cherty middle div. to which I am applying the name *Copper Ridge chert.* This is flanked above and beneath by much thinner and very sparingly cherty members, for which no names have been proposed. [Page 548.] [In chart, pl. 27, the subdivisions of the Knox in Knoxville trough are called *Upper Knox, Copper Ridge,* and *Lower Knox.*] Occasionally, as in River Ridge, 3 mi. NW. of Morristown, Tenn., the Copper Ridge chert rests on the Nolichucky. More commonly the Knox begins with an older div., 300 to 700 ft. thick, while in vicinity of Montevallo, Ala., three still older fms. [Bibb, Ketona, and Brierfield], aggregating something near 2,500 ft. of dol., intervene btw. base of typical Knox and top of the Conasauga. [Page 628.] *Basal div. of Knox dol. (s. st.).*—Rather generally in eastern Tenn. and SW. Va. grayish dol. and ls., practically free of chert, constitute lower part of Knox proper. So far as known, this lower div., which I formerly thought to represent the Ketona but now believe to be a younger and quite distinct fm., does not occur on W. side of Murphrees Valley, Ala., nor has it been recognized in Cahaba Valley. Even in Tenn. basin it varies considerably in thickness, possibly being absent altogether locally, as in River Ridge N. of Norristown, while in other places it seems to exceed 600 or 700 ft. The latter figure is attained btw. Clinchport and Speers Ferry, Va. The fm., which for present remains unnamed, was recognized at Knoxville; hence it is a part of typical Knox dol. of Safford. In Tenn. and SW. Va., where the Brierfield, Ketona, and Potosi fms. have not been detected, the Knox rests on upper Camb. fms., either the Nolichucky or the Conasauga sh. When present the lower memb. of the Knox is readily distinguished by its more calc. and much thicker beds. Most of its beds are mag., but few, if any, are dol. Many contain so little magnesia that they may justly be called ls. The latter are fine-grained and not infrequently contain more or less shaly layers. Chert is very sparingly developed, not only in the unweathered rock but also in the residual-clays of the surface. The practical absence or scarcity of chert and the presence of nearly pure and often shaly ls. distinguishes this lower memb. of the Knox from the profusely cherty main mass of the fm. which overlies it and for which the name *Copper Ridge chert* is proposed. [Page 635.] *Copper Ridge chert (new).*—Of the three divisions commonly recognizable in the Knox, the highly cherty ridge-making middle div. is most persistent and by far the greatest. This middle div., for which term *Copper Ridge chert* is here proposed, is readily distinguished from the lower and upper div. by the hard white or gray chert which is developed by segregation and liberated under the slow process of subaerial decomposition of the dolomitic matrix. The resistant character and finally great abundance of this chert almost invariably gives rise to broad and long ridges, among which that known as Copper

Ridge, in NE. Tenn., is the excellent example chosen to supply the name and type of the memb. or fm. As a fm. the Copper Ridge chert is best displayed, and probably also best developed, in middle and western parts of Appalachian Valley in Tenn. and Ala. Here its average thickness is nearly 2,000 ft., and it rarely falls under 1,200 ft., except along the Rome barrier, where, as btw. Birmingham and Gadsden, it was greatly reduced locally by pre-Ord. erosion. Max. thickness observed is in Chestnut Ridge S. of Sneedville, Tenn. Here, deducting some 600 to 700 ft. apparently repeated by faulting, an estimate based on dip and width of outcrop indicated a thickness of 2,800± ft. Both the lower and upper members of the Knox are relatively thin in Chestnut Ridge, the former being 360 ft., the latter only 200± ft. [Pages 635–636.]

In 1911 (Geol. Soc. Am. Bull., vol. 22, pp. 549, 638, 639, and pl. 27) Ulrich introduced *Chepultepec chert fm.* for rocks in Murphrees Valley, Ala., which he then considered to be younger than his so-called *Upper Knox* of Tenn. But in 1915 (U. S. Nat. Mus. Bull. 92, vol. 1, p. vii, and vol. 2, pls. 1 and 2) R. S. Bassler, who collaborated with Ulrich, redefined Chepultepec dol. as resting on Copper Ridge chert and as synonymous with so-called *Upper Knox*, but he still defined Copper Ridge chert as resting on *Lower Knox*, which he showed to be younger than Bibb dol. In 1924, however (Tenn. Dept. Ed., Div. Geol., Bull. 28, p. 34, and Bull. 31, p. 16), Ulrich redefined the Copper Ridge so as to include all of the pre-Chepultepec part of Knox dol. in Knoxville trough and W. part of Valley in Tenn., or the *Lower Knox* or the *Knox proper* of his previous publications, while to the still older rocks in Athens trough of Tenn. (which according to his charts are absent in Knoxville trough, and which it is understood he regards as=in whole or part to the Bibb, Ketona, and Brierfield dolomites of Ala.) he applied the new name *Greenville dol.* The present definition of Copper Ridge dol. therefore applies to all beds btw. Chepultepec dol. above and Bibb dol. below, with both of which fms. it is conformable.

C. Butts has extended the name as far N. as Newcastle, Craig Co., Va.

Named for Copper Ridge, NE. of Knoxville, Tenn., which is composed of this fm.

Copper River silts and gravels.

Pleistocene: Alaska (Copper River region).

F. C. Schrader, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 410–412). *Copper River silts and gravels,* 0 to 1,000± ft. thick, form bluffs and terraces all along Copper River above Taral and on tributaries of that part of river.

Copps group.

Pre-Cambrian (upper Huronian): Northwestern Michigan and northwestern Wisconsin (Gogebic Range).

R. C. Allen and L. P. Barrett, 1915 (Jour. Geol., vol. 23, p. 697). *Copps group.*—Great thickness of graywacke sl., highly ferruginous in W. half of its area (E. part of Gogebic Range) and associated in certain horizons, especially the lower ones, with considerable nonclastic chert and here and there jasper. At base a true basal cgl. Uncon. overlies Presque Isle granite and Animikie, and uncon. underlies Keweenawan series. [R. C. Allen, Mich. Geol. and Biol. Surv. Pub. 18, geol. ser. 15, 1915, gave thickness of *Copps fm.* as 2,300 ft., and stated that it was named for Copps mine.]

Coqui limestone.

Age (?): Puerto Rico.

C. P. Berkey, 1915 (N. Y. Acad. Sci. Annals, vol. 26, p. 29).

Coquihalla series.

Tertiary: British Columbia.

C. E. Cairnes, 1923 (Canada Geol. Surv. Summ. Rept. 1922, pt. A, p. 99).

†Coral limestone.

Descriptive term applied in early Ala. repts to Glendon ls.

†Coralline limestone.

A descriptive term applied in early N. Y. repts to ls. later named *Cobleskill ls.*, also to ls. later named *Wilbur ls. memb. of Salina fm.*, and to a ls. in Niagara group.

Coralline Falls limestone.

Devonian: Kentucky.

D. D. Owen, 1856 (Ky. Geol. Surv. vol. 1, pp. 95–97). *Gray Coralline Falls lss.* include the Devonian lss. underlying the Dev. black Lingula shales in Ky.

Coralville limestone.

Upper Devonian: Central eastern Iowa.

C. Keyes, 1912 (Iowa Acad. Sci. Proc., vol. 19, p. 149) and 1913 (Iowa Acad. Sci. Proc., vol. 20, pp. 205, 206). *Coralville terrane.*—Lss. included in upper part of Cedar Valley ls., consisting of (descending) 2 ft. of gray, fine-grained ls. containing *Idiostroma;* 6 ft. of gray earthy ls; 10 ft. of gray, massively bedded ls. containing *Acervularia* and sponges; and 8 ft. of bluish, thin-bedded, shaly, unfossiliferous ls. Underlies Lucas ls. and overlies Rapid ls. Included in Senecan.

See 1935 entry under *Cedar Valley ls.*, of which it is a memb. In this 1935 rept the underlying beds are named *Littleton memb.* (of Cedar Valley ls.).

Named for Coralville, Johnson Co. Typically exposed in quarries 1± mi. NE. of Coralville.

Corbin conglomerate lentil.

Pennsylvanian: Central Kentucky.

M. R. Campbell, 1898 (U. S. G. S. Richmond folio, No. 46, p. 3). *Corbin cgl. lentil.*—Coarse pink ss. or cgl., 90 ft. thick, forming topmost memb. of Lee fm. in Richmond quad. Overlain by Irvine fm. (Neocene?).

Later studies by D. White show that top of Lee fm. properly belongs at top of Rockcastle cgl. memb., and that Corbin cgl. lentil and the shales separating the Corbin and Rockcastle properly belong to horizon of Sewell fm. and are probably to be correlated with Sharon cgl. memb. of Pottsville fm.

Named for Corbin, Whitley Co.

Corbin granite.

Pre-Cambrian: Northwestern Georgia (Cartersville district).

C. W. Hayes, 1901 (Am. Inst. Min. Engrs. Trans., vol. 30, pp. 406–410). *Corbin granite.*—Chiefly massive, coarse-grained rock, with large porphyritic crystals of microcline in large groundmass of plagioclase feldspar, muscovite mica, and blue quartz. Some portions of rock have undergone considerable alteration, being converted into augen gneiss. Probably Archean.

Named for development around Corbin, Bartow Co.

Corbin City limestone.

Pennsylvanian: Eastern Kansas (Montgomery County) and northwestern Missouri.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 92, 97). It is proposed to use *Drum ls.* as a fm. name, and to recognize the light-blue [nonoolitic] lower bed as *Cement City memb.* and the upper bed of oolitic ls. as *Corbin City memb.* The Corbin City (named for a locality just S. of Cherryvale [Montgomery Co.]), is very local in development, but appears to be represented in Kansas City section by a thin bed of granular fossiliferous ls. separated by a few inches of sh. from main body of Cement City ls.

N. D. Newell, 1935. See 1935 entry under *Cement City ls.*

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 106–107). *Corbin City ls. memb. of Drum ls.* rests discon. on Cement City ls. memb. in southern Kans. To SW., W., and NW. of Coffeyville it is represented by ls. cgl. Thickness of the memb. ranges from feather edge to 50± ft. Near Kansas City, Mo., a ls. 1 ft. or less thick, separated from Cement City ls. by a few inches of fossiliferous sh., is thought to represent Corbin City memb.

Cordell member.

Silurian (Niagaran) : Northern Michigan.

R. B. Newcombe, 1933 (Mich. Geol. Surv. Pub. 38, pp. 23, 37). G. M. Ehlers (unpublished ms.) has divided Manistique fm., of Niagaran age, into the *Cordell* and *Schoolcraft members*. [In table on p. 23 the Cordell is placed above the Schoolcraft. No description nor thicknesses of the members given.]

Corder "sand".

Drillers' name for a subsurface ls. in New Providence fm. (Miss.) of eastern Ky.

Cordilleran formation.

Quaternary: Canada.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 224).

Cordilleran system.

Name proposed by G. H. Ashley (Eng. and Min. Jour.-Press, vol. 115, No. 25, pp. 1106–1108, 1923) "to designate the time and the rocks from the end of Comanchian to beginning of Eogene." Corresponds to Upper Cret. series of U. S. Geol. Survey.

Cordova sands and gravels.

Pleistocene: British Columbia.

C. H. Clapp, 1913 (Canada Geol. Surv. Mem. 36, p. 110).

Corey limestone.

Ordovician: Quebec.

T. H. Clark, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 1, p. 6).

Coriba formation.

Tertiary (Miocene) : Central northern Oregon and southern Washington.

E. T. Hodge, 1931 (Geol. Soc. Am. Bull., vol. 42, p. 991, footnote). Basalt in this paper refers to Columbia River basalt fm. (*Coriba fm.*), of Mio. age.

E. T. Hodge, 1933 (Northwest Sci., vol. 7, No. 2, p. 35). *Coriba fm.*, "a mnemonic expression proposed for the cumbersome name Columbia River Basalt fm."

Coriba erosion surface.

Late Pliocene: Central northern Oregon.

E. T. Hodge, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 157). [See under *Rhododendron fm.*]

Corinth sandstone. (In Conemaugh formation.)

Pennsylvanian: Western Maryland (Allegany and Garrett Counties) and northern West Virginia.

C. K. Swartz, W. A. Price, and H. Bassler, 1919 (Geol. Soc. Am. Bull., vol. 30, p. 574). *Corinth ss.*—Underlies Irondale ls. and overlies Thornton clay; all included in Conemaugh fm.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, pp. 57–58, pl. 6). *Corinth ss.* occurs a short distance below Brush Creek coal at many places. Named for exposures at E. end of cut on B. & O. R. R. at Corinth, W. Va.

Corliss conglomerate.

Lower Ordovician (Beekmantown): Northwestern Vermont (Franklin County).

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 377). *Corliss cgl.*—Rests uncon. on Highgate sl. (Upper Camb.) and forms a series of lenticular deposits btw. the Highgate and the overlying Georgia sl. (of Beekmantown age) at intervals from Canada to their end, 5 mi. S. of St. Albans. Consists mainly of pebbles and boulders of various lss., marbles, and dolomites, mostly ls. The thin slabs of fossiliferous Upper Camb. ls. derived from Mill River cgl. (which underlies Highgate sl. and is of Upper Camb. age) are numerous and conspicuous in the Corliss, which also contains fossiliferous pebbles of Lower Camb. age and others of Williston (Upper Camb.) age. In Burlington region the Corliss overlies Williston ls. Strongly resembles Mill River cgl., but lies higher in section. Assigned to early Beekmantown. In original description of this region by writer the Mill River and Corliss cgls. were included in what writer called "Swanton cgl." [now abandoned]. Later detailed mapping and study showed that there are 2 cgls., and that the Mill River (the older) was placed by thrust faulting S. of Highgate Center in position of the Corliss, on top of Highgate sl., thus causing the confusion. Exposed at Corliss Ledge, 5 mi. NE. of St. Albans. [Not on map, but probably in St. Albans quad.]

Cornell member.

Upper Devonian: Central New York (Skaneateles quadrangle).

B. Smith, 1935 (N. Y. State Mus. Bull. 300, pp. 10, 57–62), removed *Spirifer* (*Reticularia*) *laevis* zone from top of Sherburne memb. of the Portage and named it *Cornell memb.*, from outcrops at foot of Ithaca falls, near mouth of Fall Creek gorge, at Ithaca. Type loc. on S. side of gorge, not far from Cornell Univ. campus. Overlain by Ithaca memb. of the Portage. He made the following statements: As writer interprets Kindle's lists of fossils, there are 25 definitely recognized species in Cornell memb. of Ithaca region. Of these, 12 are not found in underlying Sherburne but do occur in overlying Ithaca memb.; 8 occur in both Sherburne and Ithaca; 1 sp. appears to be confined to Cornell memb.; and 4 sp. seem doubtful or inadequate. Except in deference to historical precedent there is no particular reason for retaining the Cornell in the Sherburne. In fact, Kindle's figures and a number of other considerations argue for its transfer to the Ithaca. Although very thin, it is a tangible and fairly widespread zone (of flags and shaly flags, some barren and some fossiliferous). [Further along, on p. 59, he stated *Spirifer laevis* bed is definitely known from but few localities and upper limit of Sherburne memb. has been drawn arbitrarily. On p. 63 he stated that he had tentatively included the *Spirifer laevis* bed at Barber Point in Ithaca memb., and that *Spirifer laevis* has been reported from beds below his Cornell memb.]

Cornfield Harbor clays.

Pleistocene: Eastern Maryland.

W. H. Dall, 1897 (55th Cong., 2d sess., H. Doc. 5), also 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, p. 336 and table opp. p. 334). *Cornfield Harbor clays.*—These beds on Cornfield Harbor, near Federalsburg [Caroline Co.], Md., contain interesting marine fauna. Have generally been referred to Pleist. but may prove to be upper Plio.

G. B. Shattuck, W. B. Clark et al., 1906 (Md. Geol. Surv. Pliocene and Pleistocene vol.), assigned the beds at Cornfield Harbor (Wailes Bluff) to Pleistocene Talbot fm. The Pleist. age of the fossils contained in these beds was also verified by W. C. Mansfield in 1928 (U. S. G. S. P. P. 150, pp. 130, 136–140).

Cornfield Springs formation.

Middle Cambrian and later (?): Southeastern California (San Bernardino County).

J. C. Hazzard and J. F. Mason, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 2, pp. 229–240). *Cornfield Springs fm.*—Medium to coarse-grained sandy dol. with interbedded fine-grained shales; Middle Camb. fossils; thickness 50 ft. To this fm. there is tentatively added 700 ft. of overlying nonfossiliferous beds consisting of alternating dark smoky-gray and light-gray to light-buff dolomites, with some sandy beds. Top limit of fm. as thus tentatively defined is the base of 50 to 100 ft. of somewhat massive, nearly black dol. that is tentatively correlated with Ironside dol., the basal memb. of Sultan ls. (Dev.) of Goodsprings quad., Nev. Overlies Bonanza King fm. (Middle Camb.). Named for good exposures E. of Cornfield Springs, Providence Mtns.

Cornfields series.

Tertiary or Pleistocene: Northeastern Arizona. See 1932 entry under *Bidahochi fm.*

†Corniferous ls.

†Corniferous fm.

†Corniferous group.

Descriptive terms applied in early geologic repts on Eastern States to a ls. or dol. of Dev. age. In N. Y. applied to Onondaga ls.; in Ind. and Ky. to Sellersburg and Jeffersonville lss., also to Jeffersonville ls. alone; in

Ohio to Delaware and Columbus lss.; in Mich. to Dundee ls. The name was derived from the balls of hornstone contained in the rock.

†Corniferous period.

A term used by some early geologists to include Onondaga ls., Schoharie grit, and Esopus grit, being the same sense in which "Upper Helderberg" was commonly applied in early repts.

Corning Creek zone. (In Negaunee formation.)

Pre-Cambrian (middle Huronian): Northern Michigan (Marquette County).

J. L. Adler, 1935 (Jour. Geol., vol. 43, No. 2, pp. 113-132). *Corning Creek zone of Negaunee fm.*—Wavy-bedded (characteristic feature), dense to granular, gray to pink chert with interbedded red and blue hematite and locally some martite. Contains some straight-bedded and concretionary parts. Generally thicker-bedded than the other zones of Negaunee fm. Thickness 470 ft. Grades into underlying North Lake zone. Overlain by dolerite ("diorite") sill, or, where that is missing, uncon. overlain by Goodrich qtzite. In places Jasper Knob zone of the Negaunee may rest directly on Corning Creek zone. [Type loc. not stated, but his map shows Corning Creek and West Corning Creek.]

Cornish sandstone member.

Permian: Central southern Oklahoma (Carter and Jefferson Counties).

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z, p. 18). *Cornish ss. memb.*—One of highest members of Cisco (?) [Clear Fork ?] red beds of Carter Co. Consists of a white, massive, cross-bedded ss. which forms a scarp NE. along SW. side of Healdton field, and underlies gentle dip slopes extending from the scarp to SW. corner of Co., interrupted by valleys and ravines which have cut to lower strata. Immediately underlies city of Ringling and village of Cornish, just over the line in Jefferson Co. Assigned to Perm.

Cornishville limestone member (of Perryville formation).

Middle Ordovician: Central Kentucky.

A. F. Foerste, 1912 (Denison Univ. Sci. Lab. Bull. 17, pp. 23, 31, 33, 36, 132, 133). *Cornishville ls.*—Fossiliferous coarse-grained ls. underlying Greendale memb. of Catheys fm., overlying Perryville memb., and forming top memb. of Lexington ls.

A. F. Foerste, 1913 (Ky. Geol. Surv., 4th ser., vol. 1, pt. 1, pp. 377-385). *Cornishville bed* [of central Ky.] consists of 5 to 6 ft. of granular ls. containing a typical Trenton fauna. Top memb. of Perryville fm. Overlies Salvisa horizon of Perryville.

See further explanation under *Perryville fm.*

Named for Cornishville, Mercer Co.

†Cornitiferous limerock.

A descriptive term used in early N. Y. repts. According to L. Vanuxem (N. Y. Geol. Surv. 3d Rept., 1839), the "cornitiferous rock" of Amos Eaton (1824), who probably originated the term, is middle part of Onondaga ls. Named for presence of balls of hornstone.

Cornmeal sand.

Drillers' term for a sand in Pottsville fm. (Penn.) of Butler Co., Pa., lying lower than Homewood ss. memb. (See J. P. Lesley, 1878, 2d Pa. Geol. Surv. Rept. Q. pp. 303-305.)

†Cornwall slates.

Upper Cambrian: Southeastern Pennsylvania (Lebanon County).

J. P. Lesley and E. V. d'Invilliers, 1886 (2d Pa. Geol. Surv. Ann. Rept. 1885, p. 526). *Cornwall slates.*—Lime slates, occupying an area about 4 mi. long and ⅔ mi. wide at Cornwall [Lebanon Co.]. Hold important relations to Cornwall ore mass. Age and position in Paleozoic have been much debated. Uncertain whether they underlie or overlie Lebanon Valley ls. fm., but probably overlie it. Exposed in R. R. cut at Cornwall Station.

According to G. W. Stose (personal communication Dec. 1936) the rock exposed in R. R. cut at Cornwall Station is metamorphosed Conococheague ls.

†Cornwall limestones.

Devonian and Silurian: Southeastern New York.

E. C. Eckel, 1902 (N. Y. State Geol. 20th Ann. Rept., p. r148). A series of thin beds of ls. overlies Longwood shales at several points in Orange Co. Beds carry fossils which correlate them with Lower Helderberg and Waterlime farther W. The term "Cornwall lss." is not here proposed as a fm. name, but is used merely as a convenient designation for the series till further field work shall have decided the extent to which subdivision can be carried.

Range in age from Decker ls. to New Scotland ls., according to Hartnagel (Hdb. 19, 1912).

Name apparently taken from some one of the places in Orange Co. that bear the name Cornwall.

Cornwall shale.

Middle Devonian: Southeastern New York and northern New Jersey.

C. A. Hartnagel, 1907 (N. Y. State Mus. Bull. 107, pp. 39–54). *Cornwall sh.* replaces *Monroe shales* of Darton, because that name is preoccupied in Mich. Consists of 200 ft. of dark-gray slaty shales; in places pronounced slaty cleavage is shown. Of Hamilton age. Rests on Oriskany qtzite in N. Y., the relations of which to Newfoundland grit (which underlies the Monroe shales in N. J.) is not yet established. [This underlying fm. is now called *Kanouse ss.*, in both N. Y. and N. J.] Named for occurrence at Cornwall, Orange Co., N. Y. Eckel's use of *Cornwall lss.* not considered valid.

In N. J. the name "Monroe shales" was replaced by *Pequanac sh.* in 1908 (U. S. G. S. Franklin Furnace folio, No. 161), but *Pequanac* was discarded in 1914 (Raritan folio, No. 191), in favor of the older name *Cornwall sh.*

Cornwall formation.

Jurassic: British Columbia.

C. H. Crickmay, 1930 (Calif. Univ., Dept. Geol. Sci. Bull., vol. 19, No. 2, p. 33).

Coronach shale.

Upper Devonian: Alberta (Jasper Park).

P. E. Raymond, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 296, 300). *Coronach sh.*—Black sh. and interbedded ls.; 600 ft. thick. Type locality on road a mi. S. of Disaster Point. Named for Coronach Creek, across the Athabaska. Naples fauna. Overlies Boule dolomitic ls. and underlies Fiddle ls.

Coronado quartzite.

Upper Cambrian: Central eastern Arizona (Greenlee County).

W. Lindgren, 1905 (U. S. G. S. P. P. 43, p. 59). *Coronado qtzite.*—Chiefly heavy beds of brown, pink, or maroon qtzitic sss., usually characteristically jointed. Lowest memb., which is missing in many sections, is qtzite cgl. up to 50 ft. thick. Thickness of fm. 100 to 250± ft. Rests uncon. on granite basement. Conformably underlies Longfellow lss. Several areas of this fm. crown summit and westerly slope of Coronado Mtn, N. W. of Morenci, Greenlee Co.

Upper Camb. fossils have been found 25 ft. below top.

Corozal limestone.

Cretaceous (?): Puerto Rico.

C. P. Berkey, 1915 (N. Y. Acad. Sci. Annals, vol. 26, p. 23).

†Corral sandstone. (In Cheyenne sandstone.)

Lower Cretaceous (Comanche): Central southern Kansas.

F. W. Cragin, 1895 (Am. Geol., vol. 16, pp. 361, 366). *Corral ss.*—Ss., 30 to 50 ft. thick; lower part white; upper part often beautifully variegated with bright reds mingled with yellow, purple, and brown. Basal part of Cheyenne ss. Overlain by Elk Creek beds (upper part of Cheyenne).

Named for the Natural corral, a short box canyon on Lanphier claim, in SE. corner of Kiowa Co., long known under that name by the settlers.

This name was discarded by U. S. Geol. Survey in 1921, the bed being simply a local facies of Cheyenne ss. and without strat. value; and the name seems to have been discarded by Kans. Geol. Survey. (See last entry under *Cheyenne ss.*)

Corral formation.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 42, p. 289), applied the name "(Hector) Corral" to, apparently, all pre-Camb. rocks of Alberta, consisting of (descending order) slates 4,600 ft., qtzites 1,200 ft., and cgls. 100 ft.; which are, apparently, the same rocks that were called "Hector fm." in earlier repts.

Derivation of name not stated.

Corral Creek formation.

Pre-Cambrian: Alberta and British Columbia.

C. D. Walcott, 1910 (Smithsonian Misc. Coll., vol. 53, No. 7, p. 428).

Corral Hollow shales.

Jurassic (?): Western California (Alameda County).

C. F. Tolman, Jr., 1915 (Nature and science on Pacific coast, p. 45, San Francisco, Elder & Co.). *Corral Hollow shales.*—A subdivision of Franciscan series. Contain massive beds of crumpled and folded cherts, and, especially in vicinity of serpentine intrusions, lawsonite, chlorite, and glaucophane-bearing schists that seem to be peculiar to Franciscan series. Older than Oakridge ss., and underlain by dense blue ss. of the Franciscan.

†Corrigan formation.

Lower Devonian: Western Maryland.

A. W. Grabau, 1910 (Mich. Geol. and Biol. Surv. Pub. 2, geol. ser. 1, pp. 231, 234). *Corrigan fm.*—The succeeding "Manlius" exposed at Keyser, W. Va. (110 ft.), has recently been made subject of a careful and detailed faunal study by Dr. Poole Maynard of Johns Hopkins Univ. The series has been named [unpublished] *Corrigan fm.*, and in outline presented before Geol. Soc. Am. at Cambridge meeting, 1909–10, it was shown that the fauna was a unit and of Upper Siluric (Cobleskill-Manlius) type. A comparison of the fossils with those of Upper Monroe fm. of Mich. has convinced both Mr. Maynard and author of the relationship of the faunas, some of the characteristic Mich. species, such as * * *, being present in the Corrigan. Thus the Corrigan of Md. (Manlius of Schuchert, Helderbergian of O'Harra's Potomac section) must be regarded as representative of the Upper Monroe.

C. K. Swartz et al, 1913 (Md. Geol. Surv. Lower Dev. vol., p. 97). In 1908–9 [T. P.] Maynard (Dissert. presented for degree Ph. D. in Johns Hopkins Univ. 1909) studied the beds termed *Manlius fm.* by Schuchert, comprising most of [lower or] *Chonetes jerseyensis* zone of Keyser memb. of Helderberg fm. He named them [unpublished ms.] *Corrigan fm.* and correlated them with Cobleskill, Rondout, and Manlius fms. of N. Y., and Decker Ferry, Rondout, and Manlius fms. of N. J., believing these units are undiff. in Md.

The rocks at Corriganville, Md., are now assigned to Helderberg fm. (Lower Dev.).

Named for occurrence at Corriganville, Allegany Co.

Corrigan formation.

Miocene? (lower Miocene?): Eastern Texas (Polk County).

E. T. Dumble, 1911 (Tex. Acad. Sci., vol. 11, p. 51). The *Corrigan beds*, as Kennedy called [where?] the sands which overlie the Frio as now determined, are therefore later than any previously recognized Eocene deposits. Referred to Jackson by Prof. Harris.

E. T. Dumble, 1915 (Geol. Soc. Am. Bull., vol. 26, p. 465). *Corrigan sands.*—Coarse "rice" sands and sss. at base, overlain by finer sands and by yellowish green clay and claystones with plant remains. The clays and claystones carry pyritic nodules and streaks of lignite and weather yellow to cream color. Local unconformities btw.

sands and clays. Occasionally cross bedded. Mapped [p. 448]. Assigned to Olig. *Named for town in Polk Co.* "It is here proposed to use Kennedy's older term *Corrigan sands* for the group of deposits lying between the known Jackson and the Fleming, which while forming the only mappable unit, probably includes beds of later age than the Catahoula of Veatch, which name should be retained for that portion of the Corrigan to which it strictly applies."

E. T. Dumble, 1920 (Univ. Tex. Bull. 1869). *Corrigan fm.*—We will use Kennedy's older name *Corrigan* for entire group of non-marine deposits which lie btw. the Jackson and the Fleming and together constitute our only mappable unit. They are supposedly for most part of upper Olig. age.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 715, 717), replaced *Corrigan* in narrow sense by *Chita sand memb.*, and *Corrigan* in broad sense by *Catahoula fm.* (See under *Chita sand memb.*)

Named for Corrigan, Polk Co.

Corry sandstone.

Mississippian: Northwestern Pennsylvania.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. Q_4, pp. 92–94). *Corry ss.*—Yellowish white or buff gray ss., compact, fine-grained, at one or two places some pebbles. Thickness 20 ft. Quarried about 1 mi. S. of Corry, Erie Co. Top fm. of Oil Lake group. Overlies Cussewago Upper Shales and underlies Orangeville sh. Corry and Cussewago probably = Berea ss. of Ohio.

H. P. Cushing (1888) and E. Orton (1893) correlated Corry alone with Berea ss.; J. J. Stevenson (1903) correlated Cussewago and Corry with Berea.

G. H. Girty, 1905 (Wash. Acad. Sci. Proc., vol. 7, p. 6). Berea grit of Ohio is White's Cussewago ss. together with probably the Cussewago flags and Corry ss. It initiates the Miss.

C. Butts, 1910 (U. S. G. S. Warren folio, No. 172), used *Berea ss.* in this quad., and stated: Berea ss. has been traced eastward from Ohio by Girty and found to be same as "Corry" ss. at Corry, Pa. Identifying it by its abundant and highly characteristic fauna he was able to follow it still farther E. into this quad.

C. S. Prosser, 1912 (Ohio Geol. Surv. Bull. 15, p. 395), correlated Cussewago and Corry with Berea.

W. A. VerWiebe, 1916 (Am. Jour. Sci., 4th, vol. 42, p. 46), and 1917 (vol. 43 of same journal, pp. 301–318). Berea fm. is represented in Pa. by Corry ss. and Cussewago sh. and ss. of I. C. White, and should be considered base of Miss.

G. H. Chadwick, 1925 (Geol. Soc. Am. Bull., vol. 36, pp. 455–464), correlated Berea ss. with Corry ss. only, but used Corry ss. in Pa.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, pp. 49–52, table opp. p. 61, pp. 122–128 and later pp.). Strat. position is substantial proof of equivalence of Corry ss. and some part of Berea ss. The detailed sections of Prosser's voluminous rept establish that fact. Also, the Corry fauna occurs in upper Berea of Ohio. [p. 49.] The Corry is of remarkable lithic similarity to Berea ss. of Williamsford P. O., Ohio. [p. 51.] The lower Berea seems to be identical with Cussewago ss. (and sh.?). [p. 52.] "Berea stage" is a new stage created to include Corry ss. only. [p. 52.] There is reasonable certainty Corry is eastward continuation of upper Berea ss. of Ohio. [p. 52.] [Fauna listed on pp. 123–124.] [In table opp. p. 61 he used *Berea stage* to include *Corry ss. memb.* only. On p. 122 he correlated Berea ss. of Ohio with Cussewago ss. and Corry ss. of Pa., and stated that Corry is "correlated with Upper true Berea ss. of Ohio." Fossils listed. On p. 126: "The relation of the Corry ss. to the true Berea grit of Ohio is as yet obscure. It would appear that the upper Berea ss. of Ohio is continuous with the Corry ss."]

K. E. Caster, 1935 (A. A. P. G. Bull., vol. 19, No. 6, p. 913). Corry ss. (possibly of Berea age) occurs in upper part of Oil Lake series in western Pa. The Corry fauna is of a characteristic Kinderhook aspect.

The U. S. Geol. Survey classifies Berea ss. as of Kinderhook age, and for many years discarded Corry, regarding it as a synonym of Berea; but in view of doubt that now exists as to exact equivalency of the two, *Corry* has been restored to good standing.

Corryville shale member (of McMillan formation).

Upper Ordovician: Southeastern Indiana and southwestern Ohio.

J. M. Nickles, 1902 (Cincinnati Soc. Nat. Hist. Jour., vol. 20, pp. 75, 83). *Corryville or Chiloporella nicholsoni beds.*—About 60 ft. of thin ls. and yellowish, also blue, sh. interbedded. Overlain by Mount Auburn or *Platystrophia lynx* beds and underlain by Bellevue or *Monticulipora molesta* beds.

Middle memb. of McMillan fm.

Named for Corryville, near Cincinnati.

Corsicana marl. (In Navarro group.)

Upper Cretaceous (Gulf series): Northeastern Texas.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, pp. 342–343). *Corsicana beds.*—Fine, brown, sandy marl, with occasional bands of hard calc. ss. in upper part. Included in upper part of Navarro fm. Underlies Kemp clay bed of Navarro fm. Extends from Sulphur River, Delta Co., to the Brazos. [According to L. W. Stephenson (Univ. Tex. Bull. 3232, p. 516, 1933) this unit probably included (ascending) *Exogyra cancellata* zone (Neylandville marl of Stephenson), Nacatoch sand, and the chalky marl (*Corsicana marl restricted* of Stephenson).]

W. S. Adkins, 1933 (Univ. Tex. Bull. 3232, pp. 239, 270, 488, 516). *Corsicana fm. (restricted).*—Dr. L. W. Stephenson suggests that the basal Navarro clays (*Exogyra cancellata* zone) below the Nacatoch be called *Neylandville fm.*, and that if the name *Kemp beds* of Hill is retained, as in this paper, for the portion of the Navarro above Nacatoch sand, the lower part (chalky marl) of the Kemp be separated as the *Corsicana fm. (restricted)*. It appears from Hill's description that he included in his "Corsicana beds" the Navarro clays below the Nacatoch, the Nacatoch, and a portion at least of the chalky marl. Dr. Stephenson says (personal communication, March 6, 1933): [See Stephenson 1933 entry.] Although not entirely satisfactory, it is considered best here to *restrict and redefine "Corsicana"* of Hill to include all beds in Navarro Co. section above top of Nacatoch sand and below base of upper clay or "chalk marl" of Stephenson. The beds (of Navarro age) btw. top of the Taylor and base of the Nacatoch are here called *Neylandville fm.*, as suggested by L. W. Stephenson.

L. W. Stephenson, 1933 (Univ. Tex. Bull. 3232, p. 516). *Neylandville* would be appropriate name for unit I have heretofore called *Exogyra cancellata* zone, which includes all beds btw. Taylor marl below and Nacatoch sand above. Exposures occur in washes in a field just S. of fair grounds at SE. edge of Greenville, and in ditches along Dixon road for a mi. or more SE. of fair grounds. Type exposures occur along Bankhead highway btw. Liberty School and Neylandville, 3 to 6 mi. in air line NE. of Greenville, and in first cut of Texas Midland Ry. W. of Neylandville Station. *Kemp fm.* as used by Bur. Econ. Geol. in this rept. includes the units which I have called chalky marl memb. and upper clay memb. Since the chalky marl memb. underlies city of Corsicana, it would be appropriate to *restrict Corsicana* to it. As Hill originally used "Corsicana" it probably included *Exogyra cancellata* zone, Nacatoch sand, and the chalky marl. The pit of Corsicana Brick Co. 2 mi. S. of court house at Corsicana, might appropriately be regarded as type loc. If *Kemp* is retained it should be restricted to the upper clay memb., but exposures of this are rare in vicinity of Kemp, and desirability of applying the name to this unit has not been fully considered. The names *Neylandville* and *Corsicana restricted* have not yet been formally adopted by U. S. Geol. Survey. [They were later adopted.]

See U. S. G. S. 1937 geol. map of Tex., where Navarro group is divided into (ascending) Neylandville marl, Nacatoch sand, *Corsicana marl (restricted)*, and Kemp clay (restricted). This is present approved classification.

Corsicana sand.

The lower subsurface oil sand in wells of Corsicana oil field of northern Tex. It is in Taylor marl, and lies 500 to 800 ft. below Corsicana beds of Hill, which outcrop at Corsicana and are now considered same as Nacatoch sand memb. of Navarro fm.

Corson diabase.

Pre-Cambrian: Northwestern Iowa and southeastern South Dakota (?).

C. [R.] Keyes, 1914 (Iowa Acad. Sci. Proc., vol. 21, p. 187; Sci., n. s., vol. 40, p. 144). *Corson terrane.*—Diabase included in top of Keweenawan series.

Probably named for Corson, Minnehaha Co., S. Dak.

Cortlandt series.

Age undetermined: Eastern New York (Westchester County).

J. D. Dana, 1880 (Am. Jour. Sci., 3d, vol. 20, pp. 194–220); also see 1881 (same jour., vol. 22, pp. 103–119). Hornblendic, augitic, and associated rocks cover a large part of Twp of Cortlandt (the NW. of Westchester Co.) btw. Croton River on S. and parallel of Peekskill on N., an area of about 25 sq. mi. They differ widely from the ordinary rocks of Westchester Co., and may well be designated *Cortlandt series.* In fact, a series so remarkable in constitution, so diversified in kinds, and so full of geological interest is seldom found together within so small an area anywhere on the globe. [Lists varieties.] They are not independent igneous rocks erupted from great depth, but are of metamorphic origin.

G. H. Williams, 1888 (Am. Jour. Sci., 3d, vol. 35, pp. 438–448, and vol. 36, pp. 254–269). The area occupied by *"Cortlandt series"* is mainly composed of norite; also includes gabbro, diorite, and mica diorite. It is bordered on S. mainly by mica schists, on W. mainly by lss., and on N. by gneisses.

G. H. Williams, 1888 (Johns Hopkins Univ. Circ., vol. 7, No. 65, pp. 63–65). *"Cortlandt series"* consists of diverse eruptive rocks, which, although very ancient, are little altered.

C. P. Berkey, 1907 (N. Y. State Mus. Bull. 107, p. 377). *Cortlandt series* assigned to Lower Siluric [Ord.].

C. P. Berkey, 1908 (Sci., n. s., vol. 28, p. 575). *Cortlandt series* includes a wide range of granitoid medium to basic types of igneous rocks. It seems certain they represent a case of magmatic differentiation that includes not only the Cortlandt series as outlined by Dana and Williams but also two or three occurrences of typical granite.

G. S. Rogers, 1911 (N. Y. Acad. Sci. Annals, vol. 21, pp. 11–20). *Cortlandt series,* a small but remarkably complete igneous complex of granite, syenite, sodalite syenite, diorite, gabbro, norite, biotite norite, hyporite, quartz norite, etc. Surrounded on every side by Manhattan schist. Is a very complex and intricate mass. Unquestionably younger than Manhattan schist and Inwood ls., which it intrudes. Must be post-Ord. [Manhattan schist and Inwood ls. are now classified by U. S. Geol. Survey and other geologists as pre-Camb., but they were formerly regarded as Ord.] It is practically certain it is not post-Permian. In writer's opinion it is probably late Paleozoic.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 24). The *Cortlandt series* includes a group of gabbroic and dioritic rocks found just S. of Peekskill, in town of Cortlandt. It covers area of some 20 sq. mi., and is regarded as the latest intrusives in SE. N. Y. excepting Palisade diabase, of Postpaleozoic age.

J. F. Kemp, 1912 (Int. Geol. Cong. Comptes rendus, 11th sess., Stockholm, p. 701). *Cortlandt series* assigned to Ord.

C. P. Berkey and Marion Rice, 1921 (N. Y. State Mus. Bull. 225, 226). *Cortlandt series of intrusives* cuts Manhattan schist. Its age is not known but it probably is not pre-Camb. Is tentatively classified as later than Hudson River-Wappinger-Poughquag series of sl., ls., and qtzite of Cambro-Ord. age. The rocks of Westchester Co. freest from metamorphism are the members of Cortlandt series. Age of Manhattan schist, Inwood ls., and Lowerre qtzite, is uncertain.

Corwin formation.

Cretaceous: Northwestern Alaska (Cape Lisburne region).

F. C. Schrader, 1902 (Geol. Soc. Am. Bull., vol. 13, p. 244). *Corwin series.*—Medium to heavy-bedded impure, gray and brown ss. and arkose, with sh., shaly sl., and coal beds. Occurs on coast near Wainwright Inlet, and extends SW. 180 mi. to near Cape Lisburne, where it plays important part in geology of that region. Provisionally assigned to Jura-Cret.

Named for Corwin Bluff, about 30 mi. E. of Cape Lisburne.

†Coryphodon beds.

A paleontologic name applied in some early repts to Wasatch fm. (lower Eo.) of Rocky Mtn region. According to H. F. Osborn (U. S. G. S. Mon. 55, 1929, pp. 58, 59) this genus occurs throughout the beds now assigned to Wasatch fm. by U. S. Geol. Survey, and is not recorded from overlying and underlying fms.

Cosden sand.

A subsurface sand, of Penn. age, in Okmulgee dist., central eastern Okla., lying lower than Oswego lime, higher than Bartlesville sand, and reported to correlate with Boggy sh. The name has also been applied to a sand in Fayette ss. (of Eocene Jackson age) of Pettus area, Bee Co., SE. Tex.

Cosmos sand.

A subsurface sand, about 60 ft. thick, forming basal bed of Kootenai fm. (Lower Cret.) in Border-Red Coulee oil field of NW. Mont. and SW. Alberta. In E. part of field the Cosmos sand is split into two parts by 10 to 15 ft. of gray-green pyritic siltstone, and the upper tongue, which is 5 to 15 ft. thick, is locally called *Vanalta sand*. The lower part of the Cosmos sand is characterized by presence of thin local lenses of gray-green and dark-gray ss. and an abundance of mud-pellet cgl. In places the basal bed is cgl. The sand may consist chiefly of black chert. Named for Cosmos-Iowa No. 1 well, by which it was first penetrated.

Cottage Grove sandstone.

Pennsylvanian: Central and southern Kansas and northern Oklahoma.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 92, 97). In central and southern Kans. the Chanute includes a persistent bed of ss. (*Cottage Grove*), and just beneath the ss. is Thayer coal. These beds persist into northern Okla. and are of value in correlation of adjacent lss.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, p. 49). For upper ss. mass of Chanute sh. the term *Cottage Grove ss.* is here applied, from Twp in Allen Co., Kans. It overlies Thayer coal. Is generally soft, light-buff, cross-bedded or even-bedded. Thickness 1 to 30 ft. [R. C. Moore, 1936, says 50 ft. in southern Kans.]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), stated that Newell is author of this name.

Cotter dolomite.

Lower Ordovician (Beekmantown): Northern Arkansas and southern Missouri.

A. H. Purdue and H. D. Miser, 1916 (U. S. G. S. Eureka Springs-Harrison folio, No. 202). *Cotter dol.*—Chiefly two kinds of dol.—a fine-grained, argill., earthy textured, relatively soft, white to buff or gray variety known as "cotton rock," and a more massive medium-grained gray variety that weathers hackly on the surface and becomes dark on exposure. Contains some chert and a little interbedded saccharoidal ss. and green sh. Thickness 500+ ft. Uncon. underlies Powell ls. Base not exposed in these quads, but in Mo., and farther E. in Ark., where erosion has cut through it, the Jefferson City ls. underlies it. Named by E. O. Ulrich from exposures at Cotter, Baxter Co., Ark. In 1911 (Geol. Soc. Am. Bull., vol. 22) was called *Jefferson City* by Ulrich, but in 1912 he determined that Jefferson City at type loc. is older than the dol. here named *Cotter*.

Cottonwood limestone. (In Council Grove group.)

Permian: Eastern Kansas, central northern Oklahoma, and southeastern Nebraska.

E. Haworth and M. Z. Kirk, 1894 (Kans. Univ. Quart., vol. 2, pp. 112–114). Ls. No. 13 of section along Neosho River from Indian Territory to White City, Kans., is famous *Cottonwood Falls ls.*, quarried near Cottonwood Falls, where it consists of two layers, the upper one 2½ ft. thick and the lower one 3 ft. thick. Underlain and overlain by 30 ft. of dark sandy sh.

The abbreviated form *Cottonwood ls.* is well established in the literature. The fm. is overlain by Florena sh. memb. of Garrison fm. and underlain by Eskridge sh.

See also under *Beattie fm.*

Named for Cottonwood Falls, Chase Co., Kans.

†Cottonwood formation. (In Council Grove group.)

Permian: Eastern Kansas.

C. S. Prosser, 1894 (Geol. Soc. Am. Bull., vol. 6, pp. 37–41). *Cottonwood fm.* proposed to include Manhattan stone or Cottonwood ls. and overlying Cottonwood sh.

Includes Cottonwood ls. and Florena sh. memb. of Garrison fm.

Named for Cottonwood Valley, Chase and Lyon Counties.

†Cottonwood shales. (In Council Grove group.)

Permian: Eastern Kansas.

C. S. Prosser, 1894 (Geol. Soc. Am. Bull., vol. 6, pp. 38–39). *Cottonwood shales.*—Yellow fossiliferous shales, 10 ft. thick, forming upper part of Cottonwood fm. in Cottonwood Valley and at Manhattan and vicinity. Overlies Manhattan stone or Cottonwood ls.

Conflicts with Cottonwood ls. Replaced by *Florena sh. memb.*

Cottonwood beds.

Miocene: Central northern Oregon (John Day region).

W. D. Matthew, 1900 (Am. Mus. Nat. Hist. Bull., vol. 12, p. 23), gave (in table) a column headed "John Day R., Oreg., Wortman, 1880," under which appears *Cottonwood beds (Protolabis)*, shown as older than Loup Fork of Llano Estacado, Tex., and as younger than John Day.

J. C. Merriam, 1901 (Jour. Geol., vol. 9, p. 72), in a description of rocks of John Day Basin used *Cottonwood (Loup Fork) fm.*, nearly 1,000 ft. thick, uncon. underlying Rattlesnake fm. and overlying Columbia [River] lava.

J. C. Merriam, 1901 (Univ. Calif. Pub., Bull. Dept. Geol., vol. 2, No. 9), replaced *Cottonwood beds* (preoccupied) with *Mascall fm.*, and stated that at Rattlesnake Creek, near Cottonwood, the Mascall is not less than 800 to 1,000 ft. thick.

Cottonwood white layer.

Name applied by W. D. Matthew and W. Granger (Am. Mus. Nat. Hist. Mem., vol. 9, 1909, p. 295) to a bed in their horizon B of Bridger fm. in Bridger Basin. (See under *Lone Tree white layer* for their subdivisions of Bridger fm.) H. F. Osborn (U. S. G. S. Bull. 361, p. 51, 1909) placed this bed in basal part of div. C of Bridger fm.

Cottonwood rhyolite.

Tertiary (middle or late): Northwestern Arizona (Oatman district).

F. L. Ransome, 1923 (U. S. G. S. Bull. 743). Very glassy spherulitic lava flows. Thickness 600± ft. Occurs about headwaters of Cottonwood Canyon.

Cottonwood schists and gneisses.

A name that has been rather loosely applied to the pre-Camb. schists and gneisses of Cottonwood Creek region, central Wasatch Mtns, Utah.

†Cottonwood granite.

See under *†Little Cottonwood granite.*

Cottonwood Creek bed. (In Strawn formation.)

Pennsylvanian: Central Texas (Colorado River region).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 374, 382). *Cottonwood Creek bed.*—Chiefly nearly white friable ss., 300 ft. thick; in places part of bed consists of massive, moderately hard strata. Memb. of Strawn div. Underlies Hanna Valley bed and overlies Spring Creek bed.

Named for Cottonwood Creek, San Saba Co.

Cottonwood Draw banded layers.

Name applied by W. Granger (Am. Mus. Nat. Hist. Bull., vol. 28, 1910, pp. 244, etc.) to basal part of Wind River fm. along Cottonwood Creek, near Lost Cabin, NE. corner of Fremont Co., Wyo.

†Cottonwood Falls limestone.

Permian: Eastern Kansas.

See *Cottonwood ls.*

†Couchiching.

Same as †Coutchiching.

Coudersport member (of Cattaraugus formation).

Upper Devonian or Mississippian: Central northern Pennsylvania (Potter, Tioga, and probably McKean Counties).

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, p. 581). *Coudersport memb. of Cattaraugus fm.*—Heavy green memb., 10–20 ft. thick, about 100 ft. above base of Cattaraugus fm. Useful key bed. Persistent in adjacent parts of Potter, Tioga, and probably McKean Counties, and perhaps occurs in Cameron, Clinton, Lycoming, and Sullivan Counties. Closely resembles Oswayo, but is more massive and less cross bedded. What has been called *Oswayo* in northern Potter and Tioga Counties is probably the green Coudersport memb. of Cattaraugus fm. Named for Coudersport, Potter Co., where it occurs in quarries along W. side of town. Assigned to Upper Dev.

Cougar formation.

Pre-Cambrian: British Columbia.

R. A. Daly, 1913 (12th Int. Geol. Cong. Guidebook 8, p. 136).

Cougarian series.

A term introduced by C. [R.] Keyes to cover rocks of Cordilleran region interpreted by him as having been formed during the upper Huronian epoch. (See Iowa Acad. Sci. Proc., vol. 24, p. 56, 1917.)

†Coulter's Ferry sands.

Upper Cretaceous: Northeastern Mississippi (Monroe County).

E. W. Hilgard, 1860 (Rept. Geol. and Agric. Miss., pp. 66, 67, 73). *Coulter's Ferry sands.*—Grayish yellow, stratified, noneffervescent sand, 120 ft. thick at Coulter's Ferry. Not infrequently small lenticular masses and thin layers of gray laminated clay occur in the sand. In lower portion of the bed occur large round concretions, 3 to 4 ft. in diam., of calc., nonfossiliferous ss., usually vary hard, sometimes soft. Underlies Rotten ls. [Selma chalk] and overlies dark-colored, bluish, laminated clay.

Replaced by Coffee sand, the better established name.

Named for exposures at Coulter's Ferry, on Old Town Creek (near its confluence with the Tombigbee), sec. 34, T. 10, R. 7 E., Monroe Co.

Council Grove group.

Permian: Eastern Kansas, northern Oklahoma, and southeastern Nebraska.

C. S. Prosser, 1902 (Jour. Geol., vol. 10, p. 709). *Council Grove stage.*—It is perhaps a more satisfactory classification to regard base of Perm. as marked by lower limit of Wreford ls., and writer is inclined to accept this as div. line, as indicated by Dr. Frech. If this be done the writer would class the two fms. succeeding Eskridge shales (Cottonwood ls. and Garrison) together to form a stage, for which he would propose the name *Council Grove.* The upper part of stage is well shown in bluffs of Neosho River and its tributaries in vicinity of this city, while Cottonwood ls. and overlying Florena shales may be found in Neosho Valley about 6 mi. below Council Grove. Underlies Chase stage and overlies Wabaunsee stage.

Above definition of Council Grove group was followed until 1922, when J. W. Beede (Geol. Soc. Am. Bull., vol. 33, No. 4) extended base of the Council Grove down to base of Neva ls. This change was not adopted by other geologists, however.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3), expanded *Council Grove group* by including in it Eskridge sh., Neva ls., Elmdale sh., and Americus ls., and Moore and G. E. Condra in their Oct. 1932 revised classification chart of Penn. rocks of Kans. and Nebr. followed this definition, as did G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8), and R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22). The U. S Geol. Survey has not yet had occasion to consider, for its publications, this modified definition.

See Kans.-Nebr. Perm. chart compiled by M. G. Wilmarth, 1936.

Named for Council Grove, Morris Co., Kans.

†Courtland quartzite.

Pre-Cambrian (Huronian): Central southern Minnesota (Nicollet County).

C. W. Hall, 1899 (U. S. G. S. Bull. 157, pp. 20–25), described the red qtzite of Courtland dist., and on pp. 23 and 24 used the term *Courtland qtzites,* stating that there is evidence the *Courtland qtzites* underlie a considerable belt of territory, and he also made following statements: Around Swan Lake, from 4 to 6 mi. NE. of exposures near Redstone and New Ulm, bowlders of red qtzites strew the ground in places. In Cottonwood and Watonwan Counties, about 25 mi. to SW., many sq. mi. are underlain by vitreous qtzites, and many broad surfaces appear, representing a thickness of strata of at least 1,500 ft. The fm. is, therefore, several times as thick as at Courtland, where only 250 to 300 ft. is exposed. There is no doubt the extensive exposures of red qtzites in Rock and Pipestone Counties, Minn., and in many counties of SE. S. Dak. belong to this fm.

F. W. Sardeson, 1908 (Geol. Soc. Am. Bull., vol. 19, pp. 221–242). *Courtland qtzite.*—Local name proposed for the pre-Camb. qtzite at Redstone, a conspicuous hill of qtzitic rock in Courtland Twp, Minn., midway btw. towns of New Ulm and Courtland. Is same as Sioux qtzite.

Courtney granite.

Mesozoic: Northern California (Trinity County).

O. H. Hershey, 1900 (Sci., n. s., vol. 11, pp. 130–132). *Courtney granite.*—The granite of Mount Courtney batholith. A nearby batholith is composed of entirely different granite.

†Coutchiching series.

Name proposed for oldest known pre-Camb. rocks in Rainy Lake region of NE. Minn. and adjacent parts of Ontario. Included in Keewatin series by U. S. Geol. Survey. (For definition see U. S. G. S. Bull. 769, pp. 132–135.) The spelling adopted by U. S. Geog. Bd. is *Koochiching.*

†Coutchichingan series.

A term used by C. [R.] Keyes for Coutchiching series of other geologists.

Covada group.

Probably Mesozoic, Carboniferous, and Devonian: Northeastern Washington.

C. E. Weaver, 1913 (Wash. Geol. Surv. Bull. 16, pp. 20–30). *Covada fm.*—Slates, schists, qtzites, and dolomitic lss. No fossils. Provisionally assigned to Carbf. (?) or early Mesozoic. Resembles Cache Creek beds of B. C. and Peshastin fm. of Central Cascades of Wash. Named for Covada, Ferry Co.

J. T. Pardee, 1918 (U. S. G. S. Bull. 677). *Covada group.*—Metamorphosed sh., sl., argillite, schist, qtzite, cgl., and ls. Argillite or schist predominates and is characteristic of mass as a whole. It may be subdivided. Covada fm. of Weaver includes a large part of the rocks here called *Covada group.*

†Cove limestone.

Ordovician: Appalachian region.

H. D. Rogers, 1836 (Pa. Geol. Surv. 1st Ann. Rept., pp. 12–22). The *cove ls.* is a very thick blue ls., containing layers of chert or hornstone, and ranging through many of larger valleys. Underlies cove slate and overlies a fm. of ls. and sl.

H. D. Rogers 1838 (Pa. Geol. Surv. 2d Ann. Rept., table opp. pp. 19, 30, and pl. opp. title page). *No. II.*—Blue ls. with beds of chert, about 6,000 ft. thick. Called *Cove ls.* in my first rept., but I shall drop that name. Overlies No. I, which consists of about 1,000 ft. of compact white ss., resting uncon. on Primary rocks.

The ls. referred to includes beds of Trenton to Beekmantown age, both inclusive. It was later called *Shenandoah ls.*, and is now subdivided into several named fms.

Origin of name not known. May have been derived from Cove Mtn, Franklin Co., Pa.

†Cove slate.

Ordovician: Appalachian region.

H. D. Rogers, 1836 (Pa. Geol. Surv. 1st Ann. Rept., pp. 12–22). The *cove slate* consists of dark blue, drab, and yellow sl., generally found at foot of the mtns, and in places containing rich deposits of iron ore.

H. D. Rogers, 1838 (Pa. Geol. Surv. 2d Ann. Rept., table opp. p. 19 and pl. opp. title page). *No. III.*—Called *Cove sl.* in my first rept. Consists of 6,000 ft. of dark sl., argill. sss., and some cgl., with roofing slates at top and ls. near base. Underlies No. IV (white ss.) and overlies No. II (Blue ls., called *Cove ls.* in my first rept).

Practically synonymous with Martinsburg sh.

Origin of name not known. May have been derived from Cove Mtn, Franklin Co., Pa.

Cove Creek limestone.

Mississippian; Southwestern Virginia.

C. Butts, 1927 (Va. Geol. Surv. Bull. 27, p. 16). *Cove Creek ls.*—Predominantly argill. ls., like underlying lss. of Gasper, Ste. Genevieve, and Warsaw age. Thickness 1,003 ft. Generally unfossiliferous, but one fossiliferous bed, 5 to 10 ft. thick, occurs at base and a few fossils higher up. Lower 500 ft. has considerable proportion of fairly pure ls. conspicuously shown along Cove Creek [Scott Co.] and elsewhere. Includes some coarse-grained crinoidal ls. and one bed of red ss. was noted. Underlies Pennington sh. and overlies Fido ss.

Coventry limestone.

Coventry phase of Waits River limestone.

Ordovician: Northeastern Vermont (Orleans County).

C. H. Richardson, 1908 (6th Rept. Vt. State Geol., pp. 265–291). *Coventry phase of Waits River ls.*—Youngest phase of Waits River ls. Is darker than the other 2 phases of that fm. (the Washington phase and the typical phase), more carbonaceous, sometimes shaly, and never susceptible of polish. Traverses Irasburg, Coventry, and Newport, and dips uniformly to W. [Type loc. is in Coventry, Irasburg quad.], where it is uniformly of dark color, often pyritiferous, and compact. *No fossils.*

C. H. Richardson and E. F. Conway, 1912 (8th Rept. Vt. State Geol., pp. 146–160). *Coventry phase of Waits River ls.* is dark-gray pyritiferous siliceous ls. which underlies half of Irasburg Twp.

Coventry conglomerate.

Lower Ordovician: Northeastern Vermont (Orleans County).

C. H. Richardson, 1919 (11th Rept. Vt. State Geol., p. 47). *Coventry cgl.*—Appears 10 mi. N. of Irasburg. Contains quartz pebbles 1 inch to 1 ft. diam. and fragments of Camb. schist which are occasionally at right angles. Also carries angular fragments of Ord. sl. and ls. It is a meta-cgl., for the lime has been calcitized. Can not be contemp. with Irasburg cgl. May have been formed at close of Ord. or may represent a fault breccia.

C. H. Richardson, 1929 (16th Rept. Vt. State Geol., pp. 107–110). *Coventry phase of Irasburg cgl.* is markedly different from any of the other phases of that fm. It is characterized by well-rounded, smoothed, sometimes faceted and sometimes apparently striated boulders of pure white quartz from an inch to a foot in diam. Fragments of Camb. schists up to 1 ft. in diam. and set at right angles to each other are embedded in an Ord. paste of ls. and sl. Writer believes this rock is a fault breccia cgl. This breccia-cgl. is located about 10 mi. N. of Craftsbury, near contact of Camb. and Ord. terranes. Main road from Newport to South Troy passes over this terrane [and crosses N. part of Coventry Twp].

†Covington group.

Upper Ordovician: Southwestern Ohio and north-central Kentucky.

R. S. Bassler, 1906 (U. S. Nat. Mus. Proc., vol. 30, p. 9). *Covington group* proposed to embrace all strata in Cincinnati area from top of Trenton to base of Richmond. It thus includes Utica and Lorraine of previous authors.

Includes Maysville and Eden groups.

Named for Covington, Ky.

Covington sand.

A subsurface sand, of Penn. age, in Garber pool, Garfield Co., central northern Okla., which lies at 2,100 ft. depth, the Garber sand lying at 2,000 ft. and the Hoover sand at 2,400 ft.

Cowanesque.

Name applied to a glacial lake in Cowanesque Valley, north-central Pa. (See B. Willard, Geol. Soc. Am. Bull., vol. 43, No. 1, p. 192, 1932, and vol. 43, No. 2, p. 441, 1932.)

Cowaselon clay.

Pleistocene: Southeastern New York (Madison County).

B. Smith, 1914 (Am. Jour. Sci., 4th, vol. 38, p. 463). Bluish clay, 2+ ft. thick, forming basal part of Aftonian deposits. Named for Cowaselon Creek, Madison Co.

Cow Creek beds. (In Travis Peak formation.)

Lower Cretaceous (Comanche series): Central Texas.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, pp. 141–143). *Cow Creek beds.*—In descending order: (1) Cross-bedded shell breccia, 7 ft.; (2) *Ostrea* bed, 3 ft.; (3) brecciated grit, 5 ft.; (4) stratified friable bluish sh. and calc. sand, 15 ft. Memb. of Travis Peak fm. in Burnet Co. Underlies Hensell sands and overlies Sycamore sand.

Named for Cow Creek, Burnet Co.

Cow Head limestone breccia.

Middle Ordovician: Newfoundland.

C. Schuchert and C. O. Dunbar, 1921 (Geol. Soc. Am. Bull., vol. 32, p. 38).

Cowichan group.

Upper Cretaceous: British Columbia (Vancouver Island).

C. H. Clapp, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 89).

Cowiche gravel.

Pleistocene: Central Washington (Ellensburg quadrangle).

G. O. Smith, 1903 (U. S. G. S. Ellensburg folio, No. 86). *Cowiche gravels.*—Coarse gravel and sand with covering of silt, forming terraces produced by dammed streams. Occur in broad terrace in valley of Cowiche Creek. Rest uncon. on Ellensburg fm. (Mio.).

Cow Island beds.

Upper Cretaceous: Central northern Montana (Judith River region).

C. H. Sternberg, 1914 (Sci., n. s., vol. 40, pp. 134–135). At Dog Creek [E. of Judith River and in Fergus Co.] are the typical Judith River beds of Hayden and Cope, followed below by Fox Hill-Pierre, which are in turn underlain by the *Cow Island beds*, the Judith River correlating with the Edmonton, and the Cow Island with Belly River series. Evidence of fossils corroborates distinction btw. Cow Island beds and Judith River beds at Dog Creek. [These so-called *Cow Island beds* are not described, but name is used in heading and columnar section. According to map of F. Reeves in U. S. G. S. Bull. 751C, pl. 11, Oct. 13, 1924, the beds along Dog Creek are Judith River fm. underlain by Claggett sh. Reeves's map shows several islands in Missouri River above and below mouth of Cow Creek (which empties into the Missouri near Fergus-Blaine Co. line). Some of these islands are mapped as Judith River and some as Claggett sh. The Cow Island beds of Sternberg therefore appear to belong to Claggett sh., since he states that the fossils are older than Judith River fossils.]

Cowlitz formation.

Eocene: Southwestern Washington (Lewis County) and northwestern Oregon.

C. E. Weaver, 1912 (Wash. Geol. Surv. Bull. 15, pp. 10–22). In southern Lewis Co., E. of Little Falls, there are shales and shaly lss. containing a fauna that is seemingly older than typical Tejon, but more closely related to it than to Martinez or Lower Eo. of Calif. In order to distinguish this from typical Tejon the term

Cowlitz fm. is suggested. Thickness 500 ft.; base unknown. [Probably named for Cowlitz River.]

C. E. Weaver, 1930 (Geol. Soc. Am. Bull., vol. 41, p. 87), called this fm. *Cowlitz or marine Upper Eocene fm.*

H. G. Schenck, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 217), in description of NW. Oreg. counties, stated that Keasey sh. rests on *Cowlitz Eocene fm.*

R. W. Chaney and E. I. Sanborn, 1933 (Carnegie Inst. Wash. Pub. 439). *Cowlitz fm.* contains marine fauna indicating late middle to early upper Eo. age.

Cow Run sandstone. (In Conemaugh formation.)

Pennsylvanian: Eastern Ohio and western West Virginia.

J. J. Stevenson, 1906 (Geol. Soc. Am. Bull., vol. 17, p. 154). *Cowrun ss.*, 0 to 40 ft. thick, is="Salzburg" ss. of W. Va. drillers.

D. D. Condit, 1912 (Ohio Geol. Surv., 4th ser., Bull. 17, p. 39). *Cowrun ss.*, 20 to 25 ft. thick, consists of massive to thin-bedded and shaly ss. Underlies Ewing ls. and overlies Portersville fossiliferous horizon. Named for stream [village?] in eastern Washington Co., Ohio. Outcrop not great in Ohio. Drillers apply name to almost any shallow sand, hence it is rather indefinite.

Cow Run sand.

Name applied to a subsurface sand in Conemaugh fm. (Penn.) of Ohio and W. Va. that has been said to correspond to Buffalo ss. memb., also to the younger Saltsburg ss. memb. This sand has also been called *First Cow Run sand*, and the name *Second Cow Run sand* has been applied to an older sand, formerly said to correspond to Homewood ss. memb. of Pottsville fm., also to correspond to the still older Connoquenessing ss. memb. In Pa. the name *Second Cow Run sand* has been applied to a sand that has been correlated with Freeport ss. memb. of Allegheny fm. According to G. H. Ashley and J. F. Robinson (Pa. Geol. Surv., 4th ser., vol. 1, 1922) and G. H. Ashley, 1931 (Topog. and Geol. Surv. Pa. Bull. G_1), the *First Cow Run sand* of Pa. is same as Big Dunkard sand and corresponds to Mahoning ss., the basal memb. of Conemaugh fm., and the Second Cow Run is the Freeport ss. memb. of Allegheny fm. But later work resulted in correlating First Cow Run sand of Pa. with Saltsburg ss. memb. of Conemaugh fm. (See G. H. Ashley and J. D. Sisler, Pa. Geol. Surv., 4th ser., Bull. M_{18}, 1933, p. 6.) According to W. Stout et al., 1935 (Geol. of nat. gas, A. A. P. G., pp. 900–901), the First Cow Run sand of Ohio lies btw. Cambridge and Ames ls. members of Conemaugh fm., and the Second Cow Run or Peeker sand is=†Lower Freeport ss. memb. (now called *Freeport ss. memb.*) of Allegheny fm.

The name is derived from Cow Run, SW. part of Lawrence Twp, Washington Co., Ohio, where the sand was discovered in wells drilled in 1861.

Cox sandstone. (In Trinity group.)

Lower Cretaceous (Comanche series): Western Texas.

G. B. Richardson, 1904 (Univ. Tex. Min. Surv. Bull. 9, p. 47). *Cox fm.*—Massive soft brownish ss., some intercalated gray ls., and near base a red-drab shaly memb. 100 ft. thick. Thickness averages 600 ft. Middle fm. of Fredericksburg group. Overlies Campagrande fm. and underlies Finlay fm.

C. L. Baker, 1927 (Univ. Tex. Bull. 2745), transferred this fm. to Trinity group.

This fm. is now regarded as a transgressing unit, which in places extends upward into Fredericksburg time.

Named for Cox Mtn, El Paso Co.

Coxville sandstone.

Pennsylvanian: Central western Indiana.

G. H. Ashley, 1899 (Ind. Dept. Geol. and Nat. Res. 23d Ann. Rept., pp. 300–303, 385). *Coxville ss.* (*Merom?*).—Channel filling, in Parke Co., deposited either a short time after laying down of coal No. 6 or at a time entirely subsequent to deposition of coal measures proper, or at a time corresponding with laying down of Merom ss. of Sullivan Co. Formerly considered to be Mansfield ss. Latter theory is considered best sustained. Fills deep and broad erosion channel or system of channels carved in upper coal measures. Best exposed on NE. side of Raccoon Creek at Coxville.

Coyote sandstone member (of Madera limestone).

Pennsylvanian: Central northern New Mexico.

C. L. Herrick, 1900 (Jour. Geol., vol. 8, p. 115; Am. Geol., vol. 25, pp. 234–237; N. Mex. Univ. Bull., vol. 2, pt. 3, pp. 1–14). *Coyote ss.*—Thick ss. or cgl. Separated from overlying Manzano series by a thick series of massive gray siliceous lss., and from underlying Sandia series by a series of dark conchoidal lss. and shales. Present in Sandia, Manzano, and San Andres Mtns.

Named for Coyote Springs, Sandia Mtns.

Coyote formation.

Eocene(?): Central southern Oregon.

W. D. Smith, 1926 (Oreg. Univ. Commonwealth Rev., vol. 8, pp. 207–214). *Coyote fm.*—Massive effusives of reddish andesites, rhyolites, and andesitic tuffs. Thickness undet. Type loc., Coyote Hills (near Plush), Lake Co.

†Coyote Mountain clays. (In Imperial formation.)

Miocene (lower): Southern California (Imperial County).

G. D. Hanna, 1926 (Calif. Acad. Sci. Proc., 4th ser., vol. 14, No. 18, p. 435). Above the Latrania sands there are enormous deposits of clay, the peculiar properties of which may make it of commercial value at some future time. I would propose that they be called *"Coyote Mountain clays."* They are extensively developed over wide areas, but type loc. has been selected in foothills bordering SE. slope of Coyote Mtn. Above these clays, and interbedded with them near top to some extent, are extensive deposits of oyster shells for which the name "Yuha Reefs" has been selected. Assigned to Plio., probably middle or upper Plio. [For further explanation by Hanna see 1926 entry under *Imperial fm.*]

See W. P. Woodring, 1931, under *Imperial fm.*

Coys Hill granite.

Late Carboniferous or post-Carboniferous: Western central Massachusetts and southwestern New Hampshire.

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, pp. 319–320, map, pl. 34). *Coys Hill granitite.*—Coarse porphyritic biotite granite.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 240–241 and map). *Coys Hill granite.*—Coarse porphyritic granite. Composes mass of Coys Hill, Mass.

Cozy Dell shale member.

Eocene: Southern California (Ventura County).

P. F. Kerr and H. G. Schenck, 1928 (Geol. Soc. Am. Bull., vol. 39, p. 1090). *Cozy Dell sh. memb.*—The rhythmically bedded, fossiliferous, marine, green micaceous sh. and ss. that is typically exposed in Cozy Dell Canyon, on E. side of Ventura River, and forms middle memb. of Tejon fm. Thickness 2,500± ft. Underlies Coldwater ss. memb. and discon. overlies Matilija ss. memb.

Crab Orchard shale.

Silurian (Niagaran): Central Kentucky.

W. M. Linney, 1882 (Ky. Geol. Surv. Repts. on Garrard and Lincoln Counties). *Crab Orchard shales.*—Soft clay shales, 16 to 40 ft. thick in Garrard and Lincoln Counties. Are blue, black, olive, and brownish red; weather gray, white and sometimes green; contain few thin lss. Included in Clinton(?) group. Overlie buff Medina ss. (35 ft. thick) and underlie Corniferous lss. (Dev.).

A. F. Foerste, 1906 (Ky. Geol. Surv. Bull. 7). *Crab Orchard div.*—Chiefly clay sh., 110 to 180 ft. thick. Divided into Alger and Indian Fields fms. Includes all Sil. strata of east-central Ky. above Brassfield ls. [Appears to correspond in a general way to Crab Orchard shales of Linney.]

A. F. Foerste, 1935 (Denison Univ. Bull., Jour. Sci. Lab., vol. 30, pp. 127–134). *Crab Orchard group* assigned to Clinton epoch. [Many details given.]

Named because they are the shales from which the celebrated Crab Orchard salts are manufactured. Town of Crab Orchard is in Lincoln Co.

Craftsbury granite.

Devonian: Northeastern Vermont (Orleans County).

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), listed this name in Dev. of "Central Vt.," but without definition. Probably named for Craftsbury Twp, or one of villages of that name within that Twp, in unnamed quad. in S. part of Orleans Co.

Craggy gneiss.

Jurassic (?): Southwestern Oregon (Curry County).

G. M. Butler and G. J. Mitchell, 1916 (Min. Res. Oreg., vol. 2, No. 2). *Craggy gneiss.*—A metamorphic rock that is different from any other found in S. part of Curry Co. Diller has described a similar rock under name of amphibole schist as occurring in small masses in N. part of Co. He considers this material to be a metamorphosed phase of Myrtle fm. The Craggy gneiss consists chiefly of hornblende, feldspar, and quartz, with minor quantities of biotite, no actinolite, glaucophane, or garnet. It seems likely it is metamorphosed phase of adjacent Dothan ss. Composes West Craggy.

Craghead.

Upper Devonian: Missouri.

H. A. Buehler, 1922 (geol. map of Mo.).

Same as *Craghead Creek sh.* of other authors.

†Craghead Creek shale.

Upper Devonian: North-central Missouri.

D. K. Greger, 1909 (Am. Jour. Sci., 4th, vol. 27, p. 375). *Craghead Creek sh.*—Light-gray, highly fossiliferous, siliceous sh. at top; light-drab argill. ls., with few fossils, in middle; dark-blue and drab sh. with bands of shaly ls., highly fossiliferous, at base. Thickness 35 ft. Overlies Callaway ls. and [uncon.] underlies Kinderhook.

Replaced by *Snyder Creek sh.*, the older and better established name.

Named for Craghead Creek, 6 mi. S. of Fulton, Callaway Co.

Craig shale.

Pennsylvanian: North central Oklahoma.

G. C. Clark and C. L. Cooper, 1927 (Okla. Geol. Surv. Bull. 40H, fig. 3). [*Craig sh.* is shown as composing basal part of Cherokee fm. in geol. section for north-central Okla. Is shown as older than Little Cabin ss., but it is not clear whether it includes all beds (125± ft.) up to that ss. or only the basal 50± ft. of the beds separating the ss. from underlying Mississippi lime. Derivation of name not stated.]

Craigsville limestone.

Lower Devonian: Central western Virginia.

R. J. Holden, 1920 (Geol. Soc. Am. Bull., vol. 31, p. 137). *Craigsville ls.*—Pure ls., 150± ft. thick, underlying Longdale ls., and forming a part of Lewistown ls. Correlated with New Scotland ls. [Probably named for Craigsville, Augusta Co.]

Crain sand.

A subsurface sand, of Upper Cret. age, in Rainbow City field, Union Co., Ark.

†Crainesville horizon. (In Midway group.)

Eocene (lower): Southwestern Tennessee and northeastern Mississippi.

G. D. Harris, 1896 (Bulls. Am. Pal., vol. 1, No. 4, pp. 18–25). *Crainesville horizon.*—Fossiliferous, gray, calc., hardened clays with green grains and peculiar ss. concretions, exposed in vicinity of Crainesville, Hardeman Co., Tenn., and also identified in northern Miss. Is of Midway age.

Occurs near top of Porters Creek clay. According to E. N. Lowe, 1919 (Miss. Geol. Surv. Bull. 14, p. 64), it corresponds to his Tippah ss. memb. of Porters Creek.

G. T. Whitlatch, 1936 (Tenn. Acad. Sci. Jour., vol. 11, No. 2, p. 139). The glauconitic beds (Crainesville horizon of Harris) occurring near top of the Porters Creek in western Tenn. bear striking lithic resemblance to Lowe's Tippah ss. and probably represent the zone to which he applied that name. Writer, like Lowe (Miss. Geol. Surv. Bull. 25, 1933, p. 23), believes these beds are too local in extent and variable in strat. position to warrant a formational name, though, as suggested by Lowe, they may actually be representative of Naheola fm. of Ala.

Cranberry granite.

Pre-Cambrian: Western North Carolina and eastern Tennessee.

A. Keith, 1903 (U. S. G. S. Cranberry folio, No. 90, p. 3). *Cranberry granite.*—Granite, of varying texture and color, and schists and granitoid gneisses derived from the granite. Includes small or local beds of schistose basalt, diorite, hornblende schist, and pegmatite. Intrusive into Roan and Carolina gneisses. Archean.

Named for development at Cranberry, Mitchell Co., N. C.

Cranberry formation.

Upper Cretaceous: British Columbia.

C. H. Clapp, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 98).

Cranberry Island series.

Cambrian or pre-Cambrian (?): Southeastern Maine (Cranberry Islands and southern part of Mount Desert Island).

N. S. Shaler, 1889 (U. S. G. S. 8th Ann. Rept., pt. 2, pp. 1037, 1042–1047, 1059, 1061, and map). On N. border of Little Cranberry Island we have a series of siliceous flaggy layers, which are probably closely related to the stratified rocks of Sutton's Island [see *Sutton Island series*]. The section is not over 100 ft. thick, but it probably occupies a considerable area beneath the surface of the strait which separates the two islands. Above this we find a very extensive series of volcanic rocks, which have a thickness of at least 2,000 ft.; to which I give the name of *Cranberry Island series*. At their contact with Sutton's Island series the volcanic beds of Cranberry Islands consist of porphyries, breccias, and amygdaloids, all apparently bedded, probably by a succession of lava flows and volcanic ash showers. On Cranberry Island we find essentially a repetition of the section shown on Little Cranberry Island, with exception that proportion of clay slates and bedded qtzites is much larger than the volcanic materials, and the schists and slates are more distinctly mingled with the igneous materials. [Map explanation states: "Cranberry Island series essentially the same as the Sutton Island series [which he assigned to Camb. or pre-Camb.] with many beds of volcanic ash."] No fossils.

On the 1933 geologic map of Maine, by A. Keith, the rocks of Cranberry Islands and S. part of Mount Desert Island are mapped as Devonian igneous, and the rocks of Sutton Island appear to be mapped as "igneous, mainly Carbf."

Named for development in Great Cranberry and Little Cranberry Islands, S. of Mount Desert Island.

Cranbrook formation.

Cambrian: British Columbia.

S. J. Schofield, 1922 (Canada Geol. Surv. Bull. 35, p. 12).

Crandall Hill sand.

Drillers' term for a sand of Chemung age in Potter Co., Pa., that is said to occur in strat. position of Bradford Third sand. It is main producing horizon of Coudersport gas pool. (See C. R. Fettke, Geol. Soc. Am. Bull., vol. 44, No. 3, pp. 602–603, 632, 636, 1933, and Pa. State Coll. Bull., Min. Industries Exp. Sta. Bull. 19, 1935, p. 110.)

Cranktown sandstone.

Tertiary: Mogollon district, New Mexico.

H. G. Ferguson, 1927 (U. S. G. S. Bull. 787). *Cranktown ss.*—Ss. with cgl. lenses; the ss. commonly red to deep purple, nearly everywhere cross-bedded, commonly rather fine-grained, and largely composed of small fragments of feldspar, for most part angular. Thickness 0 to 500 ft. Deposition thrice interrupted by volcanic activity, resulting in an andesite flow (Houston andesite) near base, a bed of rhyolite tuff, and several flows of rhyolite near top. Upper part of the ss. is younger than Pacific quartz latite.

Named for exposures at a small group of prospectors' cabins, locally called Cranktown, on Silver Creek about 1 mi. below Mogollon.

Cranston beds.

Pennsylvanian: Eastern Rhode Island (Cranston Township, Providence County).

J. B. Woodworth, 1899 (U. S. G. S. Mon. 33, pp. 134, 159–164). *Cranston beds.*—Metamorphosed sss., shales, and pebbly beds. Poorly exposed, but seen in SW. part of Cranston [Twp, R. I.]. Form basal part of Rhode Island Coal Measures and believed to be in large part older than Tenmile River beds. Include Sockanosset sss. and Pawtucket shales. Rest on Wamsutta series.

†Crawford shale.

Mississippian and Devonian (?): Northwestern Pennsylvania.

J. F. Carll, 1879 (2d Pa. Geol. Surv. Rept. I_3 Atlas, pl. 11). *Crawford shales,* 450 ft. thick, underlie Mountain sands and overlie Venango oil sand group in NW. Pa. oil region. Include Pithole grit [Berea ss.] in middle.

H. M. Chance, 1879 (2d Pa. Geol. Surv. Rept. V, pp. 221–226). *Crawford Upper (Cuyahoga) shales,* 135 ft. thick, underlie Congl. series (No. XII), and are separated from *Crawford Lower (Bedford red) shales* by Berea grit.

J. P. Lesley, 1879 (2d Pa. Geol. Surv. Rept. V, p. 224, footnote). I propose for the shales above and below the Berea grit the term *Crawford sh. group,* as they make the broad belt of lake and swamp land across that county.

J. P. Lesley, 1880 (2d Pa. Geol. Surv. Rept. Q_3, p. 59, footnote). *Crawford shales* [restricted].—Argill. bluish-gray shales, 90 ft. thick. Underlie Shenango ss. [Burgoon ss.] and overlie Sharpsville ss. Include Meadville Upper ls. about 25 ft. below top. [The beds btw. Burgoon ss. memb. and Sharpsville ss. memb. have for many years been called *Meadville sh. memb. of Pocono fm.*]

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. Q_4, p. 68). The name *Crawford shales* if retained should be confined to that part of Cuyahoga series beneath Shenango ss. and above Corry ss., a vertical interval of about 200 ft., but as this interval contains the Meadville lss., which have played so distinguished a rôle in settling our northwestern State geology, the name *Meadville group* may replace that of *Crawford sh.* entirely.

Crawford series (also Crawford subseries).

Mississippian: Northwestern Pennsylvania.

K. E. Caster, 1934 (Bulls. Am. Pal. vol. 21, No. 71, pp. 40–46, table opp. p. 61, 129). *Crawford series (or "subseries")* includes highest Miss. strata in NW. Pa. and NE. Ohio. The strata from top of Shenango sh. down to top of Berea ss. constitute a genetic series such as merits a series designation. They are a faunal and depositional entity. The name "Crawford sh." has fallen into desuetude. Gradational contacts in this section are universal. Wherefore it has seemed advisable to resurrect the available and entirely satisfactory term "Crawford" for this sequence of serial or sub-serial rank. It is naturally divisible into 2 groups, Meadville monothem and Shenango monothem. There is discon. at top of Berea ss.

†Crazy Mountain beds.

A term applied by G. H. Eldridge (U. S. Tenth Census, vol. 15, maps 50 to 54, 1886) to the rocks of the Crazy Mtns, Little Belt Mtns quad., Mont., which were later formally named and mapped by W. H. Weed as Livingston fm. (See U. S. G. S. Little Belt Mtns folio, No. 56, 1899.)

Crazy Mountain granite.

Eocene: Central southern Montana (Little Belt Mountains).

W. H. Weed, 1899 (U. S. G. S. Little Belt Mtns folio, No. 56). Light-colored, coarse-grained hornblende granite of lighter color and coarser grain than Loco diorite, which it cuts. Assigned to Eocene. [Mapped over considerable area in Crazy Mtns.]

†Creamy sandstone.

Pennsylvanian: Eastern Colorado (Denver Basin region).

G. H. Eldridge, 1896 (U. S. G. S. Mon. 27). [See definition under †*Wyoming fm.*]

N. M. Fenneman, 1905 (U. S. G. S. Bull. 265, pp. 20, 22–24). *"Creamy" ss.* of Eldridge [color term] replaced by *Lyons ss.*

W. T. Lee, 1927 (U. S. G. S. P. P. 149, pp. 5, 12, pl. 1). The beds called Lyons ss. in Colorado Springs and Castle Rock folios are correctly correlated with "Creamy" ss. of Morrison region, which in turn was formerly correlated, erroneously, with Lyons ss. of Lyons, Colo. These beds can not be same as Lyons ss. of type loc., which consists of 100 ft. of hard, ledge-making ss., characterized by conspicuous cross bedding. As originally defined, however, some of red sed. rocks here referred to Ingleside fm. were included in lower part of Lyons ss. In this paper Lyons ss. is restricted to the cross-bedded upper part of the Lyons of previous repts. The "Creamy" ss. of Morrison region is of Penn. age and belongs to Fountain fm. The white cross-bedded ss. at Lyons, or Lyons ss. as here restricted, is considered to be of Perm. age, and is absent in Morrison, Colorado Springs, and Castle Rock areas. The Ingleside fm. and underlying Fountain fm. are of Penn. age.

Credit member.

Upper Ordovician: Toronto, Canada.

W. A. Parks, 1924 (Geol. Soc. Am. Bull., vol. 35, pp. 103–104).

See quotation under *Dundas fm.* Type loc. not stated.

Creede formation.

Miocene (probably upper Miocene): Southwestern Colorado (Creede district).

W. H. Emmons and E. S. Larsen, 1923 (U. S. G. S. Bull. 718). *Creede fm.*—Water-laid deposits, 0 to 2,000± ft. thick. Upper memb. consists of breccia, cgl., and tuff with intercalated lava flows. Lower memb. consists of thinly laminated white shaly tuff, in part sandy and with some breccia and cgl., and interbedded with travertine. Plants from lower tuffs indicate correlation with Miocene Florissant lake beds. Uncon. overlain by Fisher quartz latite and uncon. underlain by Potosi volcanic series. Named for development on slopes of both sides of Willow Creek about town of Creede.

Crekola sandstone member (of Boggy shale).

Pennsylvanian: Eastern Oklahoma (Muskogee County).

C. W. Wilson, Jr., 1935 (A. A. P. G. Bull., vol. 19, No. 4, pp. 503–520). *Crekola ss. memb. of Boggy sh.*—Brown ss., regularly bedded, blocky, medium texture, 10 ft. thick. Lies 10± ft. below Inola ls. memb. of Boggy and 6± ft. above Secor or Upper Witteville coal. Named for fact that village of Crekola, in E½ sec. 10, T. 14 N., R. 17 E., is located on this ss.

Cresaptown iron sandstone.

Silurian: Western Maryland.

C. K. Swartz, 1923 (Md. Geol. Surv. Sil. vol., pp. 28–31). *Cresaptown iron ss.*—An iron-rich ss. or lean "iron ore," of deep-red color, lying about 175 ft. above base of Rose Hill fm. [pre-Rochester part of Clinton fm.] and overlain by upper sh. beds of Rose Hill fm. Some of Cresaptown beds are distinctly oolitic; and interbedded with the iron ss. are variable amounts of sh. Thickness 30 ft. at Pinto; 10 ft. at Cumberland. Contains fossils.

Crescent formation.

Eocene: Northwestern Washington.

R. Arnold, 1906 (Geol. Soc. Am. Bull., vol. 17, pp. 451–468, map). *Crescent fm.*—Black basalt and greenish basalt tuff and tuffaceous sands, 1,200 ft. thick. Uncon.

underlies Clallam fm. Named for occurrence in vicinity of Port Crescent. Comprises region immediately W. of Crescent Bay and a prominent ridge extending from there eastward to Freshwater Bay. Eocene fossils.

Crescent City beds.

Miocene and Pliocene: Northwestern California (Del Norte County).

J. S. Diller, 1902 (U. S. G. S. Bull. 196, pp. 31–35). Somewhat similar beds [to those northward and southward from Point St. George, Del Norte Co., Calif., which consist of soft yellowish and gray shaly sss. and whitish shales full of Mio. fossils] occur by wharf at Crescent City (*Crescent City beds*), and among their fossils Dr. [W. H.] Dall recognizes *Pecten parmeleei* and *Terebratalia hemphilli*, species heretofore known only from southern Calif. Plio. It is probable that these soft Mio. and Plio. beds have a wide extent under the Pleist. of the low, broad coastal plain extending from Smith River to 3 mi. S. of Crescent City.

Crescent Crater dacites.

Age (?): Lassen Volcanic National Park, California.

H. Williams, 1932 (Calif. Univ. Dept. Geol. Sci. Bull., vol. 21, No. 8, geol. map). [See under *West Prospect basalt*.]

Cresswell limestone. (In Chase group.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., p. 51). *Cresswell ls.*—Top memb. of Winfield fm. Has been called the "concretionary ls." Persists from Nebr. to Okla. in a thickness of 4 to 11 ft. Is solid massive ls. at most points in southern Kans., but northward from there it carries large concretions, a small amount of chert, and at most places is interrupted by a thin sh. near middle. Becomes less massive and non-concretionary in its northern occurrence. Named for Cresswell Twp, Cowley Co., Kans. Type loc. on E. side of golf course, in NE. ¼ sec. 18, T. 34 S., R. 4 E., N. side of E. edge of Arkansas City. Overlies Grant sh. memb. of Winfield fm. and underlies Luta ls. in central and southern Kans. The Luta probably does not extend to Nebr., where Odell sh. memb. of Enterprise sh. overlies Cresswell ls. [On p. 56 Luta ls. is included in Marion fm. On pp. 57–58 Condra says:] The *Luta ls.* is thought not to extend to northern Kans. and Nebr., but it is possible that part of lower gray zone of Odell sh. memb. of Enterprise sh. in this area may be correlative with it in age and thus represent a sh.-mudstone facies of its development. The Luta has a thickness of 7 ft. or more in central and southern Kans., reaching 18 ft. or more at a few places. It appears that some authors have assigned too great a thickness to the Luta in various exposures by including part of Cresswell ls., and we find its thickness at type loc. not as great as given by Dr. Beede. There is a small deformation at type loc. and Luta-Winfield contact is not very definite. Whether the Luta should be correlated with the Winfield or with the Marion has not been determined to full satisfaction of all geologists concerned, nor is it agreed that it is not a zone of Cresswell ls. It seems, however, that it was developed in the cycle which produced the Cresswell, in which deposition changed from lime to lime and sh., becoming more shaly at top as a transition to lower zone of Odell sh. It also appears that faunal content is not markedly different from that of Winfield fm.

R. C. Moore, 1936 (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 12), treated Luta ls. as top memb. of Winfield ls. This change has not yet been considered by U. S. Geol. Survey for its publications.

Creston quartzite.

Pre-Cambrian: Southeastern British Columbia and northwestern Montana (Purcell Range).

R. A. Daly, 1905 (Canada Geol. Surv. Summ. Rept. 1904, pp. 96–100; Am. Jour. Sci., 4th, vol. 20, pp. 186+). *Creston qtzite.*—Wonderfully homogeneous, highly indurated, thick platy structure, gray sss., with occasional intercalations of argill. material. Thickness 9,900 ft. Conformably underlies Kitchener qtzite. Both probably pre-Camb. Occurs at int. bdy, 49 Par., in section from Port Hill, Idaho, to Gateway, Mont.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, map 4, 115° 30' to 116°). *Creston fm.*—Generally thick-bedded gray qtzite and metargillite; sometimes dolomitic.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast., 1910, vol. 2, pp. 120, 178). Named for station on Canadian Pacific Ry (in Kootenay Province, SE. part of B. C.).

Creston shale. (In Washington formation.)

Permian: Western West Virginia and southeastern Ohio.

R. V. Hennen, 1911 (W. Va. Geol. Surv. Rept. Wirt, Roane and Calhoun Counties, p. 154). *Creston red sh. or Creston Reds.*—Dark red sh. with ls. nuggets. Thickness 40 to 60 ft. Underlies Washington A coal and overlies Lower Marietta ss.

Named for occurrence at Creston Flats, 1 mi. E. of Creston, Wirt Co., W. Va.

Crestone conglomerate phase.

Permian: Southern-central Colorado (Sangre de Cristo Range).

F. A. Melton, 1925 (Jour. Geol., vol. 33, p. 812). The largest boulders in Upper Sangre de Cristo cgl. have diam. of 8± ft., but this extreme coarseness, even though it is a very prominent feature near Crestone, is only of local development, and in both directions along the range the upper series becomes thinner and finer in grain. For this reason the coarse conglomeratic series has been named by the writer the *Crestone conglomerate phase of the Upper Sangre de Cristo conglomerate.* Near Crestone the coarse phase overlaps the Lower cgl. and rests on Pre-Camb. granite. Though an angular uncon. was not seen btw. the two divisions of Sangre de Cristo cgl., it is believed that further search in this area may reveal such a break.

Creta dolomite. (In Blaine formation.)

Permian: Southwestern Oklahoma (Greer and Jackson Counties).

G. G. Suffel, 1930 (Okla. Geol. Surv. Bull. 49, pp. 29–40, 42, 47, 48, 63). *Creta dol. memb. of Blaine fm.*—Very pure dol., light gray, fine-grained, porous, and in some places platy. Thickness 13'' to 25''. South of Mangum it lies 26 to 30 ft. below Mangum dol. memb. of the Blaine. Rests on 3 ft. of massive gyp. Occurs S. of Elm Fork. Named for station of Creta, in W. part of Jackson Co.

Cretaceous period (or **system**).

The youngest system of Mesozoic era. The U. S. Geol. Survey includes in it both Upper Cret. and Lower Cret. Some geologists, however, restrict the name to Upper Cret., while others restrict it to Upper Cret. plus some older deposits which are by most geologists included in Lower Cret. For definition see U. S. G. S. Bull. 769, pp. 56–61.

†Cretaceous No. 1.

A term applied in early repts of some pioneer American geologists (F. V. Hayden and others) to the rocks now known as *Dakota ss.*

†Cretaceous No. 2.

A term applied in early repts of some pioneer American geologists (F. V. Hayden and others) to the rocks now known as *Benton sh.*

†Cretaceous No. 3.

A term applied in early repts of some pioneer American geologists (F. V. Hayden and others) to the rocks now known as *Niobrara ls.*

†Cretaceous No. 4.

A term applied in early repts of some pioneer American geologists (F. V. Hayden and others) to the rocks now known as *Pierre sh.*

†Cretaceous No. 5.

A term applied in early repts of some pioneer American geologists (F. V. Hayden and others) to the rocks now known as *Fox Hills ss.*

Cretacic.

A variant of *Cretaceous* employed by some geologists.

Crews sand.

A subsurface sand, of Penn. age, in Garber pool, Garfield Co., central northern Okla., which lies at 1,800 ft. depth, the Campbell sand lying at 1,700 ft. and the Garber sand at 2,000 ft.

Crill terrane.

Upper Cretaceous: Northwestern Iowa.

C. [R.] Keyes, 1912 (Iowa Acad. Sci. Proc., vol. 19, pp. 148, 150). *Crill chalks and lss.*, 100 ft. thick, underlie Hawarden sh. and overlie Woodbury [restricted] sh. All included in Coloradan series.

See Keyes' statement under †*Dixon chalk*.

Named for old site of Crill mill, on Sioux River, above Sioux City.

Criner formation.

Middle Ordovician: Central southern Oklahoma (Arbuckle Mountains).

E. O. Ulrich. See under *West Spring Creek fm.*

C. E. Decker (1930) proposed abandoning *Criner* for *Bromide fm.* See under *Bromide fm.*, Decker 1930 entry, also Decker and C. A. Merritt, 1931 entry under *Bromide fm.* They discarded Criner fm.

E. O. Ulrich, 1933 (Geol. Soc. Am. Bull., vol. 44, p. 105). *Criner fm.* should be retained.

C. E. Decker, 1933, did not use *Criner fm.* See this entry under *Simpson fm.*

Named for exposures at S. end of Criner Hills, S. of Overbrook, Love Co.

Crinerville limestone member (of Hoxbar formation).

Pennsylvanian: Central southern Oklahoma (Carter County).

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z, p. 15). About 600 ft. above Westheimer memb. of Hoxbar fm. occurs *Crinerville ls. memb.* of Hoxbar, 10 or more ft. thick. Lower layers locally crammed full of *Fusulinae*.

C. W. Tomlinson, 1929 (Okla. Geol. Surv. Bull. 46, pp. 42–43). *Crinerville memb.* is 10 to 30 ft. thick. Lies 400 to 500 ft. above Westheimer memb. Type loc. is near center of W½ sec. 28, T. 5 S., R. 1 E., a few rods N. and NE. of Crinerville schoolhouse.

C. W. Tomlinson, 1934 (A. A. P. G. Bull., vol. 18, No. 8, p. 1085). Recent tracing has proved Westheimer ls. to be same as Confederate ls. (basal memb. of Hoxbar fm.) and Westheimer ls. has been dropped. (See under *Confederate ls. memb.*) It has also proved that Union Dairy ls. is same as Crinerville ls., and Union Dairy has been dropped.

†Crinoidal limestone.

Descriptive term applied in early repts to many lss., of different ages, containing crinoid remains. In early Pa., Ohio, W. Va., and Md. repts it was applied to Ames ls. memb. of Conemaugh fm. (Penn.).

†Cripple Creek breccia.

Tertiary: Central Colorado (Teller County).

W. Cross, 1896 (Colo. Sci. Soc. Proc., vol. 5, p. 30). *Cripple Creek breccia.*—Of volcanic origin. Contains nearly all productive gold veins of Cripple Creek dist.

In U. S. G. S. Pikes Peak folio, No. 7, 1894, Cross mapped this fm. as andesitic breccia. The geographic name is considered unnecessary and has fallen into disuse.

Cripple Creek granite.

Pre-Cambrian: Eastern Colorado (Pikes Peak).

E. B. Mathews, 1900 (Jour. Geol., vol. 8, pp. 214–240). *Cripple Creek type of granite.*—Appears finer than Pikes Peak type and more evenly grained than Summit type. Is younger than Pikes Peak type. Most characteristically developed in area to W. of line drawn from Lake George to town of Cripple Creek, and thence in a somewhat sinuous line to waters of Oil Creek. Is saccharoidal with rectangular feldspars; poor in perthitic feldspars, micropegmatite, and fluorite.

W. Lindgren and F. L. Ransome, 1906 (U. S. G. S. P. P. 54, pp. 20, 28). *Cripple Creek granite* cuts the gneiss and schist and probably intrudes Pikes Peak granite.

L. C. Graton, 1906 (U. S. G. S. P. P. 54). *Cripple Creek granite.*—Light-red, medium, fairly even-grained; slight porphyritic appearance; quartz more abundant and more evenly distributed than in Pikes Peak granite. Suffered much less shearing and deformation than Pikes Peak granite, and is undoubtedly younger than Pikes Peak granite. Contains streaks and patches of reddish to dark-gray gneissic rocks.

G. I. Finlay, 1916 (U. S. G. S. Colorado Springs folio, No. 203). In Colorado Springs and Manitou quads. Cripple Creek granite occurs in a few small irregular masses and in numerous thin dikes that cut Pikes Peak granite.

On 1935 Colo. geol. map included in Front Range granite group.

Cripple Deer sandstone member (of Alsobrook formation).

Mississippian: Northeastern Mississippi (Tishomingo County) and northwestern Alabama.

W. C. Morse, 1928 (Jour. Geol., vol. 36, pp. 31–43). *Cripple Deer ss. memb.*—Upper third [30 ft.] of Alsobrook fm. on Cripple Deer Creek. Impregnated with petroleum residue; largely barren of fossils.

W. C. Morse, 1930 (Miss. Geol. Surv. Bull. 23, pp. 17, 128, 179, 182). *Cripple Deer ss. memb.*—Upper memb. of Alsobrook fm. At type loc. consists of 36½ ft. of thin-bedded ss. to sandy sh., ripple-marked and with wavy deposition lines; much of it impregnated with asphalt. Type loc. along highway on N. side of Cripple Deer Valley [Miss. and Ala., according to his map].

Cristobal limestone.

Ordovician: Southern New Mexico.

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257–259; Conspectus of geol. fms. of N. Mex., pp. 4, 6). *Cristobal lss.*—Main body of late Ordovicic ls. section in Franklin, Caballos, Fra Cristobal, and Mimbres Ranges. Thickness 165 ft.

Cristobal formation.

Cretaceous: Southern Mexico.

W. A. VerWiebe, 1925 (Pan-Am. Geol., vol. 44, p. 132). Named for excellent outcrops near city of San Cristobal, in central Chiapas.

C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 328), assigned "San Cristobal ls. of VerWiebe, 1925" to Lower Cret.

Critizer limestone.

See *Critzer ls.*, correct spelling.

Critzer limestone.

Pennsylvanian: Eastern Kansas.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 90, 97). [See under *Schubert Creek ls.*] Named elsewhere in this Guidebook by Jewett.

J. M. Jewett, 1932 (pp. 99, 100, 103 of book cited above). *Critizer ls.* is second ls. lentil from base of Swope fm. It is brown, earthy, massive, and varies from an oolite to a dense crystalline ls. A large *Bellerophon* abundant. Thickness locally 15 ft. To S. pinches out near Linn-Bourbon Co. line. Type loc. is S. of Critizer, Linn Co., in sec. 17, T. 22, R. 23 E. Is believed to extend well into Mo.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 74–75, 80). *Critzer* is correct spelling. Jewett classed it as memb. of Swope fm., and, according to F. C. Greene, N. D. Newell, and me, based on 1934 field work, assigned it to erroneous position above Schubert Creek ls. It is believed by Greene and me to be="Fragmental ls." of Iowa geologists. For present recognition of "Critzer" as a named memb. of Bourbon fm. is withheld, although it may prove to be useful name for a marker bed near top of Bourbon fm. from Linn Co., Kans., northeastward.

Croasdale quartzite.

Silurian: Northeastern Pennsylvania (Delaware Water Gap region).

A. W. Grabau, 1913 (Geol. Soc. Am. Bull., vol. 24, p. 479). *Croasdale qtzite.*—Qtzitic ss. underlying Decker Ferry beds and uncon. resting on 15 ft. of greenish shales that overlie Bossardville ls. in Kittatinny Valley. Apparently represents Sylvania horizon of Mich. A detailed study of the fms. as exposed in Broadhead Creek section of Pa., will soon be published by Miss E. Kurtz.

The compiler cannot find any record of Miss Kurtz having published the promised paper, and the foregoing is only record of *Croasdale qtzite.*

Croatan sand.

Pliocene (lower): Coastal Plain of North Carolina north of Hatteras axis.

W. H. Dall, 1892 (Wagner Free Inst. Sci. Trans., vol. 3, pt. 2, pp. 209, 213–216). For the beds found along estuary of Neuse River, N. C., the local Indian name of *Croatan beds* may be used. [Fossils listed.] The Croatan beds are obviously newer than those of the Waccamaw, yet when compared with the admitted Pleist. beds of S. C., such as those of Simmon's Bluff, the presence in the Neuse of 41 out of 96 species which have not been known later than Plio. forbids us to regard the fauna as later than Plio.

W. C. Mansfield, 1928 (U. S. G. S. P. P. 150, pp. 134–140), after a study of typical Croatan deposits and their fossils, discovered that beds of both Plio. and Pleist. age had been included in the fm., and he restricted the name to the Plio. beds, which consist chiefly of coarse ferruginous more or less fossiliferous sand rising to an observed max. height of about 4 ft. above the beach, and are uncon. overlain by Pleist. beds. He also changed name to Croatan *sand*.

Now regarded as approx.=Waccamaw marl, a name applied to the Plio. deposits S. of Hatteras axis.

Named for development around Croatan, near Neuse River, Craven Co.

Crockett member. (In Claiborne group.)

Eocene: Eastern Texas (Houston to Sabine Counties) and northwestern Louisiana.

A. C. Ellisor, 1929 (A. A. P. G. Bull., vol. 13, pp. 1339–1346). *Crockett memb. of Claiborne fm.*—Name proposed by E. A. Wendlandt and G. M. Knebel for that memb. of Claiborne fm. in Tex. which occurs below Milams memb. and above Sparta sand memb. At type loc., in vicinity of Crockett, Houston Co., the Cockfield overlies the Crockett, overlapping the Saline Bayou and Milams members. A composite section extending from 1.8 mi. N. of Crockett on Palestine road to 2.6 mi. SW. of courthouse on Midway road, is as follows (descending): (1) calc., brownish gray, fossiliferous clay with zone of small ferruginous concretions, 15 ft.; (2) brown, medium-fine sand, 2 ft.; (3) grayish-brown clay with sand partings and a few ferruginous concretions, 14 ft.; (4) brown clay, much weathered, 30 ft.; (5) brown, sandy clay with streaks of laminated clay, much weathered, 30 ft.; (6) ferruginous glauconitic ss., 1 ft.; (7) gray sandy clay with streaks of weathered glauconitic ss., 10 ft.; (8) gray, calc., fossiliferous clay and chocolate-brown carbonaceous clay with streaks of light-gray sand, 25 ft.; (9) ferruginous sand, cross-bedded, and clay lumps, 5 ft.; (10) grayish-brown clay with selenite, 30 ft.

E. A. Wendlandt and G. M. Knebel, 1929 (A. A. P. G. Bull., vol. 13, pp. 1351, 1360–1361). *Crockett fm.*—Chocolate brown and gray clay containing some beds of fossiliferous glauconite with concretionary zones of fossiliferous brown sandy ls., some thin beds of sand, clay, ironstone concretions, and in places is calc. Thickness 350 to 450 ft. Underlies Milams memb. of Cook Mountain fm. Overlies Sparta sands. Where overlain by Yegua fm. the contact is transitional and is usually selected where the last macro fossils appear. Well exposed SW. of Crockett, Houston Co., Tex.

In eastern Tex. these beds are treated as a memb. of Cook Mtn fm. by U. S. Geol. Survey and in La. as a memb. of St. Maurice fm.

F. B. Plummer, 1933 (Univ. Tex. Bull 3232, pp. 612, 655+). *Crockett fm.*—Underlies Cockfield fm., overlies Sparta fm., and includes Little Brazos ls., Moseley ls., and, at base, Eaton greensand lentil.

H. B. Stenzel, 1935 (Univ. Tex. Bull. 3501, pp. 267–279), restricted *Crockett* to the 100 ft. of partly marine beds above Moseley ls. and named the 85 ft. of underlying beds in Stone City section, Burleson Co., the *Stone City beds*. He included in his Stone City beds the Moseley ls. and Eaton greensand lentil of Renick, and stated that Crockett as restricted included a cgl. at base which rested discon. on Moseley ls.

Croghan moraine.

Pleistocene: Northwestern New York (Lowville quadrangle).

A. F. Buddington, 1934 (N. Y. State Mus. Bull. 296, p. 41). Well-defined ridge from just W. of Petries Corners nearly to Croghan.

Croghan syenite granite complex.

Pre-Cambrian: Northwestern New York.

See under *Diana syenite complex.*

Croghan West moraine.

Pleistocene: Northwestern New York (Lowville quadrangle).

A. F. Buddington, 1934 (N. Y. State Mus. Bull. 296, p. 42). Lies about 1 mi. W. of Croghan moraine and parallel to it from 2 mi. E. of Bush's Landing to Beaver River. Can be traced intermittently 6 mi. farther, to NW. of Croghan.

Croixan.

Croixian.

Variants of *St. Croixan series* that are used by some geologists.

Cromwell sand.

A subsurface sand, of early Penn. age, in Cromwell field, Seminole Co., central Okla.

C. O. Rison and J. R. Bunn, 1924 (Pet. Engineering in Cromwell oil field, Seminole and Okfuskee Counties, Okla., Reprint from Mid-Continent Oil and Gas Assoc. Year Book, Dec. 1, 1924, p. 7). *Cromwell sand zone* top is penetrated at 3301 to 3557 ft. depth. Thickness 125 to 174 ft. Lies 175 to 250 ft. below Harjo sand and 300 to 370 ft. below Brunner sand. All Penn.

A. I. Levorsen, 1927 (A. A. P. G. Bull., vol.. 11, No. 7), showed *Cromwell ss.* as underlying Pitkin ls. [Miss.] in south-central Okla., and as older than Gilcrease sand.

A. I. Levorsen, 1928 (Okla. Geol. Surv. Bull. 40BB, p. 17). [See under *Lyons ls.*, also under *Papoose sand* (of Okla.).]

This sand at its outcrop has been named *Union Valley ss. memb. of Wapanucka ls.*, by R. V. Hollingsworth (1934), and said to compose middle memb. of the Wapanucka, which is of early Penn. (Pottsville) age.

Cromwell moraine.

Pleistocene (Wisconsin stage): Northeastern Minnesota.

F. Leverett, 1928 (U. S. G. S. P. P. 154). Named for Cromwell, Carlton Co.

Crooked River formation.

Recent(?): Central northern Oregon (Cascade Mountains).

E. T. Hodge, 1927 (Geol. Soc. Am. Bull., vol. 38, p. 163). The *Crooked River fm.* partially fills great canyons cut in the *Madras fm.* and has been cut into canyons. In the high Cascade Mountains the drainage is deranged by the recent lavas. [All there is about *Crooked River fm.* and *Madras fm.* As the other fms. are described in ascending order, and as this is described after Deschutes sand, "probably post-Pleistocene," it is assumed it is probably Recent. Was this intended as a name for the intracanyon lavas that Hodge says overlie his Cascade fm. ?]

Crooks complex.

Pre-Cambrian: Central Arizona (Bradshaw Mountains).

T. A. Jaggar, Jr., and C. Palache, 1905 (U. S. G. S. Bradshaw Mtns folio, No. 126). *Crooks complex.*—Is closely associated with Bradshaw granite, but differs from it in that it is marked by alternations of diorite, aplite, gabbro, schist, and granite. Is largely intrusive igneous, and trend of its bands is often transverse to adjacent schists. In places it merges into Bradshaw granite. Although mapped as a single fm. it is really a mixture of diorite-granite and schist units in bodies too small to be differentiated on the map. The granite of the complex is identical with Bradshaw granite. The fm. is probably Algonkian. Named for exposures in Crooks Canyon in NW. part of this quad.

Cropsey morainic system.

Pleistocene (Wisconsin stage): Central eastern Illinois. See F. Leverett, 1899 (U. S. G. S. Mon. 38, p. 258). *Cropsey Ridge* runs past Cropsey, McLean Co.

†Cropsy Peak type.

A field named applied by E. S. Larsen to part of Fisher quartz latite on Cropsy Peak, Platoro-Summitville region, SW. Colo. (See Colo. Geol. Surv. Bull. 13, 1917.)

Crosby sandstone.

Upper Devonian: Western central New York (Keuka-Seneca Lake region).

I. W. Fox, 1932 (A. A. P. G. Bull., vol. 16, No. 7, pp. 677, 681, 687). *Crosby ss.*—Heavy, massive, brown ss., in 2 or more members, 6 ft. or less in thickness; in places weathers reddish brown. [According to scale of columnar section the 6 ft. is total thickness of Crosby ss.] The upper members are more massive and extremely hard. Rests on West River fm. and is basal memb. of Standish fm. in Keuka and Seneca Lake area.

Cross Cut sand.

A subsurface sand in Cross Cut-Blake dist., Brown Co., north-central Tex., that lies at 1,200 ft. depth, near div. line btw. Strawn and Canyon groups (Penn.), but whether it is of late Strawn or early Canyon age cannot be determined because of absence of Palo Pinto ls. (See E. D. Klinger's rept on the Cross Cut-Blake dist., Brown Co., Tex.) In Burkett deep well, Coleman Co., it lies at 1,400 ft. depth.

Cross Lake group.

Pre-Cambrian: Manitoba (Cross Lake area).

H. C. Horwood, 1935 (Roy. Soc. Canada Trans., 3d ser., vol. 29, sec. 4, p. 140).

Cross Plains sandstone.

Pennsylvanian: Western Arkansas coal field and central eastern Oklahoma.

A. Winslow, 1896 (N. Y. Acad. Sci. Trans., vol. 15, p. 51). *Cross Plains ss.*—Ss. 50 to 200 ft. thick, lying near or 40 ft. below top of Appleton stage. Overlies Russellville shales. [Derivation of name not stated.]

Is a part of Atoka fm.

Cross Plains sand.

A subsurface sand, of Penn. age, in Baum field, Callahan Co., north-central Tex., lying at 1,650 ft. depth.

†Cross Timbers.

See under †*Upper Cross Timbers* and †*Lower Cross Timbers*. Named for development in physiographic province in eastern Tex. locally called "Cross Timbers."

Crosswicks clay.

Upper Cretaceous: New Jersey.

T. A. Conrad, 1869 (Am. Jour. Sci., 2d, vol. 47, pp. 359–360). *Crosswicks group.*—The lower beds of eastern Cret. are exposed in sections of the deep cut of Chesapeake and Delaware Canal and at Crosswicks. Fossils [listed].

W. B. Clark, R. M. Bagg, and G. B. Shattuck, 1897 (Geol. Soc. Am. Bull. vol. 8, pp. 315, 329). *Crosswicks clays.*—Chiefly very dark-colored or black clays, at times slate or drab-colored toward top, or, as in vicinity of Matawan Creek, interstratified with layers of white sand; the dark clays frequently glauconitic. Named for village of Crosswicks, on Crosswicks Creek, Burlington Co. Composes lower part of Matawan fm. in Monmouth, Middlesex, Mercer, Burlington, and Camden Counties, N. J.

W. B. Clark, 1904 (Am. Jour. Sci., 4th, vol. 18, pp. 435–440). The *Crosswicks clays* include Woodbury clay bed above and Merchantville clay bed below, and compose basal part of Matawan fm. [group].

Based upon recent field work of C. W. Carter (under supervision of L. W. Stephenson), the U. S. Geol. Survey has recently adopted *Crosswicks clay* for the deposits in region of Chesapeake and Delaware Canal, Md.

and Del., which include the equivalents of Merchantville and Woodbury fms. of N. J., but which can not be differentiated either lithologically or faunally. *Crosswicks* was originally introduced to include the Merchantville and Woodbury fms. of N. J., which can be differentiated, and for that reason the name was many years ago discarded by U. S. Geol. Survey as unnecessary. It is now, however, considered more desirable to use *Crosswicks* in the Canal region of Md. and Del. than to introduce local name for the undiff. Woodbury and Merchantville deposits of that area.

Croton limestone. (In St. Louis limestone.)

Mississippian: Southeastern Iowa.

F. M. Van Tuyl, 1925 (Iowa Geol. Surv. vol. 30, p. 231). *Croton ls.* substituted for "Springvale beds" of Bain, for lower memb. of St. Louis ls. in Iowa, because the beds at Springvale are now believed to be of Keokuk age. Discon. underlies Verdi or Upper St. Louis lss. and overlies Spergen fm. Consists for most part of massive, compact, buff to brownish dolomitic ls., but frequently these beds are found to grade laterally in short distances into dense, fine-grained gray nondolomitic ls. Again, the two phases may have an interbedded relationship. Is brecciated at many localities.

Named for exposures in vicinity of Croton, Lee Co.

Croton gypsum.

Permian: Central northern Texas (Stonewall County).

A. M. Lloyd and W. C. Thompson, 1929 (A. A. P. G. Bull., vol. 13, pl. 9). [*Croton gyp.* is shown as higher in section than Eskota dol. and lower than Memphis ss., all of which are included in so-called Whitehorse-Cloud Chief fm. Is mapped in Stonewall Co. Derivation of name not stated.]

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 167). Croton gyp. is same as Eskota gyp. and is discarded.

Croton Falls hornblendite.

Age (?): Southeastern New York (Westchester and Dutchess Counties).

C. R. Fettke, 1914 (N. Y. Acad. Sci. Annals, vol. 23, p. 228). *Croton Falls hornblendite.*—Massive, dark-green, coarsely crystalline hornblendite. A basic intrusive. Starts at Croton Falls and extends as a ridge, 2½ mi. long and ½ mi. wide, in NE. direction on E. side of Croton River. Associated with Manhattan schist.

Crouse limestone member (of Garrison shale).

Permian: Central northern Oklahoma (Osage County).

K. C. Heald, 1916 (U. S. G. S. Bull. 641B, pp. 21, 22). *Crouse ls.*—A prominent ls., 3± ft. thick, which lies 70± ft. below Wreford ls. and 50 ft. above Cottonwood ls. in Foraker quad., Osage Co. Characteristic features are form of outcrop, which shows many large massive blocks; absence of recognizable fossils in any abundance, with exception of small Fusulinas, which are plentiful; and presence of many smooth round holes, which are vertical or steeply inclined to the bedding.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8), used this name in SE. Nebr. See under *Bigelow ls. fm.*

Named for Crouse Hill, Foraker quad., Osage Co.

Crowduck Lake conglomerate.

Pre-Cambrian: Ontario.

L. Greer, 1931 (Ontario Dept. Mines 39th Ann. Rept., pt. 3, p. 47).

Crowleyan series.

A term introduced by C. [R.] Keyes (Iowa Acad. Sci. Proc., vol. 22, p. 252, 1915) for early Tert. deposits of Mo. Derivation of name not stated. In Pan-Am. Geol., vol. 39, No. 4, 1923, p. 320, he used *Crowleyan* to include Wilcox group and Porters Creek clay of Ill.

Crown conglomerate.

Upper Cretaceous (Gulf series): Western Texas.

J. A. Udden, 1907 (Univ. Tex. Bull. 93, pp. 66–67). *Crown cgl.*—Three cgls., each 10 or 20 ft. thick, interbedded with strata resembling typical Chisos beds. Many of pebbles and bowlders well rounded; most of them consist of various kinds of lavas and trap rocks, but lss. are also well represented, and some of these contain Lower Cret. fossils. Regarded as uppermost part of Chisos beds.

Named for Crown Peak, Brewster Co.

Crown Point limestone.

Lower Ordovician: Eastern New York (Champlain Valley).

H. P. Cushing, 1905 (N. Y. State Mus. Bull. 95), adopted the subdivisions of the Chazy proposed by E. Brainerd and H. M. Seely in 1888 (Am. Geol., vol. 2, pp. 323–330), as explained under *Chazy group*, and proposed *Crown Point ls.* for group B or middle Chazy, probably from exposures at or near Crown Point, Essex Co.

†Crow Ridge series.

Cretaceous and Jurassic: Western central Montana (Elkhorn region).

W. H. Weed, 1901 (U. S. G. S. 22d Ann. Rept., pt. 2, pp. 399–455). *Crow Ridge fm.* [on map], *Crow Ridge series* [text heading].—Altered argill. siliceous rocks—hornstone, adinoles, and qtzites—comprising all Mesozoic rocks of Elkhorn min. dist. Thickness 1,680 ft. Overlain by andesites. Underlain by Quadrant fm. Named for SW. spur of Crow Peak, to which name "Crow Ridge" is applied.

Includes part or all of Colorado sh., Kootenai fm., and Ellis fm.

Crow River morainic system.

Pleistocene (Wisconsin stage): Southeastern Minnesota (Hennepin and adjacent counties).

F. Leverett, 1932 (U. S. G. S. P. P. 161, pp. 84–86). Includes Anoka and Montrose moraines. Named for Crow River drainage basin in Hennepin and adjacent counties.

Crow's Mill limestone. (In McLeansboro formation.)

Pennsylvanian: Central western Illinois (Springfield quadrangle).

T. E. Savage, 1915 (Ill. Geol. Surv. Bull. 20, pp. 99–107). *Crow's Mill ls.* is in McLeansboro fm. 176± ft. above coal No. 7 in Springfield quad.

G. H. Cady, 1921 (Ill. Geol. Surv. Cooperative Min. Ser. Bull. 26). *Crows Mill ls.* of Springfield region lies 230± ft. above coal No. 6 and may = either Carlinville or Shoal Creek ls. [On p. 37 he says it lies 275± ft. above coal No. 6. On p. 43 he says it is probably same as Carlinville ls.]

J. E. Lamar and H. B. Willman, 1934 (Ill. Geol. Surv. Bull. 61, pp. 129–138). *Macoupin ls.* [new (?) name] is 4 to 7 ft. thick locally in Sangamon Co. and is known as *Crows Mill ls.*

Crowsnest volcanics.

Cretaceous: Alberta and British Columbia.

W. W. Leach, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 197).

Crow Wing formation.

Huronian (upper): Central Minnesota (Crow Wing, Aitkin, and Cass Counties).

C. Zapffe, 1930 (Lake Superior Min. Inst. Proc., vol. 28, pp. 101–106). The Upper Huronian (Cuyuna series) of Cuyuna dist. is lithologically divided into 3 conformable fms. (descending) Crow Wing fm., Aitkin fm., and basal cgl. The Crow Wing is divided into Cuyuna memb. (above) and Emily memb. (below).

See under *Cuyuna memb.* and *Emily memb.* Apparently named for Crow Wing Co., in N. part of which it covers a large area.

Cruse oil zone.

Tertiary: Trinidad.

G. A. Macready, 1920 (Am. Inst. Min. and Met. Engrs. Trans. [preprint 1017], p. 9).

Cruse sand.

Miocene: Trinidad.

G. A. Waring, 1926 (Johns Hopkins Univ. Studies in geol., No. 7, p. 63).

†Crusher ledge.

A descriptive term applied in early Mo. repts to the ls. capping the bluffs at Kansas City. R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 112, 121), stated: "Crusher ledge" at Kansas City is Argentine ls.

†Crusher Hill alternating shales and limestones. (In Council Grove group.)

Permian: Central Kansas.

L. C. Wooster, 1905 (The Carbf. rock system of eastern Kansas, p. 9). [No description except statement that thickness is 140 ft. and that the beds form lower part of Strong City beds, underlie Strong flints [Wreford ls.] and overlie 12 ft. of sh. [Florena] which rests on Cottonwood ls. Derivation of name not stated.]

Same as Neosho sh. memb., older name.

Cryptozoic eon.

A term applied by C. Schuchert and C. O. Dunbar (Textbook geol., pt. 2, pp. 70, 82+, 1933) to the pre-Camb. rocks as a whole, which they divided into Proterozoic and Archeozoic. Derived from the Greek κρυπτός, hidden.

†Crystal sandstone.

A shortened form of †*Crystal City ss.*, employed by C. [R.] Keyes.

Crystal Beach moraine.

Pleistocene (Wisconsin stage): Southern Ontario. Shown on moraine map (fig. 8) in U. S. G. S. Niagara folio (No. 190), p. 17. Probably same as Alden moraine of N. Y.

†Crystal City sandstone.

Lower Ordovician: Eastern Missouri.

A. Winslow, 1894 (Mo. Geol. Surv. vol. 6, pp. 331, 352, 358). ***Crystal City ss.***—Brittle white ss., 50 ft. thick, underlying Joachim ls. and overlying Potosi ls., in SE. Mo.

Discarded many years ago, as a local term for St. Peter ss., the older name.

Named for exposures at Crystal City, Jefferson Co.

Crystal Dale moraine.

Pleistocene: Northwestern New York (Lowville quadrangle).

A. F. Buddington, 1934 (N. Y. State Mus. Bull. 296, p. 41). Extends N. from S. edge of Lowville quad. through Puffer School and just W. of Crystal Dale to within ½ mi. of Strifts School, thence bends to E. and extends 2½ mi. farther N., passing about a mi. E. of Kirschnerville. At S. end appears to merge with Dkob moraine.

Crystal Falls limestone member (of Harpersville formation).

Pennsylvanian: Central northern Texas (Stephens County, Brazos River region).

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31, 39). *Crystal Falls ls. memb.*—In lower part of Harpersville fm., of Cisco group. Occurs in vicinity of Crystal Falls, Stephens Co.

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, pp. 161–164). *Crystal Falls ls. lentil of Harpersville fm.*—Lowermost ls. of Harpersville fm. Lies 40 to 80 ft. above base of the Harpersville. Consists of yellow or gray ls., nodular, weathering locally red or purple, with av. thickness of 2 or 3 ft. Lies 60 to 80 ft. below Belknap ls. lentil of Harpersville. [Plummer and Moore distinctly showed 3 other lss. in interval btw. Crystal Falls ls. and Belknap ls., one of which is so-called "Upper Crystal Falls ls." of subsequent repts.]

The geol. maps of Coleman, Shackelford, and Stephens Counties issued by Tex. Bur. Econ. Geol. in Feb., May, and June, 1929, applied "Lower

Crystal Falls ls." to the Crystal Falls ls. of Plummer and Moore, and called a ls. lying 10 to 20 ft. above that ls. the "Upper Crystal Falls ls." They gave the thickness of the lower ls. as 5 to 10 ft. and of the upper ls. as 5 ft. E. H. Sellards, 1933 (Univ. Tex. Bull 3232), adhered to *Crystal Falls ls.* of Plummer and Moore, which is present approved definition of U. S. Geol. Survey.

Crystal Falls formation.

Upper Huronian: Northern Michigan (Crystal Falls district).

J. Zinn, 1933 (Mich. Acad. Sci., Arts, and Lett., vol. 18, pp. 446–448, 454). *Crystal Falls iron fm.*—In the past the iron fm. in Upper Huronian of Crystal Falls dist. has been called *Vulcan memb. of Michigamme sl.* But the true Vulcan of Menominee range is now thought to be Middle Huronian. For this reason the iron fm. at Crystal Falls will be referred to in this paper as *Crystal Falls fm.* It consists of rather thick horizons of cherty siderite, interlayered with thinner horizons of ferruginous or graphitic sl. The whole iron fm. is of considerable thickness if the interlayered slates be included. It rests conformably on the footwall graphitic slates, and is conformably overlain by the hanging-wall sediments. Has been traced almost continuously to Iron River dist. to W. and to Florence dist. to S.

†Crystal Falls series.

A term applied in some early repts to the Huronian rocks of Crystal Falls dist., Mich.

Crystal Mountain sandstone.

Ordovician (?) (Lower Ordovician ?): Southwestern Arkansas and southeastern Oklahoma.

A. H. Purdue, 1909 (Geol. Soc. Am. Bull., vol. 19, p. 557; Slates of Arkansas, Ark. Geol. Surv., pp. 30, 32). *Crystal Mtn ss.*—Lower 300 ft. massive, coarse-grained, white ss. which weathers light brown; upper 400 ft. massive ss. interbedded with black to gray sh., the sh. in places altered to ribboned sl. In many parts of fm. the lower ss. is thickly set with network of quartz veins from thickness of knife blade to several inches; in other parts there are fissures from several inches to several ft. wide the walls of which are lined with magnificent clusters of quartz crystals, which gave rise to name of Crystal Mtns. Overlies, probably uncon., Collier sh.; grades into overlying Ouachita sh.

H. D. Miser, 1917 (U. S. G. S. Bull. 660, pp. 67–68). "Ouachita sh." divided into 3 fms. and abandoned. The basal of the 3 fms. (here named *Mazarn sh.*) rests on Crystal Mtn ss. as here defined. The middle of the 3 fms. (here named ***Blakely ss.***) was in 1909 regarded by Purdue as upper part of Crystal Mtn ss., but has since been determined by Purdue and writer to occur in middle of "Ouachita sh." The ***Crystal Mtn ss.*** as here defined consists of 850 ft. of coarse-grained massive gray to brown ss., calc. in places, with a cgl. at base which contains ls. and chert pebbles derived from underlying Collier sh. Clusters of quartz crystals are found in fissures at many places. Has not yielded any fossils, but from strat. position is tentatively assigned to Ord. Rests uncon. on Collier sh.

Named for Crystal Mtns, Montgomery Co., Ark.

Crystal Pass limestone member (of Sultan limestone).

Devonian: Southeastern Nevada (Goodsprings region).

D. F. Hewett, 1931 (U. S. G. S. P. P. 162, pp. 10, 15, etc.). ***Crystal Pass ls. memb.***—Very thin-bedded light bluish-gray ls., of porcelain-like texture, without fossils or chert. Thickness 150 to 260 ft. Top memb. of Sultan ls. Underlies Dawn ls. memb. of Monte Cristo ls. (Dev.) and overlies Valentine ls. memb. of Sultan ls. Named for Crystal Pass, sec. 2, T. 25 S., R. 58 E.

Cuba sandstone.

Upper Devonian: Western New York.

J. M. Clarke, 1902 (N. Y. State Mus. Bull. 52, pp. 524–528). *Cuba ss.* is separated from overlying Wolf Creek cgl. by 600 ft. of beds containing common Chemung species, and rests on recognized Chemung deposits.

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, p. 25). *Cuba ss.* lies near middle of Chemung beds in Cattaraugus and Allegany Counties.

L. C. Glenn, 1903 (N. Y. State Mus. Bull. 69, p. 968). *Cuba ss. lentil.*—Medium to coarse grained, somewhat arkosic ss., usually light cream colored. Thickness 10 to 15 ft. Exposed in quarry a few rods E. of Erie depot at Cuba, Allegany Co. Included in Chemung beds, about 40 ft. above their base in Olean and Salamanca quads.

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69). *Cuba ss.* lies stratigraphically below Girard sh. and above Northeast sh.

G. H. Chadwick, 1924 (N. Y. State Mus. Bull. 251, pp. 152–153). *Cuba ss.* is a most important horizon marker; easily traced up Ischua Creek to near Machias [Cattaraugus Co.], where name *Ischua ss.* was early appropriated to it by Horseford. [Gives same strat. position as in 1923, and repeated it in 1925 (Geol. Soc. Am. Bull., vol. 36, p. 464).]

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369), placed Cuba ss. btw. Chadakoin (above) and Northeast sh. (below) and included them all in Chemung. She stated: *Cuba ss.* carries *Spirifer disjunctus* fauna and marks upper limit of *Spirifer (Delthyris) mesacostalis* in N. Y. Thickness 10 to 15 ft.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71), divided his Girard stage into Girard sh. (above) and Cuba ss. (below).

G. H. Chadwick, 1935 (Geol. Soc. Am. Proc. 1934, p. 71). [See 1935 entry under *Northeast sh.* Strat. position and names of underlying and overlying fms. changed.]

Cuba sandstone. (In Carbondale formation.)

Pennsylvanian: Central western Illinois (Fulton County).

T. E. Savage, 1927 (Am. Jour. Sci., 5th, vol. 14, pp. 307–316), applied *Cuba ss.* to beds in Carbondale fm. of Fulton Co. beneath his Big Creek sh. and uncon. above his Canton sh. Thickness and derivation of name not stated.

H. R. Wanless, 1931 (Ill. State Geol. Surv. Bull. 60, pp. 179–193). In places Cuba ss. cuts out Canton sh. and all beds down to under clay of coal No. 5.

Probably named for town of Cuba, Fulton Co.

Cuba moraine.

Pleistocene (Wisconsin stage): Southwestern Ohio. Belongs to Shelbyville morainic system. See U. S. G. S. Mon. 41 and Mon. 53. Named for Cuba, Clinton Co.

Cuchara formation.

Eocene: Southern Colorado (Huerfano County).

R. C. Hills, 1893? (Colo. Sci. Soc. Proc., vol. 4, p. 9; paper read Feb. 2, 1891). [See 1893? entry under *Poison Canyon fm.*]

H. F. Osborn, 1929 (U. S. G. S. Mon. 55). *Cuchara fm.* is of middle Wasatch age.

Cuchillo formation.

Lower Cretaceous (Comanche series): Southwestern Texas (Presidio region) and northern Mexico.

R. H. Burrows, 1909 (Min. and Sci. Press, vol. 99, p. 324), and 1910 (Soc. geol. mexicana Bol., t. 7, p. 95).

W. S. Adkins, 1933 (Univ. Tex. Bull. 3232, pp. 271, 294). *Cuchillo fm.* was named by Burrows, from Conchos Valley section N. of Kansas City, Mexico & Orient line, a short distance N. of Presidio. Overlies Las Vigas fm. and underlies the heavy-bedded main ls. called Aurora by Burrows, Mountain ls. by Hill, and upper Glen Rose-Fredericksburg. The Cuchillo is identifiable as the main horizon of *Dufrenoya* and *Douvilleiceras*, which Böse collected near Aurora mine, 5 km. S. of Cuchillo Parado.

Cucuracha formation.

Oligocene: Panama Canal Zone.

D. F. MacDonald, 1913 (Canal Record, vol. 6, p. 214, and Geol. Soc. Am. Bull., vol. 24, p. 709).

Cuesta diabase.

Lower Cretaceous: Southern California (San Luis Obispo region).

H. W. Fairbanks, 1904 (U. S. G. S. San Luis folio, No. 101). *Cuesta diabase.*—Geologically related intrusive masses and sheets of pre-Chico age, occurring upon opposite sides of the long area of Toro sh. which extends from near Cuesta Pass on S. to N. edge of San Luis quad. Other diabases occur in the area.

Named for exposures near Cuesta and Cuesta Pass, San Luis Obispo Co.

Cuesta formation.

Tertiary: Mexico (Baja California).

A. Heim, 1922 (Geol. Mag., vol. 59, p. 543).

Cueva rhyolite.

Tertiary(?): Southern New Mexico (Dona Ana County).

K. C. Dunham, 1935 (N. Mex. School Mines Bull. 11, pp. 53, 55). *Cueva rhyolite,* 120 to 250 ft. of tuffs, mud flows, and rhyolite flows. Younger than Orejon andesite and overlies Soledad rhyolite. Type loc. La Cueva, W. of mouth of Fillmore Canyon, Organ Mtns. In absence of evidence assigned to Tert.

Cuitaca granodiorite.

Age(?): Mexico.

S. F. Emmons, 1910 (Econ. Geol., vol. 5, p. 328).

Culberson series.

Permian: Western Texas.

C. [R.] Keyes, 1932 (Pan-Am. Geol., vol. 57, pp. 350, 351, 354). *Culbersonian reef series* occupies interval btw. Manzano ss. [Abo ss.] and Maderan [Madera ls.].

C. [R.] Keyes, 1933 (Pan-Am. Geol., vol. 59, pp. 143–145). The provincial assemblage of sediments centering on the Wiley ridge [Wiley Mtns, Tex.] is lately given title of *Culberson series,* a name derived from Culberson Co., Tex. Is older than Guadalupian series. Includes (descending) (1) ls., (2) Eddy sss., (3) lss. Its *most conspicuous memb. or terrane is* Eddy ss., 2,000 *ft. thick, the major part of* which is what G. B. Richardson called Delaware [Mtn] fm.

Culebra formation.

Oligocene and Miocene: Panama.

E. Howe, 1907 (*Isthmian Canal Comm. Ann.* Rept. 1907, pp. 108–138; Econ. Geol., vol. 2, p. 644) and 1908 (Am. Jour. Sci., 4th, vol. 26, p. 222).

Cullom limestone.

Pennsylvanian: Southeastern Nebraska and eastern Kansas.

G. E. Condra and N. A. Bengston, 1915 (Nebr. Acad. Sci. Pub., vol. 9, No. 2, pp. 7, 11, 20, 35). *Cullom ls.*—Massive fossiliferous ls. 4 to 8 ft. thick. Forms cliff. Overlies Kanwaka sh. and lies 6 to 8 ft. below Cedar Creek ls; all included in Platte sh. Named for town.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., p. 45). *Cullom ls.* was named by Condra and Bengston from near Cullom Station, Cass Co., Nebr. It consists of 2 lss. separated by about 1 ft. of bluish gray argill.-calc. fossiliferous sh. The upper ls. is 2 ft. thick, gray, massive. In most places lower ls. is somewhat thinner than upper one and weathers yellowish brown. The Cullom ls. is very persistent, holding its faunal and lithologic features from southern Kans. to Rock Bluff, Nebr., and Folsom, Iowa.

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, 2d ser., pp. 11, 13). *Cullom ls.* abandoned, as another name has priority. The so-called Cullom ls. of Bull. 1 is DeKalb ls. memb.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 100). Studies by Condra, F. C. Greene, and Moore in Oct. 1932, indicate that †Cullom ls. (abandoned) is equiv. lower part of Westerville ls.

Cultus formation.

Triassic: Southern British Columbia and central northern Washington.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, maps 16 and 17). *Cultus fm.*—Chiefly dark gray to black argillite, with ss. and fine-grained cgl. Overlies Chilliwack series. [Mapped around S. shore of Cultus Lake, B. C., at and near 122° mer.]

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 516). *Cultus fm.* is 3,000 to 7,000(?) ft. thick. Occurs along Cultus Ridge. Few fossils, but little doubt as to Triassic age.

Cumberland sandstone.

Ordovician (Upper): Southern Kentucky.

N. S. Shaler, 1877 (Ky. Geol. Surv., 2d ser., vol. 3, pp. 152, 153, 155, 159–160, 387). *Cumberland ss.*—Fine-grained greenish ss., 30 to 100 ft. thick, at top of Cincinnati group or Blue Limestone series. Regarded as = Oneida cgl. and Medina ss. of N. Y. [On several pages is included in "Cincinnati series."] Underlies so-called Clinton ore.

A. F. Foerste, 1900 (Ind. Dept. Geol. Nat. Res. 24th Ann. Rept.). The Clinton ls. has often been included in *Cumberland ss.* by Linney. Shaler did not give section nor describe top and bottom limits, so that it is impossible to tell just what he included. But name will be found very useful for rocks in southern Ky., and may deserve a wider application. Is typical about Burksville, Cumberland Co. Is 5 to 100 ft. thick and unfossiliferous. Correlated with Oswego ss. by Linney and Ulrich.

A. F. Foerste, 1901 (Geol. Soc. Am. Bull., vol. 12, pp. 434–436). "*Cumberland ss.*" of Shaler belongs to Richmond group, but basal part may belong to Lorraine.

A. F. Foerste, 1902 (Am. Geol., vol. 30, btw. pp. 359 and 369). Major part of Shaler's Cumberland ss. is of Lorraine age, but it probably also included some beds of Richmond age.

J. M. Nickles, 1902 (Jour. Cincinnati Soc. Nat. Hist., vol. 20, p. 89). *Cumberland ss.* of Ky. probably belongs to upper div. of Richmond group.

A. M. Miller, 1919 (Dept. Geol. and Forestry of Ky., ser. 5, Bull. 2). Saluda memb. (*Cumberland River ss.*) is top memb. of Richmond stage in Ky.

Named for exposures along Cumberland River in Cumberland and adjoining counties.

†Cumberland quartzite.

Pre-Cambrian: Northeastern Rhode Island.

J. B. Woodworth, 1899 (U. S. G. S. Mon. 33, pp. 106–107). *Cumberland qtzites.*—Bands of qtzite interbedded with schists or green slates and forming part of Blackstone series. Believed to uncon. underlie Ashton schists. One outcrop traceable from S. side of Sneech Pond, along to main street southeastward for 1½ mi. in village of Cumberland Hill.

B. K. Emerson and J. H. Perry, 1907 (U. S. G. S. Bull. 311, p. 11). "Cumberland" qtzite is same as Grafton [Westboro] qtzite, which has priority, and "Cumberland" is also in use in several other senses. Hence abandoned.

Westboro qtzite is now used instead of †*Grafton qtzite.*

Cumberland series.

Pennsylvanian: Nova Scotia and New Brunswick.

W. A. Bell, 1927 (Roy. Soc. Canada Trans., 3d ser., vol. 21, sec. 4, pp. 75–108, table).

Cumberland Gap shale member (of Chattanooga shale)

Devonian or Carboniferous: Southern Tennessee and southwestern Virginia.

J. H. Swartz, 1927 (Am. Jour. Sci., 5th, vol. 14, pp. 485–499). *Cumberland Gap memb.*—Lower black sh. memb. of Chattanooga sh. [restricted]. Conformably underlies Olinger gray sh. memb., the middle memb. of Chattanooga sh. [On p. 499: The Olinger memb. is of the same age as the [upper part of the] Cumberland Gap memb., with which it intertongues to S., representing merely a different environmental condition. In SE. Tenn. rests uncon. on Rockwood fm. From Rockwood northward it everywhere rests on interbedded gray and black sh. of Portage age. Clearly exposed along Lee Highway on N. edge of town of Cumberland Gap, Tenn. In vicinity of Chattanooga, Tenn., it is about 8 ft. thick; at Hagans, Va., 127′ 7″ thick; at Big Stone Gap, Va., about 90 ft.

J. H. Swartz, 1929 (Am. Jour. Sci., 5th, vol. 17, pp. 431–448), assigned these beds to Mississippian.

Cumberland Head shale.

Middle Ordovician: Eastern New York (Champlain Valley).

H. P. Cushing, 1905 (N. Y. State Mus. Bull. 95, map forming pl. 13). [On this map (of portion of towns of Plattsburg and Peru, Clinton Co.) *Cumberland Head shales* block is placed above Trenton lss.]

H. P. Cushing and R. Ruedemann in 1910 (N. Y. State Mus. Bull. 145, p. 97) correlated *Cumberland Head sh.* with upper part of Trenton ls. of Trenton Falls and Watertown region, and called underlying ls. Trenton ls.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27), correlated *Cumberland Head sh.* of Champlain Valley with middle and lower Trenton and as=Canajoharie and Snake Hill shales of east-central N. Y.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 39). For shaly phase of upper Trenton typically developed along East Canada Creek below Dolgeville, Herkimer Co., Cushing (1909) has proposed the name *Dolgeville sh.* These shales were previously described by Cushing as "Trenton-Utica passage beds." In Lake Champlain region to N. and E. from Plattsburg somewhat similar passage beds of uncertain strat. equivalency have been mapped as *Cumberland Head sh.* by Cushing (1905).

R. Ruedemann, 1921 (N. Y. State Mus. Bull. 227, 228, pp. 108–116). *Cumberland Head sh.* (Cushing 1905, pl. 13) consists of blue-black slaty lss. and calc. shales with some firmer ls. bands. Replaces Canajoharie sh. on N. Y. side of Champlain Basin. Lithologically very different from Canajoharie sh. of Panton shore and southern Champlain basin in general, for prevailing element is slaty ls. and graptolite sh. was not observed at all. Beds are strangely barren of fossils, but those found suggest lower and middle Trenton. Are probably in part at least= Canajoharie sh., but are lithologically and faunistically a different facies and deposited under different conditions if not in a separate basin, therefore deserve separate name. Named for Cumberland Head, near Plattsburg, N. Y. Overlain by Stony Point sh. and underlain by Trenton ls.

Cumberland River sandstone.

Upper Ordovician: Southern Kentucky.

See 1919 entry under *Cumberland ss.*

Cumnock formation. (In Newark group.)

Triassic (Upper): Central North Carolina.

M. R. Campbell and K. K. Kimball, 1923 (N. C. Geol. and Econ. Surv. Bull. 33, pp. 20, 25–43). The name *Cumnock fm.* is given to the generally light-colored rocks (shales, sss., and cgls.) bearing coal or associated with the coal. Varies greatly in thickness and composition throughout the field. On Cumnock property it includes at top brown sss. and shales. Cumnock coal bed lies from 100 to 150 ft. above its base. Thickness of fm. 600 to 1,000 ft. Is middle fm. of Newark group. Underlies Sanford fm. and overlies Pekin fm.

Named for section exposed in mine shaft at Cumnock, Lee Co.

Cundiff limestone. (In Caddo Creek formation.)

Pennsylvanian: Central northern Texas (Jack County).

J. M. Armstrong, 1929 (Tex. Bur. Econ. Geol., geol. map of Jack Co.). *Lower Cundiff ls.* lies 50± ft. above base of Caddo Creek fm. and *Upper Cundiff ls.* lies 90± ft. above Lower Cundiff ls.

G. Scott and J. M. Armstrong, 1932 (Univ. Tex. Bull. 3224, p. 40). Three ledges of ls. outcropping in E. part of Jack Co. near Cundiff, take their name from the village. The *Upper Cundiff ls.* consists of 3± ft. of hard crystalline ls. apparently of algal origin; it is present in Wise Co. The *Lower* [*Middle*] *Cundiff ls.* consists of 3± ft. of hard crystalline ls. apparently of algal origin; it is present in Wise Co. and is separated from Upper Cundiff ls. by 75± ft. of sh. The lower of the 3 ls. ledges pinches out before Wise Co. is reached. The Cundiff ls. overlies Hog Creek shales, both of which are members of Caddo Creek fm.

Cunningham sands.

Subsurface sands of Chester (Miss.) age in Ind., *Cunningham shallow sand* being applied to a sand correlated with Cypress ss., and *Cunningham deep sand* to a sand correlated with Sample ss.

†Cup Coral member. (In Dornick Hills formation.)

Pennsylvanian: Central southern Oklahoma (Carter County).

W. L. Goldston, Jr., 1922 (A. A. P. G. Bull. vol. 6, No. 1). *Cup Coral memb. of Glenn fm.*—Blue shales separated by thin sss. and an occasional ls.; 1,500 to 1,800 ft. thick. Is easily distinguished by a white ls. near top, which carries a large cup coral (*Campophyllum torquium*); S. of Ardmore the ls. is exposed in only one place. To S. of Woodford 5 of the 7 ss. beds are asphalt bearing. Fossils listed. Underlies Deese memb. and overlies Otterville ls. memb.

G. H. Girty and P. V. Roundy, 1923 (A. A. P. G. Bull., vol. 7, No. 4, pp. 331–347). *Glenn fm.* includes only Deese and Cup-Coral members of Goldston.

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z, pp. 7–21). Deese fm. (5,000± ft. thick) underlies Hoxbar fm. and rests on Dornick Hills fm., which overlies Springer fm. and includes Otterville ls. restricted.

C. W. Tomlinson, 1929 (Okla. Geol. Surv. Bull. 46). *Dornick Hills fm.*, 1,500 to 4,000± ft. thick, includes Goldston's Otterville and Cup Coral members of Glenn fm. and a little more. "Cup Coral memb." is discarded as confusing and inappropriate. As mapped by Goldston its strat. limits were rather variable, and name gives no clue to type loc. Also, cup corals are common at certain horizons in overlying Deese fm., and occur also in Jolliff, Otterville, and other ls. members of Dornick Hills fm., and at one locality in Hoxbar fm.

†Cupriferous series.

A descriptive term (meaning copper bearing) applied in early repts on Lake Superior region to *Keweenawan series* of modern nomenclature.

Curdsville limestone.

Middle Ordovician (Trenton): Central Kentucky.

A. M. Miller, 1905 (Ky. Geol. Surv. Bull. 2, pp. 9, 18). *Curdsville substage.*—Cherty crystalline ls., 30 ft. thick, characterized by *Dinorthis pectinella*. Overlies Highbridge ls. and underlies Logana bed. Basal fm. of Lexington stage.

Named for Curdsville Station, Mercer Co.

Curecanti granite.

Pre-Cambrian: Central western Colorado (Gunnison River region).

J. F. Hunter, 1925 (U. S. G. S. Bull. 777). More homogeneous than the other granitic bodies of the region. Chiefly a pink to gray fine-grained, even-textured granite in which either biotite or muscovite, or both, may be present. Small irregular patches of coarse or even pegmatitic granite are scattered throughout the mass. Intrudes the Archean biotite schist. Is exposed for 3½ mi. along Black Canyon, from a point 1½ mi. E. of Curecanti Creek to Nelson Gulch. Extends only a short distance up Curecanti Creek, but walls lower canyon of Blue Creek for 1½ mi. from its mouth.

The terms "Algonkian system" and "Archean system" were discarded by U. S. Geol. Survey in 1934. For 1935 Colo. geol. map this fm. was included in Front Range granite group and assigned to pre-Camb.

†Curl formation.

Pennsylvanian: Northeastern Oklahoma.

D. W. Ohern, 1910 (Okla. State Univ. Research Bull. 4, p. 26). *Curl fm.*—Shales and sss., with bluish or greenish clay sh. in lower part. Thickness 300 ft. Underlies Hogshooter ls. and overlies Lenapah ls.

Same as Coffeyville fm., older name.

Named for Curl Creek, Nowata Co.

Curlew limestone member (of Tradewater formation).

Pennsylvanian: Western Kentucky and southeastern Illinois (?).

D. D. Owen, 1856 (Ky. Geol. Surv. vol. 1, pl. showing section of Lower Coal Measures) and 1857 (Ky. Geol. Surv. vol. 3, pp. 13, 23). *Curlew ls.*—Ls., 4 ft. thick, in Lower Coal Measures; separated from overlying Curlew ss. by 34 ft. of sh., including Curlew coal and with ss. or ls. at top.

Apparently named for Curlew, Union Co., Ky.

†Curlew sandstone. (In Tradewater formation.)

Pennsylvanian: Western Kentucky and southeastern Illinois (?).

D. D. Owen, 1856 (Ky. Geol. Surv. vol. 1, pl. showing section of Lower Coal Measures) and 1857 (Ky. Geol. Surv. vol. 3, pp. 13, 23). *Curlew ss.*—Massive ss., 20 ft. thick, in Lower Coal Measures; separated from underlying Curlew coal by 5 ft. 3 in. of sh. or ls. and 5 ft. of sh. Overlain by 42 ft. of sh. with clay ironstones.

Apparently named for Curlew, Union Co., Ky.

Curry iron-formation member (of Vulcan iron-formation).

Pre-Cambrian (middle Huronian): Northwestern Michigan (Menominee district).

C. R. Van Hise and W. S. Bayley, 1900 (U. S. G. S. Menominee folio, No. 62). *Curry ore-bearing memb.*—Top memb. of Vulcan fm. Consists of 100 to 225 ft. of interbedded jaspilites and ferruginous quartzose slates. Grades into underlying Brier sl. memb. Underlies Hanbury sl. Named for exposures north of Curry Mine.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), adopted *iron-fm.* and *iron-fm. memb.* as lithologic terms, and changed age of *Vulcan iron-fm.* from upper Huronian to middle Huronian, and adopted *Curry iron-fm. memb.* for the Curry rocks.

Curry Creek series.

Oligocene: British Columbia.

L. Reinecke, 1915 (Canada Geol. Surv. Mem. 79, pp. 53, 56).

Curtis formation. (In San Rafael group.)

Upper Jurassic: Southeastern and central Utah and southwestern and northwestern Colorado.

J. Gilluly and J. B. Reeside, Jr., 1926 (U. S. G. S. Press Bull. 6064, March 30, 1926. Name adopted at joint conference of J. Gilluly, J. B. Reeside, Jr., R. C. Moore, and H. E. Gregory, from area specially studied by Messrs. Gilluly and Reeside.) *Curtis fm.*—Green-gray cgl. and sh. and heavy-bedded gray ss. Thickness 76 to 253 ft. Uncon. overlies Entrada ss. and conformably underlies Summerville fm. Belongs to San Rafael group.

Named for exposures on Curtis Point, near head of Cottonwood Springs Wash, on NE. side of San Rafael Swell, SE. Utah.

For additional details see U. S. G. S. P. P. 150, 1928 (by J. Gilluly and J. B. Reeside, Jr.), and U. S. G. S. P. P. 183, 1936 (by A. A. Baker, C. H. Dane, and J. B. Reeside, Jr.).

Curzen limestone.

See *Curzon ls.*

Curzon limestone. (In Shawnee formation.)

Pennsylvanian: Northwestern Missouri, southeastern Nebraska, and northeastern Kansas.

J. A. Gallaher, 1898 (Mo. Bur. Geol. and Mines Bien. Rept., p. 57). *Curzons ls.*—Underlies Forest City sand rock and overlies sh. Higher ls. than Forbes ls. Included in Perm.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 42, 52, 53). Years ago Mo. Surv. used name *Curzen* for what seems to be basal 5 to 8 ft. of Topeka ls. memb. of Shawnee fm. It consists of bluish gray to brownish ls. interbedded with thin shales. Is overlain by Turner Creek sh. and underlain by Iowa Point sh., top bed of Calhoun sh. memb. of Shawnee. [This is definition followed by R. C. Moore and G. E. Condra, 1932.]

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 11). *Hartford (Curzon) ls.*, basal memb. of Topeka ls. fm., usually consists of 4 or 5 uneven, dark-gray beds separated by sh. seams, but in places consists of 2 beds separated by sh. Thickness 6 to 7 ft. Underlies Turner Creek sh. memb. and overlies Iowa Point sh. memb. of Calhoun sh. fm.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 195). Rock to which Gallaher referred as *Curzen's ls.* is unidentifiable; and therefore Condra is author of name. Condra gives no type loc., but presumably 1 is in vicinity of Curzon [Holt Co.], Mo. Name is discarded. Condra agrees (personal communication, July 8, 1934) *Hartford* is preferable to *Curzen.*

G. E. Condra and E. C. Reed, June 1937 (Nebr. Geol. Surv. Bull. 11, 2d ser.), restricted *Curzen ls.* as explained in June 1937 entry under *Topeka ls.* On p. 51 they state: Type loc. of Curzen ls. is E. of Curzon Station, SE. of Forest City, Holt Co., Mo. Reason for apparent change in spelling of name of station since Gallaher worked there has not been learned. It is assumed Gallaher had opportunity to secure correct spelling and that R. R. may have changed spelling through error.

Named for Curzon, Holt Co., Mo.

Cushina formation.

Lower Ordovician: British Columbia (Robson district) and Alberta.

C. D. Walcott, 1923 (Smithsonian Misc. Coll., vol. 67, No. 8, p. 458); 1924 (ditto, vol. 67, No. 9, p. 485); and 1928 (ditto, vol. 75, p. 226). *Cushina fm.*, Lower Ozarkian, B. C.

P. E. Raymond, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 304–307). *Cushina fm.* is=Mons fm. and is Lower Ord.

Cushing granodiorite.

Late Carboniferous (?): Southwestern Maine.

F. J. Katz, 1917 (U. S. G. S. P. P. 108, p. 176). *Cushing granodiorite.*—Thoroughly gneissoid, of light to dark-gray color, and for most part finely and evenly but only slightly porphyritic in texture. Assigned to late Carbf. (?). Named for exposures on Cushing Island, in Casco Bay.

On 1933 geol. map of Maine, by A. Keith, this granite appears to be mapped as Carbf.

†Cushing limestone member (of Elmdale formation).

Pennsylvanian: Central northern and central Oklahoma.

C. N. Gould, 1925 (Okla. Geol. Surv. Bull. 35, p. 80). The Elmdale fm. consists of variegated shales with thin lss., usually less than 3 ft. thick, including *Cushing ls. memb.* The Cushing memb. has been traced farther S. into the red beds than any other ls. It is exposed near [about ½ mi. W. of] Cushing [Payne Co.], and has been followed S. across Lincoln Co., passing near Chandler, Sparks, and Prague, and finally disappears N. of North Canadian River in NE. Pottawatomie Co.

This ls. is now known to be the Red Eagle ls. memb., which has priority, and the name "Cushing" has been abandoned. (See Okla. geol. map, H. D. Miser, 1926.)

Cusseta sand member (of Ripley formation).

Upper Cretaceous: Western Georgia (Stewart, Chattahoochee, Marion, Schley, Taylor, Macon, Crawford, Houston, Bibb, and Twiggs Counties).

J. O. Veatch, 1909 (Ga. Geol. Surv. Bull. 18, pp. 86–89). *Cusseta sand memb. of Ripley fm.*—Non-calc. sands and clays. The sands, which predominate, are made up of quartz and mica, are unconsolidated, varicolored, cross bedded, and generally fine grained. They are unfossiliferous except for lignitized and silicified wood, and are often very ferruginous, containing thin crusts and layers of siliceous limonite, and limonitic nodules. In the sand are pockets of white, drab, and black, massive-bedded clays, and also thin lenticular layers of laminated clays. The clay is both light and dark colored and massive bedded, and contains well-preserved fossil leaves and minute cubes of pyrite. Underlies Renfroes marl and overlies Blufftown marl, the basal memb. of Ripley. Thickness 250 to 800 ft.

J. O. Veatch and L. W. Stephenson, 1911 (Ga. Geol. Surv. Bull. 26, pp. 135, 151–153, 155). Northeastward from Chattahoochee River the basal 200 or 300 ft. of the marine beds composing Ripley fm. merge along the strike into shallow-water equivalents (*Cusseta sand memb.*), which differ in their essential lithologic characters from typical Ripley beds. The Cusseta memb. consists of irregularly bedded, unconsolidated sands, with subordinate clay lenses, probably of sound or estuarine origin, but perhaps in part of shallow marine origin. Typical marine beds ("Renfroes marl" of Veatch) separate Cusseta sand memb. from overlying Providence sand memb. in narrow belt from Chattahoochee region through Stewart, Chattahoochee, Marion, and Schley Counties, to Macon Co., where they appear to pinch out, so far as surface outcrops are concerned, but there is evidence that buried representatives of these typical marine beds extend E. at least as far as Marshallville. The similarity of the materials of Cusseta sand memb. to the shallow-water phase of underlying Eutaw fm. in its E. extension renders the two fms. separable only with difficulty, and the same is true of this memb. with respect to overlying Providence sand memb. where the intervening marine beds pinch out. The Cusseta memb. outcrops in parts of Stewart, Chattahoochee, Marion, Schley, Taylor, Macon, Crawford, Houston, Bibb, and Twiggs Counties. [pp. 151–153.] [On p. 135 of above rept. is a section at Blufftown, which gives thickness of Cusseta memb. as 100 ft., and shows it as underlain by 50 ft. of "typical marine beds" of Ripley, consisting of gray calc. sand with some fossils, which forms top bed of
