Veatch's "Blufftown marl," the rest of the †Blufftown being the gray, calc., glauconitic sand and gray calc. aren. clay that form upper 45 ft. of Eutaw fm.]

L. W. Stephenson and J. O. Veatch, 1915 (U. S. G. S. W. S. P. 341, p. 65), repeated foregoing description of *Cusseta sand memb.* but did not repeat the Blufftown section and did not describe any typical Ripley beds as underlying Cusseta memb., but described the Cusseta as basal memb. of Ripley fm. and Tombigbee sand as upper memb. of Eutaw fm. All subsequent repts (Ga. Geol. Surv. Bulls. No. 21, 1916; No. 31, 1917; and No. 44, 1929; and Jour. Geol., vol. 27, pp. 177–179, 1919) treat Cusseta sand as basal memb. of Ripley and Tombigbee sand as upper memb. of Eutaw fm. Whether the 50 ft. of Ripley marine beds said to underlie the Cusseta in the several counties mentioned above are now included in Cusseta sand memb. or in underlying Eutaw fm. is not apparent, but, being marine, they are probably included in Tombigbee sand memb.

Named for exposures in vicinity of Cusseta, Chattahoochee Co.

†Cussewago sandstone.

Devonian or Carboniferous: Northwestern Pennsylvania.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. Q_4, pp. 91–98). *Cussewago ss.*—As exhibited along Cussewago Valley [Crawford Co.] this is a very peculiar rock, usually of buffish brown color but in places dark green or greenish blue; is quite coarse, and in many places contains pebbles. Thickness 25 ft. Underlies *Cussewago Middle shales and flags* and overlies Riceville shales. Is basal fm. of Oil Lake group.

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69) and 1925 (Geol. Soc. Am. Bull., vol. 36, pp. 461, 463, 464), renamed *Cussewago sh.* (calling it *Hayfield sh.*) and retained *Cussewago ss.* for the ss. overlying Riceville sh.

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 202), divided "Knapp fm. (revised Cussewago group)" of NW. Pa. into (descending): Hayfield sh. memb., Glade ss. memb., Ridgway sh. memb., Ludlow cgl. memb., and Smethport sh. memb. (or upper "Riceville"). He did not explain relations of Glade ss. and underlying members to Cussewago ss. In 1934 (Bulls. Am. Pal., vol. 21, No. 71) Caster divided the rocks btw. the "middle sh." and the Riceville into (descending) Wetmore cgl. memb. and Kushequa sh. memb. (including Marvin Creek ls. zone), and discarded Cussewago ss.

Cussewago shales.

Devonian or Carboniferous: Northwestern Pennsylvania.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. Q_4, pp. 94–96). *Cussewago Upper shales.*—Bluish or ashen gray shales 5 ft. thick. Underlie Corry ss. and overlie *Cussewago ls.* (2 ft. thick), which rests on *Cussewago Middle shales and flags*, 30 ft. thick and lithologically like Cussewago Upper shales. The Cussewago Middle shales rest on *Cussewago ss.* In some places the whole interval btw. Corry ss. and Cussewago ss. is filled with sandy flags without the ls. The Cussewago ls. greatly resembles Meadville Upper and Meadville Lower lss. but is a better ls. All included in Oil Lake group.

G. H. Chadwick, 1925 (Geol. Soc. Am. Bull., vol. 36, pp. 461, 463, 464). *Cussewago sh.* is renamed *Hayfield sh.*, and *Cussewago ss.* is retained for the ss.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 60, etc.), included Cussewago ls. of White in Hayfield sh. of Chadwick.

Cussewago limestone.

See under *Cussewago shales.*

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 202), introduced *Littles Corner ls.* for a ls. in Hayfield sh. "that is probably the Cussewago ls. of White," but he did not define it. In 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61, pp. 116, 121) Caster stated *Littles Corner ls.* replaces Cussewago ls.; and he included it in Hayfield fm. of Chadwick, which was introduced to replace Cussewago sh. of White. Chadwick called this ls. "Hayfield ls."

Cussewago stage.

Cussewago monothem.

Terms applied by K. E. Caster (Bulls. Am. Pal., vol. 21, No. 71, 1934, table opp. p. 61, pp. 53, 103) to the rocks underlying Berea (Corry) ss. and overlying his Riceville sh. restricted in NW. Pa. Include (descending)

Hayfield sh., Littles Corner ls., Tidioute sh., Cobham cgl., East Kane sh., Wetmore cgl., and Kushequa sh., the latter the upper part of Riceville sh. of previous usage.

Custards shale member.

Mississippian: Northwestern Pennsylvania.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 137). *Custards sh. memb. of Meadville stage.*—Lies at top of Meadville monothem in Crawford Co., where it rests on French Creek ls. Was mentioned by I. C. White as "Meadville upper shales." From exposures in vicinity of Custards village, on Conneaut Creek, Crawford Co., it is proposed this memb. be known as *Custards sh.* Best exposure is at Peterson's Falls, on Rocky Creek, 2 mi. W. of Custards.

Custer granite gneiss.

Jurassic (?): Southwestern British Columbia and central northern Washington.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, map 15, 121° to 121° 30'). *Custer granite gneiss.*—Sheared granodiorite. [Forms Custer Ridge, B. C.]

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 523). Custer granite gneiss seems to cut Hozomeen series. Tentatively referred to Jurassic (?). Is possibly pre-Camb. or late Paleozoic.

Custer formation.

Triassic (?): Oklahoma, Texas, Kansas.

R. Roth, 1932 (Jour. Geol., vol. 40, No. 8, pp. 688–725). *Custer fm.* is herein proposed for those red beds which in Kans. occur btw. Dog Creek shales and Lower Cret. or Comanche group. It occupies same interval in Okla. except where Dog Creek shales are absent, in which case the Custer may rest upon various members of the Blaine or Flower-Pot shales. In Tex. the Custer occupies interval btw. base of Memphis ss. and Santa Rosa cgl., or btw. the shales that overlie Croton gyp. and Camp Springs cgl. or Comanchean at Double Mtn, Tex. In West Tex. the Custer is=interval btw. Santa Rosa cgl. and Capitan ls. or top of Carlsbad ls. Named for Custer Co., Okla., where almost whole fm. is well exposed. The uncon. at base of the Custer increases as distance from Rocky Mtns decreases, except in Tex. Writer believes it is present well above the Queen sand zone. [Assigned Custer to Lower Triassic (Bunter of Europe) and correlated it with Moenkopi, Timothy, Thaynes, Woodside and other Triassic fms. of Rocky Mtns region, which he states it resembles in lithology.]

G. E. Anderson, 1933 (Jour. Geol., vol. 41, No. 8, pp. 834–839). Roth (1932) included in Triassic the Whitehorse ss., Cloud Chief gyp., and the Quartermaster. For these 3 units he proposed *Custer.* [Anderson discusses Roth's reasons for assigning these rocks to Triassic, and does not accept them. He assigned the rocks to Perm., as heretofore.]

Custerian series.

C. [R.] Keyes, 1925 (Pan-Am. Geol., vol. 43, pp. 109, 125, 126). The Morrison strata, which because of character of their vertebrate fauna were formerly given a Late Jurassic date, are now best treated with the Early Cretacic deposits—not the marine Comanchean series of Gulf Embayment, but a distinct provincial succession, the *Custerian series* of fluviatile and epirotic accumulations of Black Hills region. The entire section is well displayed in Black Hills. [Includes Fuson, Minnewaste, and Lakota fms., and in table on p. 109 excludes "Morrisonian series."]

Named for exposures in Custer Co., S. Dak.

Cutbank sand.

Lower Cret., Mont. See under *Moulton sand.*

Cutler formation.

Permian: Southwestern Colorado, southeastern Utah, and northeastern Arizona, and northwestern New Mexico.

W. Cross and E. Howe, 1905 (U. S. G. S. Silverton folio, No. 120). Beds here named *Cutler fm.* compose greater part of "Red Beds" of region. They were hitherto provisionally included in Dolores fm. Field work of 1904 in Ouray quad. revealed notable angular uncon. immediately below the most commonly fossiliferous beds of Dolores fm. Through this uncon. the Dolores [restricted] can be seen to transgress more than 1,000 ft. of old "Red Beds" and several hundred ft. of Rico and Hermosa. In view of these facts the name *Dolores* is here restricted to the Triassic strata, embracing the fossiliferous cgl. and overlying beds up to La Plata ss., of Jurassic age, and the non-fossiliferous strata btw. Rico fm. below and base of Triassic are named *Cutler fm.*, for exposures on Cutler Creek, which enters Uncompahgre River about 4 mi. N. of Ouray, Colo. The Cutler is a complex of bright-red sss. and lighter-red or pinkish grits and cgls. alternating with sandy shales and earthy or sandy lss. of varying shades of red. It rests conformably on Rico fm. and is uncon. overlain by Telluride cgl. (Tert.), the Triassic Dolores fm. restricted being absent in this (Silverton) quad. Thickness of Cutler 1,000+ ft.

The present definition of Cutler fm. in its type region (SW. Colo.) conforms to above original definition, namely, it rests conformably on Rico fm. and is uncon. overlain by Dolores fm. (Upper Triassic and Jurassic?), where that fm. is present. In SE. Utah, NE. Ariz., and NW. N. Mex. the Cutler is overlain by Moenkopi fm. (Lower Triassic) and underlain by Rico fm. (See A. A. Baker and J. B. Reeside, Jr., A. A. P. G. Bull., vol. 13, No. 11, 1929, pp. 1413–1448.) In a part of SE. Utah (Salt Valley anticline and NW. flank of Uncompahgre Plateau, Grand Co.) where the lss. of Rico fm. are absent, the red beds corresponding to Rico fm. of SW. Colo. are now included in Cutler fm. (See U. S. G. S. Bull. 863, 1935, by C. H. Dane.)

Cutler limestone member (of McLeansboro formation).

Pennsylvanian: Southwestern Illinois (Perry County).

A. H. Bell, C. Ball, and L. McCabe, 1931 (Ill. Geol. Surv. Press Bull. 19). *Cutler ls. memb.*—Mottled ls., light-gray with pink or purplish cast, massive, fossiliferous, with black spherical concretions. Thickness 5 to 8 ft. Base lies 6 to 19± ft. above Galum ls. memb. and 52± ft. above Herrin (No. 6) coal in vicinity of Pinckneyville and Jamestown, Perry Co. Named for typical exposures in vicinity of Cutler, Perry Co.

Cutright sandstone member.

Mississippian: Southern Indiana.

P. B. Stockdale, 1931 (Ind. Dept. Cons., Div. Geol. Pub. 98, pp. 76, 118, 181, 182, 189, 212+, 250, 256, 278, etc.). *Cutright ss. memb. of Edwardsville fm.*—Massive ss. with *Taonurus;* 7 ft. thick at Gent, where it lies 6 ft. above base of Edwardsville. In other sections it is 3 to 6 ft. thick. On road leading to Cutright Ridge, S. center sec. 4, T. 7 N., R. 1 E., 1¼ mi. SE. of old Payne P. O., it is 1 ft. thick. [In pl. 5, opp. p. 212, author places Cutright ss. memb. 6± ft. below Weed Patch memb. and on p. 214 he gives a section showing it 10½ ft. above Floyds Knob fm. On p. 279 he states it is named for Cutright bridge across Salt Creek, center sec. 4, T. 7 N., R. 1 E., from Cutright Ridge to S., and from "the Cutright community" in general, and that it is fine-grained, somewhat argill., usually more tightly cemented than many of Edwardsville sss.]

Cuyahoga formation (also **Cuyahoga group**).

Mississippian: Ohio and western Pennsylvania.

J. S. Newberry, 1870 (Ohio Geol. Surv. Rept. Prog. 1869, p. 21). *Cuyahoga sh.*—Dove-colored sh. and fine blue ss., 150 ft. thick, overlying Berea grit and forming topmost fm. of Waverly group in northern Ohio. Underlies Sub-carbf. [Maxville] ls.

As above defined Cuyahoga included at base the black Sunbury sh. As later used by Prof. Newberry it included Black Hand and Logan fms. Sunbury was excluded from Cuyahoga by Orton in 1879, and Logan was excluded in 1880. Black Hand was made a distinct fm. in 1878, but some geologists now include part of Black Hand in Logan fm. and the rest of it in Cuyahoga fm. (See J. E. Hyde, Jour. Geol., vol. 23, pp. 655–682, 757–759, 1915.) The U. S. Geol. Survey at present follows the original definition of *Black Hand*, treating it as a distinct fm. underlying Logan fm. and overlying Cuyahoga fm. (See under *Black Hand fm.*) The

Ohio Geol. Survey, however, appears to follow Hyde's expanded definition of Cuyahoga, which includes, at top, the Black Hand memb. of Hyde. In NW. Pa. and NE. Ohio the *Cuyahoga group* is divided into (descending) Meadville sh., Sharpsville ss., and Orangeville sh.

Named for exposures along Cuyahoga River, btw. Akron and Cleveland.

Cuyama formation.

Tertiary (Pliocene?): Southern California (Cuyama Valley).

W. A. English, 1916 (U. S. G. S. Bull. 621, pp. 191–215). *Cuyama fm.*—Nonfossiliferous yellow and pink clays, sand, and gravel, in large part nonmarine. Thickness 250 to 600 ft. Rest on eroded edge of Santa Margarita fm. and older beds. Crop out only in Cuyama Valley. Overlain by Quat. terrace gravels.

Cuyamaca basic intrusive.

Probably pre-Cretaceous: Southern California (Cuyamaca region, San Diego County).

F. S. Hudson, 1922 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 13, No. 6, pp. 181, 192–207, map). *Cuyamaca basic intrusive.*—Chiefly gabbros, norites, and basic diorites. Three units mapped (1) hypersthene diorite, (2) augite diorite, and (3) norite, gabbro, etc. Cuts Julian schist and Stonewall quartz diorite.

Named for the three peaks of Cuyamaca Mtns.

†Cuyuna series.

Huronian (upper): Central Minnesota (Crow Wing County).

C. K. Leith, 1907 (Econ. Geol., vol. 2, pp. 145–152), described the rocks (sed. and igneous) of Cuyuna Range, Minn., but did not apply geographic names to any of the fms. On p. 147, however, he casually used the term *Cuyuna series*, stating that "the anamorphism of the Cuyuna series is probably to be explained in large part by the existence of intrusives in the area itself and to the west and south of it." On p. 149 he stated: The *Cuyuna sediments* probably belong in the same series with the slates and schists of the Carlton, Cloquet, and Little Falls areas. On p. 150 he said: Succession and lithology are in accord with distribution and general structural relations in pointing to the identity of the Cuyuna-Carlton-Little Falls series with the Upper Huronian or Animikie of the Lake Superior region. On p. 151 he spoke of the "probable equivalence of the Cuyuna and Carlton series."

C. Zapffe, 1930 (Lake Superior Min. Inst. Proc., vol. 28, pp. 99–106), described the rocks of Cuyuna dist., Minn., and divided them as follows:

Post-Keweenawan shaly sediments and cgls.
Uncon.
Keweenawan.
    Basic intrusives and extrusives.
    Acid intrusives.
Uncon.
Upper Huronian (*Cuyuna series*).
    Crow Wing fm.
        1. *Cuyuna memb.* (mainly green slaty and schistose rocks (partly volcanic), enclosing, in lower part, the Deerwood iron-bearing memb.). Strongly magnetic.
        2. *Emily memb.* (some green but largely dark-colored slaty rocks, probably few if any volcanics, and many scattering lenses of iron-bearing rocks, which are only slightly magnetic or nonmagnetic).
    Gradation.
    Aitkin fm. (gray slates and phyllites; volcanics absent; contains some iron carbonate, but extensive iron-bearing lenses virtually lacking; nonmagnetic).
    Basal cgl.
Uncon.
Middle Huronian (Mesabi group).

The U. S. Geol. Survey does not use a local geographic name for the upper Huronian rocks of the different districts of Mich., Minn., and Wis., but for many years called them all "Animikie group," to which the so-called "Cuyuna series" corresponds. "Animikie group" has now, however, been discarded, because it is said to include rocks of both upper and middle Huronian age.

Cuyuna member (of Crow Wing formation).

Huronian (upper): Central Minnesota (Crow Wing County).

C. Zapffe, 1930 (Lake Superior Min. Inst. Proc., vol. 28, pp. 101–106). *Cuyuna memb.*—Mainly green slaty and schistose rocks (partly volcanic), enclosing, in lower part, Deerwood iron-bearing memb. Is strongly magnetic. Uncon. underlies Keweenawan rocks, and overlies Emily memb. As one approaches upper part of Emily memb. of Crow Wing fm. the green-colored rocks become dominant over the darker rocks, and gradually all the differences become sufficiently pronounced to justify considering upper part of Crow Wing fm. as a separate memb., now named *Cuyuna memb.* The Cuyuna memb. contains an abundance of volcanic rocks. Some of these are contemp. basic flows and some are tuffaceous, and all are very schistose and green, wherefore the term "green schist," which has become so common a term and has been used promiscuously, applying often to rocks of all colors, has arisen. Most of drilling in Cuyuna dist. has been in this horizon. It marks the productive part of Cuyuna dist. The Cuyuna memb. contains small narrow layers of dark rocks but none of these are extensive nor are they horizon markers. It also contains nearly all the qtzite that drilling has disclosed, and none of these are horizon markers. It also contains very extensive bands of iron-bearing fm., which were originally a cherty iron carbonate and now show all stages of metamorphism. Near base is a persistent layer of ore fm. About 500 ft. or more above it is a second layer. Collectively these have heretofore been called *Deerwood ore-bearing memb.*

Cygne shales.

A corruption of "Marais des Cygnes shales," employed by C. [R.] Keyes, instead of *Pleasanton fm.*, the commonly accepted name. (See Pan-Am. Geol., vol. 56, pp. 348–349, 1931.) He also uses *Cygnes shales* for same fm. (See Pan-Am. Geol., vol. 58, No. 3, p. 223, 1932.)

Cynthiana formation.

Middle Ordovician (Trenton): East-central Kentucky, southwestern Ohio, and southern Indiana.

A. F. Foerste, 1906 (Ky. Geol. Surv. Bull. 7, pp. 10, 13, 14, 211–212). *Cynthiana fm.*—Lss., with interbedded clay and clay sh., 40 to 90 ft. thick, divided into Greendale bed below and Point Pleasant bed above. Overlain by Utica sh. and underlain by Lexington ls.

A. F. Foerste, 1909 (Denison Univ. Sci. Lab. Bull. 14, pp. 295–297), divided *Cynthiana fm.* into (descending): Nicholas ls., 35 ft.; Greendale bed, and Perryville bed. He repeated this classification in 1910 (Denison, vol. 16), and stated that *Cynthiana fm.* is essentially exact equiv. of Catheys fm. of Tenn. In 1912 (Denison, vol. 17) he stated that Nicholas and Greendale are = Catheys and that Perryville is older than Catheys. In 1913 (Ky. Geol. Surv., 4th ser., vol. 1, pt. 1) he stated that Catheys (= Cynthiana) is younger than Perryville.

A. M. Miller, 1913 (Ky. Geol. Surv., 4th ser., vol. 1, pt. 1, btw. pp. 317 and 342), decribed *Cynthiana* as 38 to 45 ft. thick in Georgetown quad., Ky., and as underlying Eden sh. and overlying Perryville.

A. F. Foerste, 1914 (Cincinnati Soc. Nat. Hist. Jour., vol. 21, pp. 109–145). *Cynthiana fm.* was introduced to include all strata btw. top of Lexington ls. as here defined, i. e., top of Cornishville ls., and base of Eden, i. e., base of Fulton layer.

A. M. Miller, 1915 (Am. Jour. Sci., 4th, vol. 40, pp. 651–657) divided *Cynthiana fm.* of Ky. (40 to 90 ft. thick) into Point Pleasant ls. above and Greendale ls. below, and described it as resting discon. on Cornishville ls. memb. of Perryville ls., with minor discon. at its top. He repeated this classification in 1919 (Dept. Geol. and Forestry of Ky., ser. 5, Bull. 2).

A. F. Foerste, 1924 (Canada Dept. Mines, Geol. Surv. Mem. 138, No. 121 geol. ser., chart opp. p. 58), divided *Cynthiana fm.* into (descending) Rogers Gap, Gratz, Bromley, and Greendale, and showed it as underlying Fulton sh. and overlying Cornishville memb. of Perryville.

Named for Cynthiana, Harrison Co., Ky.

Cypress sandstone. (Of Chester group.)

Mississippian: Southern Illinois and Indiana, western Kentucky, Tennessee, and northwestern Alabama.

H. Engelmann, 1868 (St. Louis Acad. Sci. Trans., vol. 2, pp. 189–190; paper read in 1862). *Cypress sss.*—Quartzose sss. with some shaly portions, about 150 ft. thick, in midst of Lower Carbf. of southern Ill. Overlain by 150 ft. of siliceous lss. and shales and underlain by siliceous lss. and shales, the latter in places aren. Regarded as more fully developed equiv. of Ferruginous [Aux Vases] ss. of Mo.

Later work by S. Weller, E. O. Ulrich, and C. Butts established fact that Cypress ss. is much younger than Aux Vases ss., and present generally accepted definition is that Cypress ss. underlies Golconda fm. and overlies Paint Creek fm. or, to east (in Crittenden Co., Ky.), the Gasper fm., the upper part of which is=Paint Creek fm.

Named for exposures on Cypress Creek, SE. Union Co., Ill.

Cypress Creek chert.

Lower Devonian: Southwestern Tennessee.

C. O. Dunbar, 1917 (Geol. Soc. Am. Bull., vol. 28, p. 207). The remnant of a southward extension of N. Y. Oriskany, for which the name *Cypress Creek chert* is proposed. It is white or yellowish chert carrying fossils [listed]. Separated from overlying Camden chert by a time break, and from underlying Linden sh. and ls. by a longer time break. [Appears to occupy position of Harriman chert.]

Cypress Hills beds.

Oligocene: Saskatchewan.

N. B. Davis, 1918 (Canada Dept. Mines, Mines Branch Rept. clay resources of southern Saskatchewan, p. 11).

Cyrene member (of Edgewood limestone).

Silurian (early): Southwestern Illinois and northeastern Missouri.

T. E. Savage, 1913 (Geol. Soc. Am. Bull., vol. 24, pp. 361, 376). *Cyrene memb.*—Gray to brown ls., 0–15 ft. thick, forming lower fossiliferous ls. phase of Edgewood ls. In places overlain by Bowling Green memb. of Edgewood ls. Upper half to two-thirds of Cyrene memb. is oolitic and=Noix oolite memb.

In later repts this name has been applied to beds beneath Noix oolite memb. See under *Noix oolite memb.*

Named for exposures at Cyrene, Pike Co., Mo.

†Cyril gypsum member.

Permian: Central Oklahoma (Caddo County).

F. G. Clapp, 1920 (Min. and Met., Am. Inst. Mg. and Met. Engrs, No. 158, sec. 27, Feb. 1920). *Cyril gyp. bed.*—Most prominent fm. in Cement field, Caddo Co., Okla. Believed to underlie Whitehorse ss. Rests on a great mass of generally gray sss. of Perm. age. In southern Caddo Co. is thought to be practically synonymous with Blaine fm. There is no sign of division into 3 gyp. beds, as in central Okla.

F. Reeves, 1921 (U. S. G. S. Bull. 726, p. 48). *Cyril gyp. memb. of Greer fm.*—Consists of 2 gyp. beds separated by 0 to 20 ft. of gypsiferous shales. The upper gyp. is massive, pink to white crystalline gyp., with occasional lentils of gray ss. and a thickness of 0 to 85 ft. The lower gyp. resembles the upper gyp., except that at certain localities it is laminated and has appearance of thin-bedded ls.; its thickness is 0 to 40 ft. The Cyril rests uncon. on Day Creek dol. At E. end of Keeche Hills the upper gyp. rests uncon. on Whitehorse ss.

This name is now replaced by *Cloud Chief gyp.*, for reasons stated under *Cloud Chief gyp.*

Named for exposures near Cyril, Caddo Co.

Dadina schist.

Mississippian: Southeastern Alaska (Dadina and Chetaslina Rivers).

W. C. Mendenhall, 1905 (U. S. G. S. P. P. 41, p. 27, map). *Dadina schists.*—Sed. and igneous. Coarse quartz biotite schist along S. side of a tributary of Dadina

River that drains from flanks of Snider Peak. Across the Dadina the rocks consist of (ascending): Near base a succession of dark, bedded, crushed and altered lavas of andesitic type; higher are amphibolite schists, mica schists, and small bodies of gray marmorized lss., all cut by quartz diorite dikes; in gorge of Chichokna Creek several varieties of schist outcrop. The phases of schists on Dadina and Chetaslina Rivers that are not demonstrably igneous are very similar to Klutina series of Schrader. The rocks are pre-upper Carbf., tentatively pre-Sil.

†Daemonelix beds.

A paleontologic name that has been applied to a part (*Daemonelix* zone, lower Mio.) of Arikaree fm. of western Nebr.

Dagger Flat sandstone.

Upper Cambrian: Southwestern Texas (Brewster County).

P. B. King, 1931 (A. A. P. G. Bull., vol. 15, No. 9, pp. 1064–1066). *Dagger Flat ss.*—Oldest rock found in place in Marathon region. Base nowhere exposed. Is exposed in long narrow belts in center of anticlines in both Marathon and Dagger Flat anticlinoria, but widest area of exposure is on S. side of Dagger Flat NE. of Buttrill ranch, where massive sss. form conspicuous ledges. This is type loc. The beds in all places are so intricately contorted that exposed thickness not exactly known, but a probable max. of 300 ft. is found on S. side of Dagger Flat. Here lowest strata are conspicuous ledges, each 4 to 5 ft. thick, of white saccharoidal, moderately coarse-grained ss., weathering pale brown. In places these pass into fine cgl. of rounded vein quartz pebbles, some of which show a notable secondary regrowth of quartz crystals. The massive sss. pass up into flaggy and thinly laminated brown and greenish micaceous sss. with much interbedded sh., the latter predominating toward top. In upper part several layers of laminated calc. brown ss. contain fossils [listed]. There are also several layers of cgl. composed of small block chert, gray ls., and clear quartz pebbles in a brown sandy ls. matrix. To NE. of Woods Hollow Tank nodular layers of sandy ls., which weathers to peculiar chocolate-brown velvety surface, are plentiful. Underlies Marathon ls., but in places younger fms. are overthrust onto Dagger Flat ss. Fossils are Upper Camb., according to E. Kirk and C. E. Resser.

Daggett sand.

A subsurface sand, of early Penn. (Cherokee) age, in Henryetta dist., central eastern Okla., which is reported to correlate with upper Dutcher sand and to lie higher than Deaner sand.

Dagmar limestone.

Middle Cambrian: Central northern Utah (Tintic district).

G. F. Loughlin, 1919 (U. S. G. S. P. P. 107). *Dagmar ls.*—Argill. ls., medium to dark-gray on fresh fracture, yellowish to grayish white on weathered surface; some parts finely banded; others consist of alternating lenses or layers of dense and oolitic rock of medium gray color. Distinct horizon marker. Thickness 75 to 100 ft. Underlies Herkimer ls. and overlies Teutonic ls. Named for Dagmar Mine.

Daguilla diorite schist.

Age (?): Isle of Pines.

C. Schuchert, 1935 (Hist. Geol. Antillean-Caribbean region, p. 526).

Dake quartzite.

Pre-Cambrian: Central southern Wisconsin (Sauk County).

A. Leith, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., fig. 216, pp. 329–330). *Dake qtzite.*—Encountered in 42 diamond drill holes in Baraboo dist., all of which penetrated the qtzite and entered underlying Freedom fm. Thickness varies up to max. of 214 ft., where it is overlain by Rowley Creek sl. It is coarse-grained qtzite containing large amount of sericite and chlorite as a matrix to the quartz grains. Large part of fm. is coarsely conglomeratic, with large and sometimes angular pebbles. Occasionally lower part is loosely cemented with iron oxide, possibly derived from underlying Freedom fm. The qtzite is not known to outcrop, but writer believes that one, and possibly several, surface exposures formerly thought to be the much older Baraboo qtzite are Dake qtzite. One is on S. bank of Baraboo River, near W. Baraboo; another, more extensive, is on a low ridge 2± mi. E. of Baraboo on N. side of main highway from Baraboo to Portage. Because sole description of the qtzite which was found in the drill holes was made by C. L.

Dake, and because writer believes the rock exposed on this ridge is same as that found in the drill holes, he has named it Dake Ridge. There being no other topog. feature after which the fm. could be appropriately named the qtzite is named *Dake qtzite.*

Dakota sandstone.

Upper Cretaceous: North Dakota, South Dakota, southeastern Montana (?), eastern Wyoming (?), eastern Colorado, Nebraska, Kansas, northeastern New Mexico, northwestern Oklahoma.

F. B. Meek and F. V. Hayden, 1862 (Phila. Acad. Nat. Sci. Proc., vol. 13, pp. 419, 420). *Dakota group* (*Formation No. 1 of Cret.*).—Yellowish, reddish, and occasionally white ss., with, at places, alternations of various-colored clays and lignite beds. Thickness 400 ft. Occurs in hills back of town of Dakota; extensively developed in Dakota Co. [Nebr.] below mouth of Big Sioux River, thence S. into NE. Kans. and beyond. Underlies Fort Benton group, of which it may probably be only a memb.

The name *Dakota ss.* has in the past been applied over large areas in the Western States where the correctness of its application has in recent years been seriously questioned. At present the name is restricted by U. S. Geol. Survey to areas E. of Front Range, and the rocks occupying approx. the same strat. position in areas W. of Front Range are tentatively called *Dakota (?) fm.* In some parts of eastern Colo. the name as used by Hayden and other early workers included marine beds of Lower Cret. age now called *Purgatoire fm.* The geographic extent of Purgatoire fm. remains to be determined. In Bellevue section of Larimer Co., Colo., the rocks believed by some geologists to be wholly of Dakota age are divisible into several units, which, although unnamed, are at present collectively called *Dakota group.* Other geologists, however, believe that the Purgatoire is represented in Bellevue section. If the Purgatoire proves to be present in Bellevue section it will be removed from Dakota group of W. T. Lee. The Dakota is chiefly of continental origin.

The ss. in Black Hills region, Wyo.-So. Dak., that for many years was called *Dakota ss.* is now known not to be true Dakota ss., but a ss. of Lower Cret. age, to which the name *Fall River ss.* is now applied. It is opinion of some geologists that the younger Newcastle ss. may be true Dakota of this region, but this is undet.

Dakota moraine.

Pleistocene: South Dakota and southwestern Minnesota.

T. C. Chamberlin, 1883 (U. S. G. S. 3d Ann. Rept., p. 394).

Dakotan series.

A term introduced by C. R. Keyes to cover Dakota ss. and correlated deposits.

Dale quartzites.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, p. 38). *Dale qtzites.*—Qtzites, 2,800 ft. thick, composing basal fm. of Uintan series (Early Cambric) of Utah. Overlain by 100 ft. of unnamed sh. and underlain by Monon series. [Derivation of name not stated.]

Dalhousie limestones.

Silurian: Canada.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 204).

Dalhousie shales.

Lower Devonian (Helderbergian): New Brunswick.

J. M. Clarke, 1911 (N. Y. State Mus. Bull. 149, p. 126).

Dalhousie sand.

A subsurface sand at base of Blairmore fm. of southern Alberta, Canada.

Dalhousie Mountain andesites.

Age (?): Quebec

F. J. Alcock, 1935 (Canada Dept. Mines Geol. Surv. Bur. Econ. Geol. Mem. 183, p. 70).

†Dallas limestone.

Upper Cretaceous (Gulf series): Northern Texas.

R. T. Hill, 1887 (Am. Jour. Sci., 3d, vol. 33, p. 298). *Dallas ls.*—Soft mag. ls., earthy fracture, fine texture, highly foraminiferous; blue on fresh exposure but decomposes and bleaches rapidly. Underlies Navarro beds (*Exogyra ponderosa* marl) [as here used included Taylor marl] and overlies Eagle Ford shales.

Same as Austin chalk, better established name.

Named for occurrence at Dallas.

Dallas deposits.

Pleistocene: Central southern Iowa.

J. L. Tilton, 1913 (Sci., n. s., vol. 38, p. 241; Iowa Acad. Sci. Proc., vol. 20, p. 218). *Dallas deposits.*—Deposits, of whatever nature (partly gravel, partly sand, partly gumbo, either without pebbles or with a few pebbles), formed in closing stages of Kansan ice age as Kansan ice melted, leaving a surface deposit over Kansan drift. Loveland of Shimek and Buchanan gravel correlate in part with these deposits, but have more restricted definitions.

Named for Dallas, Marion Co.

Dalles formation.

Miocene or Pliocene: Central northern Oregon and central southern Washington.

E. D. Cope, 1880 (Am. Phil. Soc. Proc., vol. 19, p. 61; Am. Nat., vol. 14, p. 458). A lacustrine fm. which is found on Columbia River, Oreg. Contains many vegetable remains. *Material is coarse and sometimes gravelly. Prof. Condon in his* unpublished notes calls it *Dalles group.* Overlain by beds of second great volcanic outflow and underlain by lava flow which has furnished the material for the lacustrine fm.

T. Condon, 1902 (The two islands, pp. 13–14, 139, 142, 145). *Dalles group.*—Well-defined ledge of gray ss. Remnant of an old lake bed. All Mio. deposits in Oreg. are disturbed; this deposit was not disturbed. Is a Plio. lake bed. Years ago writer designated [but did not publish] the group of rocks to which this gray ss. belongs as *The Dalles group, Plio.* [He appears to consider Dalles older than his Silver Lake group (Plio.) and younger than his Yakima group (Plio.).]

I. A. Williams, 1916 (Oreg. Bur. Mines and Geol. Min. Res. Oreg., vol. 2, No. 3), practically traces Satsop fm. into *The Dalles beds,* but says he can not say they are exactly equivalent.

J. H. Bretz, 1917 (Jour. Geol., vol. 25, p. 454). In vicinity of The Dalles is a stratified deposit of volcanic aggl., tuff, and ash, with strata of river sand and gravel, 1,000 ft. thick, capped by a flow of gray basalt. Western margin of deposit is uptilted on flank of eastern anticline. Though no pebbles of qtzite or granite were found, it seems probable from strat. evidence that the deposit is a local phase of Satsop fm.

R. W. Chaney, 1921 (Geol. Soc. Am. Bull., vol. 32, p. 137). A collection from *The Dalles group* is of particular interest, since few fossils have previously been obtained from this fm. The flora suggests Plio. or Pleist.

J. H. Bretz, 1921 (Geol. Soc. Am. Bull., vol. 32, pp. 36–37). *The Dalles beds* of Oreg. are thought to be made up of 2 fms.: (1) a post-deformation deposit of volcanic ejectamenta of local origin and small extent, of Pleist. age; and (2) a lower fm. that is thought to be a phase of Satsop fm.

J. P. Buwalda, 1921 (Min. Res. Oreg., Oreg. Bur. Mines and Geol., vol. 2, pp. 19–20). *The Dalles fm.*—White to gray and bluish white beds of ss. and volcanic ash with some cgl. strata. *Apparently deposited in lakes and by streams.* Overlain by basic volcanic rocks and underlain by Columbia River basalt.

J. H. Bretz, 1925 (Jour. Geol., vol. 33, p. 246). At The Dalles, Oreg., there is an upper sed. fm. that has never been described, consisting largely of volcanic debris, and a pre-deformation river deposit commonly known as *The Dalles beds* and in all probability a phase of Satsop fm.

J. P. Buwalda and B. N. Moore, 1927 (Sci., n. s., vol. 67, p. 236). Geologists have differed regarding ages of "Satsop" and *Dalles* fms. Writers have obtained fragmentary mammalian fossils from *Dalles fm.* representing not Quat. but approx. upper Mio. or lower Plio. This age determination is corroborated by lithologic resemblance to middle Neocene Ellensburg fm. of central Wash., by apparently similar relations of the 2 fms. to Columbia lavas, and by induration of Dalles beds, which is = that of lower or middle Neocene deposits of West and is much greater than that of Quat. fms. *Hood River fm.* is new name proposed for unique cgl. and ss. strata underlying Dalles fm. in Columbia River gorge, which was heretofore called "Satsop fm." but is older than typical fossiliferous marine Satsop fm. of Wash. coast. [See also papers by these authors in Geol. Soc. Am. Bull., vol. 39, pp. 116–117, 1929, and Carnegie Inst. Wash. Pub. 404, pp. 11–26, 1930.]

A. M. Piper, 1931 (U. S. G. S. Press Notice 52,343, Apr. 7). *Dalles fm.* of Dalles region uncon. overlies Yakima basalt and uncon. underlies late Plio. or early Pleist. andesite.

Dalmar sand.

A subsurface sand in Cisco group (Penn.) of Archer County, Tex., lying a little more than 300 ft. above Gose sand, and approx. at horizon of Newcastle coal.

Dalton formation.

Lower Cambrian: Western Massachusetts.

B. K. Emerson, 1892 (U. S. G. S. Hawley sheet, i. e., proof sheets of geol. maps and text intended for a geol. folio, but never completed and published in that form, although cited in U. S. G. S. Bull. 191, 1902). [*Dalton phyllite* is shown as underlying Hoosac schist and as overlying [underlying] Cheshire qtzite, which rests on Becket gneiss.]

B. K. Emerson, 1899 (U. S. G. S. Bull. 159), included the Dalton in Cheshire qtzite as defined and mapped. His map included Dalton type loc.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 32–34 and map). *Dalton fm.*—At some places in western Mass. the lowermost Camb. strata consist of gneissoid cgl. having max. thickness of 600 or 700 ft. The pebbles are chiefly quartz (black, blue, and commonly white) but a few are feldspar or gneiss. This cgl. can be traced for miles across Hinsdale and into Washington. Is best exposed at site of former Dalton clubhouse, on high hill S. of Dalton Station, in open pasture farther S., and on SE. to new lookout tower. The cgl. was originally feldspathic and has generally changed to a thin fissile light-colored gneiss or schist in which the muscovite is generally a greasy hydrated sericite. Grades into overlying Cheshire qtzite. Rests uncon. on Becket gneiss. [According to personal communication of B. K. Emerson, the *Dalton fm.* of 1917 publication is same as *Dalton phyllite* of 1892 Hawley sheet.]

Dalton phyllite.

See under *Dalton fm.*

Dalton gneiss.

Pre-Cambrian: Northwestern Connecticut.

W. M. Agar, 1932 (Am. Jour. Sci., 5th, vol. 23, p. 35), mapped a fm. called *Dalton gneiss*, but this name was not mentioned in text, and map did not show town of Dalton.

Dalton sandstone member (of Mesaverde formation).

Upper Cretaceous: Northwestern New Mexico (Gallup region).

J. D. Sears, 1934 (U. S. G. S. Bull. 860A). *Dalton ss. memb. of Mesaverde fm.*—Massive sss. that laterally replace the upper part of Dilco coal memb. of Mesaverde fm. in part of area from Gallup eastward toward Mount Taylor. In N. part of T. 16 N., R. 17 W. this ss. body is 180± ft. thick, and includes only 2 thin beds of softer ss. and sandy sh. To E. it is both split and underlain by beds of marine sh. composing the W. end of Mulatto tongue of Mancos sh. Where split by Mulatto tongue the upper memb. of Dalton ss. is 100± ft. thick and the lower memb. 72± ft. thick. Still further E. both sss. are completely replaced by marine

Mancos sh. Named for excellent exposures at Dalton Pass, where it supports the divide and forms a conspicuous bench in canyon draining to N. Is of Colorado age.

Damascus red shale.

Upper Devonian: Northeastern Pennsylvania (Monroe, Pike, Wayne, Susquehanna, Perry, and Bradford Counties).

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 571, 584–585). *Damascus red sh.* introduced to replace *Montrose red sh.* of I. C. White, preoccupied by Montrose ss. of N. Y., and poorly exposed at White's type loc., Montrose, Susquehanna Co., Pa. Crops out around Beach Lake (also written Beech Lake) on main highway, and thence N. to and along Delaware River, where it is well exposed near Damascus, Wayne Co. At Montrose, Susquehanna Co., it is probably less than 100 ft. thick, in central Wayne Co. 200 ft., near Damascus 400 ft. and possibly considerably more. [Distribution described.] Underlies Honesdale ss. and overlies Paupack ss. memb. of Shohola fm. Is lowest persistent red div. of Catskill group, and is of Canadaway age. North of the Anthracite fields the Damascus overlies New Milford fm.

Dam Lake quartzite.

Pre-Cambrian: Minnesota.

H. B. Ayers, 1911 (Sci., n. s., vol. 33, p. 465). *Dam Lake qtzite.*—The qtzite of Dam Lake (Aitkin Co., Minn.) has been explored by drilling through both contacts with adjoining rock, and results prove it to be Pokegama qtzite, here overlying Keewatin fm.

Damnation limestone.

Middle (?) Cambrian: Northwestern Montana.

C. F. Deiss, 1933 (Mont. Bur. Mines and Geol. Mem. 6, pp. 35 and passim). *Damnation ls.*—Most distinguishing feature is bright buff color to which it weathers. At type loc. consists of platy, dull-gray to tan-gray, fine-grained, fairly pure ls. in beds averaging 1 inch in thickness, with irregular bedding surfaces, and with a few flakes and nodules of buff clay irregularly distributed both btw. and within the lss. Thickness averages 25 ft. Overlies Wolsey sh. (Middle Camb.) and underlies Nannie Basin ls. Forms the steep slope at foot of the cliffs on SW. side of Pagoda Mtn in NE. ¼ sec. 9, T. 22 N., R. 13 W. This slope lies at head of Damnation Creek, which flows SW.

C. F. Deiss, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 1, p. 98), assigned this fm. to Middle Camb. without a query.

Dana diorite.

Late Carboniferous or post-Carboniferous: Central Massachusetts and southwestern New Hampshire.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 244–247 and map). *Dana diorite.*—A broad band of black hornblende-plagioclase rock, generally foliated and then commonly called hornblende schist, which forms a selvage to Monson granodiorite and follows all the sinuosity of its boundary. It also borders all large areas of schistose rocks resting in this gneiss. A second band of white, very fine-grained granite or aplite [New Salem aplite] commonly occurs next inward, separating this mafic zone from the normal coarser gray granite gneiss of central area. The alternating layers of black diorite and white aplite make up the "ribbon gneiss." Is well developed across Ware and Dana, Mass.

Dana.

Name applied to a glacial lake, of Pleist. age, in Great Lakes region. (See U. S. G. S. Mon. 53, 1915, p. 469.)

Danbury granodiorite gneiss.

Pre-Cambrian (?): Western Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 104, 108, and map). *Danbury granodiorite gneiss.*—Presents two important facies—biotite granite and a diorite in which hornblende becomes an important constituent and quartz is less prominent. The two grade into each other, although generally speaking, more hornblende occurs in Greenwich and Wilton areas and parts of

Monroe than in the mass N. of Danbury. The rock is prevailingly porphyritic, with pink or white phenocrysts of feldspar, closely crowded, often attaining a length of 1 to 2 inches. The groundmass in which the larger feldspar crystals are set consists essentially of two varieties of feldspar, quartz, and biotite or hornblende or both. Of igneous origin and intruded before metamorphic action converted igneous and sed. rocks alike into gneisses and schists.

W. M. Agar, 1933 (Am. Jour. Sci., 5th, vol. 25, pp. 1–19). *Danbury granodiorite gneiss* of 1907 map of Conn., by H. E. Gregory and H. H. Robinson, continues into Westchester Co., N. Y., where it is called *Harrison diorite*. It includes a number of more or less intermingled rock types whose different phases are not equally developed in all areas in which they occur. It is not a unit but a very variable fm., usually with high content of hornblende and a porphyritic aspect. It grades into biotite schists and quartz-oligoclase-biotite gneisses and all these types are intersected and sometimes intimately penetrated by granite and pegmatite. Writer tentatively places the complex in pre-Camb. with probably exception of the youngest granite, which may be as young as Ord.

W. M. Agar, 1934 (Am. Jour. Sci., 5th, vol. 27, pp. 354–373). *Danbury gneiss* is in part composed of Thomaston granite. It intrudes Grenville.

Danby formation.

Lower Cambrian: Southwestern Vermont (Rutland County).

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 396). *Danby fm.*—Is a departure from the usual carbonate deposits of the Valley. Great variety of beds in the fm., but they are separated from the other fms. chiefly by amount of ss. and qtzite and by their varicolored dolomites. The qtzite beds are composed of clean white sand, in layers 1 or 2 ft. thick, interbedded with massive dolomites like those of underlying Rutland dol., and with transitional strata, like sandy dolomites and ss. The qtzite beds usually stand out like white reefs above the other layers. Some peculiar dolomites, of pink, buff, and green colors, also occur. These are very fine-grained and tough and form ridges. Associated are thin seams and layers of greenish sl. Beds considerably folded. Thickness 300± ft. Grades into overlying Wallingford dol. Is=Hubbardton sl., Stiles phyllite, and Brezee phyllite.

Named for fact that it surrounds town of Danby, Rutland Co., in Wallingford quad.

Danby member.

A term applied by G. H. Chadwick (Pan-Am. Geol., vol. 60, 1933, pp. 99, 348, 349, 350, 354) to *Dalmanella danbyi* zone of Cayuta sh. memb. of Chemung fm. of central southern N. Y.

Danforth member (of Dundas formation).

Ordovician: Ontario.

W. A. Parks, 1925 (Ontario Dept. Mines 32d Ann. Rept., pt. 7, p. 107).

Danforth formation.

Pliocene: Southeastern Oregon (Harney Basin).

A. M. Piper, T. W. Robinson, and C. F. Park, Jr. (U. S. G. S. W. S. P. in press). *Danforth fm.*—In vicinity of Burns the upper part consists of a distinctive rhyolitic tuff-breccia memb., also stratified siltstone, ss., tuff, and volcanic ash, with layers of glassy or perlitic rhyolite at a few horizons; and the lower part consists of massive rhyolite, commonly spherulitic. In dist. S. of Harney Playa the fm. consists of (descending): (1) the distinctive tuff-breccia memb. and associated rocks; (2) an equally distinctive basaltic breccia memb. and associated siltstone, ss., and cgl. and 2 intercalated layers of basalt; (3) stratified siltstone, ss., and ash; and (4) spherulitic rhyolite. Thickness 20 to 800+ ft. Rests uncon. on Steens basalt. Is uncon. overlain by Harney fm. in some areas and by fangl. that may be younger than Harney fm. in other areas. Named for Danforth Ranch.

†Dannemora formation.

Pre-Cambrian: Northeastern New York (Clinton and Franklin Counties).

H. P. Cushing, 1901 (N. Y. State Mus. 53d Ann. Rept., pt. 1, pp. r36 to r69 and map). *Dannemora fm.*—A complex of gneiss and granite. Gneisses of unknown origin (probably mostly igneous, in part certainly igneous), and include four varieties, which grade into one another through intermediate varieties. Whether Dannemora rocks are older, younger, or of same age as sedimentary Grenville rocks does not appear. If there is any fm. in northern Adirondack region which is= Ottawa gneiss of Canada, or which may be of Archean age (in restricted sense in which that term is now employed by U. S. Geol. Survey) it is this Dannemora fm. Unfortunately, in the dist. in Clinton and Franklin Counties where it prevails, the Grenville series is practically absent. Very similar gneisses are associated with undoubted Grenville rocks in western Adirondacks. In ordinary Dannemora gneiss garnet is rare but it is abundant in the Grenville gneisses. The fm. is well exposed all over Dannemora Mtn and throughout Dannemora Twp, Clinton Co.

H. P. Cushing, 1902 (N. Y. State Mus. 54th Ann. Rept., pt. 1, pp. r81 to r82). *"Dannemora" fm.*—Closely interbanded with the lss. and schists of the Grenville are granitic, gabbroic, and other gneisses which seem to represent closely contemp. igneous intrusions. In other districts (Clinton Co., for example) these or similar gneisses are found by themselves and represent the fundamental gneiss, if that fm. appears at all in Adirondack region. From difficulty of establishing this and of defining any separation from Grenville rocks, the writer a year ago proposed to refer such rocks to "Dannemora" fm., the term being wholly provisional, and to apply to areas of gneiss where the distinctive rocks of the Grenville are absent, yet whose proper reference to the fundamental gneiss is wholly doubtful. It is thought likely these rocks belong with Grenville series, but it is convenient to give them a separate designation for present. In western Adirondacks Smyth's recent work has shown an abundance of a granitic gneiss which has unmistakable irruptive contacts against the Grenville rocks quite like those to N. in Canada. Whether these granites are the equivalents of those in the eruptive center of the Adirondacks, or of the Dannemora granitic gneiss, or are wholly distinct from either, seems entirely uncertain.

H. P. Cushing, 1905 (N. Y. State Mus. Bull. 95). *Doubtful gneisses (Saranac fm.)*.—Red acid gneisses, practically but not utterly free from Grenville admixture and at same time seem to have no connection with the later igneous intrusions; often interbanded with and often in large masses are two other kinds of gneiss of common occurrence, gray and black. Nearly all or quite all seem to be igneous. Uncertain whether same as Ottawa gneiss of Canada. *Saranac fm.* is here introduced to replace "Dannemora fm.," because of possible confusion of latter name with a noted Scandinavian locality. The rocks are well exposed along Saranac River, Clinton Co., and its near vicinity.

D. H. Newland, 1908 (N. Y. State Mus. Bull. 119, pp. 8–22). *Saranac fm.*—Gneisses of undet. origin. Mainly red acid gneisses, but other gneisses also present. More detailed investigation may resolve them into elements which can be classed with the igneous or the sed. series, but they have been found so far to have no well-defined connection with either. Principal area of these gneisses seems to be on northern borders in Clinton and Franklin Counties.

H. L. Alling, 1919 (N. Y. State Mus. Bull. 207, 208, pp. 113–145). North of town of Saranac Lake are a variety of gneisses and granitelike rocks that are today a puzzle to most observant and careful workers. Some may be igneous but others are sed. These doubtful gneisses are sometimes referred to as *Saranac fm.* Many of these gneisses are certainly later than the Grenville. Some of granites may be older than Grenville, but this is not determined.

W. J. Miller, 1919 (Jour. Geol., vol. 27, pp. 28–54). The Lyon Mtn granite is perhaps most conspicuous memb. of Cushing's Saranac fm.

†Dan River series.

A name applied by E. Emmons (Geol. Rept. of Midland Counties of N. C., N. C. Geol. Surv., 1856) to the Upper Triassic rocks (Newark group) of Dan River region of central northern No. Car.

Danville stage.

Pennsylvanian: Western Arkansas coal field and central eastern Oklahoma.

A. Winslow, 1896 (N. Y. Acad. Sci. Trans., vol. 15, p. 51). *Danville stage.*—Undiff. Coal Measures, underlying Appleton stage in Ind. Terr. and Ark. Thickness not measured.

Represents lower part of Atoka fm.

Probably named for Danville, Yell Co., Ark.

Danville Landing group.

Danville Landing beds.

Synonymous terms applied to uppermost part of Jackson fm. of La. and Miss. by M. A. Hanna, D. Gravell, and J. McGuirt (11th Ann. Field Trip Shreveport Geol. Soc., 1934, table opp. p. 30, pp. 35–37). Not described, but said to correspond to Cocoa sand of Cushman and to be younger than typical Cocoa sand. Said to overlie Yazoo "group," but apparently the beds were in previous repts included in Yazoo of Miss. Fossils mentioned. Danville Landing is said to be on Ouachita River in Catahoula Parish, La.

Darby formation.

Upper and Middle Devonian: Northwestern Wyoming.

E. Blackwelder, 1918 (Wash. Acad. Sci. Jour., vol. 8, p. 420). *Darby fm.*—Introduction of this new name is made necessary because none in present use fits stratigraphy of western Wyo. The Darby is apparently = Peale's Three Forks sh. plus upper part of his Jefferson ls. It rests discon. on Leigh dol. memb. of Bighorn dol., and in some places on underlying massive memb. of the Bighorn. It is separated from overlying Madison ls. locally, if not generally, by eroded surface. Consists of a varied sequence of shales and dolomites, of white, gray, green, lavender, buff, red, brown, and black colors; but somber colors predominate. Some beds are massive, others thin and brittle. Fossils rare. Named for canyon of Darby Creek, on W. slope of Teton Range, where well exposed. Extends over most of NW. Wyo. [Gives detailed section (footing 428½ ft.) on E. slope of Sheep Mtn near head of Green River.]

Daredevil formation.

Pre-Cambrian: Kenora district, Ontario.

F. J. Pettijohn, 1935 (Geol. Soc. Am. Bull., vol. 46, pp. 1895, 1900, map, etc.).

Darien moraine.

Pleistocene (Wisconsin stage): Southern Wisconsin. Shown on moraine map (pl. 23) of U. S. G. S. P. P. 106. Named for Darien, Walworth Co.

Darling oil sand.

A subsurface oil sand in Warren Co., Pa., stated by Carll (1883) to lie 190 ft. higher than Sheffield or Blue Jay oil sand and lower than Balltown oil sand. Probably of Chemung age.

Darling sand.

A subsurface sand in lower part of Kootenai fm. (Lower Cret.) in Cutbank dist., Glacier Co., NW. Mont. According to J. G. Bartram (Geol. of nat. gas, A. A. P. G., 1935, pp. 257, 267) this sand is now called *Cutbank sand.*

Darlington shale. (In Allegheny formation.)

Pennsylvanian: Southwestern Pennsylvania (Beaver County).

J. P. Lesley, 1878 (2d Pa. Geol. Surv. Rept. Q, pp. 308–316). [See under *Darlington underclay.*]

Darlington underclay. (In Allegheny formation.)

Pennsylvanian: Southwestern Pennsylvania (Beaver County).

J. P. Lesley, 1878 (2d Pa. Geol. Surv. Rept. Q, pp. 308–316). [The following succession of beds is given (descending): Darlington coal (Upper Kittanning); *Darlington underclay; Darlington shales; Darlington plant bed;* Kittanning coal.]

Darlington plant bed. (In Allegheny formation.)

Pennsylvanian: Southwestern Pennsylvania (Beaver County).

J. P. Lesley, 1878 (2d Pa. Geol. Surv. Rept. Q, pp. 308–316). [See under *Darlington underclay.*]

Darlington granodiorite.

Jurassic (?): British Columbia.

W. L. Uglow, 1922 (Canada Geol. Surv. Summ. Rept. 1921, pt. A, p. 80).

Dashner limestone.

Pennsylvanian: Northeastern Kansas.

R. C. Moore, Sept. 4–7, 1936 (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 41). *Dashner ls.*—Basal memb. of Topeka ls. Rests on Calhoun sh. and underlies Jones Point sh. Consists of light-bluish ls. that weathers brown, fine grained, dense, massive; upper 1 ft. contains chert nodules and *Osagia;* lower 2½ ft. has some large *Triticites, Allorisma,* and *Osagia.* Brachiopods and Bryozoans common throughout. Thickness 5½ ft. [Derivation of name not stated.]

G. E. Condra and E. C. Reed, June 1937 (Nebr. Geol. Surv. Bull. 11, 2d ser., p. 52). Dr. Moore in 1935 [not regarded as publication] and again in 1936 (10th Ann. Field Conf. Kans. Geol. Soc. Guidebook, p. 41) used "Dashner ls." for the lower memb. of Topeka ls. but in a publication issued in 1936 (Kans. Geol. Surv. Bull. 22, pp. 194, 195 [issued Aug. 31, 1936]) did not use the name. Dr. Moore states (personal communication) that his type loc. is Dashner farm, SE. of Haynies Station (now Sargents siding) in Iowa. The interval which Moore classified as "Dashner" at his type loc. appears to have included not only the interval which he classified as "Dashner" in Kans. River Valley, but also the Iowa Point sh. and Curzen ls. members. This memb. is too poorly defined on Dashner farm to permit its being a good type loc. But at mouth of Wolf River the Wolf River ls. is separated from Curzen ls. above by 10± ft. of sh. and shows as complete a development as was seen in all of area covered in this study. In view of these facts and because Dr. Moore may have abandoned "Dashner," writers feel they are justified in giving new name *Wolf River* to lower memb. of the Topeka, defining a type loc. where it is well developed and clearly set off from other ls. members both above and below.

Datil formation.

Tertiary (probably late): Southwestern New Mexico (Alamosa Creek Valley, Socorro County).

D. E. Winchester, 1920 (U. S. G. S. Bull. 716A). *Datil fm.*—Well-indurated tuffs, rhyolites, cross-bedded sss., and cgls. Members very variable. Thickness 2,000± ft. Underlies Quat. gravels and uncon. overlies Chamiso (Upper Cret.) and older fms. No fossils. Regarded as probably late Tert. Named for fact it is the mountain-forming series of Datil Mtns.

Daube member (of Hoxbar formation).

Pennsylvanian: Central southern Oklahoma (Carter County).

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z, p. 16). Some 600 ft. above Anadarche memb. of Hoxbar fm. is *Daube memb.* of Hoxbar, including a ls. similar to Anadarche ls., associated in one locality with a ls. cgl. Just below Daube ls. occurs only bed of coal known in Ardmore basin. It reaches max. reported thickness of 4 ft., and is known for at least 4 mi. along the strike in T. 5 S., R. 2 E. Above Daube ls. the upper 1200 ft. of Hoxbar fm. consist of tan to brown shales with several sandy lss. or calc. sss., including *Zuckerman sandy ls. memb.*

C. W. Tomlinson, 1929 (Okla. Geol. Surv. Bull. 46, p. 44). Some 400 to 600 ft. above Anadarche memb. occurs the 10-foot *Daube ls.,* so named for occurrence at abandoned coal mine of Daube, Westheimer, Munzesheimer, and Zuckerman, in SE¼ of sec. 8, T. 5 S., R. 2 E. Of similar character to Anadarche ls. Immediately beneath it lies only known coal bed (4 ft. thick) in Ardmore Basin. Lies 400 to 500 ft. below Zuckerman memb. of Hoxbar fm.

Davenport beds.

Middle and Upper Devonian: Eastern Iowa.

W. H. Norton, 1894 (Iowa Acad. Sci. Proc., vol. 1, pt. 4, p. 24). The name *Lower Davenport beds* is suggested for lower nonfossiliferous ls. at Davenport, which furnished the fragments for second stage of Fayette breccia; and *Upper Davenport beds* is suggested for fossiliferous ls. overlying Lower Davenport beds and heretofore called *Gyroceras* beds, also included in Fayette breccia. The Lower Davenport beds overlie Kenwood beds.

In 1895 (Iowa Geol. Surv. vol. 4, pp. 121+) Norton introduced *Wapsipinicon stage* for beds underlying Cedar Valley ls. and overlying Coggon substage, and included in it the Davenport, Kenwood, and older beds. In 1901 Norton transferred his Coggon beds to Dev. and to Wapsipinicon ls. This definition of Wapsipinicon ls. was followed for many years; but in 1928 (Iowa Univ. Studies, vol. 12, No. 7, n. s. No. 14) C. H. Belanski treated Upper Davenport beds of Iowa Geol. Survey as basal memb. of Cedar Valley ls., "in accordance with field work done by M. A. Stainbrook (unpublished thesis, State Univ. of Iowa)." Rept. 9th Ann. Field Conf. Kans. Geol. Soc., 1935, fig. 1, divided Wapsipinicon ls. into (descending) Davenport memb., Spring Grove memb. (new name), Kenwood memb., Otis memb., and Coggon memb. and showed *Davenport memb.* as older than Independence sh., a distinct fm. (See also under *Independence sh.*) In this same vol. (p. 260) M. A. Stainbrook stated: "Upper" Davenport is sublithographic and belongs to Cedar Valley ls. [Upper Dev.].

Davenport member.

Upper Ordovician: Toronto, Canada.

W. A. Parks, 1924 (Geol. Soc. Am. Bull., vol. 35, pp. 103–104).

See quotation under *Dundas fm.* Type loc. not stated.

†David City formation.

Pleistocene (early Nebraskan): Eastern Nebraska.

A. L. Lugn and G. E. Condra, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, p. 190). *David City fm.* (early Nebraskan), a gravel and sand deposit 20 to 100 ft. thick is at base of Pleist. section in eastern Nebr. Is overlain by Nebraskan till and gumbotil up to 100 ft. in thickness.

A. L. Lugn, 1934 (Nebr. State Mus. vol. 1, Bull. 41, pp. 326, 332–333). *David City fm.* (Nebraskan) consists of outwash fluvioglacial material of sand, gravel, and some clay. Thickness few ft. to 150 ft. Underlies Nebraskan till and is believed to be of Nebraskan age. Is widespread, but not a continuous sheet, because of bedrock on which it was deposited. Fills old buried pre-Pleist. valleys. Said to be 150 ft. thick E. of David City, where it has been penetrated in deep test wells. Rests uncon. on Cret.

Davidson sands.

Davidson shallow sand has been applied to a subsurface sand in Brazil fm. (Penn.) of Ind. and *Davidson deep sand* to a subsurface sand of Chester (Miss.) age in Ind. that has been correlated with Tar Springs ss.

Davidson granophyre.

Pre-Cambrian: Southwestern Oklahoma (Wichita Mountains).

M. G. Hoffman, 1930 (Okla. Geol. Surv. Bull. 52, pp. 39–48). *Davidson granophyre.*—Very fine-grained to dense granophyre, of light pink to dark gray color, with blackish streaks. Is a fine-grained intergrowth of quartz and alkali feldspar. Outcrops in W. half of Davidson Hill and NW. along Little Medicine Creek for about ½ mi. Considered younger than Saddle Mtn granophyre and older than Carlton granophyre. Is intruded by Lugert granophyre.

†Davion rock.

Miocene: Southern Mississippi.

B. L. C. Wailes, 1854 (Rept. Agric. and Geol. Miss., pp. 214–216). *Davion Rock of Fort Adams.*—Ss. of argillo-siliceous composition, dingy white color, small proportion of sand, cemented together and tinged by brownish red metallic oxide. [Distribution described. Seems to regard it same as †Grand Gulf ss.]

E. N. Lowe, 1915 (Miss. Geol. Surv. Bull. 12, p. 90). *Davion rock* (*Miocene ?*), 350 to 400 ft. thick, sandy clay rock of light gray to brownish gray color with a cementing material of reddish brown to purple iron oxide. Should probably be considered a fm. in Grand Gulf group. Underlies Pascagoula fm. and overlies Grand Gulf ss.

The Davion Rock of Wailes is now considered to probably be Catahoula ss. The Davion rock of Lowe is Hattiesburg clay, in whole or in part.

Named, according to E. N. Lowe, for outcrops in precipitous bluff at Fort Adams, Wilkinson Co., "which is now usually called Fort Adams Hills, but is also called Loftus Heights, a name by which it was exclusively known in early part of 19th century. During the French occupation of Miss., about beginning of 18th century, this bluff was called La Roche à Davion, so named for a pious and devoted priest of that name, who had established a mission there."

Davis formation. (In Elvins group.)

Upper Cambrian: Missouri.

E. R. Buckley, 1907 (Mo. Bur. Geol. and Mines vol. 10, 2d ser., *separate*), in a table divided Elvins fm. into (descending) Doe Run, Derby, and Davis, without defining the subdivisions.

H. A. Buehler, 1907 (Mo. Bur. Geol. and Mines vol. 6, 2d ser., p. 231). *Davis fm.*—Bluish, impure, calc. sh. intercalated with thin beds of mag. ls. and dol. Underlies Derby and overlies Bonne Terre. Thickness 100 ft.

E. R. Buckley, 1909 (Mo. Bur. Geol. and Mines vol. 9, pt. 1, p. 33). *Davis fm.*—Much blue sh. with aren. dol., ls., and ls. cgl. Thickness 150 to 190 ft. The persistent Central marble boulder memb. lies 63 ft. below top. Underlies Derby fm. and overlies Bonne Terre fm. Is lower part of Elvins fm. of Ulrich.

G. W. Crane, 1912 (Mo. Bur. Geol. and Mines vol. 10, 2d ser.). *Davis fm.*—Mainly alternating beds of soft sh., shaly ls., and cgl. Upper memb., 70 ft. thick, can be distinguished from lower memb. by comparative abundance of soft sh. beds from a few inches to 9 ft. thick, and by absence of "edgewise" cgl. Lower memb. consists of 100 ft. of very shaly mag. ls., thin beds of "edgewise" cgl., and thicker beds of soft sh. with horizontal thin plates or discs of ls. Overlies Bonneterre fm. and conformably underlies Derby fm.

H. A. Buehler, 1917 (Am. Inst. Min. Engrs. Bull. 130, pp. 1699–1718). *Davis sh.*—Chiefly thin-bedded dolomitic ls. and sh. with several layers of edgewise cgl., the latter chiefly in lower part and distinctive of fm. A boulder horizon of pure ls., the boulders usually less than 6 ft. thick, lies 100 ft. above base.

Named for outcrops on Davis Creek, St. Francois Co.

Davis oil and gas horizon.

Name applied to 85± ft. of lenticular subsurface sands, ls., and sh. in Cotton Valley field, Webster Co., NW. La., stated to lie at a horizon corresponding to a lower part of Glen Rose fm. of Trinity group (Lower Cret.). Named for lease on which first well was drilled to these beds. Includes at top a bed that has been called *Tillman sand lens*, and lower down a bed that has been called *Bodcaw sand lens.*

Davis Creek beds.

Miocene: Northwestern Nevada (Washoe County).

R. W. Chaney, 1924 (Geol Soc. Am. Bull., vol. 35, pp. 162–163). *Davis Creek beds.*—A series of tuff, ss., and sh. underlying Modoc lavas in Washoe Co. Fossil plants in white diatomaceous ash in these beds seem to clearly establish their Mio. age.

Dawn limestone member (of Monte Cristo limestone).

Mississippian (lower): Southeastern Nevada (Goodsprings region).

D. F. Hewett, 1931 (U. S. G. S. P. P. 162, pp. 10, 17, etc.). *Dawn ls. memb.*—Thin-bedded dark-gray ls.; little chert; in large part of area altered to dol. Thickness 60 to 400 ft. Many lower Miss. fossils. Basal memb. of Monte Cristo ls. Underlies Anchor ls. memb. Well exposed W. of Dawn mine, SW¼ sec. 15, T. 23 S., R. 58 E., Goodsprings quad.

Dawson arkose.

Upper Cretaceous and Eocene (?): Eastern Colorado (Douglas County region).

G. B. Richardson, 1912 (Geol. Soc. Am. Bull., vol. 23, pp. 267–276). *Dawson arkose.*—Varicolored cgl., ss., sh. and clay, rhyolitic tuff and lava, but chiefly sss. and arkosic grits, with basal cgl. Thickness 2,000 ft. Contains vertebrates of Eocene age, according to Gidley. Is basal fm. of Monument Creek group of Hayden. Uncon. underlies Castle Rock cgl. and uncon. overlies Laramie fm. Lower part is regarded as = Arapahoe and Denver fms. [See also G. B. Richardson, U. S. G. S. Castle Rock folio, No. 198, 1915.]

The age of this fm. (previously classified as *Eocene*) was changed, in Dec. 1935, to *Upper Cret. and Eocene (?)*, as explained under *Lance fm.*, last entry.

Named for Dawson Butte, about 6 mi. SW. of Castle Rock, Douglas Co.

Dawson sand.

Drillers' name for a sand in Mauch Chunk sh. (Miss.) of W. Va. that probably corresponds to Droop ss. memb. of W. Va. Survey.

Dawson.

Name applied to a Pleist. glacial lake in Great Lakes region. (See H. L. Fairchild, Geol. Soc. Am. Bull., vol. 43, No. 3, p. 614, 1932.)

Day Creek dolomite. (In Cimarron group in Kansas; in Woodward group in Oklahoma.)

Permian: Central southern Kansas and northwestern Oklahoma.

F. W. Cragin, 1896 (Colo. Coll. Studies vol. 6, pp. 3, 44). *Day Creek dol.*—Nearly white true dol., 1 to 5 or more ft. thick, overlying Red Bluff sss. [Whitehorse ss. of present nomenclature] and underlying Hackberry shales in Kans. Included in Kiger div.

For subsequent interpretations see under *Quartermaster fm.*

R. W. Sawyer, 1929 (Okla. Geol. Surv. Bull. 40HH). The term "Day Creek dol." of Cragin has been applied to Weatherford dol., Greenfield dol., and Quartermaster dol. It is believed its continued use will only serve to confuse. Writer does not know what bed, if any, in SW. Okla., corresponds to Day Creek dol. of Kans.

N. Evans, 1931 (A. A. P. G. Bull., vol. 15, No. 4, pp. 405–432). *Day Creek dol.* has 2 members, Upper and Lower Day Creek dolomites, separated by 1 to 3 ft. of brown to maroon sh. The Day Creek was formerly supposed to occur below Cloud Chief gyp. In this paper it is placed above Cloud Chief gyp. and conformably below Quartermaster fm. The Day Creek of type area (central Clark Co., Kans.) consists of 2 ft. of hard light-gray ls. or dolomitic ls. Characteristic Whitehorse sand and sh. are below it, and above is the dark red or maroon sh. which makes a contrast in color to the reddish buff of the Whitehorse below. In this type area the Day Creek commonly contains aggregates of smoky or reddish chert. In Okla., particularly in eastern Harper, western Woods, and NE. Woodward Counties, this same description applies to the Day Creek. Here, however, occurs a pinkish or purplish calcitic or dolomitic bed, about 3 inches thick, 3 ft. above *Lower Day Creek dol.* It seems well to include this upper thin dol. bed as a part of the Day Creek and it is here called *Upper Day Creek dol.* and the lower bed, which was called originally the *Day Creek*, is here called *Lower Day Creek dol.* Brown sh., weathering maroon, separates these 2 dolomites. It is not recalled whether this Upper Day Creek bed occurs at type area in Clark Co., Kans., but it probably does, as it is widespread in its exposures in NW. Okla. Unless removed by erosion this Upper Day Creek dol. can almost everywhere be found above horizon of the Lower Day Creek. To W. and S. of Supply the Lower Day Creek becomes very sandy and even grades into ss. [Mentions localities where "the Lower Day Creek horizon is merely the top of Whitehorse ss. and Upper Day Creek is poorly exposed."] The Day Creek dolomites are somewhat lenticular or grade laterally into sand or sh. Their horizon can be definitely placed by sequence of beds and change from Whitehorse fm. to Quartermaster.

S. Buckstaff, 1931 (A. A. P. G. Bull., vol. 15, No. 4, pp. 434–437), does not regard Mr. Evans's interpretation of strat. relations of various fms. as proved.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232), does not recognize this unit in Tex.

D. A. Green, 1936 (A. A. P. G. Bull., vol. 20, No. 11, p. 1474). Which of the dol. beds of lower part of Quartermaster fm. is = Day Creek dol. of NW. Okla. is open question.

Named for Day Creek, Clark Co., Kans.

Day Point limestone.

Lower Ordovician: Eastern New York (Champlain Valley).

H. P. Cushing, 1905 (N. Y. State Mus. Bull. 95), adopted the subdivisions of the Chazy proposed by E. Brainerd and H. M. Seely in 1888 (Am. Geol., vol. 2, pp. 323–330), as explained under *Chazy group*, and proposed *Day Point ls.* for group A or lower Chazy, which is well exposed at Day Point, Peru Twp, Clinton Co.

Dayton limestone.

Silurian (Niagaran): Southwestern Ohio.

E. Orton, 1870 (Ohio Geol. Surv. Rept. Prog. 1869, p. 143) and 1871 (Ohio Geol. Surv. Rept. Prog. 1870, pp. 271, 297, 299–301, 309, fig. 1, opp. p. 310). *Dayton stone* (1870 rept.), *Dayton ls.* (1871 rept.). Even-bedded massive ls. 5 to 10 ft. thick, sparingly charged with fossils and containing at least 90 per cent of carbonate of lime. Lowest memb. of Niagara group in Montgomery and Highland Counties. Overlain by Niagara sh. and underlain by Clinton [Brassfield] ls.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 28), assigned this ls. to Clinton epoch, as did A. F. Foerste, 1931 (Ky. Geol. Surv., ser. 6, vol. 36, pp. 172, 173). He gave further details on pp. 138, 149–150, listed the fossils, and stated that in Adams and Highland Counties it is conformably overlain by Alger clay.

A. F. Foerste, 1935 (Denison Univ. Bull., Jour. Sci. Lab., vol. 30, p. 133), stated *Dayton ls.* is probably younger than Oldham ls.; is typically exposed in vicinity of Dayton, Ohio; and is probably lower Clinton.

†Dayton moraine.

See under *Lake Escarpment morainic system.*

Deadman limestone.

Triassic (?): Southeastern Idaho.

G. R. Mansfield, 1915 (Wash. Acad. Sci. Jour., vol. 5, p. 492). *Deadman ls.*, 150 ft. thick. A memb. of Nugget ss. of Fort Hall Ind. Res. Overlies Higham grit and underlies Wood sh.

G. R. Mansfield, 1916 (Wash. Acad. Sci. Jour., vol. 6, pp. 32, 41). *Deadman ls. memb. of Nugget ss.*—Dense purplish-gray ls. of almost lithographic quality, with subordinate amounts of gray and greenish chert. Thickness 150± ft. Overlies Higham grit memb. of Nugget and underlies Wood sh. memb. of Nugget. Named for Deadman Creek, in NE. part of T. 4 S., R. 38 E. Boise meridian, in NE. part of Fort Hall Ind. Res., near headwaters of which it is exposed.

G. R. Mansfield, 1920 (U. S. G. S. Bull. 713, pp. 29, 52), treated Deadman ls., Wood sh., and Higham grit as distinct fms., and restricted Nugget ss. to upper part ("main ss. memb.") of Nugget ss. as recognized by him in previous repts. This is present generally accepted definition.

Deadman Island beds.

Pleistocene: Southern California.

J. P. Smith, 1910 (Jour. Geol., vol. 18, chart opp. p. 217), applied *Deadman Island beds* to lower part of San Pedro fm. and *Los Cerritos beds* to upper part of San Pedro.

U. S. Grant, IV, and H. R. Gale, Nov. 3, 1931 (Mem. San Diego Soc. Nat. Hist., vol. 1, pp. 37, 43). *Deadman Island "Plio."* [of some early repts] is here called *Timms Point zone,* because Deadman Island no longer exists; and, because of its cold-water fauna, it is correlated with a glacial age and assigned to Pleist. Deadman Island was an island formerly located in San Pedro Harbor but has now been entirely removed by steam shovels.

Deadwood formation.

Upper Cambrian: Western South Dakota (Black Hills), eastern Wyoming, and southeastern Montana.

N. H. Darton, 1901 (U. S. G. S. 21st Ann. Rept., pt. 4, p. 505). *Deadwood fm.*—Red brown qtzite and ss., locally conglomeratic, and partly massive. Thickness 4 to 150 ft. in Black Hills. Upper part is thinner bedded softer sss., in some cases interbedded with more or less sh. Basal memb. is usually hard massive reddish brown qtzite; portions of basal beds are conglomeratic, ranging from a sprinkling of quartz pebbles in the ss. to a very coarse heavy cgl. of large rounded masses of crystalline rocks and vein quartz in a red-brown matrix. Rests uncon. on pre-

Camb. granites and schists and underlies Englewood ls. [Miss.]. In northern Black Hills is separated from Englewood ls. by a mass of buff ls. of Sil. age [Whitewood ls., of pre-Richmond Upper Ord. age].

W. M. Furnish, E. J. Barragy, and A. K. Miller, 1936 (A. A. P. G. Bull., vol. 20, No. 10, pp. 1329–1341), reported finding of poorly preserved Ord. (Middle?) fossils [listed and figured] in upper 70 ft. of Deadwood fm. of type section, and they recommended transfer of these beds from Deadwood fm. to overlying Whitewood ls. (which is classified by U. S. Geol. Survey as Upper Ord.). These 70 ft. of beds are described as consisting of (descending): (1) Transitional, 10 ft.; (2) siltstone memb., 20 ft., numerous fossils; and (3) sh. memb. 40 ft., few fossils. They rest on a ss., called "Scolithus ss.," 15 ft. thick, which has not yielded fossils. Authors conclude with following statements: Data presented seem to indicate that all beds in northern Black Hills above Scolithus ss. and below typical Whitewood dol. may be correlated with Middle Ord. Nó diagnostic fossils were found in Scolithus ss. or subjacent beds, and their age was not determined. Typical Whitewood dol. presumably is Upper Ord. It seems advisable for the present at least to include all Ord. beds above Scolithus ss. in Whitewood fm.

Deadwood Gulch rhyolite tuff.

Tertiary: Mogollon district, New Mexico.

H. G. Ferguson, 1927 (U. S. G. S. Bull. 787). *Deadwood Gulch rhyolite tuff.*—White banded rhyolite, in small fragments, in an exceedingly fine-grained siliceous matrix. Thickness 10 to 400 ft. Older than Mogollon andesite and younger than Last Chance andesite.

Named for exposures in upper part of Deadwood Gulch, Mogollon dist.

Deanefield shale. (In Pottsville formation.)

Pennsylvanian: Western Kentucky (Hartford quadrangle).

J. H. Gardner, 1927 (Ky. Geol. Surv., ser. 6, vol. 26, pp. 135, 137, 153). *Deanefield sh.*—Very dark sandy clay sh., which weathers brownish gray. Thickness 75 ft. Holds Hamlin coal, about 25 ft. above base. Included in lower part of Pottsville group. Extends throughout territory from Butler to Daviess Counties, and is widely exposed around Deanefield and Fordsville. Forms surface rock, capped by Aberdeen ss., over large portion of Whitesville and Owensboro quads.

Deaner sand.

A subsurface sand, 0 to 60± ft. thick, of early Penn. or late Miss. age, in Okla., correlated by some with lower part of Dutcher sand series (Penn.) and by others with Miss. In type region (Deaner-Clearview pool, Okfuskee Co.) the sand lies at 2,800 ft. depth and Lyons sand at 3,150 ft. depth. Considered younger than Kingwood sand.

Dean Lake chert member.

Mississippian: Northwestern Montana.

C. F. Deiss, 1933 (Mont. Bur. Mines and Geol. Mem. 6, pp. 47 and passim). *Dean Lake chert memb.*—Generally thinnest memb. of Madison ls. in this area but the most persistent and striking. Outstanding characteristics are great amount of black, blue-black, and dark-gray chert, which occurs as nodules and as intercalated beds btw. the lss. In type loc. lower 23 ft. is blackish-gray lss. interbedded with black-gray and dull tan-gray chert in nodules up to 5 inches diam. Upper 37 ft. massive, blue gray, thick-bedded lss. with crinoid stems and brachiopod fragments, interbedded with beds of very fossiliferous dark chert up to 7 inches thick. Thickness 51 to 74 ft. Underlies Rooney chert memb. and overlies Saypo ls. memb., all in Madison ls. Named for small cirque lake lying at foot of cliffs that form upper part of E. side of Pentagon Mtn. Type loc. SE. side of the mtn, in SW¼ sec. 14, T. 25 N., R. 14 W.

Deanville moraine.

Pleistocene (Wisconsin stage): Southeastern Michigan. Shown on moraine map (pl. 32) in U. S. G. S. Mon. 53. Named for Deanville, Lapeer Co.

Dearborn limestone.

Middle (?) Cambrian: Northwestern Montana.

C. F. Deiss, 1933 (Mont. Bur. Mines and Geol. Mem. 6, pp. 36 and passim). *Dearborn ls.*—At type loc. (North Fork of Dearborn River, in W. ⅓ sec. 6, T. 17 N., R. 7 W.) can be roughly divided into (descending): (1) Irregularly bedded, platy dull-gray fine-grained lss. in beds averaging 1 inch in thickness, interbedded with thin olive-gray calc. sh. in upper part, 127 ft.; (2) massive, thick-bedded crumbly gray argill. lss. with flakes and nodules of buff and some orange clay, 152 ft.; (3) thin-bedded micaceous gray-buff shaly lss. with green-gray micaceous calc. sh. in upper fourth, 180 ft. Thickest (459 ft.) in Dearborn region; thinnest (135 ft.) in vicinity of Prairie Reef. Overlies Nannie Basin ls. and underlies Steamboat ls.

Dease series.

Permian to Ordovician (?): British Columbia.

F. A. Kerr, 1926 (Canada Geol. Surv. Summ. Rept. 1925, pt. A, p. 80).

Death Canyon member (of Gros Ventre formation).

Middle Cambrian: Western Wyoming (Teton, Owl Creek, and Wind River Mountains).

B. M. Miller, 1936 (Jour. Geol., vol. 44, No. 2, pp. 119+). *Death Canyon memb.*—Largely fine-grained dark-gray and black ls. mottled with brown; the lss. thin-bedded for most part, in layers ½ to several inches thick, separated by argill. seams and partings. Fossils. Thickness 285 ft. in Teton Range. Gradually thins and interfingers with sh. to E., disappearing in middle parts of Owl Creek and Wind River ranges. Is 219 ft. thick at DuNoir, with many sh. beds in lower part; 100± ft. at Torry Creek; about 40 ft. at Bull Lake Creek. [See *Bull Lake Creek sh.* of Branson.] Overlies lower sh. div. (100± ft. thick) of Gros Ventre fm. and underlies upper sh. div. (200 to 300 ft. thick) of the Gros Ventre. Type section is along divide btw. Death and Teton Canyons, in Teton Range.

Death Valley formation.

Lower Paleozoic (?): Southeastern California (Inyo County).

F. M. Murphy, 1933 (Calif. State Div. Mines, Rept. 28 of State Min., July–Oct. 1932, pp. 329–356). *Death Valley fm.*—A considerable number of interbedded lss., calc. argillites, and schists that occupy E. flank of S. part of Panamint Range. Thickness unknown. Little time could be devoted to this large area and present descriptions are necessarily sketchy. If there is any ascertainable strat. sequence it is unknown. The interbedding of rocks, which do not vary greatly in lithologic details, would probably seriously hamper separating Death Valley fm. into mappable units. Apparently nonfossiliferous. Conformably overlies Telescope group. Referred to lower Paleozoic (?). [Mapped over large area to W. of Death Valley.]

Deaton formation.

Deaton series.

Deaton iron-ore series.

Ordovician (Middle): Northwestern Georgia.

J. W. Spencer, 1893 (Ga. Geol. Surv. Paleozoic group, pp. 46, 83). *Deaton ore beds or series.*—Ferruginous lss., 100 to 200 ft. thick, included in Chickamauga series of Polk Co. and probably of Whitfield Co. Underlie Rockmart sl. and overlie Maclurea ls.

According to C. W. Hayes (U. S. G. S. Rome folio, No. 78, 1902) these beds belong in lower part of Rockmart sl., and rest on Chickamauga ls.

Named for exposures at Deaton mine, Polk Co.

Decatur limestone.

Silurian (late Cayugan): Western Tennessee.

W. F. Pate and R. S. Bassler, 1908 (U. S. Nat. Mus. Proc., vol. 34, pp. 410–432). *Decatur ls.*—Massive white crinoidal ls. with some mag. beds. Sometimes 70 or more ft. thick. Toward top becomes slightly shaly and more fossiliferous. At Lady's Bluff consists of (descending): Yellow argill. ls., 2 ft.; massive white mag. ls., 30 ft.; argill. grayish ls. weathering into sh., 11 ft.; massive mag. ls., grayish at top and yellowish toward bottom, 20 ft. Top fm. of Niagaran of West Tenn. Uncon. underlies Linden fm. (Lower Dev.) and overlies Lobelville fm., top fm. of Brownsport group. [See also under *Brownsport fm.*]

E. O. Ulrich has for years classified this fm. as of late Cayugan age. Some geologists, however, still consider it of Niagaran age. (See A. F. Foerste, Denison Univ. Bull., Jour. Sci. Lab., vol. 30, 1935, pp. 184–185.)

Named for Decatur Co., but type section is at Tuck's Mill, 1½ mi. N. of Decaturville.

†Decatur sand. (In Claiborne group.)

Eocene (middle): Southeastern Mississippi.

E. N. Lowe, 1919 (Miss. Geol. Surv. Bull. 14, p. 78). *Decatur sand.*—Unconsolidated sand, white to yellowish, nonfossiliferous, probably marine; persistent; 18 to 25 ft. exposed. Outcrops mainly in SE. Miss., near Enterprise, Wautubbee, and Decatur. Rests on Enterprise green marl (probably conformably) and is overlain by Wautubbee marl (perhaps uncon.). Included in Lisbon fm.

The name is preoccupied. Replaced by Kosciusko ss. memb. of Lisbon fm. Named for exposures near Decatur, Newton Co.

†Decaturville limestone.

Upper Cambrian: Central Missouri.

E. M. Shepard, 1904 (Bradley Geol. Field Sta. Drury Coll. Bull., vol. 1, pt. 1, p. 42). *Decaturville ls.* 200 ft. thick, the Fourth Mag. ls. or Proctor ls. Underlies Gunter ss. and overlies Lesueur ls. Assigned to Camb. or Ozark.

G. H. Scherer, 1905 (Bradley Geol. Field Sta. Drury Coll. Bull., vol. 1, pt. 2, p. 67). *Bonne Terre ls.* is=Decaturville ls.

H. F. Bain and E. O. Ulrich, 1905 (U. S. G. S. Bull. 260, p. 234, and Bull. 267). Decaturville ls.=Bonneterre ls.

The 1922 geol. map of Mo. shows the rocks at and around Decaturville to be Roubidoux and underlying fms.

M. E. Wilson, 1922 (Mo. Bur. Geol. and Mines vol. 16, 2d ser.). Proctor fm. is about 60 ft. thick in type loc., in Miller, Morgan, and Camden Counties. The only outcrops of Bonne Terre fm. are in St. Francois Mtn region, over about 200 sq. mi.

The 1926 geol. map of Mo. shows the rocks at and around Decaturville to be pre-Gasconade.

J. Bridge, 1930 (personal communication). The Decaturville ls. is Bonneterre dol., and Proctor dol. is absent at Decaturville.

Named for exposures at Decaturville, Camden Co.

Decaturville chert.

Upper Ordovician (Richmond): Central Missouri (Camden County).

G. H. Scherer, 1905 (Bradley Geol. Field Sta. Drury Coll. Bull., vol. 1, pt. 2, p. 67), divided Richmond of Greene and Camden Counties into Maquoketa shales and *Decaturville chert,* which rested on Joachim ls. On p. 59 of same vol. he called the chert *Spencer chert.*

Decaturville chert.

Lower Devonian (Helderbergian): Western Tennessee.

C. O. Dunbar, 1918 (Am. Jour. Sci., 4th, vol. 46, p. 744). *Decaturville chert.*—Porous gray chert, 0 to 6± ft. thick. At base thinner bedded sandy chert which weathers more readily and is not well exposed. Although thin extends half way across State. Not identified E. of Tenn. River except in Hardin Co. Fauna closely allied to Birdsong, New Scotland, and Becraft. Seems best referred to earliest Becraft time. Well developed in vicinity of Decaturville, Decatur Co. Uncon. overlies Birdsong sh. and uncon. underlies Quall ls. Is top fm. of Helderbergian or Linden group.

Deception porphyry.

Pre-Cambrian: North-central Arizona (Jerome district).

L. E. Reber, Jr., 1922 (Am. Inst. Min. and Met. Engrs Trans., vol. 66, p. 12). In Deception Gulch, at N. end of Jerome area, where it adjoins the quartz porphyry, the nature of the material is open to question. The appearance is similar to that of known volcanic fragmentals and locally there are some obscure indications of its fragmental character. The microscopic evidence is conflicting but seems to point in same direction. But the rock resembles an intrusive igneous rock, and Finlay has named it [where?] *Deception porphyry.* The nature of its contact with the quartz porphyry indicates that one or both of the rocks must be intrusive.

J. L. Fearing, Jr., 1926 (Econ. Geol., vol. 21, pp. 757–773). *Deception quartz porphyry* is a sill of pre-Camb. rock intrusive into greenstone complex in Deception Gulch, Jerome dist., Ariz., and is older than Cleopatra quartz porphyry.

DeCew limestone.

Silurian: Western New York and Ontario.

E. M. Kindle, June 19, 1914 (Sci., n. s., vol. 39, p. 918). *DeCew ls.*, name proposed by M. Y. Williams, in paper read before Geol. Soc. Am. January, 1914. Basal memb. of Lockport dol. Underlies Gasport ls. and overlies Rochester sh.

M. Y. Williams, 1914 (Canada Geol. Surv. Summ. Rept. 1913, p. 186). *De Cew ls.*—Fine-grained, dark grey, argill. ls., 2 to 9 ft. thick. Basal bed of Lockport memb. of Niagara fm. in Niagara Peninsula. Well exposed at DeCew falls. Is 9 ft. thick at Niagara River, 8 ft. at Grimsley, and 2 ft. at Hamilton, Ont. At some places shows on weathered surfaces cross-bedding and remarkable churned structure. The material of the beds suggests reworked Rochester sh. to which lime has been added. Heretofore included in the Lockport. Difficult to separate from Rochester memb., which is essentially sh., although toward top some calc. beds appear. Underlies Gasport ls. [Schuchert (Geol. Soc. Am. Bull., vol. 25, p. 307, 1914) stated 5 ft. of DeCew ls. is present at Lockport, N. Y., beneath Gasport ls. and 2 to 5 ft. at Rochester, N. Y.]

†Decewsville formation.

†Decewville formation.

Middle Devonian: Western New York and southeastern Ontario.

E. O. Ulrich and C. Schuchert, 1902 (N. Y. State Mus. Bull. 52, p. 653, chart opp. p. 659). *Decewville fm.*—Coarse ss. filled with late Oriskany fossils, overlain by sandy ls. containing a fauna of marked Onondaga aspect and extending up to where typical Onondaga ls. appears. The latest Oriskany invasion came from SE. and arrived at Cayuga, Ont., at about same time as Onondaga invasion from SW., causing a blending of Onondaga and Oriskany faunas. Remnants seen in cement quarries at Buffalo, N. Y. Named for exposures near village of Decewsville, Ontario.

C. Schuchert in 1903 (Am. Geol., vol. 31) placed the *Decewville* in top of Oriskanian, underlying Schoharie grit and overlying Esopus grit. G. H. Chadwick, 1908 (Sci., n. s., vol. 28, pp. 346–348) used *Esopus* (*Decewville*) in N. Y. C. Schuchert, 1910 (Geol. Soc. Am. Bull., vol. 20, p. 541), correlated *Decewville of Ontario* with Esopus and Glenerie. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22) correlated Schoharie and *Decewville* of western N. Y. with Schoharie of eastern and central N. Y. In 1912 (Geol. Soc. Am. Bull., vol. 23, p. 376) C. R. Stauffer stated that *Decewsville fm.* of Ontario is not an independent unit, but that the upper ss. and aren. material carries an Onondaga fauna and forms basal layers of Onondaga fm., while the basal ss. contains characteristic Oriskany fossils; and that relations of Oriskany and Onondaga are same in Ont. as in N. Y. In 1913 (Jour. Geol., vol. 21, pp. 310–311) E. M. Kindle stated *"Decewsville fm."* has no standing, and that Decewsville section of the "formation" consists of 2 ft. of Onondaga ls., underlain by 17 inches of Oriskany ss., which rests on 30 ft. of ls. belonging to Salina fm.

DeChelly sandstone member (of Cutler formation).

Permian: Northeastern Arizona, southeastern Utah.

H. E. Gregory, 1915 (Am. Jour. Sci., 4th, vol. 40, p. 102). *DeChelly ss.*—Name adopted for forthcoming rept for beds overlying Moenkopi fm. and underlying Shinarump cgl. in Navajo Ind. Res., Ariz. [Not described.]

H. E. Gregory, 1916 (U. S. G. S. W. S. P. 380), and 1917 (U. S. G. S. P. P. 93). *DeChelly ss.*—Massive, very cross-bedded light-red or brown ss., 0 to 585 ft. thick, uncon. underlying Shinarump cgl. and overlying Moenkopi fm. in Navajo country. Mapped along Canyon de Chelly, Apache Co., Ariz.

A. A. Baker and J. B. Reeside, Jr., 1929 (A. A. P. G. Bull., vol. 13, No. 11, pp. 1424–1448), after considerable field work in SE. Colo., NE. N. Mex., SE. Utah, and NE. Ariz., made the following changes in nomenclature of SE. Utah and NE. Ariz.: (1) They identified all red beds (including 2 conspicuous light-colored sss.) btw. base of Shinarump cgl. and above top of "Goodridge fm." as belonging to Cutler fm.; (2) they divided the "Goodridge" into Rico fm. and Hermosa fm.; (3) they divided the Cutler of SE. Utah and NE. Ariz. into (descending) Hoskinini tongue (red), DeChelly ss. memb. (light-colored), Organ Rock tongue (red), Cedar Mesa ss. memb. (white), and Halgaito tongue (red); (4) they restricted the name *DeChelly ss.* in Utah to southern part of San Juan Co. and applied the new name *White Rim ss. memb.* to the 0 to 100 ft. of white ss. in northern part of San Juan Co., of approx. the same age as upper part of typical DeChelly and called DeChelly and De Chelly (?) in previous repts. "NE. from Monument Valley the DeChelly ss. thins out and disappears near San Juan River at Clay Hill Crossing, and the upper and middle red beds merge." "In walls of Canyon De Chelly an incomplete exposure of DeChelly memb. shows a thickness of 800+ ft." This is the present approved nomenclature of SE. Utah and NE. Ariz.

Decker limestone.

Silurian (late): Southeastern New York, northern New Jersey, and northeastern Pennsylvania.

I. C. White, 1882 (2d Pa. Geol. Surv. Rept. G_6, pp. 76–77, 137–141). *Decker Ferry ls.*—Bluish gray, usually brecciated ls., 20 ft. thick, underlying Stormville cement bed (which separates it from the overlying Stormville ls.) and overlying Decker Ferry ss., which rests on Decker Ferry shales. The ls. often becomes slaty in lower portion, and is usually more or less sandy. In Ross Twp, Monroe Co. [Pa.], iron ore occurs at horizon of this ls. and in base of overlying Stormville ls. The Decker Ferry ls., Decker Ferry ss., and Decker Ferry shales are all exposed near Decker's Ferry below Flatbrookville, Sussex Co., N. J.

S. Weller, 1903 (N. J. Geol. Surv. Pal., vol. 3, p. 62), applied *Decker Ferry ls.* to same unit defined by White, stating that it "is quite distinct, both faunally and lithologically from underlying *Decker Ferry fm.* here recognized." Weller's *Decker Ferry fm.* included *Decker Ferry ss.* and *Decker Ferry sh.* of White, which he stated are closely allied.

According to C. A. Hartnagel, 1903 (N. Y. State Mus. Bull. 69), the "Decker Ferry fm. of N. J." is=Cobleskill, Rosendale, and Wilbur lss. of N. Y. In 1905 (N. Y. State Mus. Bull. 80, pp. 342–357) Hartnagel restricted name *Decker Ferry fm.* to the beds (41 ft. thick at Nearpass, N. J.) beneath the Cobleskill and above Bossardville ls., or to equivalents of Rosendale and Wilbur lss. of repts., and stated that *Decker Ferry fm. of Weller* included also the equiv. of the Cobleskill. Hartnagel's Decker Ferry fm. consisted of 15 ft. of lss. and shales, underlain by 2 ft. of red crystalline ls. characterized by *Ptilodictya frondosa*, which rested on 24 ft. of highly fossiliferous hard crystalline ls. designated *Chonetes jerseyensis* zone. In 1908 (N. Y. State Mus. Bull. 107, p. 51) Hartnagel divided the Salina of Ulster Co., N. Y., into (descending): Decker Ferry (=Rosendale cement and Wilbur ls.); Binnewater ss.; and High Falls sh.; the latter two correlated with Longwood sh. (At Port Jervis, Orange Co., N. Y., he identified the Decker Ferry beneath the Cobleskill and above the Bossardville ls.). In Hdb. 19, 1912, Hartnagel stated that *Decker Ferry fm.* is best developed in Pa. and N. J., and that most favorable place for its examination in N. Y. is at Accord [Ulster Co.], where entire thickness is shown.

In 1908 (U. S. G. S. Franklin Furnace folio, No. 161) the name was shortened to *Decker ls.* and was applied to 50 ft. of dark-gray impure siliceous and shaly ls. overlying Longwood sh. and containing fossils which correlated it "with the lower portion of the 'Decker Ferry' ls. on Delaware River and the upper Salina beds of N. Y."

In 1913 (Md. Geol. Surv. Lower Dev. vol., table opp. p. 30) C. K. Swartz, C. Schuchert, and C. S. Prosser correlated *Decker Ferry ls.* of N. J. with *Decker Ferry* of N. Y., and with Cobleskill, Rosendale, and Wilbur lss., the Cobleskill being overlain by Rondout ls. All of these fms. they classified as Lower Dev. The same year, and on pp. 115 to 116 of same volume, E. O. Ulrich assigned the Decker Ferry of N. Y. to Lower Dev., and showed it as underlying the Rondout and as younger than *typical* Manlius ls., which he stated rests on the Cobleskill and which he assigned to Sil. In 1915 (N. J. Geol. Surv. Bull. 14) J. V. Lewis and H. B. Kümmel gave the following sequence of Sil. fms. of N. J. (descending): Manlius ls.; Rondout ls.; Decker ls. (52 ft. of ls. to NE. and calc. sss. to SW., with Salina fossils); Bossardville ls.; Poxino Island sh.; High Falls fm. (=Longwood sh.); Shawangunk cgl.

The age and strat. relations of Decker ls. are still debated.

†Decker Ferry limestone.

†Decker Ferry formation.

See under *Decker ls.*

Decker Ferry shales.

Silurian: Northeastern Pennsylvania (Monroe County) and northwestern New Jersey (Sussex County).

I. C. White, 1882 (2d Pa. Geol. Surv. Rept. G_6, pp. 77, 141). *Decker's Ferry shales.*—Greenish shales, often limy, 15 ft. thick. Underlie Decker's Ferry ss. and overlie Bossardville ls. Well exposed at Decker's Ferry [Sussex Co., N. J.].

Decker Ferry sandstone.

Silurian: Northeastern Pennsylvania (Monroe County) and northwestern New Jersey (Sussex County).

I. C. White, 1882 (2d Pa. Geol. Surv. Rept. G_6, pp. 77, 140–141). *Decker's Ferry ss.*—A grayish white, pebbly, calc. ss., very fossiliferous, 15 to 25 ft. thick. Underlies Decker's Ferry ls. and overlies Decker's Ferry shales. Forms low cliff just above road leading SW. from Decker's Ferry [below Flatbrookville, on Delaware River, in Sussex Co., N. J.], and is exposed at many places btw. there and Delaware Water Gap.

Decorah shale.

Middle Ordovician (Trenton and late Black River): Southwestern Wisconsin, southern Minnesota, Iowa, western Illinois, and Missouri.

S. Calvin, 1906 (Iowa Geol. Surv. vol. 16, pp. 60, 84). *Decorah (Green) sh.*—Very calc. green sh., with numerous bands and nodules of ls., 25 to 30 ft. thick, forming top shaly memb. of Platteville stage. Overlies Platteville ls. (lower fm. of Platteville stage) and underlies Galena ls. Within city of Decorah [Winneshiek Co., Iowa] and vicinity is everywhere very calc.

Adopted by U. S. Geol. Survey in 1910 as a distinct fm., overlying Platteville ls. restricted and underlying Galena dol. It was understood to have been included in Platteville ls. as originally defined, and to include "glass rock" of miners and here and there a thin layer of "oil rock," but that main "oil rock" of miners was in overlying Galena dol.; also that it is "Green shales" of early Minn. repts. Fauna considered by E. O. Ulrich (1923) to be of late Black River age.

G. M. Kay, 1928 (Sci., n. s., vol. 67, p. 16), divided *Decorah fm.* into 3 members, named (descending) *Ion memb.*, *Guttenberg memb.*, and *Spechts Ferry memb.*, the latter said to include the "glass rock." (See descriptions of these members.) Kay stated upper 2 members are of Trenton age and lower memb. of latest Black River age; also that his Guttenberg memb. is the "oil rock" *at base of the Galena* in NW. Ill. This seems to mean a restriction of *Galena* and an expansion of *Decorah* of previous repts. In 1931 (Jour. Geol., vol. 39, p. 370) Kay redefined his *Spechts Ferry memb. of Decorah fm.* by excluding the "glass rock." In 1932 (Jour. Geol., vol. 40, No. 3, pp. 259–269) V. T. Allen proposed drawing line btw. Platteville and Decorah at base of a 1- to 3-inch layer of metabentonite, which he reported as present 12 to 18 inches above base of Decorah in Minn., Iowa, and Wis.

G. M. Kay and G. I. Atwater, 1935 (Am. Jour. Sci., 5th, vol. 29, Feb., pp. 98–99, 101), continued to include Kay's Spechts Ferry memb. in the Decorah and to classify it as of late Black River age and rest of Decorah as of Trenton age. They stated that Platteville as defined by Bain did not include Ion and Guttenberg members of Kay.

A. C. Trowbridge et al, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., fig. 1), treated Galena as a *group*, all of Trenton age, and included in it *Decorah sh.* (restricted to beds above the basal or Spechts Ferry memb. of Kay, which they included in Platteville ls.). Page 64, however, excluded all of *Decorah fm.* from the Galena, but included it in the Trenton, and transferred Kay's Spechts Ferry memb. to the Platteville.

G. M. Kay, 1935 (pp. 286–287, 295 of 1935 Conf. rept. cited above), also restricted *Decorah fm.* by transferring to the Platteville his Spechts Ferry memb. restricted and the underlying "glass rock" (which he included in his newly named McGregor memb. of the Platteville), leaving Decorah fm. near Platteville as composed wholly of his Guttenberg memb. But on p. 288 he stated that in Minn. and northern Iowa it is "more convenient to consider the Spechts Ferry as a lowest memb. of Decorah fm." Kay stated (p. 286) his restricted Spechts Ferry memb. includes a thin bed of metabentonite 18 inches above its base. On p. 295 he showed an uncon. btw. his Guttenberg and Spechts Ferry members in Minn. and Ill.

The U. S. Geol. Survey has for many years followed the definitions of Decorah sh. and Platteville ls. that include the "glass rock" in Decorah sh. Its present age designation of Decorah sh. is late Black River and early Trenton. The sh. separating Plattin and Kimmswick lss. in Mo., SW. Ill., and central western Ill. has for several years been called *Decorah sh.* This sh. is now said to correspond to only the Spechts Ferry memb. of Kay. If so, and Kay's Spechts Ferry memb. is transferred to Platteville ls., *Decorah* is no longer an appropriate name for the sh. separating Plattin and Kimmswick lss.

Decota sandstone. (In Kanawha formation.)

Pennsylvanian: West Virginia.

C. E. Krebs and D. D. Teets, Jr., 1914 (W. Va. Geol. Surv. Rept. Kanawha Co., p. 292). *Decota ss.*—Grayish brown, medium grained, often current bedded. Thickness 15 to 25 ft. Lies 2 to 5 ft. below Eagle coal and overlies Little Eagle coal. Named for Decota, Kanawha Co.

R. V. Hennen and D. B. Reger, 1914 (W. Va. Geol. Surv. Rept. Logan and Mingo Counties, p. 206). *Decota ss.* is 20 to 50 ft. thick, and lies 5 to 10 ft. below Bens Creek coal and 5 to 10 ft. above Little Eagle coal.

De Courcy formation.

Upper Cretaceous: British Columbia.

C. H. Clapp, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 99).

Dederick shale member.

Pennsylvanian: Western Missouri (Vernon County).

F. C. Greene and W. F. Pond, 1926 (Mo. Bur. Geol. and Mines vol. 19, 2d ser., pp. 38–44). *Dederick sh. memb.*—Chiefly dark blue to black sh. containing upper Dederick, middle Dederick, and lower Dederick coal beds, and, locally, a coal bed at top. The coal beds are underlain by clay and locally ss., cgls., and ferruginous ls. appear at base. The black sh. contains numerous thin bands and plates of dark, impure iron carbonate. Thickness 27 to 75 ft. Is basal memb. of Cherokee fm. in Vernon Co. Is overlain by Clear Creek ss. memb. of Cherokee, and uncon. underlain by Miss. rocks. Best exposures in vicinity of Dederick, along railroad in N. part of sec. 26, T. 36 N., R. 29 W., and in NE. ¼ SE. ¼ sec. 36, T. 36 N., R. 29 W. The name is not intended to apply to the Cherokee section outside of the area in SW. Mo.

Dedham granodiorite.

Early Paleozoic (pre-Devonian): Eastern Massachusetts and southeastern New Hampshire.

W. O. Crosby, 1880 (Boston Soc. Nat. Hist. Occ. Papers No. 3, with map), mentioned *Dedham granite.*

G. F. Loughlin and L. A. Hechinger, 1914 (Am. Jour. Sci., 4th, vol. 38, p. 49). The *Dedham granite* with associated basic plutonic rocks covers a large area, including NW. corner of Narragansett Basin and almost entire NW. side of Norfolk County Basin. The complete series probably includes all types and gradations, from alaskite and aplite, through common biotite granite, granodiorite, diorite, and gabbro.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 175–177). *Dedham granodiorite* (or the several types of rock mapped under that name) occupies a larger part of eastern Mass. than any other fm. and is more widely distributed than any other rock in State except the Triassic diabase. As mapped it includes several lithologic varieties, the most abundant and typical of which is a rather coarse biotitic granodiorite, composed essentially of microcline, plagioclase (generally andesine), quartz, and chlorite, and commonly more or less epidote and kaolin. Named for typical exposures about Dedham, Mass. Assigned to Dev. (?).

L. LaForge, 1932 (U. S. G. S. Bull. 839), assigned *Dedham granodiorite* to "early Paleozoic, certainly pre-Dev."

M. Billings, 1929 (Am. Jour. Sci., 5th, vol. 18, pp. 99–112), definitely assigned *Dedham granodiorite* to pre-Camb.

E. J. Rhodes and W. H. Graves, Jr., 1931 (Am. Jour. Sci., 5th, vol. 22, pp. 371–372), after studying *Dedham granodiorite* in N. part of Dedham quad., Mass., stated: "We would place the Dedham tentatively in Dev., where originally placed by Emerson." "It would not be surprising to find that a pre-Camb. body in R. I. and a post-Camb. body in Mass. have been included under the broad term 'Dedham granodiorite.' "

W. G. Foye and A. C. Lane, 1934 (Am. Jour. Sci., 5th, vol. 28, p. 137). *Dedham granodiorite* is probably Dev.

Deep Canyon fanglomerate.

Quaternary: Southern California (San Bernardino Mountains).

F. E. Vaughan, 1922 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 13, No. 9, pp. 344, 384–385, and map). *Deep Canyon fangl.*—Detrital rocks, consisting largely of angular and subangular boulders derived from older rocks to N. Contain notable proportion of rounded material and many strata of ss. comparable to that in Hathaway fm. Rest on basalt, of probably early Quat. age, on both sides of Deep Canyon. Across upturned and eroded edges of the fangl. and basalt a later fangl. has been deposited. Is older than Coachella fangl. and younger than Pipes fangl.

Named for Deep Canyon, Riverside Co.

Deep Creek division.

Lower Ordovician: Central Texas.

T. B. Comstock and E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. 302–306). *Deep Creek div.*—Siliceous rocks (descending): (1) Fossiliferous largely decomposed cherty beds, 50 to 100 ft.; (2) 10 ft. or less of massive chert beds; (3) 25 ft. of thinly laminated tough cherty dolomites, white to dull gray or chalky, sometimes with interstratified chert beds 1 to 3 ft. thick; (4) 40 ft. of dol., gradually becoming tough and cherty and weathering with deeply pitted surfaces, containing cherty nodules; (5) 50 ft. of gritty, fine-grained, saccharoidal light-gray or slightly yellowish highly siliceous dol. Top div. of San Saba series. Overlies Hinton div.

Named for Deep Creek, San Saba Co.

†Deep Creek beds.

Miocene (middle): Central southern Montana (Little Belt Mountains region).

See under *Deep River beds*.

Deepkill shale. (In Beekmantown group.)

Lower Ordovician: Eastern New York.

R. Ruedemann, 1902 (N. Y. State Mus. Bull. 52, pp. 546–575), recognized within the Beekmantown of Deep Kill section, in vicinity of Albany, three graptolite zones, which he enumerated in table on p. 575, and after each zone inserted, in parens, *Deep Kill*. This is apparently a geographic and not a geologic designation. The lowest zone was said to be underlain by some nonfossiliferous beds, and zones 2 and 3 to be separated by some nonfossiliferous beds.

In 1903 (N. Y. State Mus. Hdb. 19, chart) J. M. Clarke applied *Deepkill sh.* to beds btw. Chazy ls. and Beekmantown ls. In 1912 (N. Y. State Mus. Hdb. 19, p. 34) C. A. Hartnagel stated that *Deepkill sh.* is especially characterized by graptolite-bearing zones, is typically exposed near Grant Hollow, in Rensselaer Co., along the Deepkill, a small eastern tributary of Hudson River, and is of Beekmantown age, as determined by fossils. In the chart he assigned it to a strat. position btw. Normanskill sh. above and Schaghticoke sh. below.

R. Ruedemann and H. P. Cushing in 1914 (N. Y. State Mus. Bull. 169, pp. 66–99 and p. 140) assigned *Deepkill sh.* to position btw. Bald Mtn ls. (uncon. below Normanskill sh.) and Schaghticoke sh., and included it all in Beekmantown. In 1921 (N. Y. State Mus. Bull. 227, 228, p. 130) Ruedemann classified *Deep Kill sh.* as of lower Chazy and Beekmantown age, and assigned it to position btw. Normanskill and Schaghticoke shales.

R. Ruedemann, 1929 (Geol. Soc. Am. Bull., vol. 40, No. 2). *Deepkill sh.* is a mass of graptolite sh., 300 or more ft. thick, that corresponds to Beekmantown and probably also to Lower Chazy. [In chart on p. 414 he placed Deepkill below Bald Mtn ls. (which he assigned to Beekmantown) and above Schaghticoke sh.]

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 272). *Deepkill sh.* is for most part equiv. to Beekmantown ls., but uppermost graptolite zone carries Chazy fauna (Ruedemann).

Deep Lake argillite.

Paleozoic (?): Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20). *Deep Lake argillite.*—Dark to light-colored calc. argillite, with interbedded bluish-gray fine and coarse bands of argill. ls. showing well-defined stratification. So calc. as to render it difficult whether to map it as ls. or argillite. Thickness 2,500± ft. Exposed along wagon road on E. shore of Deep Lake. To E. of the lake it extends up into steep mtn slopes where it is heavily covered with glacial material.

Deep Lake metaquartzite.

Pre-Cambrian: Southeastern Wyoming (Medicine Bow Mountains).

E. Blackwelder, 1926 (Geol. Soc. Am. Bull., vol. 37, pp. 620, 623, 625). *Deep Lake metaqtzite.*—Coarse to fine, massive to slabby metaqtzites, of grayish-white, dark-gray, light-gray, and brownish-gray colors, with a few beds of fine fluvial cgl. and also scattered pebbles and clay balls; cross-bedding very regular; concealed beds probably schists. Thickness 2,000+ ft. Underlies Headquarters schist, probably conformably. Overlies gneissic complex, but contact not seen and relation unknown. Outcrops around Deep Lake. Assigned to early Algonkian.

†Deep River formation.

†Deep River series.

Triassic (Upper): Central North Carolina (Deep River region).

E. Emmons, 1856 (N. C. Geol. Surv. Rept. of Midland Counties, pp. 255, 273+). *Deep River series* (also *Deep River fm.*).—Trias and Perm. rocks of Deep River region, consisting of (descending): (1) red sss., marls, etc.; (2) black or blue sl. with plants and a coal seam; (3) cgl.; (4) drab-colored sss., calc. and bituminous shales; (5) coal, fire clay, oxide of iron; (6) red ss., sometimes gray and drab; and (7) cgl.

Replaced by Newark group.

Named for exposures along Deep River.

Deep River beds.

Miocene (middle): Central southern Montana (Little Belt Mountains region and Meagher County).

W. H. Dall and G. D. Harris, 1892 (U. S. G. S. Bull. 84, p. 287). *Deep Creek beds.*—Still farther E. [of Fort Ellis] along Deep Creek, exist remarkable lake deposits of both "Miocene" and "Pliocene" age, which represent *Ticholeptus* beds of Cope. [Same as *Deep River beds,* the stream having been called by both names and also called *Smith River.*]

W. B. Scott, 1894 (Geol. Soc. Am. Bull., vol. 5, p. 595). *Deep River beds* are upper Mio. [See also Am. Phil. Soc. Trans., vol. 18, pp. 55–63, and other repts of Scott.]

E. Douglass, 1903 (Carnegie Mus. Annals, vol. 2, pp. 150–151). *Deep River beds* restricted to what has previously been called *Upper Deep River,* and *Fort Logan beds* introduced for *Lower Deep River.* Faunas differ. Cope's collections of fossils all came from upper beds.

H. F. Osborn, 1909 (U. S. G. S. Bull. 361, p. 76). "Upper part of Deep River sequence (Smith Creek) or *Ticholeptus* zone of Cope," is middle Mio., and (pp. 65, 112) *Fort Logan beds* are lower Mio.

See also †*Smith River lake beds.*

Deep Run member. (In Ludlowville shale.)

Middle Devonian: Central New York.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 218, 226, 227, etc.). *Deep Run memb. of Ludlowville fm.*—Brittle bluish sh., overlying true Tichenor ls. and underlying Menteth ls. (basal bed of Portland Point memb. of Ludlowville fm.) in Deep Run ravine, near Cottage City, Canandaigua Lake. Contains a variety of pelecypods and great abundance of large specimens of *Tropidoleptus carinatus.* Recognizable from Seneca Lake to Hills Gulch, 5 mi. S. of LeRoy. At type loc. is 55 ft. thick, but diminishes rapidly to W. At Jacox Run, Genesee Valley, it is 9 ft. thick, at Hills Gulch about 3 ft., and from there tapers to feather edge. Also diminishes in thickness E. of type loc., being 49 ft. on Kashong Creek. Not distinguished E. of Seneca Lake, but it evidently forms upper part of King Ferry memb. to E.

Deep Spring formation.

Pre-Cambrian: Eastern California (Inyo Range).

E. Kirk, 1918 (U. S. G. S. P. P. 110). *Deep Spring fm.*—About 1,600 ft. of sss. and dolomitic lss. uncon. underlying Campito ss. and uncon. overlying Reed dol. Named for exposures along W. side of Deep Spring Valley in canyons N. of Antelope Spring.

Deer Creek quartzite.

Pre-Cambrian (Glenarm series): Northern Maryland.

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Rept., vol. 1, pp. 130–132). *Deer Creek white cgl. qtzite.*—[Petrographic description given.] Occurs in center of Harford Co., Md., marking a sharp, narrow ridge 300 ft. high, 4 mi. long, and less than a mi. wide. May prove to be a basal cgl. of Peach Bottom phyllite series.

E. B. Mathews, 1898 (Md. Geol. Surv. vol. 2, p. 213). At station known as "The Rocks" the Baltimore and Lehigh R. R. and Deer Creek pass through a ridge of highly metamorphosed hard micaceous sss. in a gorge 350 ft. below summit. This ridge extends in a NE.-SW. direction for 10 or 12 mi. and forms part of the folded phyllite series, which are probably of Camb. age. The ss. of which it is composed lies some distance above base of the series and below bottom of Peach Bottom sl. The ss. is rich in quartz and locally becomes conglomeratic.

According to E. B. Knopf (letter dated Feb. 11, 1937) the relation of the rocks described as *Deer Creek qtzite* to surrounding rocks has not been definitely established, but they are probably strat. equiv. of Cardiff cgl.

Deer Creek limestone member (of Shawnee formation).

Pennsylvanian: Eastern Kansas, southeastern Nebraska, southwestern Iowa, northwestern Missouri, and central northern Oklahoma.

J. Bennett, 1896 (Kans. Univ. Geol. Surv. vol. 1, p. 117). *Deer Creek system.*—Three lss. separated by shales; aggregate thickness 26½ ft. Separated from overlying Topeka ls. by 60 ft. of sh. [Calhoun sh. memb.] and from underlying Lecompton ls. by about 100 ft. of sh. with some thin lss. [Tecumseh sh. memb.].

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., p. 48). *Deer Creek ls.* as originally defined by Bennett included 3 lss. and 2 shales. The following names are proposed for the subdivisions (descending): Ervine Creek ls., Mission Creek sh., Haynies ls., Larsh sh., and Rock Bluff ls. All of these units extend through outcrops in Nebr., Iowa, Mo., and Kans.

R. C. Moore and G. E. Condra, 1932 (Oct. 1932 revised classification chart of Penn. rocks of Kans. and Nebr.), transferred from Calhoun sh. to top of Deer Creek ls. the beds previously named *Jones Point sh.* and *Sheldon ls.*, and restricted *Calhoun sh.* to the beds previously named *Iowa Point sh.*

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 11), divided Calhoun sh. into (descending) Iowa Point sh., Sheldon ls., and Jones Point sh.; restricted Deer Creek ls. to the beds btw. base of Jones Point sh. and top of Tecumseh sh.; and divided Deer Creek ls. in section from Forest City, Mo., to DuBois, Nebr. into following members (descending): Ervine Creek ls., Larsh sh., Rock Bluff ls., Oskaloosa sh., and Ozawkie ls.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), divided Deer Creek ls. of Kans. into (descending): Ervine Creek ls., Larsh-Mission Creek sh., Rock Bluff ls., Oskaloosa sh. (formerly erroneously identified as Larsh sh. but older than true Larsh sh.), and Ozawkie ls. (formerly erroneously identified as Rock Bluff ls.). He stated that his Ozawkie and Oskaloosa members are absent in Nebr.

In Kans. the Shawnee is treated as a group and the Deer Creek as a fm. In northern Okla. the Deer Creek ls. is treated as a memb. of Pawhuska ls.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936. Also 1937 entry under *Topeka ls.*

Named for exposures on Deer Creek, E. of Topeka, Shawnee Co., Kans.

†Deerfield diabase.

Upper Triassic: Central Massachusetts (Connecticut River region).

B. K. Emerson, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 451–456). The *Deerfield diabase* rests at its northern and southern ends on Mount Toby cgl.; in its middle upon the Triassic sss. and shales [Sugarloaf arkose, Longmeadow brownstone, and Chicopee sh.].

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 97, 265–271). *Deerfield sheet of Mount Holyoke diabase* is an overflow. It rests on Mount Toby cgl. from Gill Center nearly to Fall River, then on Longmeadow ss. to Deerfield, then on Sugarloaf arkose to the Conn., and on Mount Toby cgl. to S. end of Mount Toby.

†Deer Lake conglomerates.

Pre-Cambrian (Keewatin): Northwestern Michigan (Marquette district).

See under *Kitchi schist.*

Deer Lake argillite.

Paleozoic: Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 54; map). *Deer Lake argillite.*—Interbedded quartz-mica schists, dark-gray and grayish-brown qtzites, and thin-bedded argill. shales and slates, the latter prevailing. The subordinate schists and qtzites occur in bands varying in width of thickness from 2 or 3 to over 100 ft. Exposed along shores of Deer Lake. Southern end terminates about 1 mi. S. of Deer Lake. Thickness 4,000± ft. Is in contact with Eagle Mtn qtzite, which it appears to underlie, but it is possible it overlies the Eagle Mtn and is in its present position as result of overturned fold.

Deer Lick sand.

Drillers' term for an Upper Dev. oil sand in western Pa. that is said to lie at about same horizon as Bradford Third sand.

Deer Mountain red shale member (of Hueco limestone).

Permian (?): Western Texas (Hueco Mountains).

P. B. and R. E. King, 1929 (A. A. P. G. Bull. vol. 13, p. 925). [*Deer Mtn red beds,* shown in section of Hueco Mtns as resting on Gym ls. and as=upper part of Hess fm. of Sierra Diablo.]

P. B. King, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 697–798), called these beds *Deer Mtn red sh. memb. of Hueco ls.* and assigned them to Permian (?).

Deer River shale.

Upper Ordovician: Eastern New York (Black River Valley) and southern Canada.

R. Ruedemann, 1921 (N. Y. State Mus. Bull. 227, 228, pp. 124–126, 130). *Deer River sh.* and Atwater Creek sh., of the black sh. of Black River Valley, the zone of *Climacograptus typicalis posterus* and *Glossograptus quadrimucronatus, forma typica* [respectively]. [Table on p. 130 shows Deer River sh. resting on Utica sh. and overlain by Atwater Creek sh.]

R. Ruedemann, 1925 (N. Y. State Mus. Bull. 258, pp. 49–52, 60, 76, 82, 148). *Deer River sh.* (zone of *Climacograptus typicalis posterus*) is post-Utica in age, but lithologically of character of Utica. Thickness 70 ft. on Deer River, near Copenhagen [Lewis Co., N. Y.]. Was deposited on NW. side of Adirondack mass in an embayment extending southward from Gloucester sea in Canada. Is overlain by Atwater Creek sh. (zone of *Glossograptus quadrimucronatus, forma typica*), which in turn is overlain by Whetstone Gulf sh. Is basal part of Lorraine group. The Whetstone Gulf, Atwater Creek, and Deer River fms. of Black River Valley are=*Frankfort sh. of Utica Basin.* [*In parts of rept the Atwater Creek beds* are included in Whetstone Gulf fm., and in other parts of rept they are excluded.]

Deer River moraine.

Pleistocene: Northwestern New York (Lowville region).

A. F. Buddington, 1934 (N. Y. State Mus. Bull. 296, p. 42). A group of hills, in Carthage quad., that forms belt about 4 mi. long and 1 mi. wide, from Deer River across to Black River valley.

Deer Trail argillite.

Paleozoic: Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 59; map). *Deer Trail argillite.*—Argillites, calc. argillites, phyllites, quartz mica schists, narrow bands of ls., and small discontinuous bands of qtzite; argillites and quartz-mica schist are most abundant. Thickness 3,000± ft. Includes Stensgar dol. memb. Underlies Addy qtzite. [Type loc. not stated, but Deer Trail Mine is in this fm.]

Deerwood iron-formation member (of Virginia slate).

Pre-Cambrian (upper Huronian): Northeastern Minnesota (Cuyuna district).

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, pp. 212–215+). *Deerwood iron-bearing memb. of Virginia sl.*—Principally iron carbonate where unaltered, but largely altered to amphibole-magnetite rocks, ferruginous sl. and chert, and iron ore. Found in lenses in Virginia sl., presumably near base. Named for development at and near Deerwood.

C. Zapffe, 1930 (Lake Superior Min. Inst. Proc., vol. 28, pp. 101, 103). Near base of Cuyuna memb. of Crow Wing fm. in Cuyuna dist. is a persistent layer of ore fm. About 500 ft. or more above it is a second layer. Collectively these have heretofore been called *Deerwood ore-bearing memb.* Writer has previously pointed out that he believed Deerwood memb. consisted of two major bands, rather than one, and considered the portion in N. part of North Range (T. 47, R. 29) the lower band, with the South Range band probably its extension or equiv., and the portion in S. part of North Range (T. 46, R. 29) the upper band. The lower band in many respects carries out idea of a gradation from the poorer bands of underlying Emily memb. to the better or upper band of the Deerwood. Adjacent rock fms. support this view.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), changed name to *Deerwood iron-fm. memb.*, and, although including it in Virginia sl., stated that it might be=Biwabik iron-fm., which they assigned to middle Huronian.

Dees horizon.

Dees sand.

Lower Cretaceous: Northeastern Texas (Cass County) and northwestern Louisiana (Caddo County).

J. S. Ivy, 1936 (Oil and Gas Jour., vol. 34, No. 48, April, p. 72). *Dees horizon* (in lower part of Glen Rose fm. of Rodessa field) consists of 95 ft. of beds divided into (descending): (1) Occasional coquina, (2) *Dees sand,* (3) Coquina ls., and (4) oolitic sand or "mealy" ls. The Dees sand varies from that of true quartz sand to sandy ls. interbedded with sandy sh. Its av. thickness is 15± ft. Underlies 55 ft. of mottled red and green ls. and overlies basal black sh. memb. of Glen Rose fm. [Derivation of name not stated.]

Deese formation.

Pennsylvanian: Central southern Oklahoma (Carter County).

W. L. Goldston, Jr., 1922 (A. A. P. G. Bull., vol. 6, No. 1). *Deese memb. of Glenn fm.*—Characterized by a large number of massive sss., cgls., shales, and a few lss. To N. of Ardmore the base is marked by a brown ls. bearing an abundance of *Spirifer condor;* S. of Ardmore this horizon is represented by a bed of chert, and there is a thick cgl. at base. Occurs in a NW.-SE. exposure just E. of Deese. Thickness 6,000 to 8,000 ft. Fossils listed. Underlies Hoxbar memb. and overlies Cup Coral memb.

G. H. Girty and P. V. Roundy, 1923 (A. A. P. G. Bull., vol. 7, No. 4, pp. 331–347). Glenn fm. includes only Deese and Cup Coral members of Goldston.

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z, pp. 7–21). *Deese fm.*, 5,000± ft. thick, underlies Hoxbar fm. and overlies Dornick Hills fm. (1,500 to 4,000 ft. thick), which rests on Springer fm. Top memb. of Dornick Hills fm. is here named *Pumpkin Creek ls.*, and basal memb. of Hoxbar fm. is here named *Confederate ls. memb.*

C. W. Tomlinson, 1929 (Okla. Geol. Surv. Bull. 46). *Deese fm.*, 3,000 to 7,000 ft. thick, as here defined coincides very nearly with Goldston's Deese memb. of Glenn fm. as mapped by him in type loc., in sec. 33, T. 3 S., R. 1 E., adjoining village of Deese. The village itself lies on the thin edge of red beds overlying Hoxbar fm. The Deese fm. overlies Pumpkin Creek memb. of Dornick Hills fm. and underlies Confederate ls. memb. of Hoxbar fm.

Defiance moraine.

Pleistocene (Wisconsin stage): Northern Ohio and southern Michigan. Shown in part on moraine map (pl. 32) in U. S. G. S. Mon. 53, 1915; also in part in fig. 8 of U. S. G. S. Columbus folio (No. 197), p. 12, 1915; also in fig. 7 in U. S. G. S. Detroit folio (No. 205), 1917. In SE. Mich. is locally double, and *outer ridge of Defiance moraine* is now used to replace "Northville moraine" of Mich. Geol. Surv. Wayne Co. Rept., *inner ridge of Defiance moraine* being used to replace Defiance moraine as described in earlier repts on Michigan. Named for Defiance, Ohio. Replaces "Blanchard moraine."

Degonia sandstone. (In Chester group.)

Mississippian: Southern and western Illinois and western Kentucky.

S. Weller, 1920 (Jour. Geol., vol. 28, No. 4, pp. 281–290, and No. 5, pp. 395–416; also Ill. Geol. Surv. Bull. 41). *Degonia ss.*—In typical occurrence a very massive, cliff-making ss., but locally it contains rather thick strata of thinly bedded sss., conspicuously ripple marked, which in places are almost aren. shales. Much of fm. is notably cross bedded. Light brown on fresh surfaces; weathers darker. Thickness 50 ft. or less to more than 100 ft. Rests on Clore ls., with apparent conformity. Overlain, apparently conformably, by Kinkaid ls. Heretofore included in Pottsville, but discovery above it of Kinkaid ls., which carries a Chester fauna, proves it properly belongs to Chester group. Included in Clore fm. *as mapped in earlier repts.*

Named for Degonia Twp, Jackson Co., Ill., where it is a conspicuous cliff maker in bluffs of the Mississippi and sides of tributary valleys.

DeKalb limestone member (of Kansas City formation).

Pennsylvanian: Iowa, northwestern Missouri, southeastern Nebraska, and eastern Kansas.

H. F. Bain, 1898 (Am. Jour. Sci., 4th, vol. 5, pp. 437–439). *DeKalb ls.*—Ls., known as *Fusulina* ls., 15 to 30 ft. thick, occurring in sh. interval btw. Westerville ls. above and Winterset ls. below. Included in Bethany ls.

J. L. Tilton, 1913 (Iowa Acad. Sci. Proc., vol. 20, p. 210), applied *Chanute sh.* to the sh. separating *DeKalb ls.* from overlying Westerville ls., and *Cherryvale sh.* to sh. separating the DeKalb from the underlying Winterset ls.

J. L. Tilton, 1921 (Iowa Geol. Surv. vol. 27, p. 186) and 1924 (Iowa Geol. Surv. vol. 29), correlated DeKalb ls. and Westerville ls. with Drum ls., and called the sh. overlying it *Chanute sh.* and the sh. underlying it *Cherryvale sh.* He also called the ls. overlying Chanute sh. the Iola ls., instead of Westerville.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3, p. 91). Cherryvale sh. of Kans. divided into following members (descending): Quivira sh., *DeKalb ls.* (erroneously called Drum ls. by Hinds and Greene), Wea sh., Block ls., and Fontana sh.

R. C. Moore and G. E. Condra, Oct. 1932 (revised classification chart of Penn. rocks of Kans. and Nebr.) adhered to latter definition of Cherryvale sh., but discarded *DeKalb ls.* for *Westerville ls.*, a name introduced by Bain at the same time he introduced DeKalb, in rept. cited above.

G. E. Condra, 1933 (Nebr. Geol. Surv. Paper No. 4, p. 29). "DeKalb ls." of Iowa Surv., defined by Bain, is synonym of Winterset [an older ls. than Westerville], and should be discontinued because latter has priority. The Westerville ls., defined by Bain, is "Drum ls." of Kansas City section.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, p. 40). In Oct. 1932, R. C. Moore, G. E. Condra, and F. C. Greene traced so-called Drum ls. of Kansas City area to Winterset, Iowa, and determined that type DeKalb is Winterset ls. As *Winterset* has priority, the term *DeKalb* must be dropped.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Named for DeKalb, Decatur Co., Iowa.

DeKalb granite.

Pre-Cambrian: Northern New York (St. Lawrence County).

H. P. Cushing, 1916 (N. Y. State Mus. Bull. 191, pp. 13, 17, 19, 23). *DeKalb granite.*—Most of it is a fine-grained red orthogneiss, quite like the granite at Macomb and Alexandria. Is chiefly a feldspar quartz rock, with very little mica, and with inclusions of amphibolite solely. Is pre-Camb., but uncertain whether it belongs to older Laurentian intrusives or to younger "Algoman" intrusives. Occurs in DeKalb [St. Lawrence Co.].

DeKalb moraine.

Pleistocene (Wisconsin stage): Northwestern New York. Named for DeKalb and DeKalb Junction, St. Lawrence Co. (See Jour. Geol., vol. 32, pp. 645, 664, 1924. Also A. F. Buddington, 1934 (N. Y. State Mus. Bull. 296, p. 45), who stated that this moraine is prominently developed S. of DeKalb Junction.)

Dekkas andesite.

Middle Triassic: Northern California (Redding quadrangle).

J. S. Diller, 1906 (U. S. G. S. Redding folio, No. 138). *Dekkas andesite.*—Is generally a dark-gray lava, more or less porphyritic, but not conspicuously so to naked eye. Includes a great mass of lava made up of many separate overlapping volcanic flows and sheets of tuff more or less distinctly bedded, irregularly conformable, and dipping eastward. Along E. border of quad. these rocks are overlain conformably by and to a small extent are interbedded with bottom part of Pit shales. Overlies Nosoni fm. and underlies Bully Hill rhyolite. Thickness approx. 1,000 ft. Named for exposures along Dekkas Creek.

DeKoven formation.

Pennsylvanian (Allegheny): Western Kentucky.

L. C. Glenn, 1912 (Ky. Geol. Surv. Rept. Prog. 1910 and 1911, p. 27). *DeKoven fm.*—Shales with thin sss. and thin unworkable coals, and, at base, Sebree ss., a coarse massive ss. 10 to 50 ft. thick. Thickness 100 to 400 ft. Uncon. overlies Tradewater fm. (Penn.) and uncon. underlies Mulford fm. (Penn.) in Webster Co.

Probably named for Dekoven, Union Co.

Delaneys Creek facies.

Name applied by P. B. Stockdale (Ind. Dept. Cons., Div. Geol., Pub. 98, pp. 77, 169, etc., 1931) to a lithologic facies of his Carwood fm. in Washington Co., Ind.

Delano moraine.

Pleistocene (Wisconsin stage): Southern Minnesota.

F. Leverett, 1932 (U. S. G. S. P. P. 161, p. 85). Included in Crow River morainic system. Village of Delano, Wright Co., stands on this moraine.

Delaware limestone.

Middle Devonian: Ohio.

N. H. Winchell, 1874 (Ohio Geol. Surv. vol. 2, pp. 290–302). *Upper Corniferous ls. (Delaware ls.; also Sandusky ls).*—Blue even-bedded argill. ls. 35 ft. thick (the "Delaware stone") forms lower and major part. This div. is extensively quarried at Delaware. Very hard, heavy bedded, pyritiferous dark ls. (Tully ls.), 4 to 9 ft. thick, forms upper part. Rests on Delhi ls., the top bed of Lower Corniferous [Columbus] ls.

E. Orton, 1878 (Ohio Geol. Surv. vol. 3). *Delaware ls.*, the upper part of Corniferous ls., consists of (descending): (1) Thin-bedded ls.; (2) Ferris Quarry ("Delaware stone"); (3) siliceous blue ls.; and (4) bone bed 6 ft. thick. Rests on Columbus ls. (Lower Corniferous) and is overlain by Huron sh. [The bone bed has been included in Columbus ls. since 1890. See under *Columbus ls.*]

In central Ohio the fm. overlying Delaware ls. is Olentangy sh.

Named for exposures at Delaware, Delaware Co.

Delaware flags.

Upper Devonian: Northeastern Pennsylvania.

I. C. White, 1882 (2d Pa. Geol. Surv. Rept. G_6, pp. 73, 76, 77, 80). *Delaware flags.*—Alternating beds of bluish-green and greenish-gray sss. 20 to 40 ft. thick, and greenish sandy shales, with one reddish bed 10 to 15 ft. thick. The sss. are quarried and sold under name of "Blue Stone." Thickness 1,000 to 1,200 ft. Probably represents New Milford ss. group of Susquehanna and Wayne Counties. Overlies New Milford group (consisting of red sh., 20; green ss. 40; and red sh. 15), and is overlain by 50 ft. of red sh. succeeded by 300 ft. of greenish sss. and shales, on which lies Lackawaxen cgl.

†Delaware limestone.

Silurian (Niagaran): Central eastern Iowa.

S. Calvin, 1895 (State Univ. Iowa Lab. Nat. Sci. Bull., vol. 3, pp. 183–189) and 1896 (Iowa Geol. Surv. vol. 5, pp. 49–50). *Delaware stage.*—Cherty dol., 200 ft. thick, including Coralline and *Pentamerus* beds. Underlies Leclaire ls. and forms basal part of Niagara series in eastern Iowa.

Replaced by *Hopkinton ls.* (by Calvin in 1906), because preoccupied.

Named for development in Delaware Co.

†Delaware gravels.

See under *†Delaware River gravels and clays.*

Delaware flag series.

See under *Delaware River flags.*

†Delaware sandstone.

†Delaware formation.

Shortened forms of *Delaware Mtn fm.* (Perm.) of western Tex. that are used by some writers.

Delaware Mountain formation. (Of Guadalupe group.)

Permian: Western Texas (Delaware and Guadalupe Mountains and Sierra Diablo).

G. B. Richardson, 1904 (Univ. Tex. Min. Surv. Bull. 9, p. 38). *Delaware Mtn fm.*—Essentially light and dark-colored ss. and ls., though locally includes some sh. At base 200 ft. or more of blue-black thin-bedded ls. Greatest exposed thickness 2,300 ft., but base not seen and relations to Pennsylvanian Hueco fm. not determined. Underlies Capitan ls.

Lower fm. of Guadalupe group.

P. B. and R. E. King, 1929 (A. A. P. G. Bull., vol. 13, pp. 921–922, 924, 925). *Delaware Mtn fm.* has been divided into following members: (1) Upper dark ls.; (2) *Delaware Mtn ss.*; (3) basal black ls. (here named Bone Canyon memb. of Leonard fm.). A short distance N. of Bone Canyon, on W. side of Guadalupe Mtns, a wedge of gray ls. (here named Victoria Peak memb. of Leonard fm.) appears beneath the uncon. at base of Delaware Mtn ss. and separates that ss. from Bone Canyon memb. The Delaware Mtn fm. as originally defined is not a natural group, but consists of beds of Leonard and Word age, separated by an uncon. For this reason it is here suggested that if term *Delaware Mtn* be retained it should be restricted to the beds above the basal black ls. [also to the beds above Victoria Peak memb.]. Includes near base a thin bed of gyp. (here named *Dos Alamos gyp.*).

R. E. King, 1931 (Univ. Tex. Bull. 3042, p. 13, chart opp. p. 146). *Delaware Mtn fm.* restricted to beds overlying (uncon.) Bone Canyon ls. [=Bone Spring ls., the approved name].

K. H. Crandall (A. A. P. G. Bull., vol. 13, 1929, pp. 941–943), R. E. King (Univ. Tex. Bull. 3042, 1931, p. 13), W. B. Lang (A. A. P., G. Bull., vol. 19, No. 2, 1935), and other geologists are now satisfied that typical Delaware Mtn fm. of Delaware Mtns includes in its upper part the time equiv. of Capitan ls., and that the beds underlying Capitan ls. and called Delaware Mtn fm. in Guadalupe Mtns are=only lower part of Delaware Mtn fm. of Delaware Mtns.

P. B. King, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 697–795). *Delaware Mtn fm.* restricted to beds above Bone Spring ls. (here treated as a distinct fm.) and below Castile gyp. in Delaware Mtns, and below Capitan ls. and above Bone Spring ls. in Guadalupe Mtns, the Victorio Peak memb. being here included in Bone Spring ls.

W. B. Lang, 1937 (A. A. P. G. Bull. vol. 21, No. 7). Upper part of *Delaware Mtn fm.* in the reef zone is replaced by Capitan ls., and upper portion of middle part of the Delaware Mtn grades laterally into Dog Canyon ls. The Delaware Mtn rests on Bone Spring ls.

Named for prominent exposures in Delaware Mtns, El Paso Co., Tex.

Delaware Mountain sandstone.

A name that has been applied by some geologists to the basal sandy beds of Delaware Mtn fm. in Guadalupe Mtns, Tex., that overlie the black Bone Spring ls. and underlie the upper dark ls. memb. of Delaware Mtn fm. (See under *Delaware Mtn fm.*)

†Delaware River gravels and clays.

Pleistocene: Southeastern Pennsylvania and northern Delaware.

C. E. Hall, 1881 (2d Pa. Geol. Surv. Rept. C_6). *Delaware River gravels and clays.*—Include alluvium, Trenton gravel [Cape May fm.], Philadelphia brick clay [Cape May and Pensauken fms.], Red gravel [Pensauken fm. in part], Yellow gravel [a part of Bridgeton fm.], and Bryn Mawr gravel.

F. D. Chester, 1884 (Am. Jour. Sci., 3d, vol. 27, pp. 189–199 and map). *Delaware gravels.*—Undiff. Philadelphia clay and underlying Red Gravel.

T. D. Rand, 1900 (Acad. Nat. Sci. Phila. Proc., pt. 1, p. 168). The *Delaware River gravels* occur at much lower level than Bryn Mawr gravel and overlie similar schists and gneisses.

Includes deposits ranging from top of Pamlico fm. to base of Brandywine fm.

Named for development along W. side of Delaware River in northern Delaware.

Delaware River flags.

Upper Devonian: Northeastern Pennsylvania.

I. C. White, 1882 (2d Pa. Geol. Surv. Rept. G_6, pp. 94, 99–101). *Delaware River flags,* 1,200 to 1,430 ft. thick in Pike and Monroe Counties. Underlie Montrose red sh. and overlie New Milford red ss. Include Lackawaxen cgl. and Delaware flags. In Wayne and Susquehanna rept (G_5) these beds were subdivided into several members under head of *Paupack and New Milford ss. groups,* whose combined thicknesses were 585 ft., but these intervals were found to increase so enormously southward that the Wayne and Susquehanna Co. subdivisions could not be followed, hence I deem it best to replace the names *Paupack and New Milford sss.* by a single geographical term which would include both the latter and at the same time suggest the nature of the beds. All the great flagstone quarries along Delaware River are found at different horizons in these beds. Good exposures along Delaware River btw. Narrowsburg and Pond Eddy, where they are 1,430 ft. thick.

I. C. White, 1883 (2d Pa. Geol. Surv. Rept. G_7). *Delaware flag series.*—About 357 ft. thick in Wyoming Co. Underlies Montrose red sh. and overlies Lackawaxen cgl.

B. Willard, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 8, pp. 1205–1206). *Delaware River flags* (late Portage) is retained, but the beds are older (instead of younger) than New Milford red sh., which at type loc. is upper Chemung. The red sh. [beneath Delaware River flags] is renamed *Analomink red sh.*, after village in Monroe Co., where at least 100 ft. of it is well exposed. The underlying Starrucca ss. of White in Monroe Co. is simply upper part of Trimmers Rock ss. and is dropped.

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 571, 586–588). *Delaware River flags* are 1,500± ft. thick on Delaware River N. of Hawks Nest, N. Y., the type region. They *underlie* New Milford fm., and are of upper Portage age, as determined by Prosser, although the fm. itself is nearly unfossiliferous. There is little doubt it is=Oneonta of N. Y. It locally rests on Analomink red sh. (which was mistaken by I. C. White for his New Milford fm.). In part of Pike and Monroe Counties it rests on marine Portage, the Trimmers Rock ss. Beyond the Lehigh the Delaware River and Trimmers Rock fms. have not been closely separated, both being fossiliferous marine Portage. [Table on p. 571 shows following downward succession: Delaware River flags, Analomink red sh., Trimmers Rock ss. Table on p. 606 shows Trimmers Rock ss.=Delaware River and Analomink.]

Delhi limestone.

Middle Devonian: Central Ohio.

N. H. Winchell, 1874 (Ohio Geol. Surv. vol. 2, pp. 296–301). *Delhi ls.*—Light cream-colored, crystalline or saccharoidal, very thin-bedded ls., 28 ft. thick, forming upper memb. of Lower Corniferous [Columbus] ls. in Sandusky, Seneca, Crawford, Delaware, and Marion Counties. Underlain by 10 to 15 ft. of fossiliferous bluish ls. of Lower Corniferous, and overlain by Upper Corniferous or Delaware ls.

E. Orton, 1878 (Ohio Geol. Surv. vol. 3). "Delhi stone" belongs near top of Columbus ls.

C. R. Stauffer, 1909 (Ohio Geol. Surv. Bull. 10, p. 63). The "Delhi beds" of Winchell comprise upper 32 ft. of Columbus ls.

Named for exposures at Delhi, the old name for Radnor, Delaware Co.

Delhi formation.

Mississippian: Northern California (Colfax quadrangle).

W. Lindgren, 1900 (U. S. G. S. Colfax folio, No. 66). *Delhi fm.*—Chiefly a peculiar dark-brown or black hard rock so fine-grained as to be almost flinty and rarely showing either stratification or schistosity. Often has chertlike appearance, but contains less silica than the normal chert. The peculiar petrographic character probably due to regional metamorphism. Very few lenticular ls. masses occur in it. In a few places the rock shows marked schistosity and resembles a dark siliceous clay sl. The fm. corresponds to part of Calaveras fm. Overlies Cape Horn sl. and underlies Clipper Gap fm. Typical exposures near Delhi mine, Nevada Co.

Delicias beds.

Paleozoic: Mexico.

E. Haarmann, 1913 (Deutsche geol. Gesell. Zeitschr., Bd. 65, Monatsber. 1, p. 22).

E Böse, 1921 (Am. Jour. Sci., 5th, vol. 1, pp. 188, 194), assigned these beds to Perm.

Dellville sandstone.

Upper Devonian: Southern central Pennsylvania (Perry County).

E. W. Claypole, 1885 (2d Pa. Geol. Surv. Rept. F_2, pp. 77–78, 394). *Dellville ss.*—Heavy bed of green ss., mostly in thin beds; near middle a layer of vegetable matter about 1 inch thick, consisting almost wholly of fossil plant stems. Exposed at Dellville, Perry Co. I have taken it as base of proper Catskill in Perry Co., but some may prefer to include underlying King's Mill shales and King's Mill ss. in the Catskill.

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, p. 582). In Susquehanna Valley, in Dauphin and Perry Counties, the Honesdale ss. is a distinctly gray to greenish gray, heavily bedded ss., usually carrying carbonized fragments of plants, probably unidentifiable. At low water it can be seen as prominent ledges in river bed. Possibly this is what Claypole called *Dellville ss.* in Perry Co.

Delmar sand.

Eocene: Southern California (San Diego County).

M. A. Hanna, 1926 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 16, No. 7, pp. 187–246). *Delmar sand.*—Sss., shales, and some beds, composed almost wholly of oysters, that might be considered ls. but usually the matrix surrounding the shells is argill. rather than calc. The sss. are both coarse grained and fine grained, and grade into aren. shales. They are of prevailingly brown color, but often have a tinge of green, while a few beds have a reddish and purplish cast. Many shales are well stratified, but others grade into shaly sands. Bedding is irregular. Cross bedding is prominent in many places. Upper part contains more sand than lower part, and the sands are of darker color than overlying Torrey sand, into which the Delmar sand grades. Thickness more than 200 ft. Is basal div. of La Jolla fm. in La Jolla quad. Rests uncon. on Chico Cret. Named for excellent exposures in sea cliff at town of Delmar, San Diego Co.

Delmontian stage.

Tertiary: California.

See under *Zemorrian stage*, R. M. Kleinpell, 1934.

H. G. Schenck, 1936 (A. A. P. G. Bull., vol. 20, No. 2, p. 224). *Delmontian stage* includes uppermost Monterey, upper Santa Margarita fm., etc.

DeLong cyclical formation.

A name applied by H. R. Wanless (Ill. Geol. Surv. Bull. 60, 1931, pp. 179–193) to a middle portion of Pottsville fm. (Penn.) of central western Ill., based upon the rhythmic-cycle theory of sedimentation. Derivation of name not stated.

†Delphi black shale.

Upper Devonian: Northern central Indiana.

R. T. Brown, 1883 (Ind. Dept. Geol. and Nat. Hist. 12th Ann. Rept., p. 84). *Genesee sh. or Delphi black sh.*, uppermost Dev. fm. Named for Delphi, Carroll Co. [See also †Louisville-Delphi black sl.]

Same as New Albany sh., older and better established name.

†Delphi dolomite.

Permian: Southwestern Oklahoma and northern Texas.

C. N. Gould, 1902 (Okla. Geol. Surv. 2d Bien. Rept., pp. 42, 56). *Delphi dol.*—White, drab, gray, or yellowish dol., 3 ft. thick, forming top memb. of Greer div. In places true dol., in places only a mag. ls.; in places aren. and soft, in places of cavernous or honeycombed structure; often firm and solid. Separated from underlying Collingsworth gyp. by 20 ft. of red clay sh.

Replaced by Mangum dol. memb. (of Blaine gyp.), because of prior use of Delphi for a Dev. fm. in Ind.

Named for Delphi, Greer Co., Okla.

Delphi member. (In Skaneateles shale.)

Middle Devonian: Central New York.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 219+). *Delphi memb. of Skaneateles fm.*—New name proposed for the sh. overlying Mottville memb. of Skaneateles fm. and underlying Pompey memb. of Skaneateles. At base it is soft, dark, and mostly argill., becoming gradually sandier to top, where it is hard, fine, calc. ss. characterized by great abundance of large pelecypods. Type section is Knights Falls, 1 mi. E. of Delphi, where it is fully exposed. Thickness 65 ft. (in Unadilla Valley) to 217± ft. in Bear Mtn ravine, Onondaga Valley.

Del Rio clay. (In Washita group.)

Lower Cretaceous (Comanche series): Southern Texas.

R. T. Hill and T. W. Vaughan, 1898 (U. S. G. S. Nueces folio, No. 42, p. 2; U. S. G. S. 18th Ann. Rept., pt. 2, pp. 236–237). *Del Rio clay.*—Greenish laminated clay, weathering yellow, with beds of ls. Included in Washita div. Overlies Fort Worth ls. [broad sense and=Georgetown ls.] and underlies Shoal Creek [Buda] ls.

Named for Del Rio, Valverde Co.

†Delthyris shaly limestone.

Lower Devonian: Eastern New York.

L. Vanuxem, 1840 (N. Y. Geol. Surv. 4th Rept., p. 377). *Delthyris shaly ls.*—Underlies Scutella ls. [Becraft ls.] and overlies Pentamerus ls. [Coeymans ls.].

Paleontologic name for New Scotland ls.

Demoiselle formation.

Mississippian: New Brunswick.

G. W. H. Norman, 1932 (Canada Geol. Surv. Econ. Geol. ser., No. 9, p. 171).

†Demopolis (broad sense).

Upper Cretaceous: Alabama.

E. A. Smith, 1888 (Ala. Geol. Surv. Rept. Prog. 1884–88, geographic map of Ala.; no description). [*Demopolis (Rotten ls.)* is applied on map to rocks btw. Eufaula (Ripley) above and Eutaw below. This is first geographic name introduced to replace "Rotten ls.," but in 1894 Dr. Smith introduced *Selma chalk* to replace "Rotten ls.," and in 1903 he applied "Demopolis div." to what he called middle memb. of Selma chalk in Ala.]

Apparently named for exposures at Demopolis, Marengo Co.

†Demopolis division (narrow sense).

Upper Cretaceous: Alabama.

E. A. Smith, 1903 (58th Cong., 1st sess., S. Ex. Doc. 19, pp. 12–20 and map). *Middle or Demopolis div. (of Selma chalk).*—Of more uniform composition than upper div. of the Selma, and freer from clay, being made up of ls., generally containing less than 25 percent of clayey matter. Fossils rarer than in other divisions. The lowermost beds of Demopolis div. are a compact ls. of great purity called horsebone rock. Overlain by Portland div. of Selma chalk and underlain by Selma div. of the Selma. Thickness about 300 ft.

Later workers did not find it feasible to make the 3 subdivisions of the Selma indicated in above-cited rept, and the names have been discarded. (See Ala. Geol. Surv. Spec. Rept. No. 14, 1926, p. 239.)

Named for exposures at Demopolis, Marengo Co.

Dempsey marble.

Name applied, in table, but not defined, by G. I. Adams (Jour. Geol., vol. 41, No. 2, p. 163, 1933) to a memb. of Talladega sl. in Clay Co., Ala.

Denain formation.

Jurassic (?): British Columbia.

J. D. MacKenzie, 1921 (Canada Geol. Surv. Summ. Rept. 1920, pt. A, pp. 48, 73).

DeNay limestone member (of Francis formation).

Pennsylvanian: Central southern Oklahoma (Pontotoc County).

G. D. Morgan, 1922 (Okla. Geol. Surv. Circ. No. 12, pp. 9, 10) and 1924 (Bureau of Geol. [Okla.] Bull. 2, pp. 110–115). *DeNay ls. memb.*—Basal memb. of Francis fm. In region N. of Canadian River the bed is rather dense and breaks out in elongated blocks. In road about 1/4 mi. E. of Francis the bed is slightly crinoidal. In region S. of Ada the bed is almost wholly composed of crinoids. In NE. part of T. 3 N., R. 5 E., [Pontotoc Co.] the crinoids become less abundant and the ls. develops a bright yellow color. Average thickness a little more than 1 foot. Is overlain by 30± ft. of dark blue and black shales.

Named for typical development on side of an eastward-facing bluff in sec. 5, T. 4 N., R. 7 E., about 1/4 mi. W. of DeNay School, in Stonewall quad.

Denison formation. (In Washita group.)

Lower Cretaceous (Comanche series): Northeastern Texas and southern Oklahoma.

R. T. Hill, 1889 (Am. Jour. Sci., 3d, vol. 37, p. 290). *Denison beds.*—Alternations of clay, lime, and sand, 100 ft. thick. Top fm. of Washita div. Overlies Vola ls. [not †Vola ls.] and underlies Lower Cross Timber beds [Woodbine sand].

R. T. Hill, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 504, 517). *Denison beds.*—Laminated aren. clays at base, grading upward into sandy clays and occasional lss., the chalky element of all the underlying Comanche series having finally disappeared. In Grayson, Cooke, and Denton Counties, Tex., and in Indian Territory, is divisible into (ascending): (1) Blue marly clay, weathering brown, with occasional layers of immense, rounded fissile indurations, generally of brown color; (2) more sandy and ferruginous beds, oxidizing into ironstone and almost indistinguishable from Dakota sss.; (3) impure yellow ls. underlying Main Street in Denison. Underlies, uncon., Dakota sss. [Woodbine sand] and overlies Fort Worth ls. Top fm. of Washita div. [This is present generally accepted definition of Denison fm.]

Named for exposures at Denison, Grayson Co., Tex.

Dennis limestone.

Pennsylvanian: Eastern Kansas and Nebraska and northwestern Missouri.

G. I. Adams, 1903 (U. S. G. S. Bull. 211, p. 36). *Dennis ls.*—Fossiliferous ls., 10 to 20 ft. thick, varying from heavy-bedded to thin-bedded, with sh. partings. Overlies Galesburg shales and underlies Cherryvale shales.

In 1912 the equivalency of Dennis ls. of Adams (1903) with Winterset ls. of Bain (1898) was regarded, by E. Haworth, F. C. Greene, and other geologists, as established. The name *Winterset* having priority, *Dennis ls.* was discarded by U. S. Geol. Survey, and *Winterset ls.* was adopted for the ls. underlying Cherryvale sh. and overlying Galesburg sh. This usage was followed by U. S. Geol. Survey and Kans. Survey until 1932, when R. C. Moore revived Dennis, as explained below.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3, pp. 91, 97). *Dennis fm.* underlies Cherryvale sh., overlies Galesburg sh., and includes (descending) Winterset ls., Stark sh., and Canville ls. The *Canville ls.* is a thin blue bed which has typical "middle" characteristics. The overlying *Stark sh.* is a black, fissile sh. The Winterset ls. is same as previously recognized in Kans. and Mo. Because the Canville and Stark evidently belong with the Winterset, as part of another sedimentation cycle, these terms are combined under name *Dennis fm.*, a name used in early Kans. repts to include these strata. The so-called Galesburg sh. of Kansas City area is mainly Stark sh.

J. M. Jewett, 1932 (p. 102 of rept. cited above). *Dennis fm.* includes Canville ls., Stark sh., and Winterset ls., all of which are present near Dennis, in NE. part of Labette Co., Kans.

R. C. Moore and G. E. Condra adopted this revised definition in their Oct. 1932 revised classification chart of Penn. rocks of Kans. and Nebr.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pp. 30, 32, 36). Type Dennis includes more than Winterset ls. The Canville ls. and overlying black Stark sh. [4 to 7 ft.] lie at horizon of upper part of so-called Galesburg sh. of Kansas City region. According to Jewett they both are present at both Galesburg and Dennis. The older writers did not mention any ls. or black sh. in the type Galesburg, and it is almost certain they were grouped with the overlying main ls. under the name *Dennis*, in which they are included in this rept.

See also Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936, and also see R. C. Moore, 1936 entry under *Galesburg sh.*

Named for exposures at R. R. station at Dennis, Labette Co., Kans.

Dennis Bridge limestone. (In Millsap Lake formation.)

Pennsylvanian: North-central Texas (Parker County).

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 106, 107), from ms. of rept., by G. Scott and J. M. Armstrong, on geol. of Parker Co. (See 1933 entry under *Millsap Lake fm.*) Type loc. not stated.

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, pp. 15, 16). *Dennis Bridge ls.* is included in Lazy Bend memb. of Millsap Lake fm. by Scott and Armstrong. It is 10 ft. thick and lies at base of the section conspicuously exposed on the Brazos at S. end of the bridge at Dennis, Parker Co.

Denny sand.

A subsurface sand in Chester group (Miss.) of Perry Co., Ill.

Dennys formation.

Silurian: Southeastern Maine.

E. S. Bastin and H. S. Williams, 1913 (Maine Water Storage Comm. 3d Ann. Rept., p. 168; Geol. Soc. Am. Bull., vol. 24, pp. 378, 379). [Name mentioned but not defined. Refers to Eastport folio.]

E. S. Bastin and H. S. Williams, 1914 (U. S. G. S. Eastport folio, No. 192, pp. 3, 10). *Dennys fm.*—A succession of volcanic rocks and a few small interbedded masses of fossiliferous strata. Principal rock is rhyolite of several types, occurring as flows and tuffs. Interbedded with and otherwise closely associated with the rhyolite are several varieties of andesite, in flows and tuffs. Diabase flows and tuffs also occur. The effusive rocks have been disturbed by intrusion of masses of diabase and andesite and possibly also rhyolite. Underlies, possibly uncon., Edmunds fm. Lower limit of fm. not known. Contact with older Quoddy sh. is almost certainly a fault. Fossils indicate Niagaran age. Named for exposures near Dennysville, Washington Co.

Dense limestone.

Ordovician (Lower): Central northern Oklahoma (Lucien field, Noble County).

B. B. Zavoico, 1934 (Tulsa Geol. Soc. Digest 1934, p. 60). *Dense ls.*, top memb. of Simpson group in Lucien field, is 0 to 20 ft. thick. Underlies Prosser ls. and overlies Simpson dol. [This name is capitalized wherever used in this paper, but origin of name and lithology not stated.]

Denton clay member (of Denison formation).

Lower Cretaceous (Comanche series): Northeastern Texas and central southern Oklahoma.

J. A. Taff, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, p. 272). *Denton marl.*—Chiefly friable blue marl, characterized by *Gryphaea pitcheri*, with, at top, 5 ft. of cgl. containing *Gryphaea pitcheri*, and lower down a thin bed of sand and one of ss. Thickness 40 ft. Upper part of Fort Worth ls. Underlies Denison marl.

F. W. Cragin, 1895 (Am. Geol., vol. 16, pp. 384–385). *Denton terrane* underlies North Denison terrane (basal terrane of Denison div.) and overlies Fort Worth terrane.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, pls. 18, 19, pp. 114–115, 121–124, 266–276). *Denton subgroup.*—Consists of (descending): (1) breccia of *Ostrea carinata* and *G. washitaensis*, 2 ft.; (2) brown clay marls, less calc. than No. 3, 18 ft.; (3) *Gervilliopsis* beds (marls and fissile indurated layers), 8 ft. Underlies Weno fm. and overlies Fort Worth fm. Is basal div. of Denison beds.

L. W. Stephenson, 1918 (U. S. G. S. P. P. 120H, pp. 140–141). *Denton clay memb. of Denison fm.*—Consists of (ascending): (1) 5 ft. of strongly calc. clay of a decided marly character; (2) 35 ft. of shaly, less calc. clay; (3) 3 to 5 ft. of highly fossiliferous impure ls. composed largely of shells of *Gryphaea washitaensis*, a few echinoid spines and other fossils, including a large number of *Ostrea carinata*, which led to its being called "Ostrea carinata bed."

Named for Denton Creek, Denton Co., Tex.

Denver formation.

Upper Cretaceous and Eocene (?): Eastern Colorado (Denver Basin).

W. Cross, 1888 (Colo. Sci. Soc. Proc., vol. 3, pt. 1, pp. 119–133). *Denver fm.*—Upper part predominantly coarse cgls. with minor clay and sandy beds; seen only in Green Mtn, having elsewhere been eroded away. Lower half (including all known strata except those in upper part of Green Mtn) frequent recurring alternations of cgls., grits, sss., sandy clays, and nearly pure clays; pebbles seldom exceed 3 in. in diam.; sss. are cross bedded. Thickness of fm. 1,400± ft. Embraces strata not hitherto distinguished from coal-bearing Laramie Cretaceous. Is of limited extent. Contains dinosaur remains. Uncon. overlies Willow Creek series [Arapahoe fm.] and uncon. underlies Monument Creek beds. Occupies a basin excavated out of Willow Creek fm. [Arapahoe fm.] or even in some parts cutting into underlying Laramie group.

W. Cross, 1889 (Am. Jour. Sci., 3d, vol. 37, pp. 261–282). Upper 525 ft. of *Denver fm.* is mainly coarse cgls. Lower 915 ft. is as a rule fine-grained strata, yellowish brown friable sss. prevailing, with all manner of gradations into clays and cgls.; transitions both lateral and vertical; cross bedded. Local uncon. btw. upper and lower parts.

W. Cross, 1893 (Int. Cong. Geol., Compte rendu, 5th sess., pp. 437–438). *Denver beds* are fresh-water lake deposits of sss. and cgls. and in lower part made up almost exclusively of volcanic rocks representing many varieties of andesite.

C. J. Hares, 1926 (Geol. Soc. Am. Bull., vol. 37, p. 175). The thesis is advanced that upper 525 ft. of Denver fm. should not be classed with lower 915 ft. at type loc. at Green Mtn. The lower part is well stratified sh., ss., and cgl., while upper div. is wholly conglomeratic, with no shales or sss. observable. The cgl. while rather fine at bottom of upper div. becomes coarser toward top, where boulders 2 to 4 ft. diam. are very common; the largest boulder is 6 ft. Absence of good stratification suggests its probable glacial origin. Structurally the 2 divisions are separable, for the lower one dips at high angles, while the upper is almost flat lying. It is believed that 2 distinct lithologic units are classed in Denver fm., one similar to Arapahoe below and the other of entirely different character and seemingly of glacial origin and post-Eocene age.

The age of this fm., which was formerly classified as *Eocene*, was changed, Dec. 1935, to *Cret. and Eocene* (?), as explained under *Lance fm.*, last entry.

Denver mud.

A term that has been applied (according to personal communication of J. B. Reeside, Jr.) to deposits of bentonite, of Cret. and other ages, occurring in the Western States and used in pharmaceutical preparations and for other purposes. For further particulars see Hugh S. Spence, Canada Dept. Mines, Mines Branch, Pub. 626, pp. 27, 28, etc., 1924. Spence states: "As a straight paper filler or loader bentonite is reported to have been used in large quantities by a Denver mill, most of the early production from Wyo. having been used for this purpose."

Denzer tuff.

Pre-Cambrian: South-central Wisconsin (Baraboo district).

J. T. Stark, 1932 (Jour. Geol., vol. 40, No. 2, pp. 120, 121, 132). *Denzer tuff.*—Water-laid tuff exposed in a ledge nearly 200 ft. long and 5 to 20 ft. wide on N. bank of a small stream in SE. ¼ of sec. 11, T. 10 N., R. 5 E., about 1½ mi. NE. of Denzer, Honey Creek Twp. In previous repts has been called rhyolite. Assigned to pre-middle Huronian.

A. Leith, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 329). Archean of Baraboo dist. consists of rhyolite, *Denzer tuff*, and granite.

Denzer diorite.

Pre-middle Huronian: South-central Wisconsin (Baraboo district).

J. T. Stark, 1932 (Jour. Geol., vol. 40, No. 2, pp. 120, 121, 137). *Denzer diorite* occurs in 2 areas in Baraboo dist., one NW. and one N. of Denzer, in secs. 9 and 10, T. 10 N., R. 5 E. Assigned to pre-middle Huronian.

Departure Bay calcarenites.

Upper Cretaceous: British Columbia.

C. H. Clapp, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 95).

Depass fm.

Middle Cambrian: Western Wyoming (Owl Creek and Wind River Mountains).

B. M. Miller, 1935 (Geol. Soc. Am. Proc. 1934, p. 352). The name *Depass* is here applied to all beds in the Wyo. "Deadwood" below the Gallatin, the type section being in Wind River Canyon, where Big Horn River cuts through eastern end of Owl Creek Range.

B. M. Miller, 1936 (Jour. Geol., vol. 44, No. 2, pp. 123, etc.). As Flathead and Gros Ventre fms. are followed E. through Owl Creek and Wind River Mtns, the Flathead ss. lithology rises gradually and invades lower part of Gros Ventre fm., the ss. and sh. facies interfingering and finally becoming so mixed that the 2 fms. are not separable and are together designated *Depass fm.* Type section is in Wind River Canyon at E. end of Owl Creek Range. The name is taken from the "D" Pass (now spelled "Depass"), near E. end of Bridger Range, and will apply from about middle of Owl Creek Range at least as far E. as E. end of Bridger Range, and probably in part of Big Horns. In Wind River Mtns it will apply from SE. end of the range at least as far NW. as North Fork of Popo Agie River, but not farther N. than Bull Lake Creek. Well-exposed sections of the fm. are not common.

†Depauville waterlime.

Lower Ordovician: Central New York (Jefferson County).

E. Emmons, 1840 (N. Y. Geol. Surv. 4th Rept., p. 324). Birdseye ls. not certainly identified in Jefferson Co., but I have called a ls. btw. French Creek and Depeauville the Birdseye. Is compact, breaks with conchoidal fracture, and contains no fossils. It is the first of the water limes. I have called this the water-lime rock of Depeauville; or *Depeauville water lime,* as it was at this place it was first prepared for use. If I am right the Depeauville water lime occurs in beds, or overlies the Birdseye. Its beds are rarely more than 10 ft. thick at those places where it is quarried.

H. P. Cushing, 1908 (Geol. Soc. Am. Bull., vol. 19, pp. 155+), applied *Pamelia ls.* to the beds of Chazy age in Theresa and Alexandria Bay quads., Jefferson Co., of which he stated the Depauville waterlime of Emmons constituted a small part. (See first entry under *Pamelia ls.*)

The village name is spelled *Depauville.*

†Depeauville water lime.

See †*Depauville waterlime.*

De Queen limestone member (of Trinity formation).

Lower Cretaceous (Comanche series): Southwestern Arkansas and southeastern Oklahoma.

H. D. Miser and A. H. Purdue, 1918 (U. S. G. S. Bull. 690, pp. 19, 22). *De Queen ls. memb. of Trinity fm.*—Fossiliferous ls. (usually gray, hard, and compact but much of it is earthy, platy, and yellowish gray) and an equal or greater amount of green clay; gyp. and celestite near base. Thickness 60 to 72 ft. Lies in upper part of Trinity fm., at a higher horizon than Ultima Thule gravel lentil. Passes through De Queen, Sevier Co., Ark., into Okla.

Derby dolomite. (In Elvins group.)

Upper Cambrian: Eastern Missouri.

E. R. Buckley, 1907 (Mo. Bur. Geol. and Mines vol. 10, 2d ser., separate), and H. A. Buehler, 1907 (Mo. Bur. Geol. and Mines vol. 6, 2d ser., p. 231), in tables divided Elvins fm. into (descending) Doe Run, Derby, and Davis, without defining the subdivisions.

E. R. Buckley, 1909 (Mo. Bur. Geol. and Mines vol. 9, pt. 1, pp. 15, 44). *Derby fm.*—Dol., fine-grained, crystalline, slightly calc., light gray to yellowish gray or reddish brown; some alternating soft porous beds. Thickness 38 to 40 ft. Conformably underlies Doerun fm. and conformably overlies Davis fm.

Named for Derby mine (now Federal mine), near Elvins, St. Francois Co.

Desamparados formation.

Cretaceous or Eocene: Costa Rica.

A. H. Redfield, 1923 (Econ. Geol., vol. 18, p. 359).

Descanso granodiorite.

Late Jurassic or early Cretaceous: Southern California (San Diego and Imperial Counties).

W. J. Miller, 1935 (Calif. Jour. Mines and Geol., vol. 31, No. 2, pp. 115–141, map). *Descanso granodiorite.*—Almost everywhere light gray, medium grained, with, locally, finer grained varieties. Cuts Alpine quartz diorite and is probably of about same age as Harbison quartz diorite. All assigned to late Jurassic or early Cret. Type occurrence in general vicinity of Descanso, southern Peninsular Range.

Deschutes formation.

Late Tertiary or early Pleistocene: Central northern Oregon (Deschutes Basin).

I. C. Russell, 1905 (U. S. G. S. Bull. 252, pp. 90–91). *Deschutes sand* [in heading].—The material forming the walls of outer canyon of Deschutes and Crooked Rivers and extending eastward, where it underlies Prineville Valley. It also underlies the sheet of basalt exposed here and there beneath the rich wind-deposited soils of a large section of the Haystack country, to N. and E. of Opal Canyon.

Is exposed in wall of Deschutes River for at least 25 mi. upstream from mouth of Crooked River, probably is present for a long distance below that locality, and no doubt underlies several hundred sq. mi. of Deschutes plain. Sufficient attention has not yet been given to the fm. to enable a description of it to be put on record, but such notes as are available show that it was waterlaid, probably by streams. The material forming "Deschutes sand," as the fm. will perhaps be termed when its history is more fully studied, consists largely of black basic and frequently scoriaceous grains and kernels of volcanic rock, forming a coarse sand, mingled with which are lesser quantities of quartz grains. Stratification distinct, beds thinly laminated, but layers can not usually be traced more than a few hundred yards; frequently cross bedded. Some beds are composed of well-worn gravels with pebbles 6 to 8 inches diam. Claylike beds are also present, also a bed of white diatomaceous earth.

E. T. Hodge, 1927 (Geol. Soc. Am. Bull., vol. 38, pp. 162–163). *Deschutes sand* consists of several basalt flows and interflow lake and torrential beds. Lies absolutely flat and covers an immense area N. of Bend, E. to Prineville, and extends as embayments into the valleys of the Cascades. Flows higher in Cascade Mtns may be of same age and origin.

E. T. Hodge, 1928 (Pan-Am. Geol., vol. 49, pp. 350–356), proposed *Madras fm.* to "include part of Satsop fm. and all of Dalles beds, Deschutes sands, and Deschutes fm. Latter name objectionable because Deschutes River exposes at least 8 fms., several of which occupy larger sections than Madras fm."

H. T. Stearns, 1931 (U. S. G. S. W. S. P. 637, p. 136). *Deschutes fm.*—Horizontal beds of yellow, brown, and black partly consolidated sand, silt, gravel, and stratified fluviatile deposits of volcanic detritus, mostly basic, intercalated with and in most places capped by basalt flows; in a few places beds of white diatomite with a max. thickness of 40 ft. are included. Thickness 1,000+ ft. Is same as Deschutes sand of I. C. Russell. No fossils found except the siliceous algae skeletons that compose the diatomite deposits. In places rests on Columbia River basalt (Mio.); in other places rests on andesite considered to be of Mio. or Plio. age.

Desdemona sand.

A subsurface sand, of Penn. age, in Desdemona field, Eastland Co., north-central Tex., lying at 2,600 ft. depth.

Desecheo stage.

Quaternary: Puerto Rico.

B. Hubbard, 1923 (N. Y. Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, vol. 2, pt. 1, p. 97).

Deseret limestone.

Mississippian (upper): Central northern Utah (Oquirrh Mountains region).

J. Gilluly, 1932 (U. S. G. S. P. P. 173). *Deseret ls.*—Blue-gray cherty ls. in beds averaging 2± ft. thick, with a 6 to 8-foot bed of phosphatic sh. at base. Thickness 650 ft. Conformably underlies Humbug fm., the bdy being arbitrarily placed at base of first ss. or qtzite bed of notable thickness. Rests conformably on Madison ls. Fossils are upper Miss. and correlate with lower part of Brazer ls. Exposed at Deseret mine, Dry Canyon, Stockton quad.

†De Smet formation.

Eocene and, in places, Upper Cretaceous: Northern Wyoming.

N. H. Darton, Nov. 17, 1906 (U. S. G. S. P. P. 51, pp. 13, 62–67, etc.). *De Smet fm.*—Alternating shales (mostly carbonaceous) and soft and massive sss., 5,000+ ft. thick. Overlies Kingsbury cgl. [Long description.] Is Upper Cret. and Eo. (?). May be in part Laramie and may include higher beds. The name *De Smet* (here proposed for this fm.) is from Lake De Smet [Fort McKinney quad.], where it is typically exposed.

See also N. H. Darton, 1906 (U. S. G. S. folios Nos. 141 and 142; and Geol. Soc. Am. Bull., vol. 17, p. 544, Dec. 31, 1906).

In 1910 it was decided that De Smet fm. of Darton was same as Fort Union fm., and De Smet was, accordingly, discarded. Later field work showed that Lance, Fort Union, and Wasatch fms. were all included in original De Smet fm. as mapped.

De Smet formation.

Pre-Cambrian: Southwestern South Dakota (Lawrence County).

J. O. Hosted and L. B. Wright, 1923 (Eng. and Min. Jour.-Press, vol. 115, pp. 793–799, 836–843, with maps). *De Smet fm.*—Garnet schist, alternating light and dark bands, micaceous, fibrous, thinly foliated. Most of schist is green to dark gray. Underlies Homestake fm. and overlies Poorman fm. Thickness 300 ft. Believed to be of Keewatin age.

Named for exposures around N. end of main open cut SW. of De Smet shaft, Lead dist., Lawrence Co.

Des Moines group.

Pennsylvanian: Northwestern Missouri and Iowa.

C. R. Keyes, 1893 (Iowa Geol. Surv. vol. 1, pp. 86–114). *Des Moines beds, or Lower Coal Measures.*—Shales sss., lss., clays, and coals underlying Missouri fm., or Upper Coal Measures, and uncon. overlying Lower Carbf. in Iowa. Thickness 400 ft.

Des Moines group was adopted by U. S. Geol. Survey many years ago, for NW. Mo. and SW. Iowa, to include rocks from base of Kansas City fm. to top of Mississippian. This was the commonly accepted definition. The group as defined included Pleasanton fm., Henrietta fm., and Cherokee sh., and was overlain by Missouri group, the basal bed of which was Hertha ls. (See H. Hinds and F. C. Greene, Mo. Bur. Geol. Mines vol. 13, 1915.) Owing to great number of named subdivisions of Penn. rocks in Kans. and SE. Nebr., the U. S. Geol. Survey has been accustomed to treat the major subdivisions of Des Moines and Missouri age as *groups*, and therefore does not use *Missouri group* and *Des Moines group* in its rock classification of those States. These names (*Missouri group* and *Des Moines group*) were not used by Kans. Geol. Surv. in its classification until 1917 (Moore and Haynes). In 1932 Moore redefined the names, as explained below.

R. C. Moore, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, p. 279), divided Penn. "system," as he called it, of Midcontinent region into 4 "series," named (descending): Virgil, Pottawatomie, *Des Moines*, and Bend. He stated: Des Moines series contains a huge thickness of ss., cgl., and sh. in Okla. and Ark., but to N. and S. thickness is much reduced and there are lss. in upper part. The top of the series is marked by an uncon. and by one of most clearly defined paleontologic boundaries in the Penn. A distinct and widespread uncon. marks base of the series. [The limits of this unit differ from those of *Des Moines group* of prevailing usage.]

C. [R.] Keyes, 1932 (Pan-Am. Geol., vol. 57, p. 346). The term *Des Moines*, for a provincial coal-bearing series, is a revival of Owen's early name (Proc. Am. Assoc. Adv. Sci., vol. 5, p. 47, 1851) for the coal measures of Des Moines River Valley, which in pioneer days constituted the most important coal field W. of the Appalachians. The title is not a Keyes proposal, as is so often accredited. [On p. 47 of cited vol. of Proc. A. A. A. S. is a paper by D. D. Owen entitled "On the existence of phosphorus in the carbonates of iron of the Des Moines coal fields," and on succeeding pages Owen referred to the "coal measures of the Des Moines," but nowhere did he apply the name *Des Moines* to any strat. unit. Keyes is therefore the original proposer of name *Des Moines beds*. On this same page Keyes also stated:] Recent suggestion of R. C. Moore to extend term *Des Moines* downward so as to include most of Arkansan delta deposits finds no response from regional diastrophism, or from homonymic correlation. Its paleontological reasons are already demonstrated to be entirely untenable.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936, for Moore's restricted definitions of *Des Moines series*. His 1936 definition (Kans. Geol. Surv. Bull. 22, pp. 41–43) restricts *Des Moines* to beds extending from discon. at top of Nowata (?) sh. down to base of Cherokee sh., and includes overlying rocks in his Missouri series restricted. The Mo. Geol. Surv. 1933 (57th Bien.) and 1935 (58th Bien.) repts continued to use

Des Moines group to include (descending) Pleasanton, Henrietta, and Cherokee fms.

The U. S. Geol. Survey has not had occasion to consider these innovations for its publications.

Named for exposures on Des Moines River, Iowa.

†De Soto beds.

Pliocene (lower): Southern Florida.

W. H. Dall, 1892 (U. S. G. S. Bull. 84, pp. 126, 133, 141, 157, 158, 324). [In table on p. 157 the term *De Soto beds* is bracketed opposite Alachua clays, Peace Creek bone bed, and Arcadia marl (descending order). The other pages mentioned contain references to "De Soto, a supposed Pliocene lake in Florida, named for the Spanish explorer." Page 324 states that the De Soto beds "include the lower marine Pliocene beds of Peace Creek and the Alachua clays." Page 158 states that 50 ft. "would be a liberal allowance for the De Soto beds."

Replaced by Caloosahatchee marl, the older name.

Detrick sand.

A subsurface sand in eastern central Okla. that is said to correlate with Tyner fm. (Ord.).

Detroit interlobate moraine.

Pleistocene (Wisconsin stage): Southeastern Michigan. Shown on moraine map (fig. 7) in U. S. G. S. Detroit folio (No. 205), p. 9; also on moraine map (pl. 32) in U. S. G. S. Mon. 53. Named for Detroit. Is a water-laid moraine.

Detroit River dolomite.

Lower Devonian: Southeastern Michigan and western Ontario, and northern Ohio.

A. C. Lane, C. S. Prosser, W. H. Sherzer, and A. W. Grabau, 1909 (Geol. Soc. Am. Bull., vol. 19, p. 555). *Detroit River series* here proposed for Upper Monroe, from exposure of all its members along Detroit River. Includes (descending): Lucas dol., 200± ft.; Amherstburg dol., 20 ft.; Anderdon ls., 40 to 50 ft.; Flat Rock dolomites, 40 to 150+ ft. Discon. overlies Sylvania ss.

Deutozoic.

A time (life) term applied by E. Hitchcock (Geol. Vt., 1861, vol. 1, 4 mo., p. 19) to "Triassic"—in which he probably included Lias of Europe (which is now generally classified as Lower Jurassic), because he called the overlying rocks "Oolitic."

Devils Den limestone. (In Graford formation.)

Pennsylvanian: Central northern Texas (Wise County).

E. Böse, 1918 (Univ. Tex. Bull. 1758, p. 17). *Devils Den ls.*—Quite uniform gray or dark bluish hard ls. containing rare crinoids and parts of brachiopods. Thickness in Devils Den, Wise Co., 50± ft., but top is not there visible. Covers W. side of Jim Ned Mtns. Seems to be a lenticular mass which thins out and disappears to N. Not found on N. side of Sand Flat Range. Separated from underlying Rockhill ls. by 140± ft. of sss. with intercalated shales, which compose E. slope of Jim Ned Mtns. "The highest lss. of the section [which would seem to include his Devils Den and Elm Creek lss.] should perhaps be considered as belonging to Canyon div."

G. Scott and J. M. Armstrong, 1932 (Univ. Tex. Bull. 3224, p. 33). *Devils Den ls.* belongs in Graford fm., and because top of Graford cannot actually be determined in Wise Co., the top of Devils Den ls. is arbitrarily taken as top of Graford fm. To N. of Trinity River this ls. is top tongue of Chico Ridge ls. It is older than Adams Branch ls. Is overlain by Ventioner beds.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 105, 111, 112). *Devils Den ls.* is same as Wizard Wells ls., and latter name is discarded.

†Devils Den sandstone.

Upper Devonian or Mississippian: Northwestern Pennsylvania.

G. H. Chadwick, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, pp. 332, 333 (footnote), 335, 336, 339). If, and writer is not averse to this, to succeeding Cussewago, or Knapp, group is transferred top 40 ft. of original Conewango at Warren, the Smethport (subsequently Kushequa) sh. of Caster, carrying therewith the corresponding upper part of the Riceville, and also the *Devil's Den* (*Leptodesma*) *ss.* near Smethport, then some of Miss. element (so called) is subtracted and case for Dev. age of Conewango is by that much strengthened. [Lists fossils from *Devil's Den ss.*, but does not give type loc.]

G. H. Chadwick, 1935 (letter dated Dec. 11). I do not consider Devil's Den ss. as adequately established. It was just a convenience.

Devils Glen dolomite.

Upper or Middle Cambrian: Northwestern Montana.

C. F. Deiss, 1933 (Mont. Bur. Mines and Geol. Mem. 6, pp. 40 and passim). *Devils Glen dol.*—Youngest Camb. fm. in NW. Mont. In type loc. is massive, thick beds of white-gray dol. that weathers dull gray white, usually stained buff, and occasionally with pinkish spots. Lower beds generally thinner and contain less magnesia than upper ones. Thickest (669 ft.) in Dearborn region, thinnest (41 ft.) in Pentagon Mtn region. Top is eroded. Overlies Switchback ls. and uncon. underlies White Ridge ls. memb. of Jefferson ls. (Middle Dev.). Named for Devils Glen, a local feature in S½ sec. 1, T. 17 N., R. 8 W., which is formed of the dol.

Devil's Gulch beds.

See under *Valentine beds* (*Plio.?*), where occur only known usages of this name.

Devils Island sandstone. (In Bayfield group.)

Pre-Cambrian (upper Keweenawan): Northwestern Wisconsin (Ashland, Bayfield, and Douglas Counties).

F. T. Thwaites, 1912 (Wis. Geol. Nat. Hist. Surv. Bull. 25, p. 38). *Devils Island ss.*—Pink and white pure quartz ss., thin-bedded, with abundant ripple marks. Thickness 300 ft. Middle fm. of Bayfield ss. group. Conformably underlies Chequamegon ss. and overlies Orienta ss. Named for exposures on Devils Island, Ashland Co.

Devils Kitchen member (of Deese formation).

Pennsylvanian: Central southern Oklahoma (Carter County).

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z, pp. 14–15). *Devil's Kitchen memb. of Deese fm.*—Comprises 2 massive buff sss., each 60 to 200 ft. thick, separated by a sh. interval with 10 ft. or more of fossiliferous impure ls. and calc. sh.; the upper ss. contains chert grains, and SE. of Ardmore develops into a coarse cgl. of angular to subangular chert pebbles. Lies 800± ft. above top of Dornick Hills fm. and is overlain by a series of blue and tan shales with numerous ss. ledges, which composes rest of Deese fm.

C. W. Tomlinson, 1929 (Okla. Geol. Surv. Bull. 46, pp. 35–36). *Devil's Kitchen memb.*, about 500 ft. thick, is named for a glen in sec. 10, T. 6 S., R. 2 E., which is sheltered by overhanging cliffs of the chert-pebble cgl.

Devils Lake sandstone.

Upper Cambrian: Central southern Wisconsin (Sauk County).

E. O. Ulrich, 1920 (Wash. Acad. Sci. Jour., vol. 10, pp. 74, 75). [*Devils Lake ss.* shown in diagrams as underlying Mendota dol. and overlying Jordan ss. at Madison and Devils Lake, Sauk Co., and as composing basal fm. of his Ozarkian system.]

F. T. Thwaites, 1923 (Jour. Geol., vol. 31, p. 546). *Devils Lake fm.*—Gray and yellow, more or less glauconitic ss. and qtzite pebble cgl. Thickness not definitely known; max. may be over 100 ft. Known only in a few exposures near the qtzite ranges at Baraboo, Sauk Co. Has never been located in a complete normal section away from the old beaches, and it is not positively known whether all of supposed occurrences are of same age. Possibly some strata here ascribed to Mazomanie fm. are Devils Lake. In best exposure, SW. of Baraboo, it is underlain by glauconitic ss. and purple spotted dol. unlike anything known in normal section outside the qtzite ranges. At other places the fm. has been found resting on Jordan and possibly on other fms. In some places Mendota dol. overlies Devils Lake fm. and in other places Oneota dol. overlies it.

E. O. Ulrich, 1924 (Wis. Acad. Sci. Trans., vol. 21, pp. 71–93). *Devils Lake ss.* of southern Wis., about 100 ft. thick, underlies Mendota dol. and overlies Jordan ss. Is basal fm. of Ozarkian system in that area. Absent in western Wis.

J. M. Wanenmacher, W. H. Twenhofel, and G. O. Raasch, 1934 (Am. Jour. Sci., 5th, vol. 28, pp. 24–25). Devils Lake ss. of Ulrich included (1) typical Devils Lake ss. (which is a shore phase of a part of the middle part of Trempealeau fm.), (2) the basal cgl. memb. of Trempealeau fm., and (3) the basal cgl. memb. of Franconia fm. It is recommended the term be abandoned.

W. H. Twenhofel, G. O. Raasch and F. T. Thwaites, Nov. 30, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 11, p. 1702). In region around Baraboo a fauna near top of Hudson memb. of Franconia fm. has been assigned by Ulrich to his proposed Devils Lake fm., which he placed at base of his Ozarkian system in Wis. This proposed fm. was described by Thwaites (Jour. Geol., vol. 31, 1923, p. 546) on responsibility of Ulrich, but it could not be placed in strat. section except by fossils. Later work by Wanenmacher, Twenhofel, and Raasch (Am. Jour. Sci., 5th, vol. 28, 1934, pp. 1–30) shows that the strata of most localities of Devils Lake fauna underlie Upper Greensand memb. of Franconia fm. At 2 localities a different and higher fauna was apparently confused with that from the Franconia, and at one of these (SE¼ SW¼ sec. 10, T. 12 N., R. 5 E.) it is definitely known the strata are high in Trempealeau fm. Writers understand Ulrich has recently altered his views in regard to supposed Devils Lake fm. and faunas.

Devils River limestone.

Lower Cretaceous (Comanche series): Southwestern Texas (Valverde, Presidio, and other counties).

J. A. Udden, 1907 (Augustana Lib. Pub. No. 6, p. 56). *Devils River ls.*—Mostly thick ledges of white and gray pure ls., moderately coarse grained to almost compact and structureless texture. Thickness 500 ft. Includes what in central Tex. is known as Edwards and Georgetown lss., which are not separated by any well-marked horizon of change but merge gradually. Upper 100 ft. or less corresponds to Georgetown ls.; lower 400 ft.=greater part of Edwards ls. Underlies Del Rio clay. Is exposed along entire distance of Devil's River [Valverde Co.] from Camp Hudson down to the Rio Grande.

In western Tex. the name has in some repts been used to include all beds below Del Rio clay and above Trinity group.

C. P. Ross and W. E. Cartwright, Dec. 1935 (Tex. Univ. Bull. 3401, p. 596). *Devils River ls.* in Shafter dist., Presidio Co., appears to include Comanche Peak ls., true Edwards ls., and Georgetown (?) ls., and was in 1904 called Edwards ls. by Udden.

Devoice moraine.

Pleistocene: Northwestern New York (Lewis and Jefferson Counties).

A. F. Buddington, 1934 (N. Y. State Mus. Bull. 296, p. 42). In Antwerp and Carthage quads. Named for Devoice Corners, Antwerp quad.

Devonian period (or **system**).

The time (and the rocks) of the next to youngest Paleozoic system, succeeding the Silurian and preceding the Carboniferous. For definition see U. S. G. S. Bull. 769, pp. 78–80.

Devonic.

A variant of *Devonian* employed by some geologists.

Devonshire formation.

Pleistocene: Bermuda.

A. E. Verrill, 1907 (Conn. Acad. Arts and Sci. Trans., vol. 12, p. 75).

Dewdney formation.

Pre-Cambrian: Southern British Columbia and northeastern Washington.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, map 7, 117° to 117°30′). *Dewdney fm.*—Banded qtzite with congl. interbeds. Underlies Ripple fm. and overlies Wolf fm.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, pp. 153, 178, 194). *Dewdney fm.*—Chiefly qtzite, with two thick congls. in upper part, the upper one 30 ft. thick and the other one (which lies 120 ft. lower) 225 ft. thick.

Conformably underlies Ripple fm., and grades into underlying Wolf fm. Total thickness 2,000 ft. Included in Summit series of Selkirk Mtns. Named for Dewdney Trail, B. C., on both sides of which it is exposed.

Dewdney Creek series.

Jurassic: British Columbia.

C. E. Cairnes, 1923 (Canada Geol. Surv. Summ. Rept. 1922, pt. A, pp. 97, 111). *Dewdney series, Jurassic, B. C.*

C. E. Cairnes, 1924 (Canada Geol. Surv. Mem. 139, p. 56). *Dewdney Creek series, Jurassic, B. C.*

Dewey limestone.

Pennsylvanian: Northeastern, central, and central northern Oklahoma.

D. W. Ohern, 1910 (Okla. State Univ. Research Bull. 4, pp. 30, 37). *Dewey ls. lentil.*—Bluish semicrystalline ls., usually somewhat shaly but often massively bedded, 3 to 15 ft. thick. Stratigraphically 50 to 100 ft. above Hogshooter ls. Is above horizon of Drum ls., but author cannot correlate it. In N. part of area included in Copan memb. of Wann fm.; in S. part of area is basal memb. of Ramona fm.

Some authors have regarded Dewey ls. as=upper part of Drum ls. of Kans., and it is so treated on the 1926 geol. map of Okla., but many geologists now consider it younger than Drum ls. The beds separating Dewey and Hogshooter lss. were in 1925 named *Nellie Bly fm.*

Named for Dewey, Washington Co.

Dewitt formation.

Miocene and Pliocene: Eastern Texas.

A. Deussen, 1914 (U. S. G. S. W. S. P. 335, pp. 28, 74–76). *Dewitt fm.*—All lacustrine and littoral sediments deposited on Coastal Plain of Tex. during Mio. and early Plio. time. Cross-bedded, coarse, gray, semi-indurated, highly calc. sss., with lenses of clay in places. Thickness 1,250 to 1,500 ft. Seaward the time equiv. is represented by marine sands and clays, but these are not included in Dewitt fm. Uncon. underlies Uvalde fm. and overlies Fleming clay.

In U. S. G. S. P. P. 126, 1924, footnotes on pp. 97 and 100, is statement that Dewitt fm. of U. S. G. S. W. S. P. 335 included Oakville, Lapara, and Lagarto fms.

Named for Dewitt Co.

Dexter sand member (of Woodbine sand).

Upper Cretaceous (Gulf series): Northeastern Texas.

J. A. Taff, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 285–298). *Dexter sands.*—Extensive deposit of brown ferruginous ss. heavily laden with siliceous ironstone. Middle div. of Dakota or Lower Cross Timbers fm. Underlies Timber Creek beds and overlies Basal clays of Dakota fm.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7), used *Dexter fm. or Dexter sands* to include Dexter sands of Taff and Basal clays of Taff. Underlies Lewisville beds ("Timber Creek beds") and overlies Grayson marl. [This is generally accepted definition of Dexter sand. It is basal memb. of Woodbine sand.]

Named for exposures at Dexter, Cooke Co.

Dexterville shale member.

Upper Devonian: Northwestern Pennsylvania and southwestern New York.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61, pp. 63–66). *Dexterville sh. memb.*—Middle memb. of Chadakoin stage. Underlies Ellicott sh. memb. and overlies Lillibridge ss. memb. May be regarded as typical Chadakoin, as it is memb. best shown in greater part of Dexterville quarry exposure of the Chadakoin. Named for the brick quarries S. of Chadakoin River in East Jamestown, formerly known as Dexterville. Only upper part of memb. is shown at Dexterville, where it is a blue sh. and flag series carrying the Chadakoin phase of the "C" facies fauna. To E. in Allegheny State Park and about Olean, N. Y., this memb. assumes the chocolate phase of magnafacies "B." [See under *Ellicott sh. memb.* for relations to that memb. On pp. 64–65 detailed section of his

Dexterville memb. is given, aggregating 138 ft. without explanation as to which memb. (Ellicott sh. or Dexterville) the covered interval of 140 ft. belongs.]

†Diabolo sandstone.

Pre-Cambrian: Western Texas (Sierra Diablo region).

W. H. Von Streeruwitz, 1891 (Tex. Geol. Surv. vol. 2, pp. 682, 683). [The red ss. that extends along foot of southern cliffs of Sierra Diabolo is in one place called *Diabolo red ss.* and in another place *Diabolo ss.* It is overlain by grits, and is an inseparable part of Millican fm.]

†Diamond blue limestone.

Term applied by T. C. Hopkins (N. Y. State Mus. Bull. 171, 1914) to 4 to 5 ft. of compact calc. ls. lying 4 ft. below top of Manlius ls. in Syracuse quad., Onondaga Co., N. Y.

Diamond formation.

Recent or late Pleistocene: Southeastern Oregon.

W. D. Smith, 1926 (Oreg. Univ. Commonwealth Rev., vol. 8, pp. 207–214). *Diamond fm.*—Basalt flows and scoria of undet. thickness, typically exposed at Diamond Craters, Harney Co. [See also W. D. Smith, 1927 (Jour. Geol., vol. 35, p. 428), where same definition is given.]

Diamond Head tuff.

Pleistocene (late): Hawaii (Oahu Island).

C. K. Wentworth, 1926 (Bernice P. Bishop Mus. Bull. 30, pp. 40, 42). *Diamond Head tuff.*—Tuff, 1 to 5 ft. thick, forming Diamond Head. Rests on weathered gravel composed of cobbles of Koolau basalt. Overlain by Kaimuki basalt, 4 to 9 ft. thick.

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1. *Diamond Head tuff.*—Palagonitized subaerial brown tuff containing much accessory and accidental ejecta, including appreciable amounts of reef ls. and occasional fragments of Koolau basalt. Included in middle part of Honolulu volcanic series [q. v.]. Is late Pleist. Type loc., Diamond Head. Underlies Kaimuki volcanics.

Diamond Head talus breccia.

Recent: Hawaii (Oahu Island).

C. K. Wentworth, 1926 (Bernice P. Bishop Mus. Bull. 30, pp. 40, 43). Calc. talus breccia composed of angular fragments of tuff cemented into a porous but fairly compact mass, most of which was accumulated wholly under action of gravity. Mantles extensive areas of slopes of Diamond Head with thicknesses of 5 to 25, exceptionally 50, ft. Rests against and on Diamond Head tuff. It is probable that some of this is considerably older than the younger basalts and the black ash, but it seems best to treat it as the youngest rock of Diamond Head region, exclusive of modern alluvium and talus.

Not differentiated by H. T. Stearns in his 1935 rept, in which it is included in Recent sed. rocks. (See Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1.)

Diamond Hill felsite.

Carboniferous: Northeastern Rhode Island.

C. H. Warren and S. Powers, 1914 (Geol. Soc. Am. Bull., vol. 25, p. 461). Assigned to lower Penn.

Diamondian series.

A term introduced by C. [R.] Keyes to designate the Diamond Peak qtzite of Nev.

Diamond Island slate. (In Casco Bay group.)

Carboniferous (Pennsylvanian?): Southwestern Maine.

F. J. Katz, 1917 (Wash. Acad. Sci. Jour., vol. 7, p. 198). *Diamond Island sl.*—A graphitic and pyritiferous quartz sl. Included in Casco Bay group.

F. J. Katz, 1917 (U. S. G. S. P. P. 108, p. 170). *Diamond Island sl.*—Chiefly black, pyritiferous, graphitic, and slightly micaceous quartz sl. of very fine grain; but in lesser part a black or bluish black, somewhat graphitic and also pyritiferous quartz-sericite phyllite. Is characteristically studded with small masses and crystals of pyrite, which weather out and give rise to abundant copperas and rust coatings. Equally characteristic are intricate crumpling on a small scale and an abundance of small crumpled quartz veins. Estimated thickness btw. 75 and 150 ft. Included in Casco Bay group. Underlies Scarboro phyllite and overlies Spring Point greenstone. Assigned to Penn. (?). Named for exposures on Great Diamond Island and Little Diamond Island in Casco Bay.

Diamond King member (of Esmeralda formation).

Miocene (upper): Central Nevada (Manhattan district).

H. G. Ferguson, 1924 (U. S. G. S. Bull. 723). *Diamond King memb.*—Chiefly massive, even-grained, porphyritic rhyolite flows and tuff. Upper part is bedded tuff that logically should have been included in overlying Bald Mtn lake-beds memb., but impossibility of making any good separation in field rendered it advisable to include the tuff in Diamond King memb. Thickness of memb. 100 to 800± ft. Separated from older Round Rock memb. by 0 to 80 ft. of thin-bedded quartzose ss., upon which it rests with erosion uncon. For convenience this ss. is mapped with Round Rock memb. The Diamond King memb. is prominent on Diamond King Hill.

Diamond Peak quartzite.

Carboniferous (upper Mississippian): Northern Nevada and Inyo County, California.

A. Hague, 1883 (U. S. G. S. 3d Ann. Rept., pp. 253, 268). *Diamond Peak qtzite.*—Massive, vitreous qtzite of grayish brown color, passing near summit into brown and green shales and schists, and with firmly cemented cgl. at base. A narrow belt of blue ls. about 500 ft. above base contains Carbf. fossils. Thickness 3,000 ft. Overlies White Pine sh. and is overlain by Lower Coal Measures. Named for exposures on flanks of Diamond Peak, Eureka dist., Nev.

According to G. H. Girty the fossils in the ls. 500 ft. above base of Diamond Peak qtzite are upper Miss. and rest of fm. is not fossiliferous. He would therefore tentatively assign whole fm. to upper Miss.

The Diamond Peak qtzite, with a thickness of 3,500 ft., has been identified by E. Kirk (U. S. G. S. P. P. 110, 1918) in Inyo Range, Calif., where it is separated from underlying White Pine sh. by 500 to 1,000 ft. of ls. carrying Penn. fossils.

Diamond Rock quartzite.

Lower Cambrian: Eastern New York (Rensselaer County) and western Vermont (?).

R. Ruedemann, 1914 (N. Y. State Mus. Bull. 169, pp. 67–70). *Diamond Rock qtzite.*—Div. G of [T. N.] Dale's Rensselaer series. Consists of granular qtzite and associated calc. ss., 10 to 40 ft. thick. Named for exposures at the "Diamond Rock," Lansingburgh (North Troy), [N. Y.]. Underlies Troy shales and overlies Bomoseen grit—all Lower Camb.

†Diamond Rock.

A name locally applied to lower 2 ft. of beds called Rich Hill ls. memb. of Cherokee fm. in W. part of Vernon Co., Mo., because of tendency of the rock to break into diamond-shaped or rhomboidal blocks. (See F. C. Greene and W. F. Pond, Mo. Bur. Geol. and Mines vol. 19, 2d ser., pp. 51–52, 1926.)

Diana syenite complex.

Pre-Cambrian: Northwestern New York (Lake Bonaparte and Lowville quadrangles).

A. F. Buddington, 1919 (N. Y. State Mus. Bull. 207, 208, pp. 102–110, map). The syenitic complex of Lake Bonaparte and Lowville quads. is roughly grouped as belonging to 2 masses: the *Diana mass* (which is protoclastic and uniformly has a coarse porphyritic texture) and *Croghan mass* (which is uniformly medium equigranular). Diana mass is on whole more basic than the Croghan. [He also called the rocks *Croghan syenite granite complex* and *Diana syenite complex*. Probably named for villages of Croghan and Diana.]

A. F. Buddington, 1929 (N. Y. State Mus. Bull. 281, pp. 90–92). Thickness of *Diana mass* 25,000 to 30,000± ft. *Croghan mass* is probably somewhat younger than Diana body. Both intrude Grenville series.

See also Buddington, 1934 (N. Y. State Mus. Bull. 296, pp. 101–104, 162–164, etc.).

Diana phase.

See 1928 entry under *Conway granite*.

Named for "Diana's Baths," 1 mi. due N. of summit of Cathedral Ledge, North Conway quad., N. H. (Letter from M. Billings dated July 19, 1935.)

Diboll member.

Eocene: Southeastern Texas (Duval County).

I. R. Sheldon, 1933 (A. A. P. G. Bull., vol. 17, No. 7, pp. 819, 820, 822). *Diboll memb. of Jackson fm.*—In Driscoll pool, Duval Co. Top lies at 3,810 ft. depth and bottom at 3,950 ft. depth. Thickness 140 ft. Underlies McElroy memb. of Jackson and overlies "Cockfield" zone, as it is known in South Tex., which rests in Yegua fm.

A. C. Ellisor, 1936 (Gulf Coast oil fields, A. A. P. G., pp. 474–475). The beds btw. the Claiborne and the Olig. can be divided on bases of micropaleontology and lithology into 3 major divisions or fms., which were designated by writer in 1931 (ms. read before Pal. and Min. Div. of A. A. P. G., San Antonio meeting, Mar. 20, 1931) as the Diboll, McElroy, and Fayette. *Diboll* has since been changed to *Caddell*, proposed by Dumble in 1915.

Dickerson member (of Millsap Lake formation).

Pennsylvanian: North-central Texas.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 106, 107), from ms. of rept., by G. Scott and J. M. Armstrong, on geol. of Parker Co. (See 1933 entry under *Millsap Lake fm.*) Type loc. not stated.

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, pp. 15, 16). *Dickerson memb.* of Scott and Armstrong's unpublished ms. on Parker Co., includes all Penn. strata exposed in Brazos River Valley below base of Kickapoo Falls ls. (basal bed of Lazy Bend memb.). [Derivation of name not stated. Fauna is listed.]

Dicob moraine.

Pleistocene: Northwestern New York (Lowville quadrangle).

A. F. Buddington, 1934 (N. Y. State Mus. Bull. 296, p. 40). Recessional moraine exposed intermittently along a line extending S.-SW. through Dicob School from about ¾ mi. E. of Bush's Corners to S. border of quad.

Dierks limestone lentil (of Trinity formation).

Lower Cretaceous (Comanche series): Southwestern Arkansas.

H. D. Miser and A. H. Purdue, 1918 (U. S. G. S. Bull 690B). *Dierks ls. lentil of Trinity fm.*—Fossiliferous ls. with a smaller amount of green clay. Thickness 0 to 40 ft. Separated from overlying Ultima Thule gravel lentil of the Trinity by variegated clays and from underlying Pike gravel memb. of the Trinity by a great thickness of gray cross-bedded sand with some clay. Named for exposures near Dierks, Howard Co.

Difficulty Creek latite.

Tertiary (Miocene or Pliocene): Southwestern Colorado (Ouray region).

W. Cross and E. Howe, 1907 (U. S. G. S. Ouray folio, No. 153). *Difficulty Creek latite.*—Porphyritic latite. Cut by wild canyon of Difficulty Creek. Intrusive into Potosi tuffs [Potosi volcanic series].

Dighton conglomerate.

Carboniferous: Southeastern Massachusetts and Rhode Island.

J. B. Woodworth, 1899 (U. S. G. S. Mon. 33, pp. 134, 184–187, and pl. 17). *Dighton cgl. group.*—The name *Dighton cgl.* is here given to a group of coarse cgls., with alternations of ss., found as highest members of the Carbf. in Dighton, Somerset, and Swansea, in Mass. The coarsest cgl. bed is at base of fm. Thickness 1,000–2,000± ft. Rests on Rhode Island Coal Measures. Correlated with Purgatory cgl. of Rhode Island.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 51–55, and map). *Dighton cgl.*—Long lenses of peculiar cgl. infolded in Rhode Island fm. Regarded same as Purgatory cgl. of Rhode Island.

Dilco coal member (of Mesaverde formation).

Upper Cretaceous: Northwestern New Mexico (Gallup-Zuñi Basin).

J. D. Sears, 1925 (U. S. G. S. Bull. 767). *Dilco coal memb.*—Light-gray to white lenticular ss. and light-gray clay sh., with valuable coal beds throughout basin. Thickness 240 to 300 ft. Underlies Bartlett barren memb. and overlies Gallup ss. memb.—all belonging to Mesaverde fm. Named for village of Dilco, where 4 of the coal beds have been worked in Dilco mine.

†Dillard series

Lower Cretaceous: Southwestern Oregon.

G. D. Louderback, 1905 (Jour. Geol., vol. 13, pp. 522–555). *Dillard series.*—Marine sss., shales, cgls., cherts, and lss., with abundant igneous rocks at frequent intervals. Thickness 8,000 to 10,000 ft. Mapped as *Myrtle fm.* by Diller, but is older than Myrtle fm. as defined by Diller, and is uncon. with it. Is pre-Knoxville, and made in Franciscan time, and is practically identical with Franciscan. Fossils suggest it is in part at least Jurassic. May lie stratigraphically (even uncon.) below Franciscan, but may be looked upon as a northern extension of the Franciscan. Named for village, on the railroad, which is in midst of largest area of this series in Roseburg quad.

J. S. Diller, 1907 (Am. Jour. Sci., 4th, vol. 23, pp. 401–421). Primarily upon lithological grounds "Dillard series" was proposed for the sediments of Dillard area under impression they were older than Knoxville. The presence of Knoxville fossils at so many points throughout the area demonstrates conclusively that great part if not the whole mass of sediments within Dillard area are really Knoxville, and were properly included in Myrtle fm. as originally defined and still unchanged. The Myrtle has always been regarded as practically = Shasta group of Calif. Writer is of opinion the equiv. of Franciscan of Calif. is most likely in Dothan fm.

Dillard sand.

A subsurface sand, of Penn. age, in Keystone pool, central northern Okla., which is correlated with upper part of Cleveland sand and with a part of Nowata sh.

Dillon gas horizon.

Name proposed by A. F. Crider (A. A. P. G. Structure symposium, vol. 2, 1929, p. 178) for producing horizon of Dillon No. 43 well, Pine Island oil field, Caddo Parish, La., which lies in Trinity group (of Comanche age), 90 ft. above Dixie oil horizon, and lower than Wickett oolitic zone.

Dilworth sand.

Eocene (upper): Southeastern Texas (Atascosa, Karnes, and Gonzales Counties).

A. C. Ellisor, 1933 (A. A. P. G. Bull., vol. 17, No. 11, pp. 1302, 1311, etc.). *Dilworth sand.*—Basal zone of Whitsett fm. as here defined. At Dilworth, 0.8 mi. E. of brick schoolhouse, on J. Winclarek 39.5-acre tract in Geo. Blair survey, the *Dilworth sand* consists of (descending): (1) 8 ft. of thin (1 to 2 inches) flaggy, ripple-marked ss. alternating with layers of green sh. and volcanic glass 1 to 2 inches thick; (2) 2 ft. of green clay; (3) 3 inches of thin, flaggy, very fine-grained ss.; (4) 4 ft. of green bentonitic sh.; (5) 2 inches of thin, flaggy, fine-grained ss.; (6) 2½ ft. of loose sand with green clay inclusions; (7) 2 ft. of chocolate thinly laminated sh. with streaks of sand; total 18 ft. 11 in. Underlies Falls City sh. Been traced across Atascosa, Karnes, and Gonzales Counties.

B. C. Renick, 1936 (Univ. Tex. Bull. 3619, table opp. p. 17 and pp. 34–36). *Dilworth ss. memb. of Manning fm.*—In Gonzales Co., ¾ mi. SE. of Dilworth, extending across the E. Kramling 50-acre tract, the Wm. Green 144-acre tract, and the Jno. Sewfera 105-acre tract in George Blair survey, there is a persistent ss. ledge to which Miss Ellisor applied the name Dilworth sand. In Grimes and

Brazos Counties there is a very persistent ss. 50 to 70 ft. below Whitsett fm. [as here restricted] which was used extensively in mapping structure through Grimes, Brazos, and eastern Washington Counties. This ss. was not found in western Washingtor Co. and in most of Fayette Co. On basis of strat. position and interval to base of Catahoula fm., this ss. has been tentatively correlated with Dilworth ss. of Miss Ellisor in Gonzales Co., though it is recognized the ss. designated Yuma may be=Dilworth ss. of Gonzales Co. [The table shows his expanded Manning fm. (250 to 350 ft. thick) as underlying his restricted Whitsett fm. (75 to 132 ft. thick), and divided his Manning into (descending): (1) Same as No. 5, 0 to 25 ft.; (2) Yuma ss., 3 to 25 ft.; (3) same as No. 5, 25 to 40 ft.; (4) Dilworth ss., 2 to 22 ft.; (5) chocolate colored lignitic clay with interbedded tan sand and ss. and gray tuffaceous ss., with thin beds of lignite, some thin fossiliferous marine beds, but mostly nonmarine, thickness not given.]

Dimple limestone.

Pennsylvanian: Southwestern Texas (Marathon region, Brewster County).

J. A. Udden, C. L. Baker, and E. Böse, 1916 (Univ. Tex. Bur. Econ. Geol. and Tech. Bull. 44, p. 46). *Dimple fm.*—Alternating beds of dark gray ls., black chert, and black sh., with a few beds of chert cgl. The lss. carry marine fossils. Named by Udden. Thickness 925 ft. Overlies Tesnus fm. and underlies Haymond fm.

C. Schuchert, 1927. [See 1927 entry under *Tesnus fm.*]

P. B. and R. E. King, 1928 (Univ. Tex. Bull. 2801). *Dimple fm.* grades into overlying Haymond fm. and grades into underlying Tesnus fm. Thickness 1,100 ft.

Is chiefly ls.

Named for exposures in and near Dimple Hills, Pecos Co.

Dingess limestone. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and D. B. Reger, 1914 (W. Va. Geol. Surv. Rept. Logan and Mingo Counties, p. 165). *Dingess ls.*—Marine, fossiliferous, gray and hard, frequently brown and siliceous, lenticular and ferriferous. Thickness 0 to 5 ft. Lies 1 to 30 ft. below Williamson ss. and 0 to 30 ft. above Williamson coal. Named for Dingess, Mingo Co.

Dingess shale. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties). *Dingess sh.*—Dark-green sandy sh., 0 to 30 ft. thick. Underlies Dingess ls. and overlies Williamson coal.

R. V. Hennen and D. D. Teets, Jr., 1919 (W. Va. Geol. Surv. Rept. Fayette Co., p. 927). *Dingess sh. and ls.*, 20 to 30 ft. of gray to black, limy, and siliceous sh. with ls. lenses, widely persistent in Kanawha, Fayette, Nicholas, Boone, Logan, and Mingo Counties, W. Va., and in Ky. Underlies Williamson ss. and overlies Dingess ss. (0 to 22 ft. thick) or the underlying Williamson coal.

Dingess sandstone. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and D. D. Teets, Jr., 1919 (W. Va. Geol. Surv. Rept. Fayette Co., pp. 926–928). *Dingess ss.*—Lenticular, 0 to 25 ft. thick at Dingess, Mingo Co. Underlies Dingess sh. and overlies or is separated from underlying Williamson ("Dingess") coal by 1 ft. of sl.

Dingus limestone. (In Pottsville formation.)

Pennsylvanian: Northeastern Kentucky (Morgan County).

L. C. Robinson, 1927 (Ky. Geol. Surv., ser. 6, vol. 26, p. 239). *Dingus ls.*—Fossiliferous ls., at some localities so sandy it is impossible to separate it from overlying and underlying sss. Varies in color from light gray, to yellow, and black. Overlies Amburgy coal. Included in Pottsville series of Morgan Co.

Probably named for Dingus, Morgan Co.

Dinoceras beds.

A paleontologic name applied by O. C. Marsh to basal Olig. beds of the West that contain fossil remains of *Dinoceras.*

†Dinosaur sand.

Lower Cretaceous (Comanche series): Texas.

C. A. White and R. T. Hill, 1887 (Phila. Acad. Nat. Sci. Proc. 1887, p. 40; Am. Jour. Sci., 3d, vol. 33, pp. 296–301). *Dinosaur sand.*—Purely siliceous, fine-grained, uncemented pack sands, called *Upper Cross Timbers* in previous repts. Underlies Fredericksburg div. and overlies Carbf. The upper strata abound in Dinosaurian bones and teeth.

Not a geographic name. Replaced by *Trinity group.* The name has also been applied to Travis Peak fm., the basal fm. of Trinity group.

Dinsmore limestone bed. (In Monongahela formation.)

Pennsylvanian: Southwestern Pennsylvania (Washington County) and southeastern Ohio.

W. T. Griswold and M. J. Munn, 1907 (U. S. G. S. Bull. 318, pp. 69–70). *Dinsmore ls.*—Cream-white ls., about 4 ft. thick, in beds 4 to 8 inches thick, the spaces btw. being filled with calc. sh. Lies about 35 ft. above Sewickley coal. Is overlain by about 20 ft. of sh., olive green above and red or yellow below. Named for town of Dinsmore, Washington Co., Pa.

The Dinsmore ls. bed is in lower part of Benwood ls. memb. of Monongahela fm.

Dinwoody formation.

Lower Triassic: Western Wyoming.

D. D. Condit, 1916 (U. S. G. S. P. P. 98, p. 263). In typical development Embar fm. consists of two principal parts, of which the upper is largely shaly and the lower is chiefly ls. but includes phosphatic and calc. sh. and nodular chert. The name Park City has been adopted by U. S. G. S. for lower part, on recommendation of Blackwelder, who identifies these beds with Park City fm. of Utah. [These beds in western Wyo. were later identified as Phosphoria fm.] Blackwelder has also suggested name *Dinwoody fm.* for upper shaly part, from Dinwoody Canyon, in Wind River Mtns, where the fm., 200± ft. thick, consists of pale-green to white clay and shaly ls. weathering brown and containing obscure pelecypod shells. Evidence at hand seems to indicate Dinwoody beds are Triassic. To E. they change to gypseous greenish or brownish shales devoid of fossils. They grade into Park City fm.

E. Blackwelder, 1918 (Wash. Acad. Sci. Jour., vol. 8, p. 425). *Dinwoody fm.*—Upper part of Darton's Embar fm. Consists of greenish-gray shales with many thin plates of dense calc. ss. or argill. dol., which weathers brown, tawny, and even black. Conformably underlies Chugwater fm. and conformably overlies Park City [Phosphoria] fm. Thickness 250 ft. at Dinwoody Creek, on N. slope of Wind River Range, but thins to less than 50 ft. near Lander, Wyo. In Owl Creek Mtns it is 75 to 100 ft. thick near Anchor. To E., near Thermopolis, the fm. becomes gypseous and more or less reddish. Thickens to W.; being 350 ft. thick at N. end of Hoback Range. Thickens rapidly in SE. Idaho, where it grades horizontally into Woodside and Thaynes fms. Named for canyon of Dinwoody Lakes, in Wind River Range, where it is completely exposed and has been measured in detail.

†Diplacodon beds.

A paleontologic name that has been applied to uppermost Eo. deposits in Uinta Basin, Utah, or the true Uinta fm. of Marsh and King, to which the U. S. Geol. Survey also refers as "*Diplacodon* zone."

Dirty Creek sandstone member (of Atoka formation).

Pennsylvanian: Eastern Oklahoma (Muskogee and McIntosh Counties).

C. W. Wilson, Jr., 1935 (A. A. P. G. Bull., vol. 19, No. 4, pp. 503–520). *Dirty Creek ss. memb. of Atoka fm.*—Thin to massive bedded ss., fine grained, dark blue; color changes from blue to brown and texture from fine to medium grained as ss. is traced from S. to N. Surfaces of bedding planes covered with fucoidal markings. Fossils. Thickness 5 to 20 ft. Separated from underlying Georges Fork ss. memb. by 60 ft. of varicolored sh. and from overlying Webbers Falls ss. memb. by 40 ft. of sh. Named for exposure W. of Dirty Creek, in secs. 11 and 14, T. 12 N., R. 19 E.

Dismal formation.

Pennsylvanian: Southern West Virginia and southwestern Virginia.

M. R. Campbell, 1897 (U. S. G. S. Tazewell folio, No. 44). *Dismal fm.*—Sh. and ss., with several important coal seams, and, in W. part of quad., a coarse cgl. (*Dismal cgl. lentil,* 0 to 120 ft. thick), near middle. Thickness 490 ft. Overlies Raleigh ss. and underlies Bearwallow cgl. Both the fm. and the cgl. lentil named for exposures on Dismal Creek, Buchanan Co., Va.

Dismal conglomerate lentil. (In Dismal formation.)

Pennsylvanian: Southern West Virginia and southwestern Virginia.

See under *Dismal fm.*

†Dismal Swamp formation.

Pleistocene: Coastal Plain of Virginia and North Carolina.

C. K. Wentworth, 1930 (Va. Geol. Surv. Bull. 32, pp. 691+). In 1912 (N. C. Geol. Surv. Bull. 3) L. W. Stephenson applied name *Pamlico* (from Pamlico Sound, N. C.) to the terrace and fm. E. of Chowan fm. and separated from the Chowan by a well-marked sea-facing scarp, which trends almost N. and S. through eastern Gates Co., N. C., and is continuous with Suffolk scarp in Va. The marine part of Pamlico terrace has max. elev. of about 25 ft. at foot of Suffolk scarp, and slopes gently seaward to elevations of 15 to 18 ft. along the coast. Stephenson included in Pamlico terrace the entire Coastal Plain lowland E. of Pamlico-Chowan scarp (Suffolk scarp in Va.). Field work in Va. proves that 2 terraces lower than the Chowan occur on Coastal Plain. These terraces are clearly shown on recent topog. maps of Coastal Plain of Va. The lack of such maps in N. C. makes it still impracticable to discriminate the 2 terraces there. In this rept Pamlico terrace and fm. are subdivided into *Dismal Swamp and Princess Anne terraces and fms.* The *Dismal Swamp terrace and fm.* are named for Dismal Swamp dist., E. of Suffolk scarp, where they are excellently developed. Type area of Dismal Swamp terrace is separated on N. from Princess Anne terrace by a low distinct scarp that trends almost E. and W. south of Oldtown, Norfolk Co., and Bayville, Princess Anne Co. The fm. is chiefly sand, usually clean, white, yellow or light cream; some well-sorted gravel is present. Thickness of fm. 10 to 25 ft. Contains marine fossils, and is largely of marine origin. Remnants of fluvial terraces that merge with the wave-cut Dismal Swamp terraces extend up valleys of principal streams.

C. W. Cooke, 1931 (Wash. Acad. Sci. Jour., vol. 21, Dec. 1931), and 1932 (16th Int. Geol. Cong. Guidebook 5, pp. 34–35). As "Dismal Swamp" terrace has identically same shore line (25 ft.) as Pamlico terrace, the name Pamlico, which has many years priority, should be retained.

Disraeli series.

Silurian (?): Quebec.

F. R. Burton, 1931 (Quebec Bur. Mines Ann. Rept. 1930, pt. D, p. 114).

Ditney formation.

Pennsylvanian: Southwestern Indiana.

M. L. Fuller and G. H. Ashley, 1902 (U. S. G. S. Ditney folio, No. 84). *Ditney fm.*—Ss. and sandy sh., with thin coal bed; 20 ft. thick. Overlain by Inglefield ss. and underlain by Somerville fm.

This name has been dropped by Ind. Geol. Surv., the beds now being included in upper part of their newly defined unit called *Shelburn fm.* See E. R. Cumings, 1922 (Hdb. Ind. Geol., pt. 4, Sep. Pub. 21, p. 525).

Caps Big Ditney and Little Ditney Hills, Warren Co.

Divide andesite.

Tertiary (probably upper Miocene): Southwestern Nevada (Divide district).

A. Knopf, 1921 (U. S. G. S. Bull. 715, pp. 151, 155). *Divide andesite.*—Gray porphyritic rock carrying numerous crystals of glassy striated feldspar and biotite. Weathers lilac gray. Intrudes Fraction rhyolite breccia. Is a large mass that lies SE. of Tonopah Divide mine and forms main bulk of largest and highest mountainous area in dist. Is well shown at highest point on Tonopah-Goldfield road—the divide from which the dist. was named. Appears to have no equiv. in Tonopah dist. Believed to be younger than Oddie rhyolite, but the two have not been found in contact.

Divide Peak andesite.

Age (?): Northern California (Lassen region).

H. Williams, 1932 (Calif. Univ. Pub., Bull. Dept. Geol. Sci., vol. 21, No. 5, map on p. 71), mapped (but did not describe), in Lassen region, the following units (downward order): Augite andesite, *Divide Peak andesite,* hypersthene basalt, *Brokeoff andesite, Brokeoff andesite (solfatarized),* Brokeoff vents, *pre-Lassen dacites, Loomis Peak dacites, NE. Lassen dacites, Old Lassen mud flow,* dacite tuff, domes, dacite breccias, *Lassen 1915 dacite,* and *Lassen 1914–15 mud flows.*

Divine limestone.

Upper Ordovician: Northeastern Illinois (Grundy County).

J. E. Lamar and H. B. Willman, 1931 (Ill. Geol. Surv. Rept. Invest. No. 23, passim). *Divine ls. memb. of Richmond fm.*—Coarse-grained crystalline fossiliferous ls., usually white, light gray, or buff, although locally pink or brown. Thickness 0 to 44 ft. Overlain in places by 0 to 7 ft. of dark-gray sh. belonging to Richmond fm.; in other places overlain by Penn., Pleist., or Recent deposits. Underlain by 13 to 70 ft. of gray calc. nongritty sh. of the Richmond. Is thickest high-calcium bed in Richmond fm. Top and bottom surfaces of the ls. are uneven. Locally erosion channels are cut deep into the stone. Mapped. Named for occurrence in vicinity of Divine station, on Elgin, Joliet & Eastern R. R., Grundy Co. [Shows picture of outcrop ¼ mi. N. of Divine.]

Dixie sand.

A subsurface sand, 20 to 40 ft. thick, in middle of Goodland ls. (Lower Cret.) of eastern Tex.

Dixie sand.

A subsurface sand, of early Penn. age, in Seminole Co., central Okla. In Wewoka pool it lies at 2,800 ft. depth, and the Smith sand lies at 3,132 ft.

Dixie oil horizon.

Name proposed by A. F. Crider (A. A. P. G. Structure symposium, vol. 2, 1929, p. 179) for the oil-producing horizon of Pine Island oil field, Caddo Parish, La., which lies in Trinity group (of Comanche age), 90 ft. below Dillon gas horizon and 193 ft. above Herndon oil sand.

Dixie shale.

Lower Cretaceous: Southeastern Arizona.

C. [R.] Keyes, 1935 (Pan-Am. Geol., vol. 64, No. 2, pp. 129, 138, 139). *Dixie sh.*—Name proposed for upper part of Cintura fm. of Ransome. Thickness 800 ft. Named for Dixie Canyon, near Bisbee. Overlies Mexican ss.

Dixon earthy limestone member (of Wayne formation).

Silurian (Niagaran): West-central Tennessee.

A. F. Foerste, 1903 (Jour. Geol., vol. 11, pp. 566, 578–582, 681, 694). *Dixon clay.*—Red clays, 30 to 40 ft. thick, overlying Lego ls. and underlying white lss. and clays of Brownsport bed in Tenn. River Valley. Of Niagaran age. Few fossils. Usually no sharp line btw. Lego ls. and Dixon red clay.

Top memb. of Wayne fm. Overlies Lego ls. memb. of Wayne. Underlies Brownsport fm.

Named for Dixon Spring, Decatur Co.

†Dixon sandstone. (In Henshaw formation.)

Pennsylvanian: Western Kentucky.

L. C. Glenn, 1912 (Ky. Geol. Surv. Rept. Prog. 1910 and 1911, p. 26). *Dixon ss.*—Fine-grained variable ss., 10 to 60 ft. thick, forming basal memb. of Dixon [Henshaw] fm. in Webster Co.

Preoccupied in Sil. of Tenn.

Named for Dixon, Webster Co., where it is well developed.

†Dixon formation.

Pennsylvanian: Western Kentucky.

L. C. Glenn, 1912 (Ky. Geol. Surv. Rept. Prog. 1910 and 1911, p. 26). *Dixon fm.*—Chiefly calc. sh., with 20-foot bed of ls. in upper half, Vanderburg ss. (25 ft. thick) in middle, and Dixon ss. (10 to 60 ft. thick) at base. Thickness about 340 ft. in Webster Co. Uncon. overlies Lisman fm. (Penn.), and uncon. underlies Lafayette fm. (Plio.).

Preoccupied in Sil. of Tenn. Replaced by *Henshaw fm.*

Named for Dixon, Webster Co.

Dixon schist.

Pre-Cambrian: Northern New York (Adirondacks).

H. L. Alling, 1918 (N. Y. State Mus. Bull. 199). *Dixon schist.*—Feldspathic quartz graphitic schist; upper portion and lower layers usually micaceous. Of sed. origin. Thickness 3 to 30 ft. Included in Grenville series. Probably occurs as two long lenses, which can be regarded as separate beds. Type loc. is Dixon mine, Hague Twp, Warren Co. Underlies Faxon ls. and overlies Hague gneiss. The term "Dixon schist," while open to criticism, because preoccupied, is here used for convenience and should not become an established name in Adirondack geology.

H. L. Alling, 1919 (Am. Jour. Sci., 4th, vol. 48, pp. 52–68). *"Dixon" schist.*—Quartz graphite schist. Usually a single stratum, but at American Graphite Co.'s mine at Graphite, Warren Co., it occurs as two distinct layers separated by bands of Hague gneiss. Two mi. E. of Hague it appears as a single fm. In Flake Graphite Co.'s mine, in Saratoga quad., a parting of thin beds of ls. and green qtzite separates the 20-foot seam into two more or less distinct strata. The fm. has been traced, but not continuously, from middle of Ausable quad. S. to Saratoga Springs, a distance of 90 mi., and from Hague, on Lake George, W. to Conklingville, a distance of 40 mi. Name is preoccupied [and therefore quoted]. In places underlies and in places seems to include Faxon ls.

†Dixon chalk or †Dixon limestone.

Upper Cretaceous: Nebraska and western Iowa.

C. [R.] Keyes, 1925 (Pan-Am. Geol., vol. 44, pp. 147–149). [Described Nicollet's use of "Dixon's group" or "Dixon's bluff," and said:] As a terminal title *Dixon chalk,* or *Dixon ls.,* has manifest priority over all other designations by many years, and as such should be used. If Gilbert's Greenhorn ls. of Colo. be the same fm., as Todd believes, then it, too, is in synonymy. [But on p. 148 he said that it probably is not same as Greenhorn ls.] Independent discovery of dual character of the chalk rock of upper Missouri River region, and subsequent recognition of unlikelihood of lower chalk bed being the continuity of Gilbert's Greenhorn ls. of Colo., 600 mi. away, as Todd and Darton had assumed, was brought forcibly to front after somewhat extended personal examinations of southwestern region. Not knowing of Nicollet's designation, the title of *Crill ls.* was given to this lower chalk fm. in Iowa.

†Dixon's group.

Upper Cretaceous: Eastern Nebraska and western Iowa.

I. N. Nicollet, 1843 (Rept. intended to illustrate map of hydrographical basin of Upper Mississippi River: 26th Cong., 2d sess., S. Ex. Doc. 237, pp. 35, 37). *Dixon's group or Dixon's bluff.*—In ascending order: (A) Argill. ls., containing *Inoceramus barabini* [*labiatus*] in great number and very much compressed, and so arranged as to give the rock a slaty structure; thickness variable up to 20 ft. (B) Gray, grayish-blue, and sometimes yellow calc. marl, generally from 30 to 40 ft. thick, but at Dixon's bluff reduced, by a slide, to 15 or 20 ft.; the few fossils consist of one orbicula and what appears to be a fish scale. (C) A slightly ferruginous clay bank of yellowish color with seams of selenite and affording occasionally rounded masses somewhat resembling septariae. Rests on Carboniferous or mountain ls. (D). [Not certain whether Nicollet meant to include this in his "Dixon's group."] A vast deposit of plastic clay about 200 ft. thick with loose pieces of ls. throughout the clay. [Item D is probably Niobrara ls.]

Includes, exclusive of item D, Greenhorn ls. and probably younger Cret. rocks.

Named for fact that divisions A, B, and C compose Dixon's bluff, in Dixon Co., Nebr., about 12 mi. above Sioux City, Iowa.

†Dixon's bluff.

See †Dixon's group.

Dobbs Valley sandstone. (In Millsap Lake formation.)

Pennsylvanian: Central northern Texas (Brazos River region).

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, p. 163). The upper water-bearing sand of Millsap Lake fm. lies near top of the fm. and about 300 ft. below top of Brazos River ss. It outcrops N. of Dobbs Valley and is here named *Dobbs Valley ss.* It supplies good water in deep wells NW. of Brazos River ss. escarpment in Mineral Wells gas field area. Has not been reached in wells outside the gas field, and its extent and productivity are unknown. It lies 200± ft. higher than Buck Creek ss.

Dock Street clay.

Middle Devonian: Northeastern Michigan (Alpena).

A. W. Grabau, 1902 (Rept. Mich. State Bd. of Geol. Surv. for 1901, pp. 178, 192). *Dock Street clay.*—Blue clay exposed in test well on Dock St., Alpena, Mich., where it is 6 or 7 ft. thick. Included in lower part of Traverse upper shales and lss., which overlie Alpena ls. The clay is underlain and overlain by ls.

A. S. Warthin and G. A. Cooper, 1935 (Wash. Acad. Sci. Jour., vol. 25, No. 12, p. 526). Dock Street clay of Grabau is a local clay facies of upper Alpena horizon [restricted Alpena].

Dockum group.

Triassic (Upper?): Panhandle of Texas and southeastern New Mexico.

W. F. Cummins, 1890 (Tex. Geol. Surv. 1st Ann. Rept., p. 189). *Dockum beds.*—Water-bearing cgl., ss., and red clay, 150 ft. thick, uncon. overlying clays and sss. of upper Perm., and entirely unlike anything heretofore seen in Tex. Uncon. underlies Blanco Canyon beds [Blanco fm.].

In Tex. is divided into Trujillo fm. (above) and Tecovas sh. (below). Uncon. overlies Permian (Double Mtn and Quartermaster fms.) and uncon. underlies Blanco fm. (Plio.).

Named for Dockum, Dickens Co., Tex.

Dockuman series.

A term applied by C. R. Keyes to Dockum group and its supposed equivalents.

Doctor Bond sandstone.

Commercial term for a white building stone quarried from basal ss. memb. of Morrison fm. in Boulder dist., Colo.

Documan series.

A term applied by C. R. Keyes to Dockum group and its supposed equivalents.

Dodds Creek sandstone.

Pennsylvanian: Eastern Kansas.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, p. 97). Galesburg sh. includes *Dodds Creek ss.* [All.]

J. M. Jewett, 1932 (pp. 99, 101, 103 of book cited above). *Dodds Creek ss.* is proposed for the ss. in upper part of Galesburg sh. Named for Dodds Creek, Labette Co. [On p. 102 he stated Dodds Creek ss. consists of ss. and sandy sh. On p. 26 he described it as yellow sandy sh. 5 ft. thick.]

J. M. Jewett, 1933 (Kans. Acad. Sci. Trans., vol. 36, p. 133). Upper part of Galesburg sh. is named *Dodds Creek ss.*

Dodge shale.

Upper Cretaceous or Miocene(?): Western Iowa.

C. [R.] Keyes, 1912 (Iowa Acad. Sci. Proc., vol. 19, pp. 148, 151). *Dodge terrane.*—Reddish or pink shales, 75 ft. thick, accompanying Dodge [Fort Dodge] gyp. Older than Nishnabotna ss. and overlies Carbf. Basal fm. of Dakotan series. [Later rept by Keyes assigned this sh. to Mio.]

Probably named for Fort Dodge, as author stated the sh. outcrops in Iowa farther N. than Fort Dodge.

Dodge gypsum.

A term used by C. [R.] Keyes to designate the gyp. beds at Fort Dodge, Iowa. (See Pan-Am. Geol., vol. 40, 1923, p. 219, fig. 3, and pls. 25, 26.)

Dodge limestone.

Name applied by oil geologists to a thin lime, of Penn. age, in Fairport oil field, Russell Co., Kans., lying at about 2,900 ft. depth and about 100 ft. higher than Oswald lime.

Doe Run limestone.

Pre-Cambrian: Southeastern Pennsylvania (Chester County).

P. Frazer, 1883 (2d Pa. Geol. Surv. Rept. C_4, pp. 70, 304, 307). *Doe Run ls.*—A tract of crystalline mag. ls. extending more than 1 mi. in SW. direction parallel to valley of Doe Run, from near Doe Run village to vicinity of Passmore's mill.

Same as Cockeysville marble.

Doe Run dolomite. (In Elvins group.)

Upper Cambrian: Eastern Missouri.

E. R. Buckley, 1907 (Mo. Bur. Geol. and Mines vol. 10, 2d ser., *separate*), and H. A. Buehler, 1907 (Mo. Bur. Geol. and Mines vol. 6, 2d ser., p. 231), in tables divided Elvins fm. into (descending) Doe Run, Derby, and Davis, without defining the subdivisions.

E. R. Buckley, 1909 (Mo. Bur. Geol. and Mines vol. 9, pt. 1, pp. 15, 47). *Doerun fm.*—Chiefly argill. dol. alternating with finely crystalline dense dol. and soft porous dol. Thickness 50 to 90 ft. Overlies Derby fm. and uncon.(?) underlies cherty Potosi fm., which is characterized by coarse drusy cavities.

Named for Doe Run Lead Co., which owns the lands in St. Francois Co. upon which occurs the type section.

Dog Bend limestone. (In Mineral Wells formation.)

Pennsylvanian: Central northern Texas (Palo Pinto County).

F. B. Plummer, 1929 (Tex. Bur. Econ. Geol., geol. map of Palo Pinto Co.). *Dog Bend ls.* lies in interval btw. Turkey Creek ss. and Lake Pinto ss., in Mineral Wells fm. [This interval is that occupied by Salesville sh. as defined by Moore and Plummer, 1922.]

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232), defined Salesville sh. as underlying Turkey Creek ss. and overlying Lake Pinto ss.

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534), defined Salesville sh. as consisting of gray calc., sandy sh. containing several lentils of ss. and near its base a thin stratum of impure sandy ls., and as overlain by Turkey Creek ss. and underlain by Lake Pinto ss. They did not mention Dog Bend ls. But columnar section on geol. map (of Palo Pinto Co.) accompanying Bull. 3534 shows, in lower part of Salesville sh., 3 lss. separated by sh. beds, and the name *Dog Bend ls.* appears opp. the upper of these 3 lss. The map itself shows a ss. mapped around Dog Bend of Brazos River, btw. towns of Palo Pinto and Mineral Wells.

Dog Canyon limestone.

Permian: Southeastern New Mexico (Pecos Valley region).

W. B. Lang, 1937 (A. A. P. G. Bull., vol. 21, No. 7). *Dog Canyon ls.*—Bedded lss. more than 1,000 ft. thick, which grade along their base into the thinning ss. of Delaware Mtn fm. and to S. merge with middle sss. of that fm. and possibly with basal part of Capitan ls. Is of middle Delaware Mtn age. To N. gradually thins out above San Andres ls. Overlain by Queen ss. memb. of Chalk Bluff fm. Exposed on W. flank of Guadalupe Mtns, in Dog Canyon, N. Mex.

Dog Creek shale. (In Cimarron group in Kansas.)

Permian: Central southern Kansas and western Oklahoma.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, pp. 3, 39). *Dog Creek shales.*—Dull red argill. shales, 30 ft. thick, with laminae of gyp. in basal part and one or two ledges of dol. in upper part. Basal fm. of Kiger div. Overlain by Red Bluff sss. and underlain by Shimer gyp. memb. of Cave Creek fm. [In 1897 (Am. Geol., vol. 19, pp. 351–363) Cragin suggested *Stony Hills* as more appropriate name than *Dog Creek* for these beds, which he also removed from his Kiger div. and included in top of his Salt Fork div.]

Adopted as basal fm. of Woodward group in Okla. Overlain by Whitehorse (†Red Bluff) ss. and underlain by Blaine gyp. C. N. Gould, 1925 (Okla. Geol. Surv. Bull. 35, p. 91), gave thickness as 30 to 400 ft.

Named for Dog Creek, Barber Co., Kans.

Doggett sand.

See *Daggett sand.*

Dog Gulch formation.

Tertiary: Mogollon district, New Mexico.

H. G. Ferguson, 1927 (U. S. G. S. Bull. 787). *Dog Gulch fm.*—Cgl. and ss. with a few lenses of red sh.; the cgl. beds best developed near base. Thickness 400± ft. Younger than Mogollon andesite, from which it is separated by erosion interval.

Named for exposures in upper part of Dog Gulch, Mogollon dist.

Dog Head limestone.

Upper Ordovician (Richmond): Manitoba.

A. F. Foerste, 1929 (Denison Univ. Bull., vol. 29, No. 2, Sci. Lab. Jour., vol. 24, pp. 35, 37; and vol. 29, No. 7, Sci. Lab. Jour., vol. 24, p. 130).

A. K. Miller, 1930 (Am. Jour. Sci., 5th, vol. 20, p. 211). Dog Head ls. of Manitoba seems to correspond to Lander ss. (basal memb. of Bighorn fm., of Richmond age, in Wind River Mtns, Wyo.).

Dogtown clays. (New Jersey.)

See under *Trenton clays.*

Dogwood coal group.

Pennsylvanian: Central Alabama.

A group of three or four coal beds in Pottsville fm. of Cahaba coal field, occurring within a vertical section of 100± ft., the lower coal lying 500 ft. above Montevallo coal. May be=Straven coal group. Includes Upper Dogwood, Lower Dogwood, and one or two other coals.

Dolgeville shale.

Middle Ordovician: Eastern New York (Herkimer County).

H. P. Cushing, 1909 (N. Y. State Mus. Bull. 126, p. 20). *Dolgeville sh.*—Alternating thin-bedded lss. and shales, transitional in character. Evidently a shaly eastern representative of upper Trenton ls. of type section. Overlain, conformably, by Utica sh. and underlain by Trenton lss. proper, from both of which it is separable throughout Mohawk Valley. Fully exposed, with both contacts shown, in banks of East Canada Creek just below Dolgeville, Herkimer Co. Previously called "Trenton-Utica passage series."

In 1910 (N. Y. State Mus. Bull. 145, p. 97) H. P. Cushing and R. Ruedemann correlated Dolgeville sh. with Cumberland Head sh.

In 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27) E. O. Ulrich placed Dolgeville sh. stratigraphically btw. Canajoharie and Snake Hill shales and correlated it with part of Cumberland Head sh.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 39). [See 4th entry under *Cumberland Head sh.*]

R. Ruedemann, 1921 (N. Y. State Mus. Bull. 227, 228, pp. 100–101). *Dolgeville shales* (passage beds btw. Utica sh. and Trenton ls.) and the directly overlying black sh. as far as fall below Dolgeville, contain fauna of upper Canajoharie sh., although there are present a considerable number of Utica forms.

Dolls Run sandstone. (In Washington formation.)

Permian: Northern West Virginia (Monongalia County).

E. L. Core, 1929 (W. Va. Acad. Sci. Proc., vol. 3, p. 204). In region near Core, Monongalia Co., there occurs quite generally near base of Little Washington coal a massive ss., 10 to 15 ft. thick, very prominent in topog. of region, which is here named *Dolls Run ss.*, from its excellent development along that stream. It is very hard, blue-gray in color, and weathers gray. Beneath Dolls Run ss. comes the siliceous Bristol ls.

Dolly Varden formation.

Jurassic: British Columbia.

G. Hanson, 1922 (Canada Geol. Surv. Summ. Rept. 1921, pt. A, p. 10).

Dolores formation.

Upper Triassic and Jurassic (?): Southwestern Colorado.

W. Cross, 1899 (U. S. G. S. Telluride folio, No. 57). *Dolores fm.*—Reddish quartzose sss., grits, and cgls., latter usually containing granitic debris and fragments of Algonkian schists and qtzites; several thin ls. cgls. with small pebbles characterize upper part and contain a few Triassic fossils [listed]. Below the fossiliferous horizons occurs a series of reddish grits, sss., or cgls. in which no fossils have been found. In Rico quad., adjoining on SW., an invertebrate fauna has been found in lower 200 or 300 ft. of "Red Beds," which is assigned by G. H. Girty to Permo-Carbf. The complex of strata characterized by this fauna will be described as *Rico fm.* In absence of fossil evidence the red strata btw. Rico Permo-Carbf. and the beds containing Triassic fossils are grouped with latter in *Dolores fm.* The upper, finer-grained portion of Dolores fm. is usually bright red, and includes ls. cgl. called "Saurian cgl.," 10 to 30 ft. thick, usually of pinkish color, which occurs 30 to 500 ft. below top of fm. Thickness 1,550 to 2,000 ft. Rests uncon. on Algonkian qtzite and is uncon. overlain by La Plata ss. Named for typical exposures of the fossil-bearing strata in valley of Dolores River, at present best known in Rico quad.

W. Cross and E. Howe, 1905 (U. S. G. S. Silverton folio, No. 120). Beds here named *Cutler fm.* compose greater part of "Red Beds" of region. Hitherto provisionally included in Dolores fm. Field work of 1904 in Ouray quad. revealed notable angular uncon. immediately below the most commonly fossiliferous beds of Dolores fm. Through this uncon. the Dolores [as here restricted] can be seen to transgress more than 1,000 ft. of old "Red Beds" and several hundred ft. of Rico and Hermosa. In view of these facts the strata btw. Rico beds and base of Triassic have been distinguished as a fm. and named for exposures on Cutler Creek. The name *Dolores* will continue to be applied to the Triassic strata, embracing the fossiliferous cgl. and overlying beds up to La Plata ss., of Jurassic age. The Dolores is absent in Silverton quad., where the unfossiliferous Cutler fm. is uncon. overlain by Tertiary Telluride cgl.

W. Cross, 1905 (U. S. G. S. Rico folio, No. 130), gave thickness of Dolores restricted in Rico quad. as 400 ft. Later repts give max. thickness in SW. Colo. of 800 ft.

In parts of SW. Colo. the Dolores fm. is overlain (uncon.) by Entrada ss. (Jurassic?). It rests on Cutler fm., as above defined, and includes equivalents of (descending) Kayenta fm., Wingate ss., and Chinle fm. (See A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., U. S. G. S. P. P. 183, 1936.)

†Doloresian series.

A term introduced by C. R. Keyes (Pan-Am. Geol., vol. 41) to cover Dolores fm. and the Chinle fm. (Upper Triassic) of Gregory. (See A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1936, U. S. G. S. P. P. 183, p. 37.)

†Dome formation.

Middle Cambrian: Western Utah (House Range).

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804, pp. 9, 11). *Dome fm.*—Massive-bedded gray siliceous ls., 355 ft. thick, underlying Swasey fm. and overlying Howell fm. Type loc. at head of Dome Canyon, House Range.

Same as Dome Canyon ls.

Dome conglomerate.

Pre-Cambrian: Ontario.

R. E. Hore, 1911 (Canadian Min. Inst. Quart. Bull. 15, p. 63).

Dome Canyon limestone.

Middle Cambrian: Western Utah (House Range).

C. D. Walcott, 1912, (U. S. G. S. Mon. 51, p. 157). *Dome Canyon ls.*—Massive-bedded cliff-forming, gray, siliceous ls. with small specks of calcite. Layers of brownish-yellow aren. ls., 15 in. to 2 ft. thick, occur 100 ft. below top and for 50 ft. below. Thickness 355 ft. Underlies Swasey fm. and overlies Howell fm. in House Range. See Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804, p. 11) [where he called the beds *Dome fm.*].

Domengine formation.

Eocene (middle): Southern California (Diablo Range).

F. M. Anderson, 1905 (Calif. Acad. Sci. Proc., 3d ser., vol. 3, pp. 167–168). *Domijean sands.*—Chiefly yellow sands. Thickness 350 to 1,200 ft. Greatest development in vicinity of Domijean ranch. Overlies Kreyenbagen shales and uncon. underlies Temblor beds. Correlated with part of Tejon fm.

B. L. Clark and R. B. Stewart, 1925 (Geol. Soc. Am. Bull., vol. 36, p. 227), and B. L. Clark, 1926 (Calif. Univ. Pub., Bull. Dept. Geol., vol. 16, No. 5, pp. 99–106). *Domengine horizon (middle Eo.)*.—A newly recognized div. of Eo. of Calif. Contains new fauna in beds stratigraphically below those containing typical Tejon (upper Eo.) fauna and above those of Meganos age. Beds representing this horizon were formerly included in part in Tejon and in part in Meganos. A number of species are common to the Meganos and a few to the Tejon, but taken as a whole the fauna is distinctive. *Domengine fm.* as here proposed rests uncon. on Meganos fm. [as here restricted] throughout Coalinga region. In vicinity of Domengine ranch the Tejon is absent; the Domengine consists of 100± ft. of, largely, yellow-brown, medium fine to coarse fossiliferous ss. with thin bed of well-rounded cgl. at base; and the Meganos [restricted] is 500 to 750 ft. thick, consisting largely of dark clay shales (with calc. lenses that are in places fossiliferous), becoming gradually more sandy toward top, grading into arkosic white ss., which previously was included by F. M. Anderson (1905) in his Domengine sands and by R. Anderson and R. W. Pack in their Tejon. In Simi Valley the Domengine fm. is 1,200 ft. thick. Its fauna (middle Eo.) has been recognized from Oreg. to southern Calif.

R. L. Nelson, 1925 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 15, pp. 399–402 and map). Eocene of Ventura Co., Calif., divided into (descending):

Upper Eocene
- Tejon fm.

Middle Eocene
- Domengine fm. (gray sh. interbedded with cgl. and brown ss.).
- Santa Susana fm. (fine-grained ss. and sh., fossiliferous).

Lower Eocene
- Martinez group (3 subdivisions).

"The name *Domengine* was proposed by F. M. Anderson and is now used by B. L. Clark for upper part of his Meganos group."

R. B. Stewart, 1926 (Phila. Acad. Nat. Sci. Proc., vol. 78, pp. 299–300). *Domengine* is apparently valid name for certain strata near Domengine ranch, N. of Coalinga, but I do not think it should be used so far away as Simi Valley. Local names should be used.

B. L. Clark and A. O. Woodford, 1927 (Calif. Univ. Pub., Bull. Dept. Geol. Sci., vol. 17, pp. 72, 73), gave detailed section of *Domengine fm.* in Mount Diablo quad. aggregating 1,350 ft. in thickness and resting uncon. on Meganos fm., the overlying Tejon being absent.

F. E. von Estorff, 1930 (A. A. P. G. Bull., vol. 14, No. 10, pp. 1321–1336). The 500 ft. of ss. *underlying* typical Kreyenhagen sh. in canyon of Canoas Creek is Domengine ss., of upper middle Eo. age, and the ss. uncon. overlying Kreyenhagen sh. is Temblor ss., of lower middle Mio. age, the Vaqueros ss. (of lower Mio. age) being absent.

In subsequent repts *Domengine fm.* was applied, by different geologists, (1) to rocks on Santa Cruz Island (Santa Barbara Co.) uncon. underlying Vaqueros fm. and overlying Martinez fm.; (2) to rocks in Antioch, Vacaville, and Napa quads. conformably underlying Markley micaceous sss.; and (3) to rocks in Kettleman Hills underlying Kreyenhagen. In 1933 (A. A. P. G. Bull., vol. 17, No. 10, p. 1169) G. C. Gester and J. Galloway stated *Domengine ss.* of Coalinga-Kettleman Hills area is overlain by Kreyenhagen sh. and underlain by Meganos, and is=Avenal ss. to S. of Coalinga. In 1933 McMasters introduced *Llajas fm.* for rocks on N. side of Simi Valley that were said to contain Tejon fauna in upper part, Domengine fauna in middle part, and an older Eo. fauna in lower part, and to rest on Santa Susana fm.

B. L. Clark, July 31, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 7, pp. 1049–1050), stated that *Domengine ss.* N. of Coalinga is overlain by Kreyenhagen shales and underlain by *Capay fm.* (Meganos of B. L. Clark's earlier rept.), and that Domengine and Capay are=Llajas fm.

Named for development in vicinity of Domijean or Domengine ranch, in NE¼ sec. 17, N. of Coalinga, Fresno Co.

†Domijean sands.

See *Domengine fm.*

Dominion ore bed.

Lower Ordovician: Newfoundland.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4). *Dominion ore bed.*—Oolitic hematite, fossiliferous; discon. overlain by phosphorite forming basal bed of Wabana series, and underlain by ss. and sh. Is top bed of Bell Island series. [Derivation of name not stated.]

Domino gneiss.

Pre-Cambrian: Labrador.

E. M. Kindle, 1924 (Canada Geol. Surv. Mem. 141, p. 55).

Don beds. (In Toronto formation.)

Pleistocene: Ontario.

A. P. Coleman, 1907 (10th Int. Geol. Cong., Mexico, 1906, p. 1246).

Don limestone.

A name applied by geologists of mining companies, in their company repts, to upper 260 ft. of Syrena fm. (Penn.) of Santa Rita dist., N. Mex.

Donaher sandstones.

Pre-Cambrian (Belt series): Central western Montana (Mission Range).

Name applied by C. [R.] Keyes, 1925 (Pan-Am. Geol., vol. 44, pp. 215, 217), to 4,500 ft. of sss. in Mission Range, shown as overlying Empire sh. and underlying Purcell lava. Derivation of name not stated.

Donald quartzites.

C. [R.] Keyes, 1925 (Pan-Am. Geol., vol. 44, p. 217). Qtzites, 5,000 ft. thick, forming topmost fm. of Proterozoic era in Mont. Overlie Ross qtzites. [Derivation of name not stated.]

Donald strata.

Lower Cambrian: British Columbia.

C. S. Evans, 1933 (Canada Geol. Surv. Summ. Rept. 1922, pt. A_2, p. 122).

Donegal limestone. (In Sumner group.)

Permian: Northeastern Kansas.

R. C. Moore, Jan.–Feb., 1936 (Jour. Geol., vol. 44, No. 1, pp. 5–9), divided Sumner group into (descending) Wellington [restricted], Donegal, and Nolans fms., but did not define the new names *Donegal* and *Nolans*.

R. C. Moore, 1936 (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, graphic section on p. 12). *Donegal ls.*—Underlies Wellington sh. [restricted], overlies Pearl sh. [revived], and is divided into (descending): Strickler ls., Newbern sh., and Hollenberg ls. [Derivation of new names not stated. Thicknesses shown: Strickler ls., 2½± ft.; Newbern sh., 5± ft.; Hollenberg ls. 7± ft.]

Doniphan shale. (In Lecompton limestone.)

Pennsylvanian: Southeastern Nebraska, northwestern Missouri, and northeastern Kansas.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 44, 47). *Doniphan sh.* is exposed in Mo. and Kans., but probably not exposed in Nebr. Is 14+ ft. thick in Mo. and 7 to 8 ft. thick in Kans. Underlies Big Springs ls. and overlies Spring Branch ls., all in Lecompton ls. Named for exposures in N. part of Doniphan Co., Kans.

Donley limestone member (of Greene formation).

Permian: Southwestern Pennsylvania (Washington County) and eastern Ohio.

W. T. Griswold and M. J. Munn, 1907 (U. S. G. S. Bull. 318, pp. 77+). *Donley ls. memb. of Greene fm.*—Very hard and tough ls. 5 or 6 ft. thick. Fractures unevenly with a dark steel-gray to almost black color; very coarse grain; numerous calcite crystals; peculiar jointing. Lies 18 to 45 ft. above base of Greene fm. in Claysville quad., Pa. Overlain by 15 to 20 ft. of light gray ss., and underlain by 5 to 20 ft. of gray laminated ss. Exposed in vicinity of Donley, Donegal Twp, Pa.

Donnelly iron ore.

Silurian: Central New York.

G. H. Chadwick, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 327–368). *Donnelly iron ore.*—The ore at Thomas Donnelly's has been correlated with thin seam at base of upper Irondequoit (Lakeport) ls. in Lakeport well and with that at Tipple's quarry, near Verona; all of which are above the Phoenix and close to Lockport quarries. [In section he located it beneath Lakeport ls. and above Phoenix sh. Belongs in upper part of Clinton fm.]

Don River member.

Ordovician (Upper): Ontario.

A. F. Foerste, 1924 (Canada Geol. Surv. Mem. 138, p. 52).

Dooley rhyolite breccia.

Tertiary (Miocene ?): Northeastern Oregon (Baker quadrangle).

J. Gilluly, 1937 (U. S. G. S. Bull. 879). *Dooley rhyolite breccia.*—Rhyolitic and subordinate andesitic breccias and flows. Thickness 1,500+ ft. Overlain, probably conformably, by andesite, and underlain, probably conformably, by Tert. gravels. Named for exposures on Dooley Mtn and in Stices Gulch and Mill Creek, Baker quad. May be Eocene, but more probably is Olig. or Mio.

Dorans Cove sandstone.

Mississippian: Northeastern Alabama.

J. J. Stevenson, 1903 (Geol. Soc. Am. Bull., vol. 14, p. 76). *Dorans Cove ss.*—Some deep valleys in western Jackson Co. (on Tenn. line) reach the Bangor, which shows, from 160 to 200 ft. from top, an apparently persistent ss., which is probably the upper Hartselle, the ls. below it being cherty. In Madison, just W. from Jackson, both divisions are shown fully; the Bangor exhibits abrupt variations, being 200 ft. in NE. part of county, but only 100 ft. a little way SE. from Huntsville, while it is 200 ft. at Tennessee River in SE. corner of county, beyond which it passes under the Coal Measures. These abrupt changes and the condition in western Jackson lend countenance to suggestion that Dorans Cove ss. of NE. Jackson may be upper Hartselle.

Named for Dorans Cove, Jackson Co.

Dorchester slate member (of Roxbury conglomerate).

Devonian or Carboniferous: Eastern Massachusetts (Boston Basin region).

W. W. Dodge, 1881 and 1882 (Boston Soc. Nat. Hist. Proc., vol. 21, pp. 208–210), described the geographic distribution of *Dorchester and West Roxbury slates.*

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 56, 57). *Dorchester sl. memb.*—Red and purple slates, in part cross-bedded, interbedded with ss. and fine-pebble cgl. Typically rather coarse grained; consists largely of reworked volcanic sediments. In Dorchester and in southern part of basin this memb. is 100 to 600 ft. thick, but if the sl. exposed in and about Allston Heights is assigned to Dorchester memb. its thickness may be as much as 1,000 ft. Is middle memb. of Roxbury cgl. Underlies Squantum tillite memb. and overlies Brookline cgl. memb. Named for Dorchester dist. of Boston, where it is exposed at several places.

Doré conglomerate.

Pre-Cambrian (Huronian): Western Ontario (Michipicoten region).

A. P. Coleman, 1900 (Geol. Soc. Am. Bull., vol. 9, pp. 109–110). *Doré cgl.*, Archean (Huronian), Ontario.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, p. 154), included this cgl. in Huronian.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184). *Doré cgl.* may be Lower Huronian.

Doré series.

Pre-Cambrian: Ontario.

W. G. Miller and C. W. Knight, 1914 (Ontario Bur. Mines Rept., vol. 22, pt. 2, p. 125). Doré series, pre-Camb., Ontario.

W. H. Collins, 1933 (Canada Geol. Surv. map 155 A, Lake Huron sheet, Pub. No. 1553). *Doré series*, pre-Huronian, Ontario.

Dornick Hills formation.

Pennsylvanian: Central southern Oklahoma (Carter County).

J. A. Waters, 1927 (Jour. Pal., vol. 1, p. 129). [Describes Foraminifera from *Dornick Hills fm.* of Ardmore Basin.] The fauna was obtained from the rather pure shales exposed in sec. 30, T. 3 S., R. 2 E., in Carter Co., Okla.—shales which lie btw. *Jolliff* and Otterville lss.

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z). *Dornick Hills fm.*—Bluish and tan shales interrupted by lss. and sss., with conspicuous ls. cgls. S. of Ardmore. The pebbles in cgls. consist chiefly of pre-Penn. lss. and chert such as now outcrop in Criner Hills. Basal memb. is Jolliff ls. memb.; top memb. is Pumpkin Creek ls. Also includes (descending) Lester ls., Bostwick ls. cgl., and Otterville ls. Thickness 1,500 to 4,000 ft. Underlies Deese fm. and overlies Springer fm.

C. W. Tomlinson, 1929 (Okla. Geol. Surv. Bull. 46). *Dornick Hills fm.* includes Goldston's Otterville and "Cup Coral" members of Glenn fm. and a little more.

Named for Dornick Hills, N. of Ardmore, Carter Co.

Dorothy limestone and shale. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

C. E. Krebs and D. D. Teets, Jr., 1916 (W. Va. Geol. Surv. Raleigh and western Mercer and Summers Counties, p. 353). *Dorothy ls. and sh.*—Dark, shaly, and fossiliferous beds, 1 to 2 ft. thick, underlying Upper Gilbert ss. and lying 5 to 15 ft. above Glenalum Tunnel coal. Exposed at Dorothy, Raleigh Co.

R. V. Hennen and D. D. Teets, Jr., 1919 (W. Va. Geol. Surv. Rept. Fayette Co., p. 270). Author now believes *Dorothy ls.* of Krebs is intimately associated with Gilbert sh., instead of correlating with Oceana ls., as tentatively suggested on p. 164 of Rept. on Wyoming and McDowell Counties.

D. B. Reger, 1921 (W. Va. Geol. Surv. Rept. Nicholas Co., p. 292). Gilbert sh. is probable horizon of *Dorothy ls.*

Dorset limestone.

Ordovician and Cambrian: Southwestern Vermont (Rutland and Bennington Counties).

C. H. Hitchcock, 1860 (Proc. Boston Soc. Nat. Hist., vol. 7, p. 237). *Dorset ls.* (Stockbridge ls. of Emmons) is probably upper Sil. or Dev.

E. Hitchcock, 1861 (Rept. Geol. Vt., vol. 1). [See 1861 entry under †*Eolian ls.*]

E. Hitchcock, 1863 (Elem. Geol., p. 411), assigned this ls. to Dev.

C. H. Hitchcock, 1866, also 1867 (Elem. Geol., pp. 411, 413). Some of the lss. of Emmons' Taconic contain fossils, apparently identical with certain Dev. forms, hence are regarded as Dev.; and as the place in that series is yet uncertain the name *Dorset ls.* may be applied to the group, from Dorset Mtn [Pawlet quad.], Vt., where the whole series is beautifully developed. [This mtn is partly in Rutland Co. and partly in Bennington Co.]

This name has fallen into disuse and the rocks are now generally called Stockbridge ls., which includes rocks ranging in age from Trenton to Lower Camb. (See E. J. Foyles and C. H. Richardson, 16th Rept. Vt. State Geol., 1929, table opp. p. 288, and other Vt. repts. Also see under †*Eolian ls.*)

Dorwin sandstone member (of Amsden formation).

Pennsylvanian: Northwestern Wyoming.

E. Blackwelder, 1918 (Wash. Acad. Sci. Jour., vol. 8, p. 422). *Dorwin ss. memb. of Amsden fm.*—Throughout western Wyo. Amsden fm. is divisible into two very distinct parts—an upper div. of shales, sss., and dolomites of weak character, and a lower massive resistant ss. On account of difference in resisting erosion, the upper memb. has generally been stripped off, while the lower remains capping the mtns and ridges of Madison ls. It therefore becomes advisable to map the two members separately. To the lower ss. the name *Dorwin ss. memb.* is given, from Dorwin Peak, in Gros Ventre Range, which is capped by this ss. Rests uncon. on Madison ls. Grades into overlying part of Amsden fm. No fossils. Position indicates probable Penn. age. Averages 60 ft. thickness in Gros Ventre Range; dwindles slowly to SE., and is 15± ft. thick near Lander, Wyo. Has been traced W. to Teton Pass. Ranges N. into Yel. Park and NE. as far as S. part of Bighorn Mtns. Elsewhere it is generally represented by reddish sandy sh.

Dos Alamos gypsum member (of Delaware Mountain formation).

Permian: Western Texas (Sierra Diablo).

P. B. and R. E. King, 1929 (A. A. P. G. Bull., vol. 13, pp. 922, 925). Near base of Delaware Mtn fm. is a thin bed of gyp. for which name *Dos Alamos gyp.* is suggested, from its exposures near Dos Alamos, or Cottonwood Wells, due W. of Guadalupe Point, on W. side of Salt Flat, Hudspeth Co. The gyp. memb. suggests retreat and readvance of the seas, and thus confirms existence of an uncon. at base of Delaware Mtn ss.

Dothan formation.

Upper Jurassic: Southwestern Oregon.

J. S. Diller, 1907 (Am. Jour. Sci. 4th, vol. 23, pp. 401–421). *Dothan fm.*—Chiefly ss., with much interbedded dark sh. Jurassic fossils. Lies uncon. below the Knoxville (Myrtle fm.), and with its occasional beds of chert writer believes it is=in part the Franciscan of Calif. Named for Dothan P. O., on Cow Creek. [Table puts Dothan fm. above Galice fm., but p. 421 says Dothan underlies Galice.]

J. S. Diller, 1914 (U. S. G. S. Bull. 546, pp. 17–18). Jurassic sed. rocks of Galice-Kerby-Waldo region consist of 2 fms.—Galice fm. on SE. and Dothan fm. on NW., separated by an irregular belt of igneous rocks, mainly greenstone and serpentine. Relative position indicates Dothan fm. is younger than Galice. The Cret. is markedly uncon. on Jurassic.

J. S. Diller and G. F. Kay, 1924 (U. S. G. S. Riddle folio, No. 218). Thickness of *Dothan fm.* is 1,000 to 6,000 ft. Knoxville and Horsetown fms. overlap Dothan fm. Is thought to be=Franciscan fm. of Calif.

†Dothan limestone. (In Moran formation.)

Permian: Central northern Texas.

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, pp. 133–145). *Dothan ls.* occurs in lower part of Moran fm., of Cisco group, about 160 ft. below top of the Moran and 60 ft. above Pueblo fm. Outcrops near Dothan, Callahan Co. Northward it pinches out into sands and shales.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31; Univ. Tex. Bull. 2132, pp. 177–180, charts, etc.). *Dothan ls. lentil of Moran fm.* of Brazos River Valley is approx.=Horse Creek ls. of Colorado River Valley, but it is not certain they are same bed. Is separated from overlying Sedwick ls. by 100 ft. of sh. with ss. lenses, and is underlain by 60 ft. of sandy sh. forming basal memb. of Moran fm.

Moran fm. transferred to Perm. (Wichita group) in 1933.

Dotson black sheety shale.

Mississippian: Northwestern Arkansas.

D. D. Owen, 1858 (First Rept. Geol. Reconn. northern counties of Ark., pp. 101–102). *Dotson black sheety sh.*—Black bituminous sheety sh., 15 ft. of which is exposed on Wharton's [Wharton] Creek at Dotson's farm, Madison Co. Underlies Subcarboniferous flagstones and is lowest bed visible in this part of Madison Co.

Same as lower part of Fayetteville sh. (See U. S. G. S. Eureka Springs-Harrison folio, No. 202, 1916, by A. H. Purdue and H. D. Miser, where the beds along Wharton Creek are mapped as Fayetteville sh., and Chattanooga sh. is apparently absent.)

Dotson sandstone.

Pennsylvanian: Southern West Virginia and southwestern Virginia.

M. R. Campbell, 1897 (U. S. G. S. Tazewell folio, No. 44). *Dotson ss.*—Upper part coarse thin-bedded ss. 120 ft. thick; lower part sandy sh. 60 ft. thick, containing at least one coal seam. Overlies Bearwallow cgl. and underlies Sequoyah fm. Dotson, McDowell Co., W. Va., is located on this ss.

According to H. Hinds, 1918 (Va. Geol. Surv. Bull. 18), and R. V. Hennen and D. D. Teets, Jr., 1919 (W. Va. Geol. Surv. Rept. Fayette Co.), typical Dotson ss. is same as typical Bearwallow cgl. (See W. Va. chart I.) The Dotson ss. as mapped in U. S. G. S. Tazewell folio probably included beds to base of Lower Dotson ss. of W. Va. Geol. Surv. repts.

R. V. Hennen and D. D. Teets, Jr., 1919 (W. Va. Geol. Surv. Rept. Fayette Co.), applied *Lower Dotson ss.* to a ss. lying 20 to 52 ft. below Dotson ss., and described as consisting of 50 to 100 ft. of heavy to current bedded, sometimes conglomeratic, grayish white to brown, friable ss., separated from overlying Douglas coal by 0 to 5 ft. of fire clay sh., and resting on Douglas sh.

Dotson (Lower) sandstone.

See Hennen and Teets, 1919, under *Dotson ss.* The so-called *Lower Dotson ss.* is now considered same as McClure ss. memb. of Norton fm.

Double Mer sandstone.

Paleozoic: Labrador.

E. M. Kindle, 1924 (Canada Geol. Surv. Mem. 141, p. 56).

Double Mountain formation.

Permian: Central northern and central Texas.

E. T. Dumble and W. F. Cummins, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. lxx, 187, 188). *Double Mtn beds.*—Gyp., rock salt, sands, clays, sss., shales and lss. Top fm. of Perm. Conformably overlies Clear Fork beds and uncon. underlies Dockum beds.

Named for Double Mtns, Stonewall Co.

Doublian series.

A term introduced by C. [R.] Keyes to replace *Double Mtn fm.* (Perm.) of northern Tex., "to simplify a clumsy compound name." (See Pan-Am. Geol., vol. 57, pp. 337, 350–356, 1932, and vol. 52, pp. 319–320, 1929.) In 1935 (Pan-Am. Geol., vol. 63, No. 4, p. 287) Keyes used this name in Iowa, to include deposits which he called *Dodge sh.* and assigned to late Carbf.

Douglas amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

R. D. Irving 1883 (U. S. G. S. Mon. 5, pl. 18). [Shown as older than North Star cgl.]

Belongs in Central Mine group below Allouez cgl. The mineralized part is the Douglas lode.

Named for occurrence in Douglas mine, Houghton Co.

Douglas flow.

Includes Douglas amygdaloid and underlying trap.

Douglas group (also **Douglas formation**).

Pennsylvanian: Eastern Kansas, southeastern Nebraska, northwestern Missouri, and southwestern Iowa.

E. Haworth, 1898 (Kans. Univ. Geol. Surv. vol. 3. pp. 93, 94). *Douglas fm.*—The Lawrence shales are so distinct in character, and in connection with Oread ls. overlying them produce so prominent an escarpment, which extends entirely across the State from Leavenworth to southern line, that they, with overlying Oread ls. may well be grouped in one general fm. Overlies Garnett lss.

C. R. Keyes, 1900 (Iowa Acad. Sci. Proc., vol. 7), called the lss. underlying Lawrence sh. the *Stanton lss.*, which he stated are = Garnett ls. He also applied

Weston shales to basal 40 to 75 ft. of Lawrence sh. and *Iatan ls.* to the thin ls. overlying the Weston.

The Iatan and Weston were later (see E. Haworth and J. Bennett, 1908, Univ. Geol. Surv. Kans., vol. 9) excluded from Lawrence sh. and treated as distinct fms. within Douglas group. This definition of Douglas group (to include all beds btw. top of Stanton ls. below and top of Oread ls. at top) persisted until 1931, being the definition used by H. Hinds and F. C. Greene 1915, R. C. Moore 1917 and 1920, J. W. Beede 1922, and geologists generally.

R. C. Moore, Sept. 1931 (Kans. Geol. Soc. 5th Ann. Field Conf. correlation chart), redefined Douglas group by excluding Oread ls. at top and excluding at base the Weston sh., Iatan ls., and basal part (later named *Hardesty sh.*) of Lawrence sh. These 3 units which he excluded from base of Douglas group he transferred to Lansing group, but in 1932 he assembled them into a distinct group called *Peedee group*.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3, pp. 93, 96). It is proposed to redefine *Douglas group* to include the essentially clastic strata occurring btw. the pre-Virgil uncon. and base of Oread ls. Thus delimited the group will contain 3 formational units (in ascending order): *Stranger fm.* (largely ss. and sandy sh.), *Haskell ls.* (thin, fairly persistent ls. that in many places has been mistaken for the Iatan), and Lawrence sh. [This use of Lawrence sh. is a restriction.] In central Kans., as in Woodson Co., a prominent ss. (*Ireland*) has been developed in Lawrence sh., not far below base of Oread fm. Overlies Peedee group and underlies Shawnee group redefined.

This restricted definition of *Douglas group* was also adopted by R. C. Moore and G. E. Condra in their Oct. 1932 revised classification chart of the Penn. rocks of Kans. and Nebr. and by N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21).

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 146, etc.). *Douglas group* divided into (descending): Lawrence sh. restricted and Stranger fm. expanded to include at top Robbins sh. (new name for basal part of Lawrence sh. of 1932 and 1935 classifications) and Haskell ls. Douglas fm. of Haworth extended from top of Oread ls. down to top of Stanton ls.

These modified definitions have not yet been considered by U. S. Geol. Survey for its publications.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Named for Douglas Co., Kans.

Douglas shale. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, p. 183). *Douglas sh.*—Dark to black sandy sh., 5 to 15 ft. thick. Underlies Lower Nuttall ss. and overlies Lower Douglas coal. Carries marine fauna that has not previously been described. Included in New River group. Exposed at Douglas R. R. station, McDowell Co.

R. V. Hennen and D. D. Teets, Jr., 1919 (W. Va. Geol. Surv. Rept. Fayette Co.). *Douglas sh.* and underlying Lower Douglas coal included in Kanawha group. Douglas sh., marine sh. 5 to 15 ft. thick, underlies Lower Dotson ss. and lies a few inches to 15+ ft. above Upper Nuttall ss. [This definition was also followed by D. B. Reger in W. Va. Geol. Surv. Rept. Webster Co., 1920, and in Nicholas Co. Rept., 1921.]

Douglas Canyon formation.

Miocene (late): Central Washington (Douglas County).

A. D. Hoffman, 1932 (Jour. Geol., vol. 40, No. 8, pp. 735–738). *Douglas Canyon fm.*—Well-stratified series of interbedded light-gray to buff arkosic sands and light to very dark shales, 35+ ft. thick (base not seen), containing flora [listed] of late Mio. age. All its species occur in Latah fm. of Spokane, Wash. Exposed in Douglas Canyon (one of side canyons of Moses Coulee), above and below waterfalls about ½ mi. from canyon mouth, NW¼ SW¼ sec. 30, T. 23 N., R. 24 E., Douglas Co. Plants were obtained from a thinly laminated lignitic sh. bed, approx. 1 ft.

thick, lying 11 ft. below overlying Columbia River basalt, with which it is apparently conformable.

Douglas County traps.

Pre-Cambrian (Keweenawan): Northwestern Wisconsin (Douglas and Bayfield Counties).

R. D. Irving, 1874 (Am. Jour. Sci., 3d, vol. 8, pp. 46–56). *Copper-Bearing series* of Douglas, Bayfield, and Ashland Counties is 20,000+ ft. thick and includes (descending) *Douglas County traps*, sss., ss. and sh., cgl., melaphyrs, and hornblendic and syenitic rocks.

Douglas Creek member (of Green River formation).

Eocene: Northeastern Utah (Uinta Basin) and northwestern Colorado (Garfield and Rio Blanco Counties).

W. H. Bradley, 1931 (U. S. G. S. P. P. 168). *Douglas Creek memb.*—Basal memb. of Green River fm. in E. part of Uinta Basin, Utah and Colo. Characteristically buff or yellowish brown beds of marlstone and sh. notably different from rest of Green River fm. Contains large proportions of ss., ls., algae reefs, and oolite, and small amount of oil sh. Thickness 200 to 800 ft. Underlies (with abrupt lithologic change) Garden Gulch memb. and grades into underlying Wasatch fm. (red). In W. part of Uinta Basin the lower Green River interfingers with Wasatch fm. Well exposed at head of Douglas Creek, especially in E. half of T. 5 S., R. 102 W., Garfield Co., Colo.

Douglas Island volcanic group.

Jurassic or Lower Cretaceous: Southeastern Alaska (Douglas Island).

G. C. Martin, 1926 (U. S. G. S. Bull. 776, pp. 255–256, chart opp. p. 247, p. 270). *Douglas Island volcanic group.*—Melaphyre flows, tuff, and aggl., possibly 15,000 ft. thick. Overlies Treadwell sl. with apparent conformity. No fossils found in either Treadwell sl. or Douglas Island volcanic group, but their apparent position above Thane volcanic group indicates they are post-Triassic and probably post-Middle Jurassic. Tentatively assigned to Upper Jurassic, but may be Cret.

Forms main mtn mass of Douglas Island.

Douglass.

A name applied by C. [R.] Keyes (Pan-Am. Geol., vol. 46, 1926) to upper 350 ft. of shales in Kootenai fm. of Mont. Derivation of name unknown.

Douty gravel.

Pleistocene (pre-Wisconsin?): Western Washington (Puget Sound region).

B. Willis, 1898 (Geol. Soc. Am. Bull., vol. 9, pp. 111+). *Douty gravels.*—Belong to Vashon glacial epoch. Underlie Osceola clays in section exposed in N. bank of Carbon River. Lie 600 to 655 ft. above sea. Named for Douty Station, in canyon near Carbonado, being the nearest point having a specific name and at the level of this bed. Deposited by river flowing from a glacier and sweeping down loaded ice cakes. A local deposit.

B. Willis and G. O. Smith, 1899 (U. S. G. S. Tacoma folio, No. 54), gave thickness of *Douty gravels* as 0 to 55 ft.

†Dove limestone.

Middle Ordovician: Central Tennessee.

J. M. Safford, 1869 (Geol. Tenn., pp. 277–279). *Dove ls.*—For most part three fossiliferous layers, aggregating 11 ft. in thickness. Upper layer light dove-colored, compact ls., 4 ft. thick, breaking with conchoidal fracture, containing strings of crystalline matter; middle layer mainly common dark-blue crystalline ls., 2 ft. thick; lowest layer 4 ft. thick, resembling upper layer but more or less mixed with blue layers. Included in Nashville fm. Overlies Capitol ls., and underlies 28 ft. of ls. [later named Ward ls.] resembling College Hill ls. but separated from latter by *Cyrtodonta* bed, 11 ft. thick.

Nongeographic name. The beds were formerly included in Bigby ls., but R. S. Bassler, 1932 (Tenn. Dept. Ed. Div. Geol. Bull. 38), included †Dove ls. and overlying Ward ls. of Jones in Cannon ls.

Dover limestone. (In Wabaunsee group.)

Pennsylvanian: Northeastern Kansas and southeastern Nebraska.

J. W. Beede, 1898 (Kans. Acad. Sci. Trans., vol. 15, p. 31). *Dover ls.*—Ls., 4 ft. or less thick, in Upper Coal Measures of Shawnee Co. [From statement on p. 28 appears to underlie Rossville shales and ss. and to overlie Dover sh. and ss.]

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 72, 73, 74, 75, 80, 90, 116, 222). Beede's *Dover sh. and ss., Dover ls.*, and *Rossville sh. and ss.* occupy practically all of interval represented by Admire sh. memb., but only one of these is acceptably defined; it is *Dover ls.*, which extends northward to Nebr. and Iowa. It is composed of one impure massive gray ls. or of 2 lss. separated by a thin sh. It underlies Pony Creek sh. and overlies Table Creek sh., all included in McKissick Grove sh. Thickness 2 to 4 ft. Named for exposures near Dover [Shawnee Co.], Kans.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3, pp. 94, 96). Btw. Maple Hill ls. memb. of McKissick Grove fm. and overlying Brownville ls. are two, instead of one, persistent lss. The upper one is distinguished by occurrence of coal a few inches to 2 or 3 ft. beneath the ls. The lower ls. is characterized by abundance of large *Triticites* and Cryptozoon, and, except for generally lighter color, very closely resembles Tarkio ls. Both of these lss. btw. the Maple Hill and Brownville have been identified at various places in Kans. and Nebr. as Dover ls. Study of Beede's original description of the Dover and examination in field near Dover convince writer that lower of the 2 lss. is true Dover, and name *Jim Creek*, from a locality in central Pottawatomie Co., Kans., where entire section is well exposed, is selected for the upper ls. just above the coal. Condra's name *Table Creek sh.* (which includes Nyman coal) is restricted to sh. btw. the Jim Creek and the Dover, and the new name *Frenck sh.* (from a creek NW. of Onaga, Kans.) is adopted for the sh. btw. the Dover and Maple Hill ls.

R. C. Moore and G. E. Condra, 1932 (Oct. 1932 revised classification chart of Kans. and Nebr.) transposed the names *Frenck sh.* and *Table Creek sh. restricted*, by applying former name to sh. *overlying* Dover ls. and latter name to sh. *underlying* Dover ls.

G. E. Condra, 1935. (See under *Jim Creek ls.*)

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22). The sh. overlying Dover ls. and underlying Grandhaven ls. in Kans. is here named *Dry sh.* [Moore abandoned McKissick Grove sh. and treated its subdivisions as fms. in Wabaunsee group.]

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Dover shale and sandstone. (In Wabaunsee group.)

Pennsylvanian: Northeastern Kansas.

J. W. Beede, 1898 (Kans. Acad. Sci. Trans., vol. 15, p. 31). *Dover sh. and ss.*—Nearly unfossiliferous sh., 85 ft. thick, of very aren. texture, of light-yellow to deep brownish-red color, containing much argill. ss. Included in Upper Coal Measures. [From statement on p. 28 appears to underlie Dover ls. and overlie Chocolate ls. of G. C. Swallow. Named for Dover, Shawnee Co.]

See under *Dover ls.*, 1927 entry (G. E. Condra).

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 235, 251), adopted *Dover ls.* and discarded *Dover sh. and ss.*

Dovre moraine.

Pleistocene (Wisconsin stage): Minnesota and South Dakota. See W. Upham, 1888 (Minn. Geol. and Nat. Hist. Surv., vol. 2, index). According to C. W. Hall (Geol. and Geog. Minn., vol. 1, pp. 63–73, 1903) this moraine was named for Dovre Hills, Kandiyohi Co., Minn. According to F. Leverett (personal communication) the Dovre moraine is younger than Fergus Falls moraine.

Dowell Hill facies.

Name applied by P. B. Stockdale (Ind. Dept. Cons., Div. Geol. Pub. 98, pp. 77, 95, 102, etc., 1931) to a lithologic development of New Providence fm. in Brown and Bartholomew Counties, southern Ind.

†Downs limestone. (In Greenhorn limestone.)

Upper Cretaceous: North central Kansas.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, p. 50). *Downs ls.*—Ls., 6 to 12 inches thick, in Russell fm. (lower part of Benton div.), quarried near Downs [Osborne Co.] and extensively used for fence posts, so that it may appropriately be called *Fencepost ls.*

W. W. Rubey and N. W. Bass, 1925 (Kans. Geol. Surv. Bull. 10, pp. 49–51). Cragin proposed "Downs ls." for the "fence-post ls." forming top bed of Greenhorn ls. in Russell Co. Although this bed is unusually persistent, for one so thin, it does not merit classification as a separate memb., and its local name "fence-post ls." is widely known and quite satisfactory.

Dox sandstone. (Of Unkar group.)

Pre-Cambrian: Northern Arizona (Grand Canyon).

L. F. Noble, 1914 (U. S. G. S. Bull. 549). *Dox ss.*—Micaceous shaly ss.; greenish gray in lower part, red-brown and vermilion above. Characterized by ripple marks and cross bedding. Cut by thin sills of intrusive diabase. Thickness 2,297 ft. plus unknown thickness removed by pre-Camb. erosion. Top fm. of Unkar group (Algonkian). Uncon. overlain by Tapeats ss., of Tonto group, and conformably underlain by Shinumo qtzite. Named for Dox Castle, in Shinumo quad., underneath which a typical section is found beneath Tonto group, which makes the castle.

.Doxey member (of Quartermaster formation).

See under *Bessie memb.*

Doyle shale. (In Chase group.)

Permian: Eastern Kansas, central northern Oklahoma, and southeastern Nebraska.

C. S. Prosser, 1902 (Jour. Geol., vol. 10, p. 715). *Doyle sh.*—Variously colored shales, 60 ft. thick, including a few thin beds of soft ls. Overlies Fort Riley ls. and underlies Winfield fm., which includes (descending) Winfield concretionary ls.; yellowish shales; and cherty ls. ("Marion flint"). Included in Chase stage. [This definition of Doyle sh. was followed until 1929.]

N. W. Bass, 1929 (Kans. Geol. Surv. Bull. 12), included in Doyle sh. in Cowley Co., Kans., all beds below top memb. (called Winfield concretionary ls. in early repts) of Prosser's Winfield fm. and above Fort Riley ls.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6. 2d ser.), divided *Doyle sh.* of Prosser into 3 members (descending), Gage sh. Towanda ls., and Holmesville sh., aggregating 66 ft. in thickness, and divided overlying Winfield ls. into 3 members (descending): Cresswell ls. (called "concretionary" ls. in previous repts.), Grant sh., and Stovall ls.

R. C. Moore, 1936 (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 12), dropped *Doyle sh.* and recognized Condra's 1931 members as *fms.*

These recent repts (which apparently follow Prosser's definitions of Doyle and Winfield) have not been considered by U. S. Geol. Survey for its publications.

Named for exposures on Doyle Creek, SW. of Florence, Marion Co., Kans.

Dozier sandstone member (of Peacock formation).

Permian: Texas Panhandle (Collingsworth County).

J. W. Beede, 1907 (Kans. Univ. Sci. Bull., vol. 4, No. 3, pp. 142+). [Discusses fossils collected from Whitehorse ss. of Okla. and from Quartermaster fm., and says:] The fossils collected from Quartermaster div. of the Perm. are from the ss. rolled down on W. side of "Dozier Mtns", E. of Mr. Caperton's place (then Dozier post office), 15 mi. S. or SW. of Shamrock, in Panhandle of Tex. [Fossils discussed. Mentioned "the gastropods of the *Dozier beds*" on p. 143, and farther along on same page mentions one species "from the Whitehorse and *Dozier sss.*" Under the fossil descriptions the different species are not assigned to any fm. but are said to have been collected at *Dozier, Tex.* All there is about the *Dozier ss.*]

N. H. Darton, 1932 (U. S. G. S. geol. map of Tex.). *Peacock fm.*—Red ss.; includes *Dozier* ("*Memphis*") *ss. memb.* [which he mapped separately].

See under †*Memphis ss.*

R. Roth, 1932 (Jour. Geol., vol. 40, No. 8, p. 703), believes Memphis ss. is a continuation of Dozier Hills, which are channel deposits, and that it marks base of his Custer fm., which he assigned to Lower Triassic.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 180). Eskota gyp., Dozier ss., and Claytonville dol. are members of Whitehorse-Cloud Chief interval (Perm.).

Draco moraine.

Pleistocene (Wisconsin stage): Northeastern Minnesota.

F. Leverett, 1928 (U. S. G. S. P. P. 154). Named for Draco, St. Louis Co. Included in Nickerson morainic system.

Dracut diorite.

Late Carboniferous or post-Carboniferous: Northeastern Massachusetts.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 221–223 and map). *Dracut diorite.*—A dioritic rock, with associated tonalitic and noritic phases, which seems to be closely related to Ayer granite. Named for occurrence at Dracut, N. of Lowell. Believed to be slightly older than Ayer granite.

Dracut norite.

Pre-late Carboniferous (?): Northeastern Massachusetts.

E. E. Fairbanks, 1927 (Boston Soc. Nat. Hist., vol. 38, pp. 397–407). *Dracut norite.*—A stock-like mass of norite approx. 27 sq. mi. in area. Intrudes Merrimack qtzite. Occurs at Dracut.

†Dragoon quartzite.

Cambrian (Middle): Southeastern Arizona (Dragoon Mountains).

E. T. Dumble, 1902 (Am. Inst. Min. Engrs. Trans., vol. 31, pp. 696–715). *Dragoon qtzite.*—Consists of 400 ft. of sss. and qtzite. Underlain by ls. in Dragoon Mtns and overlain by ls. containing Middle Dev. fossils. In Mule Mtns it underlies Dev. ls. and overlies a bed of porphyritic andesite which rests on schists.

F. L. Ransome, 1904 (U. S. G. S. P. P. 21, p. 28). It is probable the so-called Dragoon qtzites of Dragoon and Mule Mtns are stratigraphically the same, but Dumble not only omitted to establish this correlation, but has rather obscured it by several statements revealing misconceptions of geol. structure not altogether surprising considering the rapid character of his reconnaissance. If, for example, the two Dragoon qtzites are properly correlated by Dumble, the reported occurrence of 40 ft. of ls. underlying the qtzite in Dragoon Mtns seems, in light of work in Mule Mtns, to require confirmation, since in latter range the so-called Dragoon qtzite rests with a basal cgl. upon pre-Camb. schists. As base of these schists is nowhere exposed, and as the only granitic rocks in Bisbee quad. are post-Carbf., Dumble's statement that the schists have a thickness of only 300 ft. and rest upon granite is misleading. It was at first intended to use in this rept the term *Dragoon qtzite* for the basal sed. fm. of Bisbee quad., but for reasons just indicated this name has been reluctantly abandoned and that of *Bolsa qtzite* adopted in its stead.

Dragoonan series.

A term introduced by C. [R.] Keyes for lower part of Camb. rocks of N. Mex. and Ariz. Named for Dragoon Mtns, SE. Ariz. (See his Conspectus of geol. fms. of N. Mex., 1915, pp. 4, 6.)

Draney limestone. (In Gannett group.)

Cretaceous (?): Southeastern Idaho.

G. R. Mansfield and P. V. Roundy, 1916 (U. S. G. S. P. P. 98, pp. 76, 83). *Draney ls.*—Fairly massive ls., compact, gray; weathering dirty white. Thickness 200± ft. Underlies Tygee ss. and overlies Bechler cgl.; all in Gannett group. Named for exposure on top of ridge about 1¼ mi. E. of Draney Ranch, on Tygee Creek, sec. 10, T. 8 S., R. 46 E., Boise meridian. May be Jurassic.

Draytonville conglomerate member (of Kings Mountain quartzite).

Cambrian (probably Lower): Southern North Carolina and northwestern South Carolina.

A. Keith and D. B. Sterrett, 1931 (U. S. G. S. Gaffney-Kings Mtn folio, No. 222). *Draytonville cgl. memb.*—Hard, heavy-bedded cgl., now almost a gneiss. Thickness 25 to 50 ft. Basal memb. of Kings Mtn qtzite.

Named for exposures on Draytonville Mtn, Cherokee Co., S. C.

Dresbach sandstone.

Upper Cambrian: Southern Minnesota and Wisconsin, Iowa, and northwestern Illinois.

N. H. Winchell, 1886 (Minn. Geol. Nat. Hist. Surv. 14th Ann. Rept., pp. 334–337). *Dresbach ss.*—Gray micaceous ss. which is known recently as Dresbach ss., from a town in Winona Co., Minn., where it is wrought for construction. Lies 200 ft. below St. Lawrence ls. in vicinity of Winona. Is separated from underlying Hinckley ss. by shales [which he both included in and excluded from his St. Croix fm., and which he later named ***Dresbach sh.***].

N. H. Winchell, 1888 (Minn. Geol. Nat. Hist. Surv. Final Rept., vol. 2), assigned thicknesses of 50–82 ft. to ***Dresbach sandrock*** of Minn. and applied ***Dresbach sh.*** to underlying sh. He described Dresbach sandrock of Dakota Co., Minn., as consisting of 60 ft. of sandrock resting on 20 ft. of gray sandy sh., and as overlying Dresbach sh., the upper 70 ft. of which consists of blue sh.

C. D. Walcott, 1914 (Smithsonian Misc. Coll., vol. 57, p. 354, from *Ulrich's mss., 1914*). *Dresbach ss.* overlies Eau Claire ss., newly defined fm., named for exposures at mouth of Eau Claire River, Wis.

F. W. Sardeson, 1916 (U. S. G. S. Minneapolis-St. Paul folio, No. 201). *Dresbach ss.* is named for Dresbach, Minn., where about 200 ft. of friable white and light greenish gray ss. belonging to the fm. is exposed beneath Franconia ss. There is still difference of opinion as to lower limit of Dresbach ss., but it includes lowermost of coarse white, cross-bedded water-bearing sss. that are penetrated by deep borings in these quads.

E. O. Ulrich, 1924 (Wis. Acad. Sci. Trans., vol. 21, pp. 71–93), defined *Dresbach ss.* of SW. Wis. as underlying Ironton memb. of Franconia ss. and overlying Eau Claire sh. [The Ironton memb. had previously been included in Dresbach ss.]

C. R. Stauffer, 1925 (Jour. Geol., vol. 33, p. 709). At Dresbach, Minn., the *Dresbach fm.* underlies Franconia ss. (which is 102 ft. thick) and consists of (descending): (1) Ss., often massive but usually sandy shales, 28 ft.; (2) ss., massive, white to yellowish or brown, with *Dicelomus politus* and *Hyolithes primordialis* common, 19′8″; (3) ss., massive, gray to white or yellowish to buff and brown, well shown in old quarry, very fossiliferous, and 18 ft. thick; (4) ss. and sandy sh. alternating, white to bluish, often cross-bedded, well exposed along river bank or in lower quarry, very fossiliferous, 22′6″.

E. Peterson, 1929 (Buffalo Soc. Nat. Sci. Bull., vol. 14, No. 2). *Dresbach fm.*—Underlies Franconia ss. with suggested conformity, but there is some evidence of erosion interval btw. deposition of the two fms., and initial Franconia deposits are believed to be reworked Dresbach sands. Thickness of Dresbach btw. 300 and 400 ft., but apparently considerably thinner at some localities. At surface the lower limit of characteristic fauna usually indicates base of Dresbach. In wells the base of blue shales present in lower part of fm. is usually taken as lower limit. The Dresbach fm. of Minn. has been traced horizontally and vertically into the "Eau Claire" of Wis. The lack of either a lithological or paleontological break btw. them makes it evident they are really one strat. unit. Although the outcrops in and around Dresbach are at slightly higher horizon than those in vicinity of Eau Claire, the similarity of faunas is too great to warrant separation into two fms. Confusion would be avoided by dropping name "Eau Claire" for a part of the fm., and retaining only the original name—*Dresbach*. The unfossiliferous coarse ss. of subaerial origin referred by Ulrich and others to the Dresbach may or may not be a shore phase and contemp. with part of true Dresbach of type area. However, no such deposit is present in type section. Renaming this subaerial deposit would help to avoid confusion.

A. C. Trowbridge and G. I. Atwater, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 38–45, 79). *Dresbach fm.* should include all beds btw. base of Mount Simon ss. and base of Ironton memb. of Franconia ss. The upper ss. of this series of beds (which is 60–86 ft. thick and has heretofore been called *Dresbach ss.*) is here renamed

Galesville memb.; the underlying 200 ft. of ss. and sh. are here called *Eau Claire memb.;* and the basal 200 ft. of ss. are called *Mount Simon memb.* The Dresbach as thus defined includes all beds exposed at Dresbach, Minn. and it rests (uncon.?) upon the red clastic series. It would include some beds that have been called *Hinckley ss.,* but we believe these beds are the Mount Simon ss. and that type Hinckley is older and belongs to red clastic series. If future work should prove that type Hinckley is same as Mount Simon ss., then latter name should be abandoned, as Hinckley has priority.

J. M. Wanenmacher, W. H. Twenhofel, and G. O. Raasch, 1934 (Am. Jour. Sci., 5th, vol. 28, p. 10). The differentiation of Mount Simon ss., "Eau Claire trilobite beds," and the upper ss. is extremely questionable, as all are composed of ss. and no uncon. has been detected in the sequence. Writers incline to view that there is only a single fm., which they propose to designate *Dresbach.* The Dresbach would include topmost ss., Eau Claire silty ss., and Mount Simon ss.

A. C. Trowbridge, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 83, 88–90). *Dresbach fm.* is here used to include (descending) Galesville memb., Eau Claire memb., and Mount Simon memb. The Galesville and Eau Claire members are exposed at Dresbach, Minn. The Franconia of Minn. Survey in places includes upper part of Galesville memb. and their Dresbach includes in places the lower part of Galesville memb. and all of Eau Claire memb. and in other places is Galesville and Eau Claire. [Trowbridge's sections describe all of Franconia and Dresbach at Dresbach as composed of ss., with shaly beds at base of his Eau Claire memb. Fig. 1 of this 1935 rept. shows Dresbach of Ill. Geol. Survey= Galesville memb. of Trowbridge et al, and that Dresbach ss. of Wis. and Minn. Surveys includes his Galesville, Eau Claire, and Mount Simon members. The section of Dresbach fm. at Galesville (by Twenhofel and G. O. Raasch) divides it into 86 ft. of Galesville memb. and 81 ft. of Eau Claire memb. On pp. 127 and 139 are statements: In central Wis. the Dresbach ss. fm. is recognizable but Mount Simon, Eau Claire, and Galesville members can be distinguished only with difficulty if at all. It is this fact which led Trowbridge and Atwater, Twenhofel and Raasch to demote the fm. names proposed by Ulrich to memb. names. (See also paper by Twenhofel, Raasch, and Thwaites, Geol. Soc. Am. Bull., vol. 46, No. 11, 1935, pp. 1687–1744.)]

The U. S. Geol. Survey at present applies *Dresbach ss.* to the beds overlying Eau Claire ss. and underlying Ironton memb. of Franconia ss., or to unit which Trowbridge and Atwater have renamed *Galesville memb.*

†Dresbach shale.

Upper Cambrian: Southeastern Minnesota.

N. H. Winchell, 1888 (Minn. Geol. Nat. Hist. Surv. Final Rept., vol. 2, p. 364). *Dresbach sh.*—The lowest sh. seen at Dresbach [Winona Co.] consists of 40 ft. of gray sh. underlain by 35 ft. of green sh. Is overlain by Dresbach ss. and underlain by so-called Potsdam ss. [On p. 82 he defines *Dresbach sh.* of deep well at Hastings, Dakota Co., as consisting of (descending): Blue sh., 70 ft.; sand and pulverized green sand, 20 ft.; and dolomitic grit with gray sh. and sand, 5 ft.]

See also under *Dresbach ss.* and *Franconia ss.;* also see *Eau Claire ss.* In some early repts these shales have been called "St. Croix shales." In later repts they have been named *Eau Claire.*

Dresden sandstone. (In Pottsville formation.)

Pennsylvanian: Southeastern Ohio.

E. Orton, 1884 (Ohio Geol. Surv. vol. 5, pp. 919, 920, 991). *Dresden ss.,* 10 to 20 ft. thick, lies in interval btw. Upper Mercer clay and Lower Mercer ore, in Hocking Valley field. [On p. 991 is said to be same as Upper Conoquenessing ss., and is shown as occurring below Lower Mercer coal, as overlain by Union Furnace block ore, and underlain by Quakertown coal.]

Probably named for Dresden, Muskingum Co.

Dresden amphibolite.

Pre-Cambrian: Northern New York (Adirondacks).

H. L. Alling, 1918 (N. Y. State Mus. Bull. 199). A para-amphibolite, 120 ft. thick, included in Grenville series. Lies stratigraphically beneath Hague gneiss. Type loc. is Dresden Twp, Washington Co.

Drews Lake granite.

Carboniferous (?): Northeastern Maine (Aroostook County).

H. E. Gregory, 1900 (U. S. G. S. Bull. 165, pp. 106–107, 148–149). *Drews Lake granite.*—The granite from Ludlow quarry is considered typical for Drews Lake dist. It exhibits two well-marked varieties in different parts of quarry. The highest rock exposed by the workmen has a grayish-white color in hand specimen and its surface is sprinkled inconspicuously with dark specks; quartz is prominent. In bottom of quarry the granite becomes a dark-gray variety, in which the dark components assume a leading rôle and the quartz is scarcely noticeable under microscope. Transitions btw. these two types occur. Both types are of medium grained uniform texture, with no porphyritic tendency. Named for exposures near Drews Lake, W. of Houlton, Aroostook Co.

On the 1933 geol. map of Maine, by A. Keith, the granite W. of Drews Lake is mapped as Carbf. and the sediments surrounding the lake as Sil.

Dripping Spring quartzite. (Of Apache group.)

Pre-Cambrian: Central Arizona.

F. L. Ransome, 1903 (U. S. G. S. P. P. 12). *Dripping Spring qtzite,* 400 ft. thick, is top fm. of Apache group in Globe copper dist. It overlies Barnes cgl. and is overlain by Globe ls. Lower 175 ft. consists of massive beds of streaked buff and pink qtzite. Upper part consists of thinner-bedded, hard, laminated, rusty-colored qtzite.

F. L. Ransome, 1911 (Min. and Sci. Press, June 3, 1911). Recent work in Ray quad., which adjoins Globe quad. on S., has revealed that Dripping Spring qtzite as mapped in Globe quad. included two qtzites, each 400 ft. thick, separated by 250 ft. of cherty ls. The name *Dripping Spring* is restricted to the lower qtzite.

F. L. Ransome, 1915 (Wash. Acad. Sci. Jour., vol. 5, pp. 380–385). The ls. overlying Dripping Spring qtzite restricted is here named *Mescal ls.* and the overlying qtzite is here named *Troy qtzite.* The upper part of Dripping Spring qtzite consists of thin flaggy and rusty beds; the middle part consists of fairly massive beds of even-grained buff or pinkish qtzite with flaggy variegated red, brown, and gray beds and some layers of red and grayish sh.; lower third is hard, fine-grained arkosic qtzite striped by alternating bands of dull-red, dark-gray, and nearly black colors. Thickness 400 to 500 ft.

Named for Dripping Spring Mtns, Globe quad., which owe their boldly scarped outlines to these qtzites and the underlying Barnes cgl.

Driscoll sand.

A subsurface sand in Fayette ss. of Driscoll pool, Duval Co., Tex.

Driving Creek formation.

Pre-Cambrian: Ontario.

R. G. McConnell, 1926 (Ont. Dept. Mines 35th Ann. Rept., pt. 2, p. 13).

Droop sandstone. (In Bluefield formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Giles County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 300, 415). *Droop ss.*—Usually white, very coarse and soft, weathering into white sand. Thickness 5 to 60 ft. Overlies Talcott sh. and underlies Possumtrot sh.; all members of Bluefield group [fm.]. Type loc. on Droop Mtn, Pocahontas Co., W. Va., in vicinity of Spice, Mt. Zion Church, and West Droop School. Also observed in Mercer, Monroe, and Summers Counties, W. Va., and in Giles Co., Va.

Drum limestone. (In Kansas City group, Kansas.)

Drum limestone member (of Kansas City formation, Missouri).

Pennsylvanian: Eastern Kansas, northwestern Missouri, southeastern Nebraska, and southwestern Iowa.

G. I. Adams, 1903 (U. S. G. S. Bull. 211, pp. 37, 63, 66). *Drum ls.*—Fossiliferous ls., 25 to 40 ft. thick, overlying Cherryvale sh. and underlying Chanute sh.

In Kans. the Kansas City is treated as a group and the Drum as a fm. The terms "Drum group" and "Drum ls." have been used in central northern Okla. to include (descending) Dewey ls., Nellie Bly fm., and Hogshooter ls., but that usage has been discontinued.

The Drum ls. of Hinds and Greene (1915 rept.) at Kansas City is now stated (N. D. Newell, Kans. Geol. Surv. Bull. 21, 1935, p. 40, and R. C. Moore, Kans. Geol. Surv. Bull. 22, 1936, pp. 104–105) to be an older ls., the type Westerville. The Cherryvale sh. has been subdivided by R. C. Moore into 5 members, the upper one of which he has named *Quivira sh.* The true Drum is now divided by Kans. Geol. Surv. (R. C. Moore, Bull. 22, 1936) into 2 members, Corbin City ls. (oolitic) above and Cement City ls. (nonoolitic) below. According to Newell (1935) these 2 members are uncon. R. C. Moore states (Bull. 22, 1936) Drum is 2 to 60 ft. thick, has been traced from Okla. line to Kansas City, and has been identified at various places in northern Mo., Iowa, and Nebr. (See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.)

Named for Drum Creek, Montgomery Co., SE. Kans.

†Drum group.

Pennsylvanian: Northeastern Oklahoma.

C. N. Gould, 1925 (Okla. Geol. Surv. Bull. 35, pp. 73–74), used *Drum group* to include (descending) Dewey ls., Nellie Bly fm., and Hogshooter ls., and this usage of name was followed in several subsequent repts but has now been discontinued.

Drumlummon porphyry.

Tertiary (late?): Western central Montana (Marysville district).

J. Barrell, 1907 (U. S. G. S. P. P. 57). *Drumlummon porphyry dikes.*—Younger than Marysville batholith. [Mapped on Drumlummon Hill, just S. of Marysville. The Marysville batholith is probably late Cret. or Tert. and may be as young as Mio. (Personal communication from J. T. Pardee.)]

Drummond.

Name applied by C. [R.] Keyes (Pan.-Am. Geol., vol. 46, 1926) to "50 ft. of clays of Mid Tertic age" in Mont. Derivation of name unknown.

Drury shale and sandstone member. (In Pottsville formation.)

Pennsylvanian: Southwestern Illinois (Carbondale quadrangle).

J. E. Lamar, 1925 (Ill. Geol. Surv. Bull. 48, pp. 23, 91–95, and map). The *Drury sh. and ss. memb.* of Pottsville fm. is composed of sh., sandy sh., shaly ss. and ss., with the first three predominant. Most characteristic lithologic features are the sandy shales and shaly sss. which weather to a plastic buff, cream or gray, sandy clay. Another typical feature is the fine and very fine-grained, thin, irregularly bedded ss. which weathers white with pink blotches commonly mottling the white surface. Clay inclusions, irregular current ripple marks, and mica are common. The ss. is locally qtzitic and not micaceous. Carbonaceous material occurs throughout as thin partings or laminae. Small lenses of coal are present in W. part of quad. Thickness 50 to 120 ft. Lies conformably on Lick Creek ss. memb. of Pottsville and is conformably overlain by Makanda ss. memb. Named for excellent exposures along Drury Creek, particularly in bluffs S. of Makanda, Jackson Co.

†Dry bone limestone.

A descriptive term originally applied to Neva ls. by Swallow, according to C. N. Gould (1925).

Dry shale. (In Wabaunsee group.)

Pennsylvanian: Eastern Kansas.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 22, 236, etc.). *Dry sh.* is here applied to shaly beds, 5 to 20 ft. or more thick, that separate Dover ls. from next higher (Grandhaven) ls. Is bluish gray and for most part clayey, but sandy beds appear in places. In southern Kans. a thin coal occurs near top. Is well-defined unit from Shawnee Co., Kans., S. to Okla. line, but to N. it coalesces with Friedrich sh. above and Grandhaven ls., which disappears, although it is possible the Grandhaven beds grade laterally into the sh. Where the sh. btw. Dover and

Jim Creek lss. cannot be subdivided it may be called *Dry-Friedrich sh.* Type loc., Dry Creek, SW. of Emporia, in sec. 5, T. 20 S., R. 11 E.

This name appears to have first appeared in print, without definition, in a table by R. C. Moore published opp. p. 14 of Univ. Kans. Bull. 20, May 1, 1935.

Dry Creek shale.

Upper Cambrian: Central southern and western central Montana.

A. C. Peale, 1893 (U. S. G. S. Bull. 110). *Dry Creek shales.*—Shales or shaly calc. sss. which rest on the glauconitic or pebbly layers that cap the mottled lss. of Gallatin fm. in Threeforks region and are overlain by the pebbly lss. forming top memb. of the Gallatin. Outcrops obscure in most places. Best exposure seen is on Dry Creek [NE. corner of Threeforks quad.], where thickness is 30± ft. Here they consist of brownish-yellow, red, and pink sss., saccharoidal, breaking into thin laminae, with streaks and seams of calcite. No fossils.

A. C. Peale, 1896 (U. S. G. S. Threeforks folio, No. 24). *Dry Creek shales*, consisting of 30 ft. of brownish, yellow, red, and pink saccharoidal shales and thin-bedded sss., are overlain by 145 ft. of light-colored laminated lss., pebbly throughout and glauconitic. [Type loc. of Dry Creek sh. is in NE. corner of Threeforks quad.]

W. H. Weed, 1899 (U. S. G. S. Fort Benton folio, No. 55). The brick-red shales and lss. constituting Dry Creek sh. are overlain by 100 ft. of Yogo ls.

W. H. Weed, 1899 (U. S. G. S. Little Belt Mtns folio, No. 56). The reddish argill. or aren. beds of Dry Creek sh., usually about 40 ft. thick, are underlain by Pilgrim ls. and overlain by Yogo ls., which consists of gray or mottled ls. with a few layers of interbedded sh.

A. Knopf, 1913 (U. S. G. S. Bull. 527, p. 91). *Dry Creek sh.* of Helena dist. [NW. of Threeforks quad.] consists of 40 ft. of light-colored brownish-yellow, red, and pink shales and calc. ss. Correlated on basis of lithology and strat. position with Dry Creek sh. of Threeforks and Little Belt regions.

C. F. Deiss, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 8, pp. 1258–1342), proposed that Yogo ls. be discarded, and defined Dry Creek sh. as uncon. overlain by Dev. rocks. In upper part of his Dry Creek sh. he included a great thickness of lss.

Dry Creek formation.

Eocene: Northern California (Chico quadrangle).

V. T. Allen, 1929 (Calif. Univ. Pub., Bull. Dept. Geol. Sci., vol. 18, No. 14, pp. 367–369, 400, 401, 403). Above the Chico ss. (Cret.) of Oroville Table Mtn are gray shales with flakes of biotite and casts of Eocene fossils, overlain conformably by 80± ft. of light-colored biotite sands containing fragments of wood and leaves. Apparently it was from these shales that Turner collected casts of *Corbicula*. Best section is exposed in steep-walled valley formed by a tributary of Dry Creek. Thickness of fm. probably over 180 ft. The name *Dry Creek fm.* is suggested for these beds, from the tributary along which the section is displayed. Conformably underlies Ione fm., which here consists of white quartz-anauxite sands and clays, cross-bedded.

Dry Creek sandstone member.

Mississippian: Southern Indiana (Washington, Lawrence, and Jackson Counties).

P. B. Stockdale, 1931 (Ind. Dept. Cons., Div. Geol. Pub. 98, pp. 76, 238, 243, 246). *Dry Creek ss. memb. of Edwardsville fm.*—Persistent bed of heavy ss., not far above middle of Edwardsville fm., of sufficient areal extent to be considered a memb. Lies higher in Edwardsville fm. than Brownstown Hills ss. memb., its strat. position being 60 to 65 ft. below top of Edwardsville. It is very fine-grained ss., with some clay, and of gray to buff color. In ravine tributary to Dry Creek and along road S. center sec. 35, T. 6 N., R. 2 E., 3 mi. S. of Norman Station, it is 4 ft. thick; on road W. of Norman Station it is 2 ft. thick; and S. of Norman Station it is 5 ft. thick. It rests on a blue to blue-gray, very sandy sh. or shelly ss. Named for prominence along Dry Creek, both E. and W. of Jackson-Lawrence Co. line.

Dry Fork erosion cycle.

Name applied by G. R. Mansfield (Jour. Geol., vol. 32, 1924, p. 485) to a Pleist. erosion cycle in SE. Idaho.

Dublin blue shale.

Middle Devonian: Central Ohio.

E. Claypole, 1903 (Am. Geol., vol. 32, pp. 19, 20, 34, 35). ***Dublin blue sh.***—Thin shaly beds, known as blue lss., 32 ft. thick; fossiliferous in lower part but barren and flinty above. Overlain by thin-bedded blue Corniferous-Hamilton ls., and underlain by "Bone bed" [p. 34 states lies few ft. above "Bone bed"], which rests on Columbus ls. Of Marcellus age.

Forms lower part of Delaware ls.

Named for exposures along Scioto River near Dublin, Franklin Co.

Dubois greenstone.

Pre-Cambrian: Central western Colorado (Gunnison River region).

J. F. Hunter, 1925 (U. S. G. S. Bull. 777). *Dubois greenstone.*—A series of metamorphosed basic rocks of class called metabasites by Hackman, comprising hornblende gneisses, amphibole schists, chlorite schists, and basic associates that extend in a zone of varying width (1 to 4 mi.) and persistency from Lake Fork of Gunnison River on W. to beyond South Beaver Creek on E. Belong to the metamorphic complex of Gunnison River region, and believed to be younger than most of the schist and gneiss complex. Named for exposures at old mining camp of Dubois, on Goose Creek. Assigned to Archean.

On 1935 geol. map of Colo. this fm. was included in Gunnison River series, which comprises the oldest exposed pre-Camb. rocks of Colo. The terms "Algonkian system" and "Archean system" having been discarded by U. S. Geol. Survey, the Dubois greenstone is now classified as pre-Camb.

Du Bois limestone. (In Topeka limestone.)

Pennsylvanian: Southwestern Iowa, southeastern Nebraska, northeastern Kansas, and northwestern Missouri.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 42, 52, 53). *DuBois ls.*—One or two dark blue, dense, fossiliferous lss. forming large flat blocks. Thickness 2⅝ ft. near DuBois, Nebr., 1′ 1″ in Kans. and Mo. Underlies Holt sh. and overlies Turner Creek sh., all included in Topeka ls. Named for exposures on Turner Creek SE. of DuBois, Nebr. [This is definition followed by R. C. Moore and G. E. Condra in their Oct. 1932 revised classification chart of Penn. rocks of Kans. and Nebr. and by R. C. Moore in his 1936 classification (Kans. Geol. Surv. Bull. 22).]

Dubose sands and clays.

Eocene (Jackson): Southeastern Texas (Gonzales County).

A. C. Ellisor, 1933 (A. A. P. G. Bull., vol. 17, No. 11, pp. 1302, 1314, etc.). *Dubose sands and clays.*—Series of sands and fossiliferous green and brown shales with beds of volcanic ash and glass, also beds of ashy, peaty shales; numerous septaria and cone-in-cone concretions. One exceptionally definite boulder horizon is exposed on Sandies Creek, Dubose Ranch, Gonzales Co., where Catahoula "rice sands" lie uncon. on Dubose zone. Lies stratigraphically above Stone's Switch sand and below Callihan sand, all zones in Whitsett fm. as here defined.

Dubuque formation. (In Richmond group.)

Upper Ordovician: Eastern Iowa, southeastern Minnesota, southwestern Wisconsin, and northwestern Illinois.

F. W. Sardeson, 1907 (Geol. Soc. Am. Bull., vol. 18, p. 193). *Dubuque fm.*—Irregular ls. and interlaminated carbonaceous shales, 10 ft. thick at Dubuque, Iowa, extending from "cap rock" below up to blue shales of Maquoketa memb. of Maquoketa series. Coincides with *Triplicia* bed or zone, and forms basal part of Maquoketa series or stage. Overlain by Maquoketa fm. proper and underlain by Galena fm.

E. O. Ulrich, 1924 (Wis. Acad. Sci. Trans., vol. 21, pp. 71–93). *Dubuque ls.* is basal Richmond, and older than Fernvale ls. [which to S. underlies Maquoketa sh.], and older than Maquoketa sh. In western Wis. and Iowa the Maquoketa overlies Dubuque fm. where Dubuque is present.

See also under *Volga shales.*

A. C. Trowbridge et al, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., fig. 1, p. 61, etc.), classify *Dubuque* as of Trenton age and include it in *Galena group,* as they call the Galena dol. On p. 27 Trowbridge stated Prosser, Stewartville, and Dubuque can be seen in Jo Daviess Co., Ill.

Named for Dubuque, Dubuque Co., Iowa.

Dubuque terrane.

Quaternary: Iowa.

C. [R.] Keyes, 1914 (Iowa Acad. Sci. Proc., vol. 21, p. 186). *Dubuque terrane.*—Clays (geest), 10 ft. thick, of pre-Nebraska age. Assigned to early Quaternary or Epicene series.

Probably named for Dubuque, or Dubuque Co.

Duchesne limestone.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, pp. 36, 300). *Duchesne ls.*—Shales and ls., 250 ft. thick, underlying Bishop ss. in Utah. Stratigraphically uncon. above McElmo fm., and compose basal fm. of Flaming Gorge series. May correspond exactly to the similar Sundance shales and limestone. [Derivation of name not stated.]

According to A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1936 (U. S. G. S. P. P. 183, chart opp. p. 40), the Bishop ss. and Duchesne ls. of Keyes are=Entrada ss. and Carmel fm., both Upper Jurassic.

Duchesne formation.

Oligocene: Northeastern Utah (Uinta Basin).

O. A. Peterson, 1932 (Carnegie Mus. Annals, vol. 21, No. 2, pp. 61–63, pl. 1). *Duchesne fm.*—Name proposed (upon suggestion of Prof. W. B. Scott of Princeton Univ.) for the Olig. fm. named "Upper Uinta" by Peterson and Kay in Carnegie Mus. Annals, vol. 20, pp. 293–305, 1931. This Olig. horizon, 1,372 ft. thick, rests upon Upper Eocene (Horizon C) in Uinta Basin. Duchesne River (in Duchesne Co., Utah, which has its source on S. side of Uinta Mtns.) traverses these Basal Olig. beds before its confluence with Green River ½ mi. below Ouray, Utah. The area covered by these Olig. strata has an E.-W. extent of approx. 80 mi., and seldom exceeds 12 to 15 mi. in N.-S. direction along N. margin of Uinta Basin. From Randlette westward, along Duchesne River, these Olig. beds are quite clearly defined from underlying Uinta series (Horizon C). They consist of ss. that weather out to reddish brown cliffs, which rest on softer clays (Horizon C of the Uinta) along the streams and on the divides btw. Lake Fork, "Dry Gulch," Duchesne, and the course of other rivers. Although a tentative division was made by Peterson and Kay btw. the Duchesne beds and the underlying Uinta strata eastward from Randlette, the distinction btw. the two horizons is not so clear toward eastern end of basin. The relationship of fauna of Duchesne Olig. is less sharply defined from that of underlying Uinta (Horizon C) than is usually the case in superimposed horizons of other localities, but there is an advance corresponding to that of the lithological change noted. The Olig. may thus be regarded as a horizon perfectly transitional btw. Upper Eocene and Chadron horizon of White River series of S. Dak. But the Sage Creek beds of Mont. may have to be placed btw. the Chadron of Nebr. and Dakota and the Duchesne series of Utah. The Duchesne Olig. is overlain by talus of Bishop cgl.

J. L. Kay, 1934 (Carnegie Mus. Annals, vol. 23, pp. 357–359, map, pls. 45, 46). *Duchesne fm.* (proposed by Prof. W. B. Scott) is preoccupied by Keyes' name for a Jurassic ls. A new name is required for Olig. fm., but writer feels that there will be less confusion if "Duchesne" is retained in the new term. At Prof. Scott's suggestion the name *Duchesne River* is now proposed for the lower Olig. fm. of Uinta Basin, Utah. To S. the fm. lies conformably on horizon C of Uinta Eocene, but with greater or less uncon. on older rocks along its N. border. The fm. is divided into 3 named horizons. [For definitions of these 3 horizons see under *Randlett horizon.*]

Duchesne River formation.

Oligocene: Northeastern Utah.

See 1934 entry under *Duchesne fm.*

Duck Creek formation. (In Washita group.)

Lower Cretaceous (Comanche series): Northeastern Texas and central southern Oklahoma.

R. T. Hill, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 504, 516). *Duck Creek chalk.*—Crumbling white chalky ls. alternating with chalky marls. Thickness 100 ft.

Overlies Kiamitia clays and underlies Fort Worth ls. in Ind. Ter. and Grayson and Cooke Counties, Tex. Included in Washita div. [group].

W. M. Winton and W. S. Adkins, 1919 (Univ. Tex. Bull. 1931), divided Duck Creek fm. into several members and proposed a restriction of name to basal 2 members. (See 1919 entry under *Fort Worth ls.*)

The U. S. Geol. Survey still uses the original definition of this name. Named for Duck Creek, Grayson Co., Tex.

†Duck Creek limestone.

†Duck Creek limy marl.

†Duck Creek marl.

†Duck Creek marly lime.

See 1919 entry under ***Fort Worth ls.***

†Dudley limestone.

†Dudley series.

Ordovician: New York.

T. A. Conrad, 1839 (N. Y. Geol. Surv. 3d Rept., pp. 58–59), applied *Dudley ls.* and *Dudley series* to ls. exposed at Dudley, which he originally believed, from contained fossils, to be younger than Trenton ls., but which he finally concluded corresponds in age to Trenton ls.

Dudley shale. (In Pleasanton group, Kansas.)

Dudley shale member (of Pleasanton formation, Missouri).

Pennsylvanian: Eastern Kansas and southeastern Nebraska.

G. I. Adams, 1903 (U. S. G. S. Bull. 211, p. 34). *Dudley sh.*—Shales, about 150 ft. thick, with some ss. and some thin ls., overlying Parsons ls. and underlying Hertha ls. Top fm. of Pleasanton group in Kans. In SE. Kans. is basal memb. of Coffeyville fm. Underlies Hertha ls. and overlies Parsons fm.

This definition of Dudley sh. was followed for many years.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, p. 89). Name *Dudley sh.* is now to be applied to sh. above the Lenapah and beneath the pre-Missouri uncon., which lies at base of Bourbon group [new name]. [This is a *restriction* of Dudley sh. (to lower part). This definition was also adopted by Moore and G. E. Condra in their Oct. 1932 revised classification chart of Penn. rocks of Kans. and Nebr.]

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, p. 19). Because Des Moines-Missouri bdy lies within and probably near base of Dudley sh. it is advisable to abandon *Dudley*.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 67). *Dudley sh.* discarded. It presumably includes upper Des Moines beds and lower Missouri sh. and ss. equiv. to Bourbon fm. New name *Memorial sh.* introduced for *Dudley sh.* as defined by Moore in 1932.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936. The U. S. Geol. Survey has not had occasion to consider these modified definitions.

Named for Dudley, Neosho Co., Kans.

Duffin limestone.

Upper Devonian: East-central Kentucky.

A. F. Foerste, 1905 (Ky. Geol. Surv. Bull. 6, p. 145) and 1906 (Ky. Geol. Surv. Bull. 7, p. 97). *Duffin layer.*—Brownish-yellow ls., 2 inches to 12 ft. thick, having brecciated appearance, forming top of Dev. ls. in Lincoln, Montgomery, Boyle, Clark, and Garrard Counties. Overlain by Ohio sh. and underlain by other Dev. lss. [See also under *Boyle ls.*]

T. E. Savage, 1929 (Geol. Soc. Am. Bull., vol. 40, p. 112), stated that Duffin fossils suggest Tully (Upper Dev.) time.

T. E. Savage, 1930 (Ky. Geol. Surv., ser. 6, vol. 33, pp. 1–21), transferred *Duffin layer* to New Albany sh., because at many places in Ky. lenses and layers of a ls. or dol. similar in composition to Duffin layer and in some places carrying similar fossils, are interbedded in the black sh. for 9 to 15 ft. above its base, and stated that this indicates that basal sandy dolomitic Duffin layer belongs with New Albany period of deposition rather than with underlying Middle Dev. ls.

T. E. Savage, 1931 (Ky. Geol. Surv., ser. 6, vol. 36, pp. 218, 234). *Duffin ls.*—In Estill and Powell Counties has furnished a Tully fauna, which was also present in lenses or bands of similar ls. that was interbedded with the black New Albany sh. for several ft. above base of that fm. Fauna listed.

Named for Duffin cut, ¾ mi. N. of Junction City, Boyle Co.

Dugout clay and gravel.

Miocene and Pliocene: Western Texas.

J. A. Udden, 1907 (Univ. Tex. Bull. 93, pp. 17, 68). *Dugout clays and gravels.*—Nonfossiliferous clays, silts, sands, and gravels, chiefly the finer sediments; 100 to 300 ft. thick. Overlie Cret., and are undoubtedly older than alluvial deposits in valley of Rio Grande, for they lie at higher level and have suffered extensive erosion. Possibly an old alluvial drift laid down by Tornillo Creek. Assigned to Mio. and Plio.

Named for Dugout wells, near Boquillas, Brewster Co.

Dugout beds.

Pennsylvanian: Trans-Pecos Texas (Marathon Basin).

C. L. Baker and W. F. Bowman, 1917 (Univ. Tex. Bull. 1753, pp. 104–105) listed fossils from beds exposed in vicinity of Dugout Creek at Payne's ranch westward to "Permo-Carbf." contact, which they assigned to Tesnus fm.

C. L. Baker, 1928 (A. A. P. G. Bull., vol. 12, No. 11, pp. 1111–1116). [Discusses recent papers by C. Schuchert (Am. Jour. Sci., 5th, vol. 14, 1927, pp. 382-401) and P. B. and R. E. King (Univ. Tex. Bull. 2801, 1928, pp. 109–145), and criticises their reference to Gaptank fm. of the beds on Dugout Creek, W. of town of Marathon. He states:] Lithologically the strata show more differences than resemblances. The strata W. of Marathon have no coarse heavy cgls.; the sss. are different and have none of the typical gray ls. beds of development comparable with those of true Gaptank. Greatest resemblance is in the shales. Impossible to trace Gaptank westward into the strata W. of Marathon, because of wide belt of alluvium. Writer originally included these strata with the Tesnus because they lithologically resemble that fm. more than any other known fm. He still thinks it possible they may be a marine equiv. of the Tesnus, although of late years he has been more inclined to consider them, at least in part, the equiv. of the Strawn of central Tex., which they faunally and lithologically resemble more than any other known fm. in central Tex. Although originally reluctant to publish a new name for these strata, the writer, who was first to describe them and to collect and identify fossils from them, will now propose for them the name *Dugout beds,* his original field name. Writer still believes them to be older than Gaptank fm.

P. B. King, 1931 (Univ. Tex. Bull. 3038, pp. 31, 45–46, 49). Evidence obtained by writer and R. E. King indicate "Dugout beds" of Baker are of Gaptank age. Their Gaptank age was originally announced by Schuchert and was restated by R. E. King and writer. The beds contain diagnostic fossils, which indicate Canyon and Cisco age. Differences in lithology btw. type Gaptank and Dugout beds is explained by fact that movements inaugurating the Caballos disturbance had already begun in mid-Gaptank time, but these early phases were essentially local, so that the cgls. at Gap Tank are of Canyon age, while those W. of Marathon are somewhat younger and of different composition. The beds on Dugout Creek consist of 1,500± ft. of alternating sss. and shales, with one, perhaps two, thin beds of gray ls., and, at base, 20 ft. of gray, granular, in places conglomeratic, ls. passing upward into fine-grained sandy ls. This basal ls. contains *Chaetetes milleporaceus and Fusulinella meeki,* and is considered to = the Chaetetes ls. that forms base of Gaptank fm. in type area. It is underlain by shales and sss. assigned to Haymond fm. Along Dugout Creek overthrust the Gaptank has been overriden by great mass of pre-Carbf. rocks.

Dukes boulder bed.

Pleistocene: Southeastern Massachusetts (Marthas Vineyard) and southeastern Rhode Island (Block Island).

J. B. Woodworth and E. Wigglesworth, 1934 (Harvard Coll. Mus. Comp. Zool. Mem., vol. 52, p. 163). *Dukes boulder bed.*—A remarkable bed of glacial bowlders entirely free from clay; locally cemented by limonite. Overlies Aquinnah cgl. and underlies Weyquosque fm. Occurs only at Gay Head Cliffs fold on Marthas

Vineyard and at Clay Head on Block Island. Named for occurrence in Dukes Co., Mass. Correlated with early part of Nebraskan stage of Mississippi Valley region.

Duley Lake group.

Pre-Cambrian: Labrador.

J. E. Gill, C. Tolman, and H. M. Bannerman, 1935 (Geol. Soc. Am. Proc. 1934, p. 78).

Duluth gabbro.

Pre-Cambrian (middle or late Keweenawan): Northeastern Minnesota, northern Wisconsin, and northern Peninsula of Michigan.

R. D. Irving, 1883 (U. S. G. S. 3d Ann. Rept., pp. 124, 134), described very coarse gabbros (Bad River gabbros and *Duluth gabbros*) at base of Keweenaw series.

J. M. Clements, 1903 (U. S. G. S. Mon. 45, p. 397). *Duluth gabbro.*—Varies from coarse-grained granular rock to relatively fine-grained rock; also in places possesses a gneissic structure. Named for development near Duluth, Minn. Is intrusive.

This intrusive fm. is now regarded as middle or late Keweenawan.

†Duluth group.

Pre-Cambrian (Keweenawan): Northeastern Minnesota.

R. D. Irving, 1883 (U. S. G. S. 3d Ann. Rept., pl. 14, pp. 134, 142–146, 185; also U. S. G. S. Mon. 5, p. 266). *Duluth group.*—Succession of heavy but sharply defined beds of very fine-grained but aphanitic rocks belonging to ashbed type of diabases and diabase porphyrites, and including a few beds of rather coarse-grained orthoclase free gabbro and a little interleaved detrital material. Thickness 5,000 ft. Included in Keweenaw series. Exposed along N. side of St. Louis River up to Duluth.

A. H. Elftman, 1898 (Am. Geol., vol. 21, pp. 90–109, 175–188, and map). Part of Duluth group of Irving is included in my Temperance River memb. and part of it in my Beaver Bay diabase.

Duluth granite.

Trade name of stone quarried from Duluth gabbro.

Duluth.

Name applied to a glacial lake, of Pleist. age, and to its beaches, in Lake Superior region.

Dumble beds.

See *Swallow belt, terrane, or fms.*

Dun limestone.

Pennsylvanian: Southeastern Kansas.

Robt. Hay, 1887 (Kans. Acad. Sci. Trans., vol. 10, p. 7). *Dun ls.*—Ls., 100 ft. thick, in middle of interval btw. Fall River ss. and Neodesha lss. in Wilson Co. Probably same as thick Humboldt ls. of Neosho Valley, having same irregularity of structure and apparently same fossils. Separated from underlying Neodesha ss. by 80 to 100 ft. of sh. and from overlying Fall River ss. by 145 ft. of sh., ls., and ss.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 124). †Dun ls. of Hay included Plattsburg, Vilas, and Stanton fms.

Named for Dun, Wilson Co.

Dunbar series.

Carboniferous (Mississippian ?): Nova Scotia.

P. D. Trask and K. F. Mather, 1927 (Wash. Acad. Sci. Jour., vol. 17, p. 324).

Duncan chert.

Mississippian: Northern California (Colfax quadrangle).

W. Lindgren, 1900 (U. S. G. S. Colfax folio, No. 66, p. 2). From Duncan Peak there extends across North Fork of American River to vicinity of Monumental Hill a belt of gray or brown chert, referred to as *Duncan chert*. It is well exposed in canyons near Canada Hill and in canyon of the main river. This chert is in all probability not of clastic origin, and may have been derived from ls. by a process of silicification. Included in Blue Canyon fm.

Duncan formation.

Cretaceous (?): British Columbia.

C. H. Clapp, 1917 (Canada Geol. Surv. Mem. 96, p. 232). [Assigned to Cret.; but M. F. Bancroft (Canada Geol. Surv. Summ. Rept. 1917, pt. B, p. 36, 1918) assigned *Duncan series* to pre-Camb., B. C.]

Duncan sandstone.

Permian: Central southern and southwestern Oklahoma.

C. N. Gould, 1924 (A. A. P. G. Bull., vol. 8, pp. 324–341, map). *Duncan ss.*—Consists of two, sometimes three, ledges of white or buff ss., sometimes dolomitic, separated by shales. Thickness 75 to 250 ft. To N. of its max. development it is difficult to trace. Underlies Chickasha fm. and overlies Lower Enid. The Chickasha and Duncan correspond to Upper Enid. The presence or absence of a continuous uncon. at its top and base is still a mooted question. Forms an escarpment just N. of Duncan, Stephens Co. [This is approved definition of Duncan ss. On p. 313 of publication above cited R. W. Sawyer applied name *Duncan ss.* to Gould's Duncan ss. and overlying Chickasha fm.]

This ss. (which has been mapped on 1926 Okla. geol. map from its type loc., in Stephens Co., Okla., to Red River) is now known to be same as San Angelo ss. of Tex., which has many years priority and has been traced from its type loc. (in Tom Green Co., Tex.) to Duncan, Okla. (See 1926 entry under *San Angelo ss.*) On 1932 prel. ed. of Tex. geol. map San Angelo ss. has been mapped up to Red River.

Duncan greenstone.

Pre-Cambrian: Ontario.

R. G. McConnell, 1926 (Ont. Dept. Mines 35th Ann. Rept., pt. 2, p. 14).

Dundas formation.

Upper Ordovician: Toronto, Ontario.

W. A. Parks, 1924 (Geol. Soc. Am. Bull., vol. 35, pp. 103–104). The strata at Toronto, Ont., lying btw. black Utica shales and red Queenston shales are divisible into an upper series comparable with the Richmond and a lower series showing affinities with both the Pulaski of N. Y. and the Maysville of Ohio. It is proposed to name the lower div. *Dundas fm.* and to divide it into four members (descending): *Credit, Humber, Davenport, Rosedale.* [Fauna discussed.] While many species range throughout the fm., each memb. has its distinctive fauna; these faunas are as difficult to correlate as that of the fm. as a whole. The prevailing gray shales contain many hard, discontinuous layers. These are of two kinds—fossiliferous lss. and calc. sss., generally without fossils. Both types vary from apparent beds to small lenses. [Type loc. not stated.]

In 1927 (Geol. Soc. Am. Bull., vol. 38, p. 229) Parks stated that *Dundas fm.* rests conformably on Utica sh. See also Hume (Canada Geol. Surv., Econ. Geol. ser., No. 9, p. 23, 1932) and Coleman (Ont. Dept. Mines 41st Ann. Rept., pt. 7, p. 3, 1932).

Dundee limestone.

Middle Devonian: Michigan (Lower Peninsula).

A. C. Lane, as reported by M. E. Wadsworth, 1893 (Mich. Geol. Surv. Rept. 1891 and 1892, p. 66). *Dundee ls.,* 40 to 160 ft. thick, underlies Traverse group and overlies Monroe beds.

A. C. Lane, 1895 (Mich. Geol. Surv. vol. 5, pt. 2). *Dundee ls.*—Buff, yellow, or almost white calc. rocks, 40 to 160 ft. thick. Underlies Traverse group and overlies Monroe beds.

Named for exposures at Dundee, Mich.

Dunderberg shale.

Upper Cambrian: Eastern Nevada (Eureka district and neighboring regions).

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1812, p. 184, footnote). As result of conference with Mr. Arnold Hague, *Dunderberg sh.* is introduced to replace *Hamburg sh.*, the name *Hamburg* being retained for Hamburg ls.

Named for exposures opposite Dunderberg mine, Eureka dist.

Dunderbergian series.

A name applied by C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 53, 78), to Dunderberg sh. of Nev.

Dunham dolomite.

Lower Cambrian: Quebec.

T. H. Clark, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 1, pp. 6, 10).

Dunkard sand.

Name applied by drillers to Mahoning ss. memb. of Conemaugh fm. (Penn.), from fact that oil was struck in it near mouth of Dunkard Creek, Greene Co., Pa., in 1860. The name has also been applied to Saltsburg and Mahoning sss. combined. In Ohio the term has been applied to the 300-foot sand, in Allegheny fm.

Dunkard group.

Permian: Southwestern Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

I. C. White, 1891 (U. S. G. S. Bull. 65, p. 22). *Dunkard Creek series.*—On Dunkard Creek, Greene Co., Pa., includes 165 ft. concealed beds above Gilmore ss. and extends down to base of Cassville shales.

The above accords with present definition of Dunkard group, which is now divided into Greene fm. (above), extending down to top of Upper Washington ls. memb., and Washington fm. (below). The U. S. Geol. Survey classifies the Dunkard deposits as a *group* within Perm. *series*, but present Pa. Geol. Survey classifies them as a *series* within Perm. *system.*

†Dunkard Creek series.

See under *Dunkard group.*

Dunkirk shale (also **Dunkirk sandstone**).

Upper Devonian: Western New York.

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, p. 24 and chart). In Lake Erie section the succession [of Naples beds] is varied by introduction of a third band of black sh. lying above horizon of Westhill flags. This is *Dunkirk sh.* Overlain by Portland sh. and underlain by Angola sh., both of which contain an abundance of Naples fossils.

D. D. Luther, 1903 (N. Y. State Mus. Bull. 69, pp. 1019–1029). *Dunkirk black sh.*, 53 to 55 ft. thick, underlies Portland gray shales and overlies Silver Creek shales. Included in Portage group of Lake Erie region.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 78 and chart). The *Dunkirk sh.* is a black sh. occurring next above horizon of Grimes ss., apparently within basal Gardeau. [In chart, however, he placed it beneath Gardeau flags.] The fm. is regarded as local, not having been observed outside of Chautauqua Co. The term "Portland" has been used locally to designate certain shales and flags lying above Dunkirk sh. As this term is preoccupied, and it is now evident that these beds are embraced in upper Gardeau, the name *Gardeau* will be used to include these beds. [In chart the underlying fm. is called *Hanover.*] Included in Portage. Named for Dunkirk, Chautauqua Co.

F. Houghton, 1914 (Buffalo Soc. Nat. Sci. Bull., vol. 11, pp. 4, 7–65). *Dunkirk sh.* excluded from Gardeau sh. of Erie Co., because it is distinct enough to warrant our excluding it. Overlain by Gardeau sh., and underlain by Hanover sh. Included in Portage.

G. H. Chadwick, 1919 (Geol. Soc. Am. Bull., vol. 30, p. 157). *Dunkirk black sh.* included in Chemung. Overlain by Gowanda ("Portland") beds and discon. underlain by Hanover shales.

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69). *Dunkirk sh.* of Chautauqua Co. is overlain by Gowanda sh. and underlain by Hanover sh.; in Cattaraugus Co. *it is overlain by Gowanda beds and underlain by Wiscoy sh.* (in part=Hanover sh.). Assigned to Chemung. Equiv. to upper part of Cayuta sh. memb. of Chemung.

G. H. Chadwick, 1924 (N. Y. State Mus. Bull. 251, pp. 149–157). *Dunkirk black sh.* extends from Van Buren Point, on Lake Erie, to Holland, where it is over 160 ft.

thick. Two characteristic (and unlike) septarian zones divide it into three members, throughout this distance, the upper of which was included by Luther in his overlying Portland shales. Included in Chemung group. Underlies Gowanda beds and overlies Hanover sh.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369), included in the Chemung the Dunkirk sh. and all overlying beds up to top of Chadakoin of Chadwick.

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60), included Fall Creek cgl. in Dunkirk sh., making it basal bed of the Dunkirk. He repeated this classification in Geol. Soc. Am. Bull., vol. 46, No. 2, p. 323, 1935. In both repts he transferred to his Canadaway group (q. v.) Dunkirk sh. and all overlying beds up to top of Northeast sh.

In Steuben and adjacent counties of south-central N. Y. the Dunkirk is a ss. and is called *Dunkirk ss.* To W. the fm. is sh. and is called *Dunkirk sh.*

†Dunlap limestone.

Pennsylvanian: Eastern Kansas.

M. Z. Kirk, 1896 (Kans. Univ. Geol. Surv. vol. 1, pp. 81, 82). *Dunlap ls.*—Two lss., separated by 9 to 20 ft. of sh. Separated from overlying Cottonwood Falls ls. by 25 to 30 ft. of sh. and from underlying Americus ls. by 50 ft. of sh.

For many years considered same as later but better-established name *Neva ls.* According to Condra (Nebr. Geol. Surv. Paper No. 1, 1933, p. 8) it includes more than true Neva ls. and is = his Grenola fm. See under *Grenola fm.* and *Neva ls.*

Named for Dunlap, Morris Co.

Dunlap formation.

Lower Jurassic: Southwestern Nevada (Tonopah and Hawthorne quadrangles).

S. W. Muller and H. G. Ferguson, 1936 (Geol. Soc. Am. Bull., vol. 47, pp. 241–252). *Dunlap fm.*—Upper part dominantly red to brown ss. containing much volcanic material and probably considerable water-laid tuffs, cgls. (principally of ls. pebbles), and varying amounts of volcanic rocks. In Gabbs Valley Range and central part of Excelsior Mtns volcanic rocks predominate in upper part, but elsewhere they are subordinate; they consist of andesite, quartz latite, and rhyolite flows and breccias, and are generally much altered. Lower part of fm. is commonly conglomeratic, and a characteristic feature is presence of enormous fan cones of unsorted angular material from fm. against which it rests. In places these fangls. contain lenses of ls., sh., ss., and bedded cgl. Thickness of fm. 4,000+ ft. Assigned to Lower Jurassic and correlated with middle (?) Liassic of Europe. Few fossils. In New York Canyon it locally rests on Sunrise fm. (Lower Jurassic) with apparent conformity. Elsewhere it rests uncon. on all older fms. of the section. Named for Dunlap Canyon, in Pilot Mtns, in upper part of which a considerable thickness of lower part of fm. is exposed.

Dunlap sand.

A subsurface sand, of Ord. age, in Healdton field, Carter Co., southern Okla., which lies at 2,716 to 2,749 ft. depth.

Dunlap Quarry sandstone member.

Miocene ? (lower ?): Southeastern Texas.

B. C. Renick, 1936 (Univ. Tex. Bull. 3619, table opp. p. 17, and p. 64). *Dunlap Quarry ss. memb. of Catahoula fm.*—A massive conglomeratic noncalc. ss. present in lower part of Catahoula fm. from eastern Grimes Co. to northern Fayette Co. Consists of coarse rice sand, tuffaceous sand, grit, and cgl., and locally grades into tuff. Where present is 4 to 25 ft. thick. Well exposed in large quarry on G. W. Dunlap 165-acre tract, in SE. part of E. M. Millican survey, 2.4 mi. S. 17° E. of Millican, Brazos Co.

†Dunnellon formation.

Pliocene (lower): Northern Florida.

E. H. Sellards, 1910 (Fla. Geol. Surv. 3d Ann. Rept., pp. 22–35). *Dunnellon fm.*—The hard-rock phosphate in Suwannee, Columbia, Alachua, Marion, Citrus, and

Hernando Counties. A mixture of materials, largely residual, from several fms., from Lower Olig. to at least as late as Plio. Consists of sands, clays, boulders, cgls., pebble cgl., and phosphate rock. Although exceedingly variable from place to place, the prevailing phase of fm. is feebly coherent, more or less phosphatic light-gray sands. Overlies Ocala ls. and underlies the red clayey sand stratum known to miners as hardpan.

In a later (1914) publication Sellards abandoned the name "Dunnellon fm.," stating that it was not separable from Alachua clay, which has priority. O. P. Hay, however, in 1919 (Am. Jour. Sci., 4th, vol. 47, pp. 373–375) expressed opinion that Sellards' Dunnellon fm. is probably early (Nebraskan) Pleist. According to studies of Julia Gardner these deposits are same as Alachua fm.

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept.). The deposits to which Sellards applied name "Dunnellon fm." are included in Alachua fm., and "Dunnellon fm." has been abandoned.

Named for exposures at Dunnellon, Marion Co.

Du Noir member (of Gallatin formation).

Upper Cambrian: Western Wyoming (Wind River Mountains and Owl Creek-Bridger uplift).

B. M. Miller, 1936 (Jour. Geol., vol. 44, No. 2, pp. 124–127, etc.). *Du Noir memb.*—Lower div. of Gallatin fm. in Wind River Mtns and Owl Creek-Bridger uplift. Largely massive, dark-gray ls. mottled with yellowish brown and filled with brown oolites. In most sections contains 1 to 3 ft. of calc. ss. in middle and usually has 10± ft. of laminated ls. and glauconitic pebbly ls. at base. Av. thickness of memb. 40± ft. Fossils. Type section is along Warm Springs Creek, 2 mi. W. of Du Noir, in NW. part of Wind River Mtns. The name is not applied in Gros Ventre and Teton Mtns, where the lower lss. of the Gallatin are twice as thick as in Wind River Mtns. Overlies Gros Ventre fm. (or, in some areas, Depass fm.) and underlies middle shaly memb. of the Gallatin.

Dunvegan sandstone.

Upper Cretaceous: British Columbia and Alberta.

G. M. Dawson, 1881 (Am. Jour. Sci., 3d, vol. 21, p. 392; and Canada Geol. Surv. Rept. 1879–80, p. 15B). *Dunvegan ss.*—Sandstones in Peace River region, Canada, correlated in part with Belly River beds.

Du Page limestone.

Upper Ordovician (Richmond): Northeastern Illinois.

See under *Aux Sable ls.*

Duplin marl. (In Chesapeake group.)

Miocene (upper): Coastal Plain of North Carolina (south of Hatteras axis), South Carolina, and along Savannah River in eastern Georgia.

W. H. Dall, 1898 (U. S. G. S., 18th Ann. Rept., pt. 2, p. 388; published in 1897 as 55th Cong., 2d sess., H. Doc. 5). *Duplin beds.*—Late Mio. marls of Duplin Co., N. C. See Conrad, Am. Jour. Sci., 1st, vol. XII [XLI], 1841, pp. 335–343. [Conrad described the deposits but did not name them.]

W. B. Clark, B. L. Miller, and L. W. Stephenson, 1912 (N. C. Geol. and Econ. Surv., vol. 3, pp. 236–249, 297–298, 321–323). *Duplin fm.*—Unconsolidated sands, aren. clays, and shell marls representing latest phase of Mio. deposition in region S. of Neuse River. North of Neuse River the Yorktown fm. occupies same strat. position that Duplin strata do in S. part of State, and the two fms. may be in part contemp. The differences in faunas, however, render it inadvisable to include them in a single fm. In regions where Duplin strata occur no other deposits of Mio. age have thus far been recognized, and wherever the basal beds are exposed the fm. is seen to rest uncon. on Cret. or Eo. strata. In vicinity of Mount Olive the Duplin fm. rests on the Trent [now proved to be of lower Mio. age], with which it is markedly uncon. In vicinity of Wilmington the Duplin beds are found immediately overlying Castle Hayne deposits. The fm. is uncon. overlain by either Waccamaw marl (Plio.) or by Pleist. deposits. Thickness about 100 ft. In vicinity of Lake Waccamaw an unusual phase of Duplin fm. is developed. Outcropping along bluff on N. shore of lake there is a compact fossiliferous ls. that contains many casts of Molluscan shells, *Crepidula* being especially abundant. This ls. is overlain by a loose characteristic shell marl and underlain by yellowish-brown sand that at base contains some phosphatic pebbles and water-worn casts of Cret. fossils. This phase of Duplin fm. is not known to occur elsewhere in State, though it is well developed along Peedee River in S. C., particularly in vicinity of Bostick.

Is now considered to be=upper part of Yorktown fm. to N. and upper part of Choctawhatchee fm. of Fla. (See C. W. Cooke, U. S. G. S. Bull. 867, 1936.)

Named for exposures in Duplin Co., N. C., especially in Natural Well SW. of Magnolia.

Duquesne limestone. (In Conemaugh formation.)

Pennsylvanian: Western Pennsylvania.

M. E. Johnson, 1929 (Pa. Topog. and Geol. Surv. Atlas, No. 27, Pittsburgh quad., pp. 31, 60, 61). *Duquesne ls.*—A thin fresh-water ls. which occasionally appears in Pittsburgh quad. directly below or within a few ft. of base of Duquesne coal, which lies just below Birmingham sh. Is most conspicuous in that part of bluff on N. side of Allegheny River which faces Herrs Island, attaining its greatest thickness (3½ ft.) directly opp. N. end of the island. Overlain by Duquesne clay. [Apparently named for Duquesne, which is in Pittsburgh quad. The name *Duquesne clay* applies to clay beneath Duquesne coal.]

Durango till.

Durango glacial stage.

Pleistocene (pre-Wisconsin): Southwestern Colorado.

W. W. Atwood and K. F. Mather (U. S. G. S. P. P. 95, p. 14, map, 1915; Geol. Soc. Am. Bull., vol. 35, p. 122, 1924; U. S. G. S. P. P. 166, 1932). *Durango till.*—Glacial drift of a Pleist. stage intermediate btw. Wisconsin stage and Cerro stage (the oldest Pleist. stage in SW. Colo.). The time covered by the drift to be called *Durango glacial stage.* Replaces "Bighorn glacial epoch," "Bighorn moraine," etc., the name *Bighorn* being preoccupied. Named for Durango. It seems to us likely that this stage is=Iowan stage.

Durango sand member (of Taylor marl).

Upper Cretaceous (Gulf series): Eastern Texas.

C. H. Dane and L. W. Stephenson, 1928 (A. A. P. G. Bull., vol. 12, p. 51). The base of the sandy beds within the Taylor is a definite, sharply marked contact most of way from southern Hill Co. to Bell Co. line, about 350 to 400 ft. above top of Austin chalk, and above this contact in McLennan and Falls Counties is a sand of recognizable continuity and importance, to which name *Durango sand memb.* is here given. In Falls Co. it is thick, and 1.2 mi. S. of Chilton it consists of: (1) 50 ft. of soft calc. sand with some layers of hard gray calc. ss. and a few interbedded layers of irregular gray clay, underlain by (2) 15 ft. of thin-bedded calc. ss. and softer chalky cross-bedded sand, with, in lower half, thin beds carrying many comminuted shells, larger shell fragments, subangular grit-sized grains of black phosphatic material, and a few fish teeth. From this locality the sand extends SW. through Durango to small settlement of Theo, on Bell-Falls Co. line. In vicinity of Durango it is apparently transitional into underlying marl of the Taylor.

Durazno formation.

Age (?): Mexico.

R. T. Hill, 1904 (Greene Consolidated Gold Co. [Prospectus], p. 16).

Durbin formation.

Silurian (Niagaran): Southwestern Ohio.

A. F. Foerste, 1917 (Ohio Jour. Sci., vol. 17, p. 187). *Durbin fm.*—Proposed to include all of dolomitic series—the Euphemia, Springfield, and Cedarville dolomites (ascending order). Named for exposures at Mills quarries, about 1 mi. E. of Durbin and about 1 mi. SW. of Springfield, O. The Springfield and Cedarville dolomites are also well exposed immediately NE. of Durbin. [In 1935 (Denison Univ. Bull., Jour. Sci. Lab., vol. 30, pp. 136–137) Foerste stated these rocks are of Lockport age.]

Durham quartz diorite.

Devonian (?): Southeastern New Hampshire.

A. Wandke, 1922 (Am. Jour. Sci., 5th, vol. 4, p. 149). *Durham quartz diorite.*—An elongated body that extends from 2 mi. SW. of Exeter, N. H., to within ¼ mi. of Rollingsford, N. H. Chiefly quartz diorite, but grades from a basic margin to an acidic interior. Includes a marginal phase of gabbro, quartz norite, quartz gabbro, quartz augite gabbro; an intermediate phase of quartz augite diorite, quartz diorite, and quartz biotite diorite; and a central phase of granodiorite, granite, and granite aplite. Age, Dev. (?). Named for exposures through Durham Twp, Strafford Co.

Duskin formation.

Same as Duskin Creek fm.

Duskin Creek formation.

Pennsylvanian (early Pottsville): Southeastern Tennessee (Rhea County).

W. A. Nelson, 1925 (Tenn. Dept. Ed., Div. Geol. Bull. 33A). [*Duskin fm.* used on pp. 30, 39, 63, and in headings on pp. 68, 170, 179; *Duskin Creek fm.* used in heading on p. 53, where occurs first description.] Top fm. of Lee group in Southern Tenn. coal field. Its top memb. is a heavy, thick-bedded, very hard, yellowish ss., of which 75 ft. remains uneroded. Underlying part of fm. consists of about 150 ft. of sh. with a few thin-bedded, shaly, impure sss. The sh. is usually of dark-blue or gray color and contains several coal beds. In some places the sh. is iron-stained and weathers into long, thin slivers. The fm. varies in thickness from 0 to 250 ft. It rests on Rockcastle ss. Well exposed on Duskin Creek, a tributary of Piney Creek, which flows by Spring City, Rhea Co.

Dutch Creek sandstone.

Middle Devonian: Southwestern Illinois and eastern Missouri.

T. E. Savage, 1920 (Am. Jour. Sci., 4th, vol. 49, pp. 170–171, 175). *Dutch Creek ss.*—Iron-stained, reddish-brown or yellow, rather coarse grains of quartz sand cemented with iron oxide, in layers 10 to 24 inches thick. Thickness 0 to 30 ft. Grades into overlying Grand Tower ls. and rests conformably on Clear Creek chert. Outcrops at many places in Union and Alexander Counties, Ill., and is present in eastern Mo. Named for exposures along Dutch Creek, in SW. part of Union Co., Ill. Fossils (Onondaga) listed.

Dutch Creek formation.

Pre-Cambrian: British Columbia.

J. F. Walker, 1926 (Canada Geol. Surv. Mem. 148, p. 7).

Dutcher sand series.

A series of subsurface sands, of early Penn. (Cherokee) age, in Okla., lying lower than Bartlesville and Burgess sands. Thickness 0 to 200± ft.

Dutchman's conglomerate lens.

Devonian or Carboniferous: Northwestern Pennsylvania (Warren County).

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61, 84). *Dutchman's cgl. lens.*—Local cgl. lens in Amity sh. of Warren area. Named for good exposures along Dutchman's Run, a tributary of Allegany River in Mead Twp, Warren Co.

Dwale shale.

Pennsylvanian: Eastern Kentucky (Floyd County).

W. C. Morse, 1931 (Ky. Geol. Surv., ser. 6, vol. 36, p. 296). The lowest and oldest fossiliferous bed that was studied in the region [stretching from Tug Fork of Big Sandy River at Borderland on E. to North Fork of Kentucky River at Copeland on W.] may be designated *Dwale shales*, from town of Dwale, where they are associated with Prestonburg No. 1 coal, which underlies them. They lie 45 ft. below Elkins Fork shales. The fossils came from the dump of the abandoned mine of Dwale Coal Co. ½ mi. NW. of Dwale, Floyd Co. They belong to *Lingula carbonaria*, and hence the shales may represent brackish-water deposits rather than marine.

Dyberry glomerate.

Upper Devonian or Mississippian: Northeastern Pennsylvania (Susquehanna, Wayne, Bradford, and Wyoming Counties).

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 571, 578, etc.). White reported "ls." in lower part of Cherry Ridge group [and named it *Cherry Ridge ls.*]. The term is misleading, but the stratum (or strata) is important. His description is excellent: "An agglomeration of chips of sl. and sh.—fishbone fragments—pieces of fossilized wood—and often a large quantity of sand—all cemented together with lime." It is light-gray when fresh; weathers black, pitted. Probably more than 1 such bed exists in Cherry Ridge fm. Be it one or several, the name *Dyberry glomerate* is proposed for it, from Dyberry Creek and Twp, in Wayne Co., where residual boulders are scattered over surface. Probably in place in headwaters of creek near Cold Spring, Lebanon Twp. Writer has found this glomerate a valuable guide to Cherry Ridge fm. in Susquehanna, Wayne, and parts of Bradford and Wyoming Counties. It is lost in eastern Bradford Co. and may give out in northern Monroe Co. [Table on p. 571 shows Dyberry glomerate *above* Pimple Hill cgl., but text (p. 578) says Dyberry glomerate is in *lower* part of Cherry Ridge and Pimple Hill cgl. in *upper* part.]

Dyer dolomite member (of Chaffee formation).

Upper Devonian: Central Colorado.

C. H. Behre, Jr., 1932 (Colo. Sci. Soc. Proc., vol. 13, No. 3, p. 60). *Dyer dol. memb. of Chaffee fm.*—Light-gray sugary dolomitic ls. with a few dark-gray and ocher-colored beds, forming top memb. of Chaffee fm. Thickness 75 ft. in Weston Pass dist. Formerly included in Leadville ls. (Miss.), but fossils collected by Kirk establish its Dev. age. Typical exposure on West Dyer and Dyer Mtns, 5 mi. E. of Leadville. Overlies Parting qtzite memb. of Chaffee fm. and underlies Leadville ls. (now restricted to the upper "Blue ls." of earlier repts), the Dyer being the lower "Blue ls." of earlier repts.

Dyer Bay dolomite lentille (of Cabot Head shale member).

Silurian (early): Ontario (Bruce Peninsula and Manitoulin Island).

M. Y. Williams, 1919 (Canada Geol. Surv. Mem. 111, No. 91 geol. ser., p. 35 and chart opp. p. 18). *Dyer Bay dol. lentille.*—Impure argill., rather thin-bedded dol., 15 to 17 ft. thick, occurring in lower part of upper half of Cabot Head sh. memb. on Bruce Peninsula and Manitoulin Island. Is older than St. Edmund dol. lentille. Type loc. Dyer Bay.

E. O. Ulrich, 1923 (Md. Geol. Surv. Sil. vol., pp. 334–336). Fauna of Dyer Bay dol. is of Niagaran age, and not of Medinan age, as stated by Williams.

†Dyestone group.

Silurian: Tennessee.

J. M. Safford, 1856 (Geol. Reconn. Tenn., 1st Rept., pp. 149, 156–158, and map). *Dyestone and Gray Limestone Group.*—Includes several distinct fms. In East Tenn. consists of sss., calc. shales, including dyestone, and some ls.; in middle and western Tenn. is almost entirely ls. Includes (ascending): Clinch Mtn ss., variegated shales containing iron ore, and Sneedville ls. Underlies Carbf. black sl. and overlies Nashville memb. of Central ls. and sh. group.

In 1869 (Geol. Tenn., pp. 151, 161, 302) Safford defined "Dyestone group" as consisting of 200 ft. of variegated shales, with some thin, smooth sss., overlying White Oak Mtn ss., and underlying Meniscus ls., or beds later included, with his White Oak Mtn ss., in Rockwood fm.

Named for presence of dyestone iron ore among the strata of one of its divisions.

Dykstra sand.

A subsurface sand in Carbondale fm. (Penn.) of SW. Ill., in Centralia region, SW. corner of Marion Co. (See Ill. Geol. Surv. Bull. 54, table 5, etc.)

Eager formation.

Cambrian: British Columbia.

S. J. Schofield, 1922 (Canada Geol. Surv. Bull. 35, p. 12).

Eagle limestone. (In Kanawha formation.)

Pennsylvanian: Southwestern West Virginia.

I. C. White, 1891 (U. S. G. S. Bull. 65, pp. 140, 141, 177). *Eagle ls.*—Dark, fossiliferous impure ls. 1 foot thick, with "cone-in-cone" structure. Lies 75 ft. below Eagle coal and 55 ft. below Little Eagle coal. Rests on dark marine shales. Named for fine exposures in cuts of Chesapeake & Ohio R. R. at mining village of Eagle, Fayette Co. May be same as Ferriferous ls. Included in Lower Coal Measures or Allegheny River series.

I. C. White, 1908 (W. Va. Geol. Surv. vol. 2A), abandoned the correlation with Ferriferous ls. and transferred *Eagle ls.* and Eagle coal to "Lower Kanawha group," placing them strat. higher than Upper Nuttall ss.

R. V. Hennen and D. B. Reger, 1914 (W. Va. Geol. Surv. Rept. Logan and Mingo Counties). *Eagle ls.*, 0 to 2 ft. thick, is overlain by 15 to 20 ft. of Eagle sl. (black, laminated, and containing marine fossils), and is underlain by 10 to 25 ft. of Eagle sl. (black, marine sl. with iron ore nodules), which rests on Little Cedar coal. Occurs in basal part of Kanawha fm. [This definition is followed in all subsequent repts of W. Va. Geol. Survey.]

Eagle bed.

Upper Cretaceous (Gulf series): Western Texas (El Paso County).

J. A. Taff, 1891 (Tex. Geol. Surv. 2d Ann. Rept., pp. 733, 735). *Eagle bed.*—Local name for Lower Cross Timber or Dakota sand. Calc. sand above and yellow clay sh. below. Thickness 360 ft. Underlies Eagle Ford or Benton sh. (Carpenter bed) and overlies Washita div.

C. L. Baker, 1927 (Univ. Tex. Bull. 2745), mapped these beds as Trinity.

Apparently named for Eagle Spring, at NE. end of Eagle Mtn, El Paso Co.

Eagle sandstone. (Of Montana group.)

Upper Cretaceous: Montana and central northern Wyoming (Elk Basin region).

W. H. Weed, 1899 (U. S. G. S. Fort Benton folio, No. 55). *Eagle fm.*—Basal part consists of thinly laminated sss. stained light brown by lignitic material and containing concretions and nodular masses of iron ore. These grade up into very pure white ss., which forms bluffs 75 to 100 ft. high along Missouri River. Upper part of fm. consists of less shaly sss. with interbedded lignite seams. Total thickness 200 to 235 ft. Overlain by 2,000 ft. of marine beds, designated as *Montana fm.* Underlain by Colorado fm., 1,850 ft. thick. Named for type exposures along Missouri River about mouth of Eagle Creek [40 mi. below Fort Benton].

J. B. Hatcher and T. W. Stanton, 1903 (Sci., n. s., vol. 18, pp. 211–212), divided the beds of Montana age overlying Eagle ss. into (ascending): Claggett fm., 400 ft.; Judith River beds, 500 to 600 ft.; Bearpaw sh., 600 ft. The Eagle ss. as now defined underlies Claggett fm. and in most areas overlies Colorado sh. In Yellowstone-Bighorn Counties region of Mont., however, the 350± ft. of transition beds underlying Virgelle ss. (basal memb. of Eagle ss.) and containing a fauna of predominantly Montana types, are now known as *Telegraph Creek fm.* In that area the Telegraph Creek fm. separates the Eagle from deposits of unquestioned Colorado age, containing Niobrara fossils and designated as *Niobrara sh.*

Eagle granodiorite.

Jurassic: British Columbia.

C. Camsell, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 108).

Eagle sandstone. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and D. B. Reger, 1914 (W. Va. Geol. Surv. Rept. Logan and Mingo Counties, p. 202). *Eagle ss.*—Massive, fine grained, bluish gray, micaceous. Thickness 20 to 50 ft. Named for association with underlying Eagle coal, from which it is separated by a few inches to 15 ft. of beds. Underlies Eagle A coal.

Eagle shale. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and D. B. Reger, 1914 (W. Va. Geol. Surv. Rept. Logan and Mingo Counties, pp. 211–215). *Eagle ls. and sh.*—The upper sh. or sl. is 15 to 20 ft. thick, black, laminated, and carries marine fossils. It underlies Grapevine ss. and overlies Eagle ls. The lower sh. or sl. is 10 to 25 ft. thick, black, carries iron ore nodules and marine fossils, and underlies Eagle ls. and overlies Little Cedar coal. These represent the Eagle. [In Boone Co. Rept. of W. Va. Geol. Surv. the beds above and below Eagle ls. are called *Eagle sl.* In Lewis and Gilmer Counties Rept., 1916, the *Eagle sh.* is described as 108 ft. thick and as occupying interval btw. Decota ss. and Lower War Eagle coal. But in all later repts *Eagle sh.* (or *sl.*) is applied to the beds above and below Eagle ls.]

Eagle sand.

Name locally applied to the subsurface second gas sand in Pierre sh. of Cedar Creek anticline, SE. Mont., which appears to lie at approx. horizon of Eagle ss.

Eagle diorite.

Cretaceous: British Columbia.

C. E. Cairnes, 1924 (Canada Geol. Surv. Mem. 139, p. 89).

Eagle Bridge quartzite.

Lower Cambrian: Eastern New York (Washington County).

L. M. Prindle and E. B. Knopf, 1932 (Am. Jour. Sci., 5th, vol. 24, pp. 277–278). *Eagle Bridge qtzite.*—Compact, gray, granular ss., in places dolomitic, that weathers dark and somewhat rusty. Thickness 10 to 30 ft. Underlies Deepkill sh. with apparent conformity. Conformably overlies black sh. of Schodack fm., and ½ mi. SE. of Post Corners it overlies thin beds of fossiliferous ls. of Schodack fm. Its strat. position below sl. that carries Beekmantown graptolites and above Lower Camb. ls. indicates that it is probably Lower Camb. Is well exposed in vicinity of village of Eagle Bridge, on Hoosic River, N. Y.

Eagle City beds.

Mississippian: Central northern Iowa.

F. M. Van Tuyl, 1925 (Iowa Geol. Surv. vol. 30, pp. 52, 92–94). *Eagle City beds.*—Alternating beds of brownish dol. and gray ls.; some ls. beds oolitic. Thickness 76 ft. The lss. contain brachiopods of upper Kinderhook age. Is a fm. in Kinderhook group. Underlies Iowa Falls dol. and overlies Mayne[s] Creek fm. Named for exposures in banks of Iowa River at Eagle City, Hardin Co.

L. R. Laudon, 1931 (Iowa Geol. Surv. vol. 35, p. 404). *Eagle City memb. of Hampton fm.* is defined as embracing all strata btw. and including the banded brown ls. at base and the oolitic ls. at top. The central part of Eagle City memb. is made up of a massive soft yellow dol. Underlies Iowa Falls memb. and overlies Maynes Creek memb. Thickness 80 ft. Divided into 4 faunal zones.

R. C. Moore, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 243, 245). Eagle City ls. and Iowa Falls dol. are with little question Burlington. They contain Burlington fossils, as identified by both Van Tuyl and Laudon, mingled, it is true, with forms of Kinderhook aspect.

Eagle Cliff porphyrite.

Jurassic (?): Northwestern Washington (San Juan Islands).

R. D. McLellan, 1927 (Univ. Wash. Pub. Geol., vol. 2, pp. 142, 146–148). *Eagle Cliff porphyrite.*—The most widespread of all igneous rocks of San Juan Islands region. Consists of intrusive dikes of porphyrite, which forms all or most of many islands [listed] of San Juan group. At Eagle Cliff, on N. end of Cypress Island, these dikes cut Fidalgo fm. and Leech River group. Probably intruded intermittently during a great lapse of time in late Triassic or early Jurassic. Assigned to Jurassic (?).

Eagle Creek formation.

Tertiary (lower Miocene or Oligocene): Central northern Oregon (Multnomah County) and southwestern Washington.

I. A. Williams, 1916 (Oreg. Bur. Mines and Geol. Min. Res. Oreg., vol. 2, No. 3, pp. 95–96). *Eagle Creek cgl.* occurs a little W. of Carson [SW. Wash.], and, what is less common, a flow or lava-filled variety of it. Overlain by Carson lava as Carson Creek is approached.

R. W. Chaney, 1918 (Jour. Geol., vol. 26, No. 7, pp. 577–592). *Eagle Creek fm.*—Volcanic cgl., ash, and tuffs; cgl. most conspicuous near top. Exposed along Columbia River gorge from Warrendale to Viento, on Oreg. side, with corresponding distribution on N. side of river. Oldest fm. recognized in region. Is 500 ft. thick at Bonneville, Oreg., and 2,700 at Red Bluffs, Wash. Base not exposed. Tentatively upper Eocene. Uncon. underlies Columbia River lava.

W. D. Smith and E. L. Packard, 1919 (Univ. Oreg. Bull., vol. 16, No. 7, pp. 97–98). *Eagle Creek fm.*, Mio., is preoccupied by Eagle Creek fm. of Triassic, and is replaced by *Warrendale fm.* [They did not give reference to publication that constitutes priority of Triassic fm., and compiler has been unable to find it.]

R. W. Chaney, 1920 (Univ. Chicago, Contr. Walker Mus., vol. 2, No. 5). *Eagle Creek fm.*—Flora (listed and described) is considered Olig.

F. H. Knowlton, 1926 (U. S. G. S. P. P. 140, p. 19), assigned Eagle Creek flora to Mio. J. P. Buwalda and B. N. Moore (Carnegie Inst. Wash. Pub. 404, 1930) assigned Eagle Creek fm. to Olig. or lower Mio.

†Eagle Creek formation.

Upper Triassic: Northeastern Oregon (Wallowa Mountains region).

W. D. Smith and E. L. Packard, 1919 (Oreg. Univ. Bull., vol. 16, No. 7, pp. 88, 105, 108). *Eagle Creek series* (also *Eagle Creek fm.*) [synonymous terms].—Calc. shales, lss., aggls., basalts, andesites, and tuffs. Nearer the batholithic core of Wallowa Mtns they are altered to slates, schists, and marble. Farther W. basalts, andesites, and tuffs comprise dominant part of the series. Farther in Wallowa Mtns masses of greenstone occur that may belong to this series. Thickness 4,550 ft. Uncon. overlies Carbf. rocks. Is older than Silvies River beds (Lower Jurassic). Top eroded. Contains Upper Triassic fossils at Martin's Bridge; meager fauna.

Preoccupied. Replaced by *Martin Bridge fm.*

Eagle Ford shale (also clay).

Upper Cretaceous (Gulf series): Texas, western Louisiana, and southeastern Oklahoma.

R. T. Hill, 1887 (Am. Jour. Sci., 3d, vol. 33, p. 298). *Eagle Ford shales.*—Argill. shales, varying from blue at top to yellow in middle and blue at base, with marked faunal zones. Overlies Timber Creek group [Woodbine sand] and underlies Dallas ls. [Austin chalk].

In most early repts the name *Eagle Ford clay* was used to include Bonham clay and Blossom sand of present nomenclature, but it is now restricted to the beds beneath Ector tongue of Austin chalk. According to L. W. Stephenson (A. A. P. G. Bull., vol. 13, Oct. 1929), the Eagle Ford is uncon. with overlying Austin chalk and with underlying Woodbine sand.

Named for exposures at Eagle Ford, Dallas Co., Tex.

Eagle Gulch latite.

Tertiary: Southwestern Colorado (Bonanza district, Saguache County).

H. B. Patton, 1916 (Colo. Geol. Surv. Bull. 9, pp. 21–63). *Eagle Gulch latite.*—Gray massive rock with fine-grained groundmass and usually recognizable phenocrysts of orthoclase, also smaller plagioclase phenocrysts. Forms country rock on both sides of Eagle Gulch.

W. S. Burbank, 1932 (U. S. G. S. P. P. 169). *Eagle Gulch latite.*—Gray porphyritic quartz latite. Intrudes Bonanza and Hayden Peak latites.

Eagle Hill rhyolite.

Tertiary (Eocene?): Central northern Utah (Mercur district).

J. E. Spurr, 1895 (U. S. G. S. 16th Ann. Rept., p. 377). *Eagle Hill porphyry.*—Named for exposures in vicinity of Eagle Hill, just S. of Mercur.

J. Gilluly, 1932 (U. S. G. S. P. P. 173, pp. 58–59 and map). The Eagle Hill "porphyry" of Spurr is intrusive rhyolite and is here called *Eagle Hill rhyolite.*

Eagle Mountain quartzite.

Paleozoic: Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 56; map). *Eagle Mtn qtzite.*—Hard, massive, crystalline to vitreous qtzite that breaks with an angular to conchoidal fracture. In places it locally becomes schistose by finely divided white mica. Chiefly grayish white, which grades into grayish yellow and yellowish brown. Is sufficiently homogeneous to constitute a definite lithologic unit, but of character very difficult to distinguish from Addy and Colville qtzites. It may be an E.

extension of Addy qtzite. Thickness 1,200± ft. Lies in apparent conformity beneath Chewelah argillites. Named for occurrence on Eagle Mtn, 5± mi. NE. of Chewelah.

Eagle Pass formation.

Upper Cretaceous (Gulf series): Southwestern Texas.

C. A. White, 1891 (U. S. G. S. Bull. 82, pp. 116, 117, 124, 126, 127, 130, 138, 139). *Eagle Pass beds.*—Coal-bearing strata conformably underlying Laramie fm. in Rio Grande Valley and overlying "Ponderosa marls" [Taylor marl]. Correlated with Ripley fm. and Fox Hills. [An uncon. is now recognized at top of this fm., and the overlying beds are referred to the Midway (Eocene).]

E. T. Dumble, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 224, 230). *Eagle Pass div.*—Great series of clays, sands, and greensands, with more or less impure ls. and coal beds, overlying Pinto ls. and underlying Webb Bluff Tert. in Rio Grande section. Divided into (descending): Escondido beds, 3,300 ft.; Coal series, 900 ft.; San Miguel beds, 800 ft.; and Upson clays, 700 ft. Is Upper Cret. [This is a much larger unit than Eagle Pass beds of C. A. White.]

T. W. Vaughan, 1900 (U. S. G. S. Bull. 164, p. 21), restricted definition of *Eagle Pass fm.* so as to exclude Upson clay at base, and that definition was used by J. A. Udden in 1907 (Augustana Lib. Pub. 6), the last recorded use of the name.

These Upper Cret. rocks of Eagle Pass region (which overlie Austin chalk) are now divided into (descending) Escondido, Olmos, San Miguel, and Upson fms., and the inclusive unit "Eagle Pass" is no longer used.

Named for Eagle Pass, Maverick Co.

Eagle River porphyry.

Eocene: Central Colorado (Tenmile district).

S. F. Emmons and W. Cross, 1886 (U. S. G. S. Mon. 12, pp. 80, 188, 193, 330, 591). A sheet of porphyry closely allied to Lincoln porphyry. Named for occurrence at headwaters of Eagle River, Tenmile region, Eagle Co.

Eagle River group.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. C. Lane and A. E. Seaman, 1907 (Jour. Geol., vol. 15, pp. 680, 690). *Eagle River group.*—A group of basic lava flows, with frequent beds of sediment (10 or more sss. and cgls.). Marvine's group C. Thickness 1,417 to 2,300 ft. Underlies Great cgl. and overlies Ashbed group.

Named for exposures on Eagle River, Keweenaw Co.

Eagle Rock tuff.

Pliocene? (lower Pliocene?): Southern Idaho (Power County).

H. T. Stearns, 1932 (Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932) and 1936 (Jour. Geol., vol. 44, No. 4, pp. 434–439). *Eagle Rock tuff.*—Well-defined sequence of rhyolite tuffs, 35± ft. thick, exposed at base of American Falls and at Eagle Rock, NE. of Massacre Rocks, Power Co. Older than Massacre volcanics and younger than Neeley lake beds.

†Eangua limestone.

Lower Ordovician (?) and Upper Cambrian: Central Missouri (Camden, Hickory, and Dallas Counties).

H. King, 1844 (Am. Jour. Sci., 1st, vol. 47, p. 129). *Eangua ls.*—Mag. ls., of light brown or ashy color, very compact or hard, but decomposing rapidly on exposure. Thickness not determined, but at Prairie du Chien, Wis., rises 100 ft. above river level, and in vicinity of Eangua River, Mo., it rises much higher. Basal part of immense Mag. ls. deposit. Overlain by siliceous ss. and underlain by upheaval deposit of very ancient character, probably gneissoid.

The 1926 geol. map of Mo. shows that the rocks along and near *Niangua* River, central Mo., consist of Jefferson City dol., Roubidoux, Gasconade, and Proctor.

J. Bridge, 1930 (personal communication), states that this ls. probably extended from base of Bonneterre dol. to top of Gasconade dol., but may have extended up only to base of Gunter ss.

†Earlham limestone. (In Kansas City formation.)

Pennsylvanian: Western Iowa and Missouri and eastern Kansas.

H. F. Bain, 1897 (Iowa Geol. Surv. vol. 7, pp. 511–517). The first heavy ls. above Fragmental ls. (No. 3 of exposure in sec. 22, Lincoln Twp [Madison Co., Iowa]), is=beds quarried at Earlham and hence may be called *Earlham ls.*

Same as Bethany Falls ls., the older name.

Earlsboro sand.

Subsurface sand, of Penn. age and 16 ft. thick, in Earlsboro field, Pottawatomie Co., central Okla., which is reported by T. E. Weirick to lie at horizon 100 ft. above base of Boggy sh. In Earlsboro pool (Seminole Co.) this sand lies at 3,500 ft. depth.

†Earlton limestone.

Pennsylvanian: Eastern Kansas.

E. Haworth, 1898 (Kans. Univ. Geol. Surv., vol. 3, pp. 51, 103). *Earlton ls.*—Name proposed by G. I. Adams, for ls. near summit of Thayer shales, which in local areas is relatively prominent, developing into prominent ledge to W. and NW. of Earlton [Neosho Co.]. Separated from overlying Iola ls. by shales. [Some later repts stated this ls. is Iola ls.]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 127, 251). †*Earlton ls.* abandoned for Plattsburg ls.

Early Bird formation.

Carboniferous or pre-Carboniferous: British Columbia.

S. J. Schofield, 1919 (Canada Geol. Surv. Summ. Rept. 1918, pt. B, p. 60).

Earnest sand.

A subsurface sand, of Penn. age, in Earnest field, Eastland Co., north-central Tex., lying at 1,900 ft. depth.

Easly Creek shale. (In Council Grove group.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 229–237). *Easly Creek sh.*, in Garrison sh., consists of (descending): (1) Sh., in blue, gray, greenish-gray, and reddish bands, in part quite calc., 12 ft.; (2) gray ls., 2 to 4 ft.; (3) sh., with one ls. band 2 to 3 inches thick, 10 to 12 ft. Total thickness 26 ft. Overlies Eiss ls. and underlies Sabetha ls. Named for outcrops on Easly Creek, Richardson Co., Nebr.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., pp. 19, 21). Easly Creek sh. of Condra (1927) is here divided into (descending): *Easly Creek sh. restricted*, Middleburg ls., and Hooser sh. The Easly Creek sh. as now constituted is about 14 ft. thick in Nebr. and northern Kans. and about 11 ft. near Okla. line. At places there is a bed of gyp. in this memb., as in vicinity of Blue Rapids, Kans. Type loc. on Easly Creek, in Richardson Co., Nebr., in NE¼ sec. 35, T. 1 N., R. 13 E., which is 10 mi. S. and 1¼ mi. E. of Humboldt, Nebr. It underlies Crouse ls. (same as "Sabetha ls." and has 10 yrs. priority).

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Eastend formation.

Cretaceous: Alberta.

L. S. Russell, 1932 (Roy. Soc. Canada Trans., 3d ser., vol. 26, sec. 4, p. 132).

†Eastern sandstone.

Upper Cambrian: Northern Michigan.

A. R. Marvine, 1873 (Mich. Geol. Surv. vol. 1, pt. 2, p. 62). The *Eastern ss.* is uncon. with the trap series and dips gently to E.

R. D. Irving, 1883 (U. S. G. S. Mon. 5, pp. 351–365). By term *Eastern ss.* is meant that ss. which fills valley btw. Keweenaw or Main Trap Range of Mich. and so-called South Range. The sss. are red and often highly argill. Same as fossiliferous Camb. or Potsdam ss. of Mississippi Valley, which forms base of Paleozoic.

Replaced by geographic name *Jacobsville ss.* For many years was believed to be same as Keweenawan †Western ss. (Bayfield group).

Eastern basalts.

Age (?): Northern California (Lassen National Park).

H. Williams, 1932 (Calif. Univ. Pub. Bull. Dept. Geol. Sci., vol. 21, No. 8, pp. 214–376, map). *Eastern basalts.*—Pyroxene basalts. Extend along E. margin of Lassen Park, from slopes of Bonte Peak to vicinity of Butte Lake. Lie on Juniper lavas.

Eastern Head formation.

Lower Ordovician: Newfoundland.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4). *Eastern Head fm.*—Ferruginous ss. with oolitic hematite and some shales; fossiliferous. Overlain by unnamed grits and shales and underlain by Beach fm. Included in Bell Island series. [Derivation of name not stated.]

Eastford granite gneiss.

Late Carboniferous or post-Carboniferous: Northeastern Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 115, 127, and map). *Eastford granite gneiss.*—In general a light- or dark-gray gneiss, fine-grained or in places even porphyritic. Extends through towns of Woodstock and Eastford. Perhaps best exposure is in SE. corner of Eastford. Intruded before the metamorphism that reconstructed the rocks of the entire State.

East Fork formation.

Pre-Cambrian: Central Idaho (Hailey region).

L. G. Westgate and C. P. Ross, 1930 (U. S. G. S. Bull. 814, pp. 10–17). *East Fork fm.*—Upper 750 ft. chiefly blue-gray lss. with beds of thinly banded gneiss in upper 400 ft. This is underlain by 0 to 350 ft. of massive vitreous qtzite, which can be traced from a locality N. of Devils Bedstead a little S. of E. for 7± mi. The lower 530 ft. consists largely of beds of nearly pure ls. alternating with beds that contain diopside, with subordinate beds of qtzite intercalated in places. Age probably Algonkian. These rocks form a belt on W. side of area of metamorphosed rocks as far S. as divide btw. Hyndman Creek and East Fork of Big Wood River. Best exposed on E. side of headwaters area of Hyndman Creek.

†East Gallatin group.

Pre-Cambrian: Central southern Montana (Threeforks quadrangle).

F. V. Hayden, 1885 (U. S. G. S. 6th Ann. Rept., p. 50). A complete section of Camb. rocks exposed near mouth of East Gallatin River was made by Dr. [A. C.] Peale, and two lithologically well-defined groups (separated by a qtzitic ss. [Flathead qtzite?]) were studied. To the lower one, which was carefully searched, without success, for organic remains, the name *East Gallatin group* has been provisionally applied. It consists of a series, 2,300+ ft. thick, of alternations of green and greenish-gray micaceous sss. and clay slates (almost argillites), with thin bands of laminated lss. The central part of Bridger or Gallatin Range, from Reese Creek to N. end, is composed almost entirely of East Gallatin group. Rests on gneissic rocks. [As thus defined this name appears to have been applied to the Belt series, which has been mapped at mouth of and for some distance along East Gallatin River, although the Camb. rocks are exposed to N. of the river. See U. S. G. S. Threeforks folio.]

F. V. Hayden, 1888 (U. S. G. S. 7th Ann. Rept., p. 86). The *East Gallatin group* (probably middle Camb.) forms the foothills on the W. and a considerable part of main portion of Bridger Range itself. [Both Belt series and Camb. have been mapped over large areas in Bridger Range. See Threeforks folio.]

A. C. Peale, 1893 (U. S. G. S. Bull. 110, p. 16). *Belt fm.*—The series of beds in vicinity of Three Forks which was in U. S. G. S. 6th Ann. Rept. provisionally called *East Gallatin group*, from well-exposed outcrops along N. side of East Gallatin River near its junction with the West Gallatin, where a detailed section of 2,300 ft. has been measured. In Bridger Range the section is carried lower than on the East Gallatin. In Big Belt Range the fm. is 10,000 to 12,000 ft. thick.

†East Greenwich granite group.

Late Carboniferous or post-Carboniferous and Devonian (?): Southern Rhode Island.

B. K. Emerson and J. K. Perry, 1907 (U. S. G. S. Bull. 311, pp. 58–65 and map). [The rocks mapped as *East Greenwich granite group* in Bull. 311 were mapped by B. K. Emerson, 1917 (U. S. G. S. Bull. 597), as Quincy granite, Sterling granite gneiss, and porphyry, and *East Greenwich granite group* was not used.]

East Haven granite.

Pre-Cambrian: Central Connecticut.

E. Hitchcock, 1823 (Am. Jour. Sci., 1st, vol. 6, pp. 3–86), applied ***East Haven granite*** to rocks in East Haven and Branford, Conn., which were mapped as ***Branford granite gneiss*** by H. E. Gregory and H. H. Robinson in 1907 (Conn. Geol. and Nat. Hist. Surv. Bull. 7).

†East Iowan stage of glaciation (Pleistocene).

A name originally applied by T. C. Chamberlin (Great ice age, by James Geikie, 3d ed., 1894, pp. 724–775) to time covered by deposition of *second* drift of Laurentide ice sheet, but which he in 1895 (Jour. Geol., vol. 3, pp. 270–277) shortened to *Iowan*, at Upham's suggestion, and in 1896 (Jour. Geol., vol. 4, pp. 872–876) replaced by *Kansan*, the name by which it is now generally known. In 1894 book cited Chamberlin called this drift deposit *East Iowan fm.*

†East Iowan formation.

See under *†East Iowan stage of glaciation.*

East Kane shale member.

Devonian or Carboniferous: Northwestern Pennsylvania (McKean County).

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61, pp. 61, 112). *East Kane sh. memb.*—Middle memb. of Knapp formational suite. Fissile, chocolate to olivaceous colored sh. underlying Cobham cgl. memb. and overlying Wetmore cgl. memb. Thickness varies, since it is dependent upon amount of scour that preceded deposition of Cobham cgl. In some places along Kinzua Creek it is apparently lacking, and Cobham and Wetmore cgls. are in discon. contact. This explains abnormal thickness attributed to "Sub-Olean" cgl. of that area in old repts. Is well exposed in brick sh. quarries at East Kane [McKean Co.]. Replaces *Ridgway sh.* (preoccupied), proposed by writer in 1933.

†Eastland formation. (In Canyon group.)

Pennsylvanian: Central northern Texas.

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, pp. 133–145). ***Eastland fm.*** includes all strata from top of Ranger ls. memb. of Ranger fm. to top of Eastland ls. (top memb. of Eastland fm.). Thickness 100 to 175 ft. Is top fm. of Canyon div. Underlies Jacksboro fm. and overlies Ranger fm.

Replaced by Caddo Creek fm.

Named for Eastland, Eastland Co.

†Eastland limestone member (of Caddo Creek formation).

Pennsylvanian: Central northern Texas.

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, pp. 133–145). ***Eastland ls.***—More commonly called by Tex. geologists *Caddo ls.*, but as that name is preoccupied by a ls. in Kans. the name *Eastland* has been chosen for this Tex. ls. Is top memb. of Eastland fm. Well exposed in creek bed ½ mi. E. of Caddo and in Caddo oil field. In southern Jack Co., where Eastland ls. is expected in the section, a calc. ss. and cgl. appear, so that top of Canyon in this area is less clearly defined.

Same as Home Creek ls. memb., older name, and "Eastland" is preoccupied. (See 1921 entry under *Home Creek ls. memb.*)

Named for Eastland, Eastland Co.

Eastland shale lentil (of Bonair sandstone).

Pennsylvanian: Central Tennessee.

C. Butts and W. A. Nelson, 1925 (Tenn. Geol. Surv. Bull. 33D, pp. 9–12, pl. 4). *Eastland sh. lentil.*—Mostly greenish clay sh. with some thin ss. layers. The Clifty coal beds occur in lower 20 to 30 ft. at Clifty. Best exposed, and apparently thickest (120 ft.), on Pilot Knob. Wedges out in some and probably all directions from Clifty. Lies in midst of Bonair ss. In some places there is distinct angular uncon. btw. this sh. and overlying ss. memb. of the Bonair. Mining town of Eastland, 1 mi. W. of Clifty, White Co., is built on this sh.

Eastland sandstone. (In Graham formation.)

Pennsylvanian: Central Texas (Eastland County).

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, p. 62). *Eastland ss.* is here defined as first continuous ss. bed above Home Creek ls. Is well exposed in R. R. cut 1± mi. NW. of Eastland, Eastland Co., and the main escarpment lies N. and NE. of Lake Eastland. It caps escarpments W. of Finis in Jack Co., and many elevations along Caddo Creek NE. of Caddo in Stephens Co. Is memb. of Graham fm., and consists of 10 to 15 ft. of dark grayish brown, massively bedded ss., thin-bedded at top. Underlies Gonzales Creek sh. and overlies Finis sh.

†East Lee limestone.

A name applied by B. K. Emerson (U. S. G. S. Bull. 159, pp. 50–51, 1899), to †Hinsdale (Coles Brook) ls. as exposed at East Lee, Mass., and vicinity.

†East Lee gneiss.

Pre-Cambrian: Western Massachusetts.

See definition under *Lee quartz diorite.*

Named for exposures in hill overlooking East Lee on NE.

East Lynn sandstones. (In Allegheny formation.)

Pennsylvanian: Southern West Virginia.

C. E. Krebs and D. D. Teets, Jr., 1913 (W. Va. Geol. Surv. Rept. Cabell, Wayne, and Lincoln Counties, p. 183). *East Lynn ss.*—Massive cliff-forming ss., 50 to 100 ft. thick, underlying Upper Kittanning coal and separated from underlying Middle Kittanning coal by 0 to 5 ft. of sl. At East Lynn, Wayne Co., it forms massive cliffs 40 to 60 ft. high.

R. V. Hennen and R. M. Gawthrop, 1917 (W. Va. Geol. Surv. Rept. Braxton and Clay Counties, p. 237). *Upper East Lynn ss.*—Massive to current-bedded, medium-grained to coarse-grained, highly siliceous, grayish white, conglomeratic, frequently almost a mass of white and ovoidal-shaped quartz pebbles ¼ to 1 inch diam. Forms cliffs. Thickness 50 to 80 ft. Underlies Upper Kittanning coal and overlies Middle Kittanning coal. The name *East Lynn ss.* is herein limited to the ledge, 25 to 70 ft. thick, lying btw. Middle Kittanning coal and Lower Kittanning coal.

L. C. Robinson, 1927 (Ky. Geol. Surv., ser. 6, vol. 26, p. 240). The only representative of the Allegheny that was observed in Morgan Co., Ky., was the basal memb., which is called *East Lynn cgl.* It is a true cgl., and where it caps the hills is cliff-forming.

East Mountain shale member (of Mineral Wells formation).

Pennsylvanian: Central northern Texas (Palo Pinto County).

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 25, 31; Univ. Tex. Bull. 2132, p. 77 and charts). *East Mtn sh. memb. of Mineral Wells fm.*—Chiefly dark bluish gray sh., about 300 ft. thick. Contains near top a lentil of fossiliferous ls. and near base a bed of massive ss. Underlies Lake Pinto ss. memb. and overlies Brazos River ss.; all included in Mineral Wells fm. Named for exposures in high escarpment E. of Mineral Wells.

F. B. Plummer, 1929, and R. W. Cumley, 1930 (Tex. Univ. Econ. Geol., geol. map of Palo Pinto Co.), applied this name to a small part of East Mtn sh. as originally defined.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 108). *East Mtn sh. memb. of Mineral Wells fm.* is 300± ft. thick, includes a thin ls. near top, and is in places highly fossiliferous.

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, pp. 31, 35). *East Mtn sh.* (basal memb. of Mineral Wells fm.) consists of gray and black calc. and siliceous sh., containing in upper part the Village Bend ls. and near its base the Hog Mtn ss. lentil. It underlies Lake Pinto ss. and uncon. overlies Brazos River ss. memb. of Garner fm. Type loc. is the extensive exposure on S. end of East Mtn in Mineral Wells.

East Mountain schist.

Pre-Cambrian (?): Southwestern Vermont (Rutland County).

E. J. Foyles, 1931 (17th Rept. Vt. State Geol., p. 249, in description of East Mtn, Mendon Twp, Rutland quad., in Rutland Co.). *East Mtn schist;* oldest rock; is pre-Camb. or possibly basal Camb. Underlies Cheshire qtzite [Lower Camb.].

Easton schist.

Carboniferous (?) or pre-Ordovician (?): Central Washington (Snoqualmie quadrangle).

G. O. Smith, 1903 (U. S. G. S. P. P. 19). *Easton schist.*—Typically a silver-gray or green rock, composed chiefly of quartz and micas. Extremely crumpled and gashed, and seamed with veins and stringers of quartz. Associated with this quartz-mica rock are other schists containing hornblende or epidote; qtzite also is found in close association with the schists, which is believed to indicate sed. origin of the schist. Is probably oldest rock in central Wash. Occupies a few sq. mi. in SW. part of Mount Stuart quad. and extends W. into Snoqualmie quad. Is pre-Eocene, Carbf. (?).

G. O. Smith, 1904 (U. S. G. S. Mount Stuart folio, No. 106). *Easton schist* is probably sedimentary. Is oldest rock in Mount Stuart region; older than Hawkins fm. Forms S. wall of Yakima Valley as far as Easton [Kittitas Co.]. Is older than Peshastin fm.

W. S. Smith, 1916 (Jour. Geol., vol. 24, pp. 559–570). *Easton schist* is oldest terrane in Skykomish Basin. No definition of its age can be suggested except that it is pre-Ord.

Eastport formation.

Silurian (late): Southeastern Maine.

E. S. Bastin and H. S. Williams, 1913 (Maine Water Storage Comm. 3d Ann. Rept., p. 168; Geol. Soc. Am. Bull., vol. 24, pp. 378, 379). [Name mentioned but not defined. Refers to Eastport folio, in press.]

E. S. Bastin and H. S. Williams, 1914 (U. S. G. S. Eastport folio, No. 192, p. 7). *Eastport fm.*—The latest Sil. rocks in Eastport quad. Includes several kinds of sed. and volcanic rocks. The volcanic rocks comprise both rhyolitic and diabasic varieties occurring as flows and associated tuffs. Some intrusive rhyolite is probably mapped as part of fm. because it can not everywhere be distinguished from extrusive rhyolite. In bulk volcanic rocks greatly exceed detrital sediments, among which are ls., shales of several sorts, and very small amounts of cgl. Thickness probably about 8,000 ft. Conformably overlies Pembroke fm. Uncon. underlies Dev. (Perry fm.). Fossils indicate latest Sil. Named for exposures at Eastport, on Moose Island.

East Wellington formation.

Upper Cretaceous: British Columbia.

C. H. Clapp, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 97).

†East Wisconsin stage of glaciation (Pleistocene).

A name applied by T. C. Chamberlin (Great ice age, by James Geikie, 3d ed., 1894, pp. 724–775) to time covered by deposition of drift sheet now called *Wisconsin drift*, but which Chamberlin in 1894 called *East Wisconsin fm.* Named for thick development of the drift in eastern Wis. Now called *Wisconsin stage of glaciation.* Chamberlin stated (Jour. Geol. vol. 3, 1895, pp. 270–277) that he changed his name *East Wisconsin fm.* to *Wisconsin fm.* upon suggestion of Upham.

†East Wisconsin formation.

See under †*East Wisconsin stage of glaciation.*

Eaton beds.

Name listed on p. 147 of U. S. G. S. Bull. 191 was casually applied by A. F. Foerste (Denison Univ. Sci. Lab. Bull., vol. 3, p. 8, 1888) to Springfield ls.

Eaton greensand lentil. (In Claiborne group.)

Eocene (middle): Eastern central Texas (Robertson County).

B. C. Renick and H. B. Stenzel, 1931 (Univ. Tex. Bull. 3101, pp. 78, 90–91). *Eaton greensand lentil.*—South of Eaton, in the vicinity of Shiloh School, in southern Robertson Co., in the A. W. Rowlett, Geo. W. Cox, NW. corner of the Lavina Rollison, and S. part of the Jose Maria Viesca surveys, there are marine beds interlaminated with Sparta sand memb. of Cook Mtn fm. These marine lenses consist of fossiliferous glauconitic sand, red clay, and ferruginous ironstone, all interbedded with gray sand of Sparta lithology. Max. thickness (50 ft.) is exposed along Wheelock-New Baden road, and interval from topmost marine bed in Eaton lentil to base of overlying Crockett memb. is 15 to 50 ft.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, p. 612), showed *Eaton lentil* lying at base of the Crockett and lower in section than Moseley ls.

H. B. Stenzel, Jan. 1935 (Univ. Tex. Bull. 3501, p. 277). *Crockett* redefined to include only the 100 ft. of beds above Moseley ls. The Moseley ls. and underlying beds down to top of Sparta sand are here named *Stone City beds*. Latter includes Eaton lentil (marine) and are 85± ft. thick. They discon. underlie Crockett restricted.

Eau Claire grit.

Upper Cambrian: **Southwestern Wisconsin (Eau Claire County).**

L. C. Wooster, 1878 (Wis. Geol. Surv. Ann. Rept. 1877, p. 37). *Eau Claire grit.*—These layers mark upper limit of the coarse sss., almost cgls. [Older than Eau Claire trilobite beds.]

L. C. Wooster, 1882 (Geol. Wis., vol. 4, p. 110). *Eau Claire grit.*—Very coarse ss. exposed at mouth of Eau Claire River. So coarse it has been termed *cgl.* Thickness 9 ft. Lies 100 to 260 ft. above the granite, in lower part of Potsdam ss., and 240 ft. below Eau Claire trilobite beds.

W. H. Twenhofel, G. O. Raasch, and F. T. Thwaites, 1935 (Geol. Soc. Am. Bull., vol. 46, p. 1693). Mount Simon memb. of Ulrich is equiv. of "Eau Claire grits" of Wooster, and underlies Eau Claire memb. of Dresbach fm., which coincides with "Eau Claire trilobite beds" of Wooster.

Eau Claire trilobite beds.

Upper Cambrian: Western Wisconsin.

L. C. Wooster, 1878 (Wis. Geol. Surv. Rept. 1877, pp. 36–41). *Eau Claire trilobite beds* mark lower limit of calc. matter in Potsdam ss. They hold at least 7 sp. of trilobites, of which 3 are new, and a few brachiopods. [Lie higher than Eau Claire grit and considerably lower than Hudson trilobite beds.]

L. C. Wooster, 1882 (Geol. Wis., vol. 4, pp. 101–140). *Eau Claire trilobite beds* lie 240 ft. above Eau Claire grit and 200 ft. below Hudson trilobite beds. They mark lower limit of calc. matter in Potsdam ss., and are characterized by several sp. of trilobites not found at any other horizon and also by being lower limit at which brachiopods were found in the Potsdam.

A. C. Trowbridge, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 149). Eau Claire is not type loc. of Wooster's "Eau Claire trilobite beds." He describes that (Geol. Wis., vol. 4, p. 117, 1882) as located 4 mi. above the Dalles which occur at Mount Simon, in the high bank nearly 200 ft. above the terrace, on left side of Chippewa River.

Included in Eau Claire ss. of Ulrich.

Eau Claire shale.

See under *Eau Claire ss.*

Eau Claire sandstone.

Upper Cambrian: Western Wisconsin.

C. D. Walcott, 1914 (Smithsonian Misc. Coll., vol. 57, p. 354). *Eau Claire. (Ulrich mss., 1914).*—Mostly thin-bedded, in part shaly ss., with many fossiliferous layers, including Owen's Menominee trilobite zone and Wooster's Eau Claire trilobite zone. Usually a coarse white friable ss. with *Dicellomus* and *Lingulella* at base. Numerous characteristic Upper Camb. trilobites, *Crepicephalus iowensis* being one of best guide fossils. Thickness about 100 ft. Underlies Dresbach ss. and overlies *Mount Simon ss.*

E. O. Ulrich, 1924 (Wis. Acad. Sci. Trans., vol. 21, pp. 71–93). *Eau Claire sh.*, 200 to 350 ft. thick, underlies Dresbach ss. and overlies Mount Simon ss. in Wis.

A. C. Trowbridge and G. I. Atwater, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 38–45, 79), treated these beds as a memb. of their Dresbach fm. [See 1934 and 1935 entries under *Dresbach ss.*]

W. H. Twenhofel, G. O. Raasch, and F. T. Thwaites, 1935 (Geol. Soc. Am. Bull., vol. 46, pp. 1690, 1694). *Eau Claire memb.*—Middle memb. of Dresbach fm. Underlies Galesville memb. [Dresbach ss. of many authors and repts] and overlies Mount Simon memb. Divided, on basis of fossils, into *Crepicephalus* zone (above), 75 ft. thick, and *Cedaria* zone (below), 50 ft. thick. Coincides with "Eau Claire trilobite beds" of Wooster.

The U. S. Geol. Survey at present treats the Eau Claire as a distinct fm., underlying Dresbach ss. [Galesville memb. of some authors] and overlying Mount Simon ss.

Named for exposures at mouth of Eau Claire River, Eau Claire Co.

†Ebensburg sandstone member (of Conemaugh formation).

Pennsylvanian: Western Pennsylvania (Cambria County).

C. Butts, 1905 (U. S. G. S. Ebensburg folio, No. 133). *Ebensburg ss.*—Generally rather coarse, thick-bedded, gray ss., locally containing layers of cgl. Is the ss. upon which town of Ebensburg is built, and according to well records it is there about 150 ft. thick. What is believed to be same ss. outcrops in river bluff to E. of Summerhill, and also on top of knoll just NW. of Summerhill. Here it is coarse, thick bedded, 50 ft. thick, and lies 100 ft. above Saltsburg ss. The Ebensburg rests on 40 ft. of red sh. and lies about 100 ft. below Summerhill ss. Is a memb. of Conemaugh fm. In valley of Roaring Run the Ebensburg is only 5 ft. thick.

W. C. Phalen, 1910 (U. S. G. S. Johnstown folio, No. 174, p. 6). *"Ebensburg"* ss. is same as Morgantown ss. memb. of Conemaugh fm. and is abandoned.

Echo granite.

Pre-Cambrian (?): Southern California (San Gabriel Mountains).

W. J. Miller, 1930 (Geol. Soc. Am. Bull., vol. 41, pp. 149–150). [Name used but not defined.]

W. J. Miller, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 161). Writer has mapped [does not say where published] *Echo granite (pre-Camb.?)*, in San Gabriel Mtns, Calif.

W. J. Miller, 1934 (Univ. Calif. at Los Angeles Pub. Math. and Phys. Sci., vol. 1, No. 1, map, pp. 12–15, 63–65). [*Echo granite (pre-Camb.?)* mapped.] Comprises several sq. mi., extending from Millard Canyon to Eaton Canyon, including part of Echo Mtn.

Echo Bay series.

Pre-Cambrian: Northwest Territory.

H. S. Robinson, 1933 (Canadian Min. and Met. Bull. 258, p. 613).

Echo Island formation.

Middle Jurassic: Southwestern British Columbia (Harrison Lake region).

C. H. Crickmay, 1927 (Stanford Univ. Abstracts of dissert. 1924–26, vol. 1, p. 132).

C. H. Crickmay, 1930 (Geol. Mag., vol. 67, p. 487 and map). *Echo Island fm.*—Tuff, ss., etc., 2,700 ft. thick. Underlies Mysterious Creek fm. (basal Upper J.) and overlies Harrison Lake fm. (Middle J.). Assigned to Middle J.

Eckman sandstone. (In Pottsville group.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, p. 221). *Eckman ss.*—Massive to current-bedded, medium-grained, buff to bluish gray, 17 to 106 ft. thick. Lies 0 to 5 ft. below Pocahontas No. 6 coal and overlies Pocahontas No. 5 coal or Pocahontas No. 4 coal. Exposed at Eckman, McDowell Co.

Economy member. (In Latonia shale.)

Upper Ordovician: Southwestern Ohio, southeastern Indiana, and north-central Kentucky.

R. S. Bassler, 1906 (U. S. Nat. Mus. Proc., vol. 30, p. 9). *Economy.*—Blue shales and lss., 50 ft. thick, composing lower div. of Eden [Eden as here used excluded Fulton sh. at base]. Distinguished faunally by large number of Bryozoa. Overlain by Southgate memb. of Eden and underlain by Utica (Fulton) sh.

Is basal part of Latonia sh.

Economy was old name of village now known as West Covington, Ky.

†Ecphora bed.

†Ecphora beds.

Miocene: Western Florida.

W. H. Dall, 1892 (U. S. G. S. Bull. 84, pp. 124, 157, 158, 324). At Alum Bluff the Chesapeake group is represented by what I have termed *Ecphora bed*, of gray marl, with over 100 species of fossils, many of which are common to N. C., Va., and Md. It has a thickness here of 30 ft. or more.

A paleontologic term now abandoned for geographic name *Choctawhatchee fm.*

Ector tongue of Austin chalk.

Upper Cretaceous (Gulf series): Northeastern Texas.

L. W. Stephenson, 1918 (U. S. G. S. P. P. 120H, p. 149). *Ector tongue of Austin chalk.*—A thin tongue-like projection of chalk from basal beds of main body of the Austin, has been traced, by means of a few outcrops and the black soils to which the chalk weathers, from western Fannin Co. NE. to point about 1½ mi. SE. of Ravenna. Ector, for which the tongue is named, is a few hundred yds. W. of the belt of outcrop. Only 10 to 15 ft. of the chalk was seen in best exposures, and it probably does not exceed 50 ft. in thickness in vicinity of Ector [Fannin Co.]. The Ector tongue is underlain by shaly clay, with thin beds of sand and a basal cgl. ("fish-bed cgl."), which are regarded as distinct from underlying Eagle Ford fm. and are mapped with the Austin. [L. W. Stephenson now includes this shaly clay, sand, and "fish-bed cgl." in Ector tongue. See Am. Jour. Sci., 5th, vol. 16, p. 492, 1928; A. A. P. G. Bull., vol. 13, No. 10, 1929.]

Eddy sandstone.

Permian: Southern New Mexico.

C. R. Keyes, 1906 (Jour. Geol., vol. 14, pp. 147–154). *Eddy sss.*, 1,500 ft. thick, underlie Capitan lss. The name is substituted for Richardson's name *Delaware Mtn fm.*, which is preoccupied. [Derivation of name not given, but presumably Eddy, N. Mex.]

Delaware Mtn fm. of Richardson was not preoccupied, and there is therefore no occasion to rename it.

Eddy Hill grit.

Lower Cambrian: Eastern New York (Washington County) and southwestern Vermont (Rutland County).

R. Ruedemann, 1914 (N. Y. State Mus. Bull. 169, pp. 67–70). *Eddy Hill grit.*—The Black patch grit of [T. N.] Dale. Consists of 10 to 40 ft. of dark gray grit or ss. with black shaly patches, sometimes with calc. nodules. Underlies Schodack shales and lss. and overlies Mettawee slate; all Lower Camb. Named for exposures at Eddy Hill, near Fairhaven, Vt. [Eddy Hill is probably in Whitehall quad., but name does not appear on that map. It may be unnamed hill just SE. of Fairhaven.]

Eden group.

Upper Ordovician: Southwestern Ohio, southern Indiana and central northern Kentucky.

J. S. Newberry, 1873 (Ohio Geol. Surv. vol. 1, table opp. p. 89), and E. Orton, 1873 (same vol., pp. 371–399). *Eden shales or Middle shales of Cincinnati beds proper.*—Slightly fossiliferous blue sh. with small amount of interbedded ls. Thickness 250 ft. Overlies River Quarry beds and underlies Hill Quarry beds; all included in Cincinnati beds proper, the middle fm. of Cincinnati group. [As thus defined the Eden includes at base the Fulton sh.]

Adopted as a group name, to include beds originally included, i. e., Latonia sh. at top and Fulton sh. at base, the top memb. of the Latonia being McMicken memb. of Bassler.

Named for Eden Park, Cincinnati, Ohio.

Eden beds.

Pliocene (lower): Southern California (San Jacinto quadrangle, Riverside County).

C. Frick, 1921 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 12, pp. 283–288). *Eden beds.*—Deposits containing considerable collection of vertebrate fossils (including species of *Pliohippus*), through which they are correlated with middle of Etchegoin fm. and the Rattlesnake, Thousand Creek, and Snake Creek fms. The beds occur in Eden region, San Jacinto quad. Assigned to upper part of lower Plio.

D. M. Fraser, 1931 (Min. in Calif., vol. 27, No. 4, pp. 511-514). Frick's name *Eden beds* being preoccupied, he suggests it be replaced by *Mount Eden fm.*, which is here used for the lower Plio. ss. and shales in region about Beaumont.

Edenian.

A term applied by R. Ruedemann (N. Y. State Mus. Bull. 258) to time covered by deposition of Eden group.

Edens sand.

A thin subsurface sand, of Upper Cret. age, in either Navarro fm. or Taylor marl of eastern Tex. Produced oil at Corsicana. Is a higher sand than Corsicana sand.

Edensburg oil sandstone.

J. F. Carll, 1883 (2d Pa. Geol. Surv. Rept. I_4, well sections). *Edensburg oil ss.* lies strat. lower than "Tanners Hill red" and higher than Clarendon sand [in Warren Co., Pa.]. Is probably of Chemung age.

Edgefield-Chesterfield zone.

Pre-Cambrian: Northern South Carolina.

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 6, 10, 12). *Edgefield-Chesterfield zone (Algonkian?)*.—Bounded on NW. by Abbeville-York zone; on N. by Hornsboro zone and State line; on SE. by a line proceeding from point where Whites Creek enters S. C. (Marlboro Co.) along said creek to the Pee Dee, thence by Catarrh, thence S. of Granny's Quarter, thence crossing Wateree River, near Camden, thence up Rice Creek and down Crane Creek. and thence crossing Brook River 3 mi. N. of Columbia, thence across Dutch Fork and by Half Way Swamp, to point near Edgefield, whence it proceeds southwesterly to Savannah River (near Scotts Ferry), the river completing the bdy on W. A division extends southwesterly by Edgefield by reason of granite anticline uplift, which diverts a subzone of these schists and a part of the slates toward Hamburg, with a SE. dip. Slates derived from alteration of basic igneous rocks constitute main mass; along both sides of the argillites the sericite schists interruptedly prevail. It appears that the sericite schists originated in the alteration of the tuffs and porphyries which interruptedly occur along southerly line of Abbeville-York zone, with a corresponding but more limited belt along opposite side of Edgefield-Chesterfield zone.

Probably named for exposures in Edgefield and Chesterfield Counties.

†Edgehill quartzite.

Lower Cambrian: Southeastern Pennsylvania.

C. E. Hall, 1881 (2d Pa. Geol. Surv. Rept. C_6, map and btw. pp. 14 and 47). *Edgehill Rock (qtzite and cgl.)*, *Potsdam ss. (No. 1)* [on map].

F. Bascom, 1904 (Am. Jour. Sci., 4th, vol. 17, p. 143), used *Edge Hill qtzite (Lower Camb.)* in tables.

Same as Chickies qtzite, the older name. Edge Hill is in Montgomery Co.

Edgewood limestone.

Silurian (early): Northeastern Missouri (Pike County) and southwestern Illinois.

T. E. Savage, 1909 (Am. Jour. Sci., 4th, vol. 28, pp. 517-518). *Edgewood ls.*—Ls., 0 to 12½ ft. thick, consisting of massive layer of hard gray coarsely crystalline ls. 4 ft. thick, oolitic in upper part, underlain by few ft. of fine-grained ls. and fossiliferous dark calc. sh., with, at base, cgl. of fragments of Girardeau ls. Uncon. overlies Girardeau ls. and uncon. underlies Sexton Creek ls., or is separated from the Sexton Creek by 2 inches of red residual clay. Assigned to Sil. [Later repts give thickness 0 to 75 ft.]

T. E. Savage, 1913 (Geol. Soc. Am. Bull., vol. 24, pp. 111-112, 351-376; Ill. Geol. Surv. Bull. 23). *Edgewood ls.* includes all strata in Ill. and Mo. btw. horizon of

Girardeau ls. up to top of the mag. ls. near Bowling Green, and top of the brown ls. overlying the oolite in Lincoln, Pike, and Ralls Counties, Mo., and on opposite side of river in Ill., and their equiv. elsewhere in Miss. Valley. It includes Bowling Green ls., Noix oolite, and Channahon ls. members, which represent local facies. The lower fossiliferous part of fm. and the overlying brown, unfossiliferous Bowling Green phase are well developed in vicinity of Edgewood, Pike Co., Mo., while the lowest beds of the Edgewood are not known N. of that locality. The fm. overlies Girardeau ls. with sedimentary break. In Kankakee Co., NE. Ill., it underlies, with possible break, Essex ls., which may prove to be a memb. of overlying Sexton Creek ls. [of SW. Ill. and Mo.]. Basal 8 to 15 ft. of the Edgewood is *Cyrene memb.*, which is conformably overlain by *Bowling Green memb.* (15 to 35 ft. thick). Upper half or two-thirds of Cyrene memb. is=Noix oolite of Keyes, which is a shallow-water phase of sedimentation near Miss. River, and is here called *Noix oolite memb.* The name *Channahon ls. memb.* is retained for easy reference to the strata seen only along Des Plaines River 1 mi. SE. of Channahon, Will Co., NE. Ill., which is=some part of Edgewood fm.

T. E. Savage, 1916 (Geol. Soc. Am. Bull., vol. 27, pp. 305–324). In NE. Ill. *Edgewood ls.* is 0 to 21 ft. thick and is not known N. of Oswego. It underlies Kankakee ls. with erosional uncon. It is here proposed to shift upper bdy of Edgewood fm. and basal part of overlying Sexton Creek ls. (of SW. Ill. and Mo.) 3 or 4 ft. higher than formerly, placing it at *top* of ls. containing *Platymerella manniensis* in Ill. and Mo., instead of at *base* of this zone, as formerly.

T. E. Savage, 1926 (Ill. State Acad. Sci. Trans., vol. 19, pp. 286–287; Geol. Soc. Am. Bull., vol. 37, pp. 517–526, 533). *Edgewood ls.* is exposed near Thebes, Oswego, Channahon, Essex, and Savanna, Ill., and extends as far N. as Belvidere, near N. border of State. *Platymerella manniensis* zone is included in Kankakee ls., instead of in Edgewood.

Named for exposures 3 mi. N. of Edgewood, Pike Co., Mo.

Ediger limestone. (Buried.)

Middle Devonian: Central Kansas (Harvey County).

L. A. Johnston, 1935 (Tulsa Geol. Soc. Digest, 1934, pp. 12–17, pl. 1). *Ediger ls.*—Varies from dense and micro-crystalline to coarsely crystalline, fossiliferous ls., sandy and glauconitic at base. In places lower part is white calc. sand of rounded and subrounded grains. Upper part may contain some chert, and usually has intercalated thin light-green sh. seams containing fossils. Rests uncon. on Hollow dol., or, where that is absent, on Maquoketa sh., and uncon. underlies Sylamore ss. in Hollow pool, Harvey Co. Name proposed by F. A. Bush, unpublished paper delivered before Tulsa Strat. Soc. in 1933. Assigned to Middle Dev. [Derivation of name not stated.]

†Edison gneiss.

Pre-Cambrian: Northern New Jersey.

J. E. Wolff and A. H. Brooks, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, p. 439). Belt of gneisses characterized by their richness in disseminated magnetite, which, from extensive mining operations at old Ogden mines, now called Edison, we have named *Edison gneiss.*

In U. S. G. S. Franklin Furnace folio, No. 161, 1908, this name was discarded, the rock being an inseparable part of Byram gneiss.

†Edisto marl.

Miocene (lower): Southern South Carolina (Colleton County).

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 12, 18, 19). *Edisto phase* (also *Edisto marls and phosphates*).—Proceeding from Dorchester Strait SE. over Dorchester Ridge and the upper (Ecphora) marls, the Edisto phase is observed in compact yellow-white beds (very high in content of calcium carbonate); which rarely exceed thickness of 3 ft. This is phase of Mio. which has been phosphatized where favorably situated for accumulation of Salkehatchie oozes. This Edisto phase appears circumscribed in western Tertiary by a line extending from mouth of Wando River by Charleston, Church Flats, Port Royal, Parachucla, Givhams Ferry, Bacon's Bridge and thence back to head of Wando River. In eastern div. of Tert. the sea waves, along Myrtle Beach, cast upon the shores fragments of the equiv. marl, from bed of present ocean. Overlies Marks Head marl and is older than Goose Creek marl.

T. W. Vaughan, 1912 (U. S. G. S. P. P. 71). *Edisto marl.*—Indurated phosphatized marl in vicinity of Charleston, S. C. Thickness 2 to 3 ft. Overlies Cooper marl and underlies Goose Creek marl of Sloan, which is softer than Edisto marl.

C. W. Cooke, 1936 (U. S. G. S. Bull. 867). In this rept [on S. C. coastal plain] the lower Mio. deposits are called *Hawthorn fm.,* because the work of recent years has demonstrated that they are an eastern development of Hawthorn fm. of Fla. In previous S. C. repts all or parts of Hawthorn fm. have been called †Marks Head marl, †Edisto marl, †Parachucla sh., †Parachucla marl, and †Combahee sh., all of which are here abandoned. The Hawthorn includes †Marks Head marl and upper part of underlying Alum Bluff "fm." of Veatch and Stephenson's rept on coastal plain of Ga. (Ga. Geol. Surv. Bull. 26, 1911). It also includes part of †Ashley marl and part of †Salkehatchie phase of Sloan.

Named for exposures on Edisto River at "The Dividers," Colleton Co.

Edmonton formation.

Upper Cretaceous: Alberta, Saskatchewan, and Northwest Territory, Canada.

J. B. Tyrrell, 1887 (Canada Geol. Surv., n. s., vol. 2, pp. 74E–75E, 110E, 118E, 127E, 131E–135E, 137–138E), introduced *Edmonton series;* as he called it. Now considered=either Bearpaw sh. or Fox Hills ss. of Mont.

Edmunds formation.

Silurian: Southeastern Maine.

E. S. Bastin and H. S. Williams, 1913 (Maine Water Storage Comm. 3d Ann. Rept., p. 168; Geol. Soc. Am. Bull., vol. 24, pp. 378, 379). [Name mentioned but not defined. Refers to Eastport folio, in press.]

E. S. Bastin and H. S. Williams, 1914 (U. S. G. S. Eastport folio, No. 192, pp. 4, 10). *Edmunds fm.*—A series of alternating beds of sh. and deposits of volcanic rocks. Most abundant rock is rhyolite, both gray and red, which forms flows and associated tuffs. Next most abundant rock is purplish red andesite, which also occurs as flows and tuffs. Diabase flows and tuffs also occur. Estimated thickness 2,500 to 3,000 ft. Conformably underlies Pembroke fm. Overlies (possibly uncon.) Dennys fm. Fossils indicate Cobleskill and Niagara age. Named for exposures near Edmunds, Washington Co.

Edmunds Hill andesite.

Devonian (?): Northeastern Maine (Aroostook County).

H. E. Gregory, 1899 (Am. Jour. Sci., 4th, vol. 8, pp. 359–360). *Edmunds Hill andesites.*—Augite andesite forming entire top of Edmund's Hill, Chapman Twp, near middle of N. twp line, and being highest part of a ridge running N.-S. for several mi.

In a later rept (U. S. G. S. Bull. 165, pp. 112, 169–172, 1900) this rock was considered by Gregory to be Paleozoic. On 1933 geol. map of Maine, by A. Keith, the igneous rocks of this region, including andesite, are mapped as Dev.

Edray sandstone. (In Bluefield formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Tazewell County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 301, 413). *Edray ss.*—Gray or green flaggy or shaly ss. 0 to 75 ft. thick, in lower part of Lillydale sh., lying 0 to 50 ft. above its base. Type loc. in Pocahontas Co., W. Va., on mtn road 1.2 mi. N. of Edray. Also observed in Mercer Co., W. Va., and in Tazewell Co., Va.

P. H. Price, 1929 (W. Va. Geol. Surv. Rept. Pocahontas Co., pp. 163–164). *Edray ss.* is lenticular and does not appear in Edray section that was measured along new State road from Edray to head of Elk, but at other points it presents a prominent exposure. Occurs associated with Lillydale sh., at times coming well up in this memb., and at some points near base; and often rests directly on Alderson ls. of Greenbrier series. Best developed along waters of Elk, forming a massive cliff rock at junction of Big Spring Fork with Old Field Fork of Elk River, and is recorded in Slaty Fork and Props Run sections. In S. end of Co. it is noted in Stamping Creek and Briery Knob sections, as a brown to gray fine-grained micaceous ss., 10 to 25 ft. thick.

Edson beds. (In Ogallala formation.)

Pliocene (lower): Western Kansas (Sherman County).

M. K. Elias, 1931 (Univ. Kans. Bull., vol. 32, No. 7, pp. 161–162). [See under *Rhinoceros Hill beds.*]

Edwards limestone. (In Fredericksburg group.)

Lower Cretaceous (Comanche series): Southern Texas.

R. T. Hill and T. W. Vaughan, 1898 (U. S. G. S. Nueces folio, No. 42, p. 2; U. S. G. S. 18th Ann. Rept., pt. 2, pp. 227–235). *Edwards ls.*—Generally whitish lss., but on weathering show buff, cream-yellow, and dull-gray layers; of variable hardness, frequently massive, and contain flint nodules. Usually harder than Comanche Peak ls. and weathers into cliffs. Thickness 600 ft. Top fm. of Fredericksburg div. Overlies Comanche Peak ls. and underlies Fort Worth ls. Replaces "Caprina" ls.; also replaces "Barton Creek" ls., as Barton Creek is not good type loc., name is binomial, and *Barton* was otherwise used many years before *Barton Creek.*

Edwards ls. underlies Georgetown ls. in some areas, Fort Worth ls. in other areas, and Kiamichi clay in NE. Tex. See also under *Fredericksburg group.*

Named for Edwards Plateau, Nueces and Uvalde quads., SW. Tex., of which it is chief component of scarps and mesas.

Edwardsville formation. (In Borden group.)

Mississippian: Southeastern Indiana.

P. B. Stockdale, 1929 (Ohio Jour. Sci., vol. 29, No. 4, p. 170). [See under *Borden group.*]

P. B. Stockdale, 1931 (Geol. Soc. Am. Bull., vol. 42, No. 3, pp. 707–718). The *Edwardsville* is in many respects the most unique fm. in Borden group. Is top fm. of the Borden. Displays greatest range in thickness—from 40 to 200 ft. Predominantly sh., siltstone, and ss. A perplexing calc. lithology at extreme S. end of Ind. outcrop area and in adjacent Ky. renders it easily confused with basal memb. of overlying Harrodsburg ls. It overlies Floyds Knob fm.

P. B. Stockdale, 1931 (Ind. Dept. Cons., Div. Geol., Pub. 98, pp. 54, 76, 220, etc.). *Edwardsville fm.* in previous writings has been included in "Knob ss.," "Riverside ss.," "Knobstone ss.," and "Warsaw" of Butts (1915, 1918, 1922). Is named for village of Edwardsville, near center of NE¼ sec. 1, T. 3 S., R. 5 E., 4½ mi. W. of New Albany, Ind. It is completely exposed in clean-cut association with overlying Harrodsburg ls. and underlying Floyds Knob fm. along State Highway 62, a short distance NE. of Edwardsville, where it is 53 ft. thick. [Describes and names many local lithologic *facies* of the fm. On pp. 310–311 he suggests redefining top of fm., as explained under *Harrodsburg ls.*]

Edwin clay.

A white brittle clay, locally known as *Edwin clay*, forms lowest 8 ft. of clay at Jones Butte, Butte Co., Calif. (See V. T. Allen, Univ. Calif. Pub. Bull. Dept. Geol. Sci., vol. 18, No. 14, pp. 381, 404, 1929.)

†Efaw rocks.

A name applied locally to Gilmore ss. memb. of Greene fm. in western Monongalia Co., W. Va., from locality near Wadestown, where it litters the ground with large boulders.

Effingham terrane.

A name applied by C. [R.] Keyes (Pan-Am. Geol., vol. 39, No. 4, 1923, p. 320) to 8 ft. of ls. in upper part of McLeansboro fm. (Penn.) of Ill. He placed it 200 ft. above Martinsville ls. Derivation of name not stated, but probably named for Effingham, Effingham Co., SE. Ill.

Egan limestone.

Lower Ordovician: Eastern Nevada (Ely region).

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 53, 78). *Egan lss.* 1,100 ft. thick, underlie Cherry shales and overlie Schell shales in Nev. Named for Egan Range, of which they form E. base from Ely northward.

A part of Pogonip ls.

Eggleston limestone.

Middle Ordovician (Black River): Southwestern Virginia (Giles County).

A. A. L. Mathews, 1934 (Va. Geol. Surv. Bull. 40, pp. 7, 11, 30). *Eggleston ls.* includes the beds of upper Black River age that are younger than the upper red Moccasin memb. (Lowville) and older than Trenton ls. Although a good section of the fm. occurs 1.1 mi. S. of Eggleston, Va., the best section is along State Highway 8, 1 mi. N. of Narrows, Va. This will be considered type loc. In general consists of thin- to thick-bedded, fine-grained, argill., dark-buff to light-brown ls. which upon fracturing forms cuneiform blocks with the jointing perpendicular to bedding. Contains many thin beds and a few thicker beds of bentonite, and its peculiarities may be due to this material. Is widely distributed in Valley and Ridge province. In type loc. is more than 150 ft. thick. Contains upper Black River fossils.

Same as Chambersburg ls. restricted of C. Butts and G. W. Stose (1932), which is name at present in use by U. S. Geol. Survey. (See C. Butts, Va. Geol. Surv. Bull. 42, 1933.)

Egremont limestone.

Ordovician and Cambrian: Southwestern Massachusetts and northwestern Connecticut.

W. H. Hobbs, 1893 (Jour. Geol., vol. 1, pp. 717–736, 780–802). *Egremont ls.*—White to gray crystalline ls., often quite pure but for small scales of colorless mica and grains of pyrite. Locally contains thin qtzitic or schistose layers. Generally passes upward into Everett schist through a graphitic layer of variable thickness, and a similar graphitic rock is also found at its lower contact with Riga schist. Correlated with Bellowspipe ls. of NW. Mass. Included in Mount Washington series. Named for its wide extent in Egremont valley [Berkshire Co., Mass.].

Is a part of Stockbridge ls.

Egypt sand.

Upper Cretaceous: Missouri.

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, p. 252). *Egypt terrane.*—Sands, 150 ft. thick, of Ripley age, uncon. underlying Porter [Porters Creek] clays and uncon. overlying Dakotan series. [Derivation of name not stated.]

Eileen sandstone. (In Oronto group.)

Pre-Cambrian (upper Keweenawan): Northwestern Wisconsin (Bayfield County).

F. T. Thwaites, 1912 (Wis. Geol. Nat. Hist. Surv. Bull. 25, pp. 50, 54). *Eileen ss.*—Red and white somewhat quartzose ss. Thickness 0 to 2,000 ft.; 1,800 ft. exposed. Included in Oronto group. Underlies Amnicon fm. and overlies Freda ss. Named for exposures in valley of South Fork of Fish Creek in town of Eileen, Bayfield Co.

Einstine sandstone. (Also spelled Einstein.)

Pennsylvanian: Eastern Kansas.

G. C. Swallow and F. Hawn, 1865 (Kans. Geol. Surv. Rept. on Miami Co., p. 7). *Einstine ss.*—Thin beds of soft brown micaceous and hard gray calc. ripple-marked sss. more or less intercalated with and passing into blue and brown sandy argill. shales. Upper part marly and fossiliferous at McFaddin's and at Ward's mill. Forms bed No. 10 (35 to 60 ft. thick) of geologic section of Miami Co. Overlain by Cave ls. and underlain by older Coal Measures strata.

In later repts called "Einstein ss." and included, together with †Cave ls., in †Cave Rock series. Probably represents whole or part of Chanute sh. memb. of Kansas City fm.

Derivation of name not stated.

Eiss limestone. (In Council Grove group.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 229, 233, 234, 235, 237). *Eiss ls.*, in Garrison shale, consists of (descending): (1) Dark-grey, siliceous, hard, massive, 1 ft. 3 in. to 2 ft.; (2) sh., bluish, argill., with fine calc. material, very fossiliferous, 7 ft.; (3) ls., dark gray, earthy, hard on exposure, 1 ft. 4 in. Total thickness 9 to 10 ft. Underlies Easly Creek sh. and overlies Stearns sh. Named for Eiss farm, S. of Humboldt.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., p. 19). Type exposure of *Eiss ls.* is in SE¼ sec. 3, T. 1 N., R. 13 E., on Eiss farm, 8 mi. S. of Humboldt, Nebr.

G. E. Condra, 1935. (See under ***Bader ls.***)

Ekwan limestone.

Silurian: Canada (Hudson Bay region).

A. F. Foerste, 1927 (Denison Univ. Bull., vol. 27, No. 3, Sci. Lab. Jour., vol. 22, pp. 5, 7, 15).

Ekwan River limestone.

Silurian: Canada.

T. E. Savage and F. M. Van Tuyl, 1919 (Geol Soc. Am. Bull., vol. 30, pp. 341, 357, 365, 368).

El Abra limestone.

Lower Cretaceous: Mexico.

V. R. Garfias, 1915 (Econ. Geol., vol. 10, pp. 199, 200).

Elbert formation.

Upper Devonian: Southwestern Colorado.

W. Cross, 1904 (Am. Jour. Sci., 4th. vol. 18, pp. 245–252). *Elbert fm.*—The strata overlying Ignacio fm. (chiefly qtzite and believed to be of Upper Camb. age), underlying Ouray ls., and carrying fish remains at base and near top, which seem unquestionably to form a lithologic strat. and faunal unit. At Devon Point the Elbert consists of (descending): (1) Red sh. or clay, 5 ft.; (2) ss. or qtzite containing fish scales in places, 1± ft.; (3) calc. shales and thin ls., buff or gray, breaking readily into slabs, salt casts common, 25 ft.; (4) thin layers of alternating qtzite, dull-gray aren. ls., and red calc. sh., 8 ft.; (5) hard fine-grained gray qtzite, 2 to ½ ft.; (6) red calc. sh., 4 in. to 1 ft.; (7) yellow earthy ls., 9 in.; (8) calc. and sandy shales, variegated, yellow, buff, lilac, 4 in. to 1 ft.; (9) fine-grained yellow-brown qtzite, 1 ft.; (10) sandy sh., red, greenish, or mottled, a harder layer in middle, 5 ft.; (11) sandy ls., shaly in part, rich in fish scales and plates, 1± ft.; (12) red sh., calc. and sandy, with specks of bone or shell, 2 ft. Total thickness at Devon Point 54 ft. Named for exposures on Elbert Creek, a western tributary of Animas River, entering it just above Rockwood. The Elbert has been observed below Ouray ls. in several quads. of San Juan region, and many exposures have been studied. Its most persistent feature is the crumbling calc. sh. div., with its casts of salt crystals. The most important variation in its lithology is appearance of dense earthy ls. of conchoidal fracture, in several beds in upper part. Only fossils found are fish remains. Appears to correlate with "Parting qtzite" of central Colo.

Elbrook limestone.

Middle and Upper Cambrian: Central southern Pennsylvania, western Maryland, and northwestern Virginia.

G. W. Stose, 1906 (Jour. Geol., vol. 14, p. 209). *Elbrook ls.*—Massive bluish gray mag. and cherty ls. with red and green shales in middle. About 2,000 ft. thick. Underlies Knox ls. and overlies Waynesboro fm. Quarried at Elbrook, Franklin Co., Pa.

G. W. Stose, 1909 (U. S. G. S. Mercersburg-Chambersburg folio, No. 170), divided the beds called *Knox ls.* in 1906 into Conococheague ls. below and Beekmantown ls. above, and stated thickness of Elbrook ls. to be 3,000 ft.

El Cano formation.

Cretaceous: Cuba.

J. W. Lewis, 1932 (A. A. P. G. Bull., vol. 16, p. 539).

El Capitan granite.

Probably Cretaceous: Yosemite National Park, California.

F. C. Calkins, 1930 (U. S. G. S. P. P. 160, pp. 121–122, map). Light-colored biotite granite of moderately coarse and in part obscurely porphyritic texture, but along E. margin it passes from a porphyritic to a nonporphyritic rock. Is one of oldest intrusive rocks in Yosemite region.

Named for fact that it forms greater part of El Capitan, Yosemite Nat. Park.

†El Capitan limestone.

A term applied by some geologists to Capitan ls. of Tex.

Elco gravel.

Mississippian: Southwestern Illinois (Alexander County).

L. C. Glenn, 1906 (U. S. G. S. W. S. P. 164, pp. 22, 150–152). *Elco gravel.*—Name locally applied to 177 ft. of Miss. chert in deep wells at Cairo, Ill. Is quarried near Elco, Alexander Co., where it consists of very light-colored chert, 150 to 200 ft. thick, highly fractured; is not a gravel either in wells or in outcrop.

Elden limestones.

Mississippian: Northern Central Arizona (Flagstaff region).

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, pp. 243, 251, 336). *Elden lss.*—Name derived from Elden Mtn, near Flagstaff. Includes the beds of Miss. series carrying Keokuk fauna. Thickness 250 ft. Top fm. of Miss. series in Ariz. Younger than Truxton lss.

Eldon limestone.

Middle Cambrian: British Columbia and Alberta.

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804, pp. 2, 3). *Eldon fm.*—Massive aren., dolomitic lss., with a few bands of purer bluish-gray ls. Thickness 2,733 ft. in Mount Bosworth section and 2,195 ft. at Castle Mtn. Contains Middle Camb. fossils. Is top fm. of Middle Camb. Underlies Bosworth fm. and overlies Stephen fm. Comprises upper massive lss. of Castle Mtn, Alberta, 1 to 2 mi. N. of Eldon switch, on Canadian Pacific Ry.

Eldonian series.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 42, p. 289). *Eldonian series.*—Series of lss., aggregating 2,685 ft., uncon. underlying Bosworthian series and overlying Stephensian series. Uppermost div. of Mid Cambric in Alberta. [Apparently same as Eldon ls.]

Eldora sandstone.

Pennsylvanian: Central northern Iowa.

S. W. Beyer, 1900 (Iowa Geol. Surv., vol. 10, pp. 254, 259–278). *Eldora ss.*—Heavy-bedded ferruginous ss., 80 ft. thick, forming top fm. of Des Moines stage in Hardin Co. Overlain by Pleist. and underlain by sh. of Des Moines stage.

Named for Eldora, Hardin Co.

Eldoradan series.

A term applied by C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 51, 53, 78), to lower part of Eldorado ls. of Nev. and to supposedly contemp. deposits in other States.

Eldorado limestone.

Middle Cambrian: Eastern Nevada (Eureka district and neighboring regions).

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1812, p. 184, footnote). As result of conference with Mr. Arnold Hague, *Eldorado ls.* is introduced to replace *Prospect Mtn ls.* [the name *Prospect Mtn* being retained for the older qtzite].

Named for Eldorado mine, Eureka dist.

Eldorado sand.

A subsurface sand in Annona chalk of NE. Tex.

Eldorado series.

Eldorado granodiorite.

Cretaceous: British Columbia.

C. W. Drysdale, 1916 (Canada Geol. Surv. Summ. Rept. 1915, p. 79).

Eldoran epoch (and series).

Term proposed by G. F. Kay (Geol. Soc. Am. Bull., vol. 42, pt. 1, pp. 449–452, 1931) to include Wisconsin (glacial), Peorian (interglacial), and Iowan (glacial) stages of Pleistocene epoch (and series), which Kay would elevate to Pleistocene *period* (and *system*). In vicinity of Eldora, Hardin Co., Iowa, the 3 stages have been mapped separately.

G. F. Kay and M. M. Leighton, 1933 (Geol. Soc. Am. Bull., vol. 44, pp. 669–673), redefined *Eldoran epoch* (*series*) by including in it "*Recent age* (*stage*)"; and they agreed to define "*Wisconsin age* (*stage*)" to include the following substages (descending): Mankato (late Wisconsin), Cary (middle Wisconsin), Tazewell (early Wisconsin), and Iowan. For their complete classification see under *Wisconsin stage*.

Eleanor slate.

Pre-Cambrian (Keewatin): Western Ontario.

A. P. Coleman and A. B. Willmott, 1902 (Toronto Univ. Studies, geol. ser. No. 2, p. 10; and Ont. Bur. Mines Rept. 1902, p. 158). *Eleanor slates*, Huronian.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, p. 154). *Eleanor sl.* assigned to Keewatin.

†Electric intrusives.

Miocene: Yellowstone National Park.

A. Hague et al., 1899 (U. S. G. S. Mon. 32, pt. 2, pl. 10), mapped *Electric intrusives*. The U. S. Geol. Survey later adopted *Electric Peak intrusives* for these rocks.

Electric Peak intrusives.

Miocene: Yellowstone National Park.

A. Hague et al., 1904 (U. S. G. S. Mon. 32, Atlas, Gallatin sheet). *Electric Peak intrusives*.—Dikes of diorite porphyry and andesite of various kinds, breaking through sed. rocks of Electric Peak, in Gallatin quad., Yellowstone National Park.

Elenita syenite porphyry.

Age (?): Mexico.

S. F. Emmons, 1910 (Econ. Geol., vol. 5, p. 324).

Elephant limestone.

Pennsylvanian: Southwestern Utah (southeast of Frisco district).

B. S. Butler, 1913 (U. S. G. S. P. P. 80). *Elephant ls.*—Heavy-bedded dolomitic and siliceous lss., 1,000± ft. thick, underlying (probably uncon.) Harrington fm. and overlying (conformably to N., but uncon. suggested to S.) Talisman qtzite. Named for Elephant Canyon, SE. of Frisco dist.

†Elevator B sandstone.

A term applied by C. W. Hall (Minn. Acad. Nat. Sci. Bull., vol. 3, pp. 125–136, 1889) to a ss., in lower part of Shakopee dol. as delimited by him, that was later named *New Richmond ss.* He described the beds as 20 ft. thick in well at Elevator B, St. Paul, Minn.

Elgin sandstone.

Pennsylvanian: Southern Kansas and central northern and central Oklahoma.

E. Haworth, 1898 (Kans. Univ. Geol. Surv. vol. 3, p. 64). Name suggested by G. I. Adams. *Elgin ss.*—Sss. within Lecompton shales in S. part of State, which have great development around Elgin. [*Lecompton shales* of early Kans. repts has been replaced by *Kanwaka sh.*]

F. C. Schrader, 1908 (U. S. G. S. Independence folio, No. 159). *Elgin ss.*—Hard ferruginous ss. that weathers rough. Thickness 10 ft. in this quad. Rests conformably on Oread ls.

D. W. Ohern and R. E. Garrett, 1912 (Okla. Geol. Surv. Bull. 16, pp. 12–13). Elgin ss. is 50 to 40 ft. thick. It crops out in E. part of Osage Co., Okla., and extends across Osage and Pawnee Counties. Rests on Oread ls. and is overlain by 700 ft. of Penn. shales with thin lss.

L. C. Snider, 1913 (Petroleum and natural gas in Okla., pp. 44–49). *Elgin ss.* is 50 to 140 ft. thick. Is 140 ft. thick near Elgin, Kans., where it consists of an upper and lower ss. memb. separated by shaly ss. Rests on Oread ls.

R. C. Moore and W. P. Haynes, 1917 (Kans. Geol. Surv. Bull. 3). In N. Kans. the Kanwaka sh. is calc. and locally includes thin beds of impure ls., but to S. it becomes very sandy and may well be called a ss. The name Elgin ss. has been suggested by Haworth (1898) for this phase, on account of exposures near Elgin, Chautauqua Co., where it is nearly 140 ft. thick, but to S. it becomes thinner.

A. E. Fath, 1925 (U. S. G. S. Bull. 759, p. 12). *Elgin ss.* has been traced across Pawhuska and Hominy, Okla., quads., by C. D. Smith and R. H. Wood, to whose unpublished maps writer has had access. In Bristow quad., Okla., it is a friable gray to yellowish brown ss. 50 to 80± ft. thick. Is exposed near W. margin of quad. and is highest ss. of considerable thickness in strat. section. In west-central part of quad. it is differentiated with difficulty from underlying Bristow fm. Its upper surface is distinct across the quad. and is a good strat. bdy. It is separated from overlying Perm. beds by several hundred ft. of Penn. sh., ss., and ls.

C. N. Gould, 1925 (Okla. Geol. Surv. Bull. 35, pp. 75, 77). *Elgin ss.* is a massive ss., consisting usually of but a single memb., but it is more shaly to N. Thickness 50 to 210 ft. It rests on Nelagoney fm.

H. D. Miser, 1926 (Geol. map of Okla.). *Elgin ss.* underlies Pawhuska fm. and overlies Nelagoney fm. across central northern and part of central Okla.

†Elgin limestone. (In Maquoketa group.)

Upper Ordovician: Northeastern Iowa and western Wisconsin.

S. Calvin, 1906 (Iowa Geol. Surv. vol. 16, pp. 60, 98). *Elgin shaly ls.*—Ls., dolomites, and shaly lss., with beds of calc. sh. and thin partings of bluish, less calc. clays; generally of yellow color and 70 ft. thick. Forms basal fm. of Maquoketa stage. Includes *Isotelus* zone at base. Overlain by Clermont sh. (of Maquoketa stage) and underlain by Galena ls.

Preoccupied by Elgin ss. Is basal fm. of Maquoketa group.

Named for exposures near Elgin, Fayette Co., Iowa.

Eliot slate.

Carboniferous (Pennsylvanian?): Southwestern Maine and southeastern New Hampshire.

F. J. Katz, 1917 (Wash. Acad. Sci. Jour. vol. 7, p. 198). *Eliot sl.*—Gray sericitic and siliceous slates, argillo-qtzitic schists, calc. beds, and carbonaceous phyllites. Present in Eliot, Maine, and Dover, N. H., extending thence SW. in two belts.

F. J. Katz, 1917 (U. S. G. S. P. P. 108, p. 169). *Eliot sl.*—An assemblage of gray sericitic and siliceous sericitic slates; beds of light-gray and drab argillo-qtzitic rocks, some of which are also calc.; thin laminae of light-bluish ls.; and thin layers of black carbonaceous sericite phyllite. Uniformly fine-grained and thin-bedded. Thickness not determinable. No fms. overlie it, and top may be absent. Rests on Kittery qtzite. Contemp. with lower part of Casco Bay group, especially Cape Elizabeth fm., but may also represent part of Scarboro phyllite. Assigned to Penn. (?).

Named for development at Eliot, York Co., Maine.

Eliot phyllite.

Same as Eliot sl.

Elisa quartz monzonite porphyry.

Age (?): Mexico.

S. F. Emmons, 1910 (Econ. Geol., vol. 5, p. 329). [Age not stated. M. L. Lee, Econ. Geol., vol. 7, 1912, p. 330, assigned it to Tert.]

Elizabeth gabbros.

Pre-Cambrian: Eastern New York (Adirondack Mountains).

See under *Adirondack anorthosyte.*

Elizabeth sand.

Drillers' term, long in use, for a sand in western Pa. and W. Va. that probably lies in upper part of Chemung fm. Is younger than Warren First sand and Cherry Grove sand and older than Bayard sand.

Elizabeth Furnace conglomerate member (of Gettysburg shale).

Upper Triassic: Southeastern Pennsylvania (Lancaster County).

A. I. Jonas and G. W. Stose, 1930 (Pa. Geol. Surv., 4th ser., Topog. and Geol. Atlas of Pa., No. 168, Lancaster quad., p. 50). Heavy quartzose cgl., 2,500± ft. thick. Is closely associated with soft red ss. of type of Gettysburg sh. and is therefore treated as basal memb. of that fm. Rests on New Oxford fm. All included in Newark group. Forms prominent ridge (Elizabeth Furnace Hill) NE. of Mount Hope, Lancaster Co.

Elizabeth Islands moraine.

Pleistocene: Massachusetts. (See U. S. G. S. Bull. 597, 1917, p. 138.)

Elizabethtown gabbro.

Pre-Cambrian: Northeastern New York (Essex County).

G. H. Chadwick, 1930 (Geol. Soc. Am. Bull., vol. 41, p. 82). *Elizabethtown gabbros* occur around Elizabethtown [Essex Co.], N. Y.

Elk conglomerates.

Cretaceous: Alberta.

W. W. Leach, 1913 (12th Int. Geol. Cong. Guidebook 9, p. 24).

Elk fire clay. (In Conemaugh formation.)

Pennsylvanian: Southern West Virginia.

C. E. Krebs and D. D. Teets, Jr., 1914 (W. Va. Geol. Surv. Rept. Kanawha Co., p. 179). *Elk fire clay.*—Reddish variegated fire clay, 5 to 7 ft. thick, underlying Brush Creek coal and overlying Mahoning ss. Named for Elk River, near Charleston.

Elk sand group.

A term applied to several subsurface brown sands, of Dev. age, aggregating 400 ft. in thickness, occurring at horizons varying from 100 to 500 ft. below Bradford sand group in Elk Co., western Pa. Immediately underlies McKean sand group. Includes Kane, Elk, and other sands. Named for Elk Co., Pa. The name *Elk* has also been applied to a sand at approx. this horizon in W. Va. (See also under *Kane sand.*)

Elk Basin sandstone member (of Telegraph Creek formation).

Upper Cretaceous: Central northern Wyoming and central southern Montana (Yellowstone and Bighorn Counties).

C. J. Hares, 1917 (Wash. Acad. Sci. Jour., vol. 7, p. 430). It has been fairly definitely established that type Eagle ss. includes in lower part the massive cliff-forming ss. at Park City and Billings, but about 100 ft. below the massive ss. is a thin sand, 10 to 40 ft. thick, which contains an Eagle fauna. This lower sand is rim-forming from Park City to Elk Basin and Shoshone River, but from there S. it is represented, as is remainder of Eagle fm., by thin-bedded sss. and aren. shales. This sand has been called *Elk Basin ss. memb. of the Eagle.* It is underlain by dark-colored sh. containing thin limy layers and concretions that weather reddish brown and rest on Carlile sh.

C. F. Bowen, 1918 (U. S. G. S. Bull. 691A, section A of pl. 25, also pl. 17), published the Elk Basin, Wyo., section from C. J. Hares' unpublished rept, in which he drew base of Montana group at base of *Elk Basin ss. memb.*, and drew base of Eagle ss. *doubtfully* 100± ft. above top of Elk Basin ss. and at base of a ss. that he correlated with Virgelle ss.

In 1922 (U. S. G. S. Bull. 736B, p. 38) the 350± ft. of transition beds underlying Virgelle ss. memb. of Eagle ss. in Yellowstone-Bighorn Counties region, southern Mont. (the fossils of which are "predominantly Montana types"), were named *Telegraph Creek fm.* by W. T. Thom, Jr. These transitional beds include the Elk Basin ss. of Hares about 100 ft. below their top. (See J. B. Reeside, Jr., U. S. G. S. P. P. 151, pp. 2, 3, 1927.)

Elk City sandstone member (of Quartermaster formation).

See under *Bessie memb.*

†Elk Creek beds. (In Cheyenne sandstone.)

Lower Cretaceous (Comanche series): Central southern Kansas.

F. W. Cragin, 1895 (Am. Geol., vol 16, pp. 361, 366). *Elk Creek beds.*—Variable shaly and aren. strata composing that part of Cheyenne ss. that overlies Corral ss. Divided into Stokes ss. (a few ft. thick) above and Lanphier beds (10 to 15 ft. thick) below. Underlain by Corral ss. and overlain by Champion shell bed.

Named for Elk Creek, Kiowa Co.

This name was discarded by U. S. Geol. Survey in 1921, being a local name for major part of Cheyenne ss.

W. H. Twenhofel, 1924 (Kans. Geol. Surv. Bull. 9, pp. 13–14). *Elk Creek beds* of Cragin were named for exposures about head of Elk Creek, the lower part being differentiated by Cragin as *Lanphier beds*, from exposures on Lanphier ranch about 5 mi. SE. of Belvidere, where this memb. consists of 10 to 15 ft. of poorly cemented sands containing streaks and lenses of black to gray sh. Cross lamination is extremely common in the sss. Fragments of lignite, crystals of gyp. (selenite), and limonite concretions are commonly present. Many parts of the memb. are locally richly impregnated with gyp. Another characteristic is presence of logs composed of lignite and pyrite. All parts of Elk Creek beds contain dicotyledonous plants. Writer does not consider it possible definitely to recognize any memb. of Cheyenne ss. beyond limits of one locality. Cragin's divisions are considered to have no validity for more than local application, and as his 3 members were not differentiated in same section it is possible that 2 of them may be one.

Elk Falls limestone.

Pennsylvanian: Southern Kansas.

E. Haworth, 1898 (Kans. Univ. Geol. Surv. vol. 3, pp. 65–66, 105). *Elk Falls ls.* proposed by G. I. Adams in field notes for two well-defined lss. separated by a thin bed of aren. shales which here and there develop into well-formed ss. Overlies Lecompton shales and underlies Severy shales in Greenwood and Chautauqua Counties. Corresponds to Deer Creek ls., Tecumseh shales, and Lecompton ls., the two lss. being brought closer together to S.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 172, 182, 194). †*Elk Falls ls.* abandoned. Included Lecompton ls. to Topeka ls. inclusive.

Named for Elk Falls, Elk Co.

†Elkgarden formation.

Pennsylvanian: Northeastern West Virginia and western Maryland.

N. H. Darton and J. A. Taff, 1896 (U. S. G. S. Piedmont folio, No. 28). *Elkgarden fm.*—Chiefly sh., gray and black, variably sandy and with interstratified thin flaglike bands of argill. ss. and variable bands of coal and carbonaceous sh. Base of Elkgarden coal is base of fm. Thickness nearly 280 ft. Overlies Fairfax fm. and is overlain by gravel of possible Mio. age. Most extensive exposure is on Elkgarden Plateau, Mineral Co., W. Va.

Same as Monongahela fm.

Elk Hill complex.

Pre-Cambrian (?): Southeastern Virginia (James River Basin).

S. Taber, 1913 (Va. Geol. Surv. Bull. 7, p. 57). *Elk Hill complex* is made up of 3 principal rock types—biotite granite, hornblende schist, and pegmatite—which occur interleaved in layers of varying thickness and in places are much contorted. The hornblende rock appears to have been formed first and the granite intruded into it later, while the pegmatite frequently cuts both of the other rocks. The complex is from 1 to 1½ mi. wide where it crosses James River at Elk Hill, and best exposures are found in bluffs ¾ mi. below Elk Hill.

Elkhorn shale.

Elkhorn hornstone.

Upper Cambrian: Western central Montana (Elkhorn region).

W. H. Weed, 1901 (U. S. G. S. 22d Ann. Rept., pt. 2, map, pp. 434, 437). *Elkhorn sh.* [on map], *Elkhorn hornstone* [text heading and table].—Series of thin-bedded strata varying from nearly pure, dense, fine-grained qtzites to calc. and argill. shales indurated and metamorphosed. Thickness 100 ft. Underlies Keene ls. [Dev. and Camb.] and overlies Cemetery ls. Seldom seen in good surface exposures, but is well exposed in a hanging-wall crosscut of Elkhorn mine, Elkhorn min. dist.

Elkhorn formation. (In Richmond group.)

Upper Ordovician: Southern and eastern Indiana and western Ohio.

E. R. Cumings, 1908 (Ind. Dept. Geol. and Nat. Res. 32d Ann. Rept., p. 678). *Elkhorn div.*—Shales and shaly lss., 46 ft. thick, overlying *Rhynchotrema dentata* zone and underlying the [so-called] Clinton [Brassfield ls.]. Characterized by

Platystrophia lynx var. *moritura*, and faunally to be known as *moritura* zone. Consists of 15 ft. of very soft blue sh., overlain by 25 ft. of blocky argill.-calc. sh., overlain by 6 ft. of hard brown ls., capped by 4 ft. of clay. Top div. of Richmond group.

E. R. Cumings, 1922 (Ind. Dept. Cons. Hdb. Ind. Geol., pt. 4, Sep. Pub. 21, pp. 438+), gave further description of *Elkhorn fm.*, top fm. of Richmond group, and stated that type loc. is 3½ mi. SE. of Richmond, Ind.

Elkhorn moraine.

Pleistocene (Wisconsin stage): Southern Wisconsin. Shown on moraine map (pl. 23) of U. S. G. S. P. P. 106. Named for village of Elkhorn.

Elkhorn Ridge argillite.

Carboniferous (Pennsylvanian?): Northeastern Oregon (Baker and Sumpter quadrangles).

J. Gilluly, 1937 (U. S. G. S. Bull. 879). *Elkhorn Ridge argillite.*—Argillite, tuff, and chert, with subordinate ls. and greenstone masses. Thickness, 5,000+ ft. The interbedded lss. contain *Fusulina*, which definitely establishes Carbf. age, but possibly younger beds have been included in fm. as mapped in Baker and Sumpter quads. Relation to Clover Creek greenstone (Perm.) unknown. Named for exposures on Elkhorn Ridge, Sumpter quad.

Elkins sandstone.

Upper Devonian: Eastern West Virginia (Randolph County).

D. B. Reger, 1928 (Am. Jour. Sci., 5th, vol. 15, pp. 50–57). *Elkins ss.*—Greenish brown, generally composed of shaly, iron-stained flags or thicker beds, all separated by irregular deposits of green sh.; infrequent carbonaceous streaks. Thickness 450 to 500 ft. Marine fossils, also plants and tree trunks. Included in Chemung series. Separated from younger Valley Head ss. of the Chemung by 650 to 750 ft. of sh. and sss. Lies 1,025 to 1,250 ft. above base of Chemung. Well exposed on State road 3 mi. NW. of Elkins, Randolph Co.

Elkins Fork shale.

Pennsylvanian: Eastern Kentucky (Pike County).

W. C. Morse, 1931 (Ky. Geol. Surv., ser. 6, vol. 36, pp. 296, 297). The name *Elkins Fork shales* is proposed for the shales exposed opp. Elkins Fork school in northern Pike Co. Thickness 10 ft. The known fossiliferous portion of the shales is only 8½ ft. thick; is blue and argill., and lies only 3 ft. above creek level. Fauna (listed) chiefly species of *Productus*. By barometer the shales lie 50 ft. below Kendrick shales; and they lie 45 ft. above Dwale shales. Nothing further is known concerning the geographic distribution of these lower shales.

Elkland parvafacies.

See under *Potter parvafacies*.

Elk Lick limestone member (of Conemaugh formation).

Pennsylvanian: Western Pennsylvania, eastern Ohio, and northern West Virginia.

F. Platt, 1877 (2d Pa. Geol. Surv. Rept. H_3, p. 60). *Elk Lick (Upper Berlin) ls.*, 6 to 12 ft. thick, underlies Elk Lick coal in Somerset Co., Pa., and lies 210 to 220 ft. below Pittsburgh coal. [On p. 223 is a section at Forwardstown, Somerset Co., Pa., in which Elk Lick ls. is placed 90 ft. above Berlin ls., and latter is shown as consisting of 2 lss. separated by 1′8″ of clay and coal. A section on p. 292 shows Elk Lick ls. lying 83 ft. above Berlin ls. and 65 to 70 ft. above Berlin coal. On p. 22 is statement that *highest ls. at Berlin* is Elk Lick ls.]

I. C. White, 1891 (U. S. G. S. Bull. 65, p. 90). *Elk Lick ls.*—Light-gray ls., often tinged with buff. Thickness 0 to 12 ft. Lies a short distance below Elk Lick coal, from which fact it derives its name.

The Md. Geol. Surv. (vol. 11, 1922) applied *Barton* to the coal formerly called *Elk Lick* in that State, and also to the underlying ls.

Named for relations to Elk Lick coal, which was named for village of Elk Lick, Somerset Co., Pa.

Elk Lick clay.

A clay bed in Conemaugh fm., underlying Elk Lick coal of Appalachian region.

Elk Mountain transition group.

Upper Devonian or Mississippian: Northeastern Pennsylvania (Susquehanna and Wayne Counties region).

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. G_5, p. 235). ***Elk Mountain transition group*** [also ***Transition (Sub-Pocono) measures***].—Underlies Pocono gray ss. and overlies Catskill fm. Includes (descending): ***Elk Mountain Upper ss.***, 150 ft.; ***Elk Mountain shales***, reddish, 200 ft.; ***Mount Pleasant cgl.***, 20 to 25 ft. [On pp. 59 and 64 of this rept the name ***Elk Mountain shales and sss.*** was applied to 150 to 200 ft. of shales (largely gray, red, green, and spotted) with a few ss. layers, which crop out around slopes of North and South Knobs of Elk Mtns, are overlain by Mount Pleasant red sh. (top memb. of Catskill fm.), are underlain by Cherry Ridge group of Catskill fm., and occur much lower in section than Elk Mountain transition group. On p. 235, however, he called these shales and sss. of the Catskill the ***Elk Mountain lower sands***, having called a much higher ss. the ***Elk Mountain upper ss.*** The Elk Mtns are in SE. part of Susquehanna Co.]

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 571, 573–577, 606), restricted ***Elk Mountain*** to the flaggy sss. beneath his redefined ***Mount Pleasant red sh.*** and above Cherry Ridge group of I. C. White. These flaggy beds appear to be the *lower sands* of I. C. White. Willard stated his redefined ***Mount Pleasant red sh.*** included all beds above his Elk Mtn ss. and below Griswolds Gap cgl. (basal memb. of Pocono), or its equiv. This would include all of White's Elk Mtn subdivisions except his Elk Mtn lower sands, which becomes Elk Mtn ss. of Willard. He correlated his Elk Mtn ss. with Oswayo fm., which U. S. Geol. Survey classifies as Dev. or Carbf.

Elk Mountain shales.

Elk Mountain shales and sandstones.

Elk Mountain Upper sandstone.

Elk Mountain lower shales.

Elk Mountain lower sands.

See under *Elk Mountain transition group.*

Elk Mountain porphyry.

Eocene: Central Colorado (Tenmile district).

S. F. Emmons, 1898 (U. S. G. S. Tenmile Special folio, No. 48). ***Elk Mtn porphyry.***—Light gray, porphyritic. Named for Elk Mtn. [In inset headings he calls the mass of this rock on Copper Mtn the *Copper Mtn porphyry* and the mass on Gold Hill the *Gold Hill porphyry.*]

Elk Mountain sandstone.

Upper Devonian or Mississippian: Northeastern Pennsylvania.

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 571, 574–577). ***Elk Mtn ss.***—Green to grayish green, flaggy ss., very cross-bedded, with few sh. interbeds. The cross-bedding is most distinctive feature. The fm. extends around foot of Elk Mtns, Susquehanna Co., for which I. C. White named it. He appears to have included with the Elk Mtn some beds more truly assignable to adjacent red fms. As here used the name is applied to the nonred cross-bedded flags only, overlying Cherry Ridge red beds and underlying Mount Pleasant red sh. Latter includes all beds up to base of Griswolds Gap memb. of Pocono fm. One of best exposures of Elk Mtn ss. is in hills N. of U. S. Highway 6, near Prompton, Wayne Co., and there are many in SE. Susquehanna Co. This fm. is persistent from Wayne Co. S. into Monroe, but appears to die out there, so that it is not surely recognized W. of Pocono Plateau. Its absence prevents satisfactory separation of the Mount Pleasant and Cherry Ridge in Lehigh Valley and to W. To W. of Wayne Co., all through N. tier of counties to Potter, the fm. occurs, until it passes over into marine Oswayo sandy sh. in W. part of Potter and McKean Counties [which U. S. G. S. classifies as Dev. or Carbf.]. Probably present in Clinton Co. Thickness changes little from 150± ft. in Wayne Co. to slightly over 200 ft. in Bradford Co. In Potter Co. the cross-bedding is less pronounced, the color more olive to olive brown than green, indications of marine life appear, and at base there is a remnant of Salamanca cgl. with marine fossils. [As thus defined Elk Mtn ss. of Willard appears to replace *Elk Mtn lower sands* of I. C. White.]

Elko shale.

Elko group.

Eocene: Northeastern Nevada.

S. F. Emmons, 1877 (U. S. Geol. Expl. 40th Par. vol. 2, pp. 551–564, and other pages), stated in several sections that *Elko shales* are part of Green River fm.

C. King, 1878 (U. S. Geol. Expl. 40th Par. vol. 1, p. 458), applied *Elko group* to Eocene deposits in northern Nev., but on p. 393, where he described the deposits of Elko Range and Elko Station, he called the Eocene beds *Green River group*, and said they are same as Green River group of Hayden. This correlation with Green River fm. has not yet been established.

Elko formation.

Cambrian: British Columbia.

S. J. Schofield, 1914 (Canada Geol. Surv. Mus. Bull. 2, p. 83). [In 1915 and later repts assigned this fm. to Camb.]

Elkoan series.

C. [R.] Keyes, 1925 (Pan-Am. Geol., vol. 44, pp. 215, 217, 219). *Elkoan series.*—Includes (descending) Rooseville shales, Phillips shales, Gateway shales, Sheppard dolomites, and Purcell basalts. Uncon. overlies Helenan series [Helena ls.] and uncon. underlies Ross qtzites. Of latest Mid Proterozoic age.

Derivation of name not stated, but may be Elko, British Columbia.

Elko Prince rhyolite.

Tertiary: Central northern Nevada (western part of Elko County).

E. H. Rott, Jr., 1931 (Univ. Nev. Bull., vol. 25, No. 5). *Elko Prince rhyolite* (Tert.) occurs in both E. and W. walls of Elko Prince vein in Gold Circle or Midas mining dist. Is conformably overlain by andesite. Relations to June Bell rhyolite undet. If the June Bell is extrusive it is older than Elko Prince; if intrusive it is younger.

†Elk River series.

Pennsylvanian: West Virginia.

I. C. White, 1891 (U. S. G. S. Bull. 65, pp. 70–98). *Barren Measures or Elk River series.*—As defined [but not named *Elk River series*] by Rogers Bros. in Pa. and Va., this group extended from base of Pittsburgh coal to top of Mahoning ss., but subsequent investigations seem to render it more desirable to extend the group downward so as to include Mahoning ss.

Same as Conemaugh fm., the older name.

Elk River beds.

Pleistocene and Pliocene (?): Southwestern Oregon (Cape Blanco region).

J. S. Diller, 1902 (U. S. G. S. Bull. 196, pp. 30–31). At mouth of Elk River the Mio. sh. occurs at water's edge and is overlain (apparently conformably) by nearly 100 ft. of Pleist. gravel and sand (*Elk River beds*), near base of which, close to the Mio., is an unconsolidated shell bed rich in fossils. Toward Cape Blanco the shell bed rests uncon. on Mio. Dr. Dall says fossils are probably Pleist.

R. Arnold and H. Hannibal, 1913 (Am. Phil. Soc. Proc., vol. 52, No. 212, pp. 560, 595). *Elk River fm.* (*upper Plio.*).—Extending from the Goldwashers' cabin 1¾ mi. SE. of Cape Blanco S. to Garrison Lagoon, near Port Orford, is a gently southward-dipping cliff, essentially a raised beach composed of sands and littoral gravels, blue and more or less concretionized at base but rusty and hardly consolidated above, perhaps 250 ft. thick near their contact with underlying Empire ss., lying to N., but gradually dropping below sea level to S. This fm. has been named by Diller *Elk River beds*, from an important stream which cuts through the section. As a matter of fact Diller's name was given to only upper rusty portion of the section, while the blue beds conformable below were included with *Empire fm.* (*Cape Blanco beds*), a procedure not borne out by fauna. There is marked discrepancy btw. dip and strike of Empire beds and the overlying blue sands that was apparently overlooked by Diller. Fauna is chiefly recent species, but associated with them are others common to the Merced, thus establishing Plio. age of Elk River fm. [Fossils listed.]

B. Martin, 1916 (Univ. Calif. Bull., vol. 9, pp. 245–247). *Elk River beds* (*Pleist.*).—Consist of (descending): (1) Loose gray sand with fossils very similar to Upper San Pedro of Calif., conformable with (2), which consists of blue-gray argill. ss. or mudstone, probably late Plio.; (3) thick bed of cgl. at base. Uncon. overlies Cape Blanco beds (=Empire fm.).

L. G. Hertlein and C. H. Crickmay, 1925 (Am. Phil. Soc. Proc., vol. 64, No. 2, pp. 264–270). Diller published nothing on fauna except that Dall had reported his collections to be Pleist. In 1913 Arnold and Hannibal published a partial list of fauna, but included that of underlying Plio. argill. sands without any information about zonal distribution of species. It is therefore impossible to say which sp. belong to Elk River beds and which to Plio. beds. [Discusses Martin's 1916 paper.]

W. D. Smith, 1926 (Oreg. Univ. Commonwealth Rev., vol. 8, p. 269), and H. V. Howe, 1926 (Pan-Am. Geol., vol. 45, p. 304), followed Arnold and Hannibal by assigning this fm. to upper Plio.

Elk Valley erosion cycle.

Name applied by G. R. Mansfield (Jour. Geol., vol. 32, 1924, p. 485) to a Pleist. erosion cycle in SE. Idaho.

Ellenburger limestone.

Late Cambrian and early Ordovician: Central Texas.

S. Paige, 1911 (U. S. G. S. Bull. 450, p. 24). *Ellenburger ls.*—Chert-bearing lss. and dolomites, with usually a conglomeratic ls. at top. Thickness probably 1,000 ft. Uncon. may exist near top. Overlies, possibly uncon. in places, Wilberns fm. and underlies Carbf.

Named for Ellenburger Hills, Burnet Co.

Ellensburg formation.

Miocene: Central Washington.

I. C. Russell, 1900 (U. S. G. S. 20th Ann. Rept., pt. 2, pp. 100–137, map). *Ellensburg ss.*—Sss., loose incoherent cgls., sheets of volcanic lapilli and white volcanic dust. Thickness 800 or 1,000 ft. Fresh-water. Fossil plants are upper Mio., according to F. H. Knowlton. Floors Kittitas Valley, in which Ellensburg is situated. Separated from underlying Roslyn ss. by several sheets of Columbia lava and associated tuffs.

In 1901 (U. S. G. S. W. S. P. 55) G. O. Smith applied name *Yakima basalt* to the basalt underlying Ellensburg fm., and gave thickness of Ellensburg as 1,600 ft.

G. O. Smith, 1903 (U. S. G. S. Ellensburg folio, No. 86, and U. S. G. S. P. P. 19). *Ellensburg fm.* consists of 1,570 ft. of largely volcanic sediments, the sss. and shales composed of finely comminuted andesitic material and the cgls. containing pebbles and bowlders of andesitic lavas. In Yakima region it is of fluviatile origin, while farther E. along the Columbia it is truly lacustrine. The lava flows interbedded in lower part are here named *Wenas basalt.* [The beds farther E. along the Columbia are now known to be younger than Ellensburg fm., and to be of Pleist. age. They have been named *Ringold fm.* by J. C. Merriam and J. P. Buwalda.]

In 1924 Knowlton was inclined to classify Ellensburg flora as middle Mio. In 1930 J. C. Merriam and J. P. Buwalda classified Ellensburg as late Mio. or lower Plio., which was age designation given to it in 1918 by H. F. Osborn. E. W. Berry (1932) considered this flora in need of careful study.

Ellerslie sandstone. (In Allegheny formation.)

Pennsylvanian: Western Maryland (Allegany and Garrett Counties).

C. K. Swartz, W. A. Price, and H. Bassler, 1919 (Geol. Soc. Am. Bull., vol. 30, p. 572). *Ellerslie ss.*—Underlies Middle Kittanning (Luke) clay and overlies Lower Kittanning (Ellerslie) coal; all included in Allegheny fm.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, p. 47). A ss. is found locally over Ellerslie coal, and to it the name *Ellerslie ss.* is here applied, because of its position. [The Ellerslie coal is mined at Ellerslie, Md.]

Ellerslie fire clay. (In Allegheny formation.)

Pennsylvanian: Western Maryland (Georges Creek Basin).

C. K. Swartz, W. A. Price, and H. Bassler, 1919 (Geol. Soc. Am. Bull., vol. 30, p. 572). *Ellerslie fire clay* (*Lower Kittanning fire clay*).—Underlies Lower Kittanning (Ellerslie) coal and overlies Mount Savage ss.; all included in Allegheny fm.

Ellettsville stone.

Trade name of a ls. quarried from Spergen ls. in southern Ind.

Ellicott shale member.

Upper Devonian: Northwestern Pennsylvania and southwestern New York (Chautauqua County).

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61, pp. 66–70). *Ellicott sh. memb.*—Top memb. of Chadakoin stage. Overlies Dexterville sh. memb. and underlies, with hiatus, Panama cgl. memb. of Conewango series. Includes near top "Tanner's Hill red" band. Is well-marked lithic and faunal memb. and merits separation from Dexterville memb. In Warren folio upper part of Ellicott memb. was included in Conewango fm. because of failure to recognize Panama cgl. Fauna inadequately known, but there is abrupt faunal change at top of underlying Dexterville sh. [Thickness of Ellicott memb. not given and lithology not clearly defined, but on p. 64 author stated that 42 ft. of green platy sh. and ss., with fossiliferous lenses that weather chocolate, lie near base of Ellicott memb. at Dexterville brick sh. quarries, East Jamestown, N. Y., and that btw. this sh. and ss. and the Dexterville sh. is a concealed interval 140 ft. thick; the Dexterville sh. of this section consisting of chocolate and green shales and sss. aggregating 138 ft.] Type occurrence of Ellicott sh. memb. is along "Hunt Road," btw. Ashville and Jamestown, N. Y., where it is exposed in roadside cuts. This is in town of Ellicott, Chautauqua Co., N. Y.

Ellicott City granite.

Late Paleozoic (?): Northeastern Maryland (Baltimore County).

E. B. Knopf and A. I. Jonas, 1929 (Md. Geol. Surv. Baltimore Co. Rept., pp. 134–135). *Ellicott City granite.*—A narrow outcrop of massive biotite-quartz monzonite (very similar in appearance to Woodstock granite), which extends SW. from Ellicott City, on Patapsco River, to Orange Grove. Is quarried at Ellicott City. Intrudes Wissahickon fm. Age may be as late as close of Paleozoic.

Ellicottville conglomerate.

Name applied in some early N. Y. and Pa. repts to the cgl. at Ellicottville, Cattaraugus Co., N. Y., apparently supposed by J. P. Lesley in 1875 (see first entry under *Olean cgl.*) to be Olean cgl., but stated by J. F. Carll in 1880 (2d Pa. Geol. Survey Rept. I_3), also Lesley in 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 2, p. 1531), to be the much older Salamanca cgl.

Elliott Cove formation.

Upper Cambrian: Newfoundland.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4). *Elliott Cove fm.*—Gray and black shales with cone-in-cone concretions and thin-bedded sss. Fossiliferous. Underlies Brown Mead fm. and overlies Manuels fm. Assigned to Upper Camb. [Derivation of name not stated.]

Elliott Creek bed. (In Strawn formation.)

Pennsylvanian: Central Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 374, 376). *Elliott Creek bed.*—Chiefly bluish-gray clays, slightly shaly at places, but toward base and top interstratified with thin sss. Thickness 100 ft. Memb. of Strawn div. Overlies Burnt Branch bed and underlies Shadrick Mill ss.

Named for Elliott Creek, Lampasas Co.

Ellis formation.

Upper Jurassic: Montana (widespread) and northwestern Wyoming.

A. C. Peale, 1893 (U. S. G. S. Bull. 110, map). [This map (of "vicinity of Three Forks, Mont.") shows *Ellis fm.* as overlying Quadrant fm. and underlying Cret. (the basal fm. of which is designated *Dakota fm.*), but does not describe the deposits.]

J. P. Iddings and W. H. Weed, 1894 (U. S. G. S. Livingston folio, No. 1). *Ellis ls.*—Sandy ls. underlain by *Myacites* beds, the latter consisting of impure fossiliferous lss. or soft earthy calc. rocks of dark-gray color, with sss. at base. Thickness 400 ft. At Cinnabar Mtn the *Myacites* beds rest upon a massive cross-bedded, ripple-marked ss., underlain by a bright-red ss. which may be=the Red-bed sss. of more southern localities. Underlies Dakota fm. and overlies Quadrant qtzite.

A. C. Peale, 1896 (U. S. G. S. Threeforks folio, No. 24). *Ellis fm.* (*Juratrias.*)—As here mapped the basal part consists of 40 to 60 ft. of nonfossiliferous qtzitic ss., which probably belongs to the Juratrias but which may possibly be Carbf. Above this basal qtzite the fm. consists largely of argill. ls., many of the beds crowded with Jurassic fossils. The middle and upper parts of fm. are more aren. and devoid of fossils. Total thickness 300 to 500 ft. Overlies Quadrant fm. and underlies Dakota fm.

The commonly accepted definition of Ellis fm. applies to Upper Jurassic marine strata and excludes any older beds that may inadvertently have been included in the earlier mapping.

Named for Fort Ellis, an old military post in Livingston quad., to E. of Bozeman, Mont., near which the fm. is mapped in Livingston folio.

Ellis Bay formation.

Ordovician: Anticosti Island.

C. Schuchert and W. H. Twenhofel, 1910 (Geol. Soc. Am. Bull., vol. 21, pp. 695, 701).

Ellison formation.

Pre-Cambrian: Southwestern South Dakota (Lawrence County).

J. O. Hosted and L. B. Wright, 1923 (Eng. and Min. Jour.-Press, vol. 115, pp. 793–799, 836–843, with maps). *Ellison fm.*—Massive, hard, medium-grained qtzites, usually in beds btw. 10 and 30 ft. thick, interbedded with gray quartz mica schist. Underlies West Ledge fm. and overlies Homestake fm. Thickness 300 ft. Believed to be of Keewatin age.

Named for exposures on road to Homestake mine office and Ellison shaft.

†Ellisville phase.

Miocene and Oligocene (?): Southern Louisiana and southern Mississippi.

L. C. Johnson, 1893 (Sci., vol. 21, pp. 90–91). *Fort Adams or Ellisville phase* of Grand Gulf group Mio. has very irregular boundaries, its southern line drawn from Tunica, La., by Columbia, Miss., by mouth of Okatoma Creek, by the Falls on Leaf River near Estabuchie, passing to S. of Ellisville and crossing Chickasawhay River btw. Winchester and Waynesboro. For convenience this div. will be called *Fort Adams or Ellisville phase.* Extends into Ala.

Includes Catahoula ss., Hattiesburg clay, and lower part of Pascagoula clay. (See G. C. Matson, U. S. G. S. P. P. 98, 1916, pp. 224–225.)

Named for Ellisville, Jones Co., Miss., and Fort Adams, Wilkinson Co., Miss.

Ellsworth schist.

Cambrian or pre-Cambrian: Southeastern and central southern Maine.

G. O. Smith, E. S. Bastin, and C. W. Brown, 1907 (U. S. G. S. Penobscot Bay folio, No. 149, pp. 1–2). *Ellsworth schist.*—Highly metamorphic argill. sed. rocks, of prevailingly greenish gray color and locally much injected by quartz. In contact with granite, diorite, serpentine, and Castine fm. (volcanic), all of which are distinctly younger. Believed to be oldest fm. in quad. Since Islesboro, Castine, and Penobscot fms. and North Haven greenstone are regarded as probably Camb. or Cambro-Ord. in age, the older Ellsworth schist is presumably early Camb. or pre-Camb. Named for exposures near Ellsworth, Hancock Co.

On 1933 geol. map of Maine, by A. Keith, these rocks are mapped as pre-Camb.

Ellsworth shale.

Mississippian: Central western Michigan (Muskegon region).

R. B. Newcombe, 1932 (A. A. P. G. Bull., vol. 16, No. 2, p. 159). *Ellsworth fm.*—Blue sh. and limy ss., 509 ft. thick in H. Heinz No. 5 well at Muskegon, underlying Lower Marshall and Coldwater fms. and overlying Antrim fm. [Derivation of name not stated.]

R. B. Newcombe, 1933 (Mich. Geol. Surv. Pub. 38, pp. 22, 49). [On p. 22 the Bedford is shown as divided into (descending) (1) sh., gray, red, sandy, 0–160 ft.; (2) *Ellsworth,* sh., gray, greenish gray, sandy, 400 to 600 ft.; and as resting on Antrim sh.] The beds exposed S. of Ellsworth, Antrim Co., have not been correlated definitely with Bedford sh. of Ohio. Best exposure is about 1½ mi. S. of Ellsworth, in Petoskey Portland Cement Co. quarry, where a ledge of 30 to 40 ft. of greenish-gray sh. is being worked. Location of quarry is in NE¼ NE¼ sec. 26, T. 32 N., R. 8 W., Banks Twp, Antrim Co., Mich. Total thickness of strata btw. top of brown Antrim sh. and base of a red shaly ls., probably of Coldwater age, in W. part of State is btw. 500 and 600 ft. It is proposed that these beds be called *Ellsworth sh.*, and that type section be referred to above locality. A complete section of fm. is found in Chas. Reeths No. 1 well, NW¼ NW¼ sec. 9, T. 10 N., R. 16 W., Muskegon Twp, Muskegon Co., where the sh. series is 530 ft. thick. This section includes blue sh., light- and dark-gray sh., and greenish-gray sh. [Detailed section given.]

Elm Branch shale.

Pennsylvanian: Eastern Kansas and southeastern Nebraska.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 85, 90, 97). [See under *Swope fm.*] Named by N. D. Newell.

J. M. Jewett, 1932 (pp. 99, 101, 103 of book cited above). *Elm Branch sh.* will be proposed by Newell to include strata overlying Sniabar ls. and underlying Middle Creek ls. Where these limiting lss. are present in Kans. the thickness ranges from about 5 to 12 ft. and it contains local beds of ls. less than 1 ft. thick. [Derivation of name not stated.]

W. A. VerWiebe and W. R. Vickery also used *Elm Branch sh.* (on p. 117 of book cited above) for beds underlying Middle Creek ls. and overlying Sniabar ls.; as did R. C. Moore and G. E. Condra in their Oct. 1932 revised classification of Penn. of Kans. and Nebr., and J. M. Jewett (Kans. Acad. Sci. Trans., vol. 36, 1933, p. 132).

G. E. Condra and J. E. Upp, 1933 (Nebr. Geol. Surv. Paper No. 4, p. 7). In Madison Co., Iowa, *Elm Branch sh.* underlies Middle Creek ls., overlies Sniabar ("Hertha") ls., and consists of (descending): (1) gray calc. sh., fossiliferous at top, 1 ft. 10 in.; (2) ls.-mudstone, dark gray, probably not persistent, 1+ ft.; (3) gray argill. sh., 4 ft.; (4) ls.-mudstone, dark gray, uneven, 1 ft. 3 in.; (5) gray sh. with poorly defined reddish subzone near base, 6± ft. [Derivation of name not stated.]

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, p. 19), called the sh. underlying Middle Creek ls. and overlying Hertha (Sniabar) ls. the *Ladore sh.*, and apparently discarded *Elm Branch sh.*

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 82), formally discarded †*Elm Branch sh.*

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Elm Creek limestone member (of Admiral formation).

Permian: Central and central northern Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 421, 424). *Elm Creek bed.*—Mostly bluish-gray ls., with some yellowish, friable, dark shaly, and highly fossiliferous ls., and some marly clay. Thickness 25 to 150 ft. Memb. of Albany div. Overlies Coleman bed and underlies bed No. 8 (50 to 75 ft. of clay).

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, pp. 192–198 and charts). *Elm Creek ls.*, 20 to 50 ft. thick, is top memb. of Admiral fm. (basal fm. of Wichita group). Overlies Coleman clay and underlies Belle Plains fm., the basal bed of which is bed No. 8 of Drake.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 170, 172, 173). *Elm Creek ls.*, 20 to 50 ft. thick, is top memb. of Admiral fm., and a prominent escarpment-forming ls.

Named for Elm Creek, Brown Co.

Elm Creek limestone. (In Canyon group.)

Pennsylvanian: Central northern Texas (Wise County).

E. Böse, 1918 (Univ. Tex. Bull. 1758, p. 18). *Elm Creek ls.*—Light-gray ls. in moderately thick beds, with an irregular surface. Thickness 8 ft. We find it in middle part of Elm Creek, Wise Co. Farther W. it is well exposed in lower part of Indian Creek and upper part of Big Creek, and to S. it forms an extensive plain slanting NW. to W. of Jack Co. line. Contains fossils. Is overlain by 20 ft. of gray shales with rare fossils and underlain by 40± ft. of gray shales with intercalated sss. Lies 140± ft. higher than Devils Den ls. Probably belongs to Canyon div.

Elm Creek limestone. (In Cherokee shale.)

Pennsylvanian: Northeastern Oklahoma (Ottawa County).

S. Weidman, 1932 (Okla. Geol. Surv. Bull. 56, pp. 25–26). *"Elm Creek" ls.*—A 6- to 10-inch band of ls., containing abundant fossils, is present in several places within Cherokee fm. in NW. part of Ottawa Co. and adjoining area in Kans. It occurs along Elm Creek, S. of the road, in NW¼ SE¼ sec. 10, T. 28 N., R. 22 E.; along Fourmile Creek in central part of sec. 30, T. 29 N., R. 22 E., and along E. bank of Neosho River in E. part of sec. 15, T. 29 N., R. 21 E. Also on S. slope of a hill in W. part sec. 15, T. 35 S., R. 3 E. (Kans.), a short distance N. of Kans. State line. Exact horizon of the ls. could not be definitely determined, but where developed it probably occurs 10 to 20 ft. below Bluejacket ss.; but it was not found in sections where the Bluejacket is known to occur. It is such a thin bed that it may not have been developed except in a few places, and it is possible the above occurrences do not represent same horizon.

Elmdale shale (Kansas). } (In Wabaunsee group.)
Elmdale formation (Oklahoma). }

Pennsylvanian: Eastern Kansas, southeastern Nebraska, and central northern and central Oklahoma.

J. W. Beede, 1902 (Kans. Univ. Sci. Bull., vol. 1, p. 178). *Elmdale fm.* proposed in unpublished mss. by C. S. Prosser and J. W. Beede. Consists of shales with occasional thin lss.; 111 to 118 ft. thick; containing many fossils in lower part. Underlies Neva ls. and overlies ls. which is probably = Americus ls.

C. S. Prosser, 1902 (Jour. Geol., vol. 10, p. 708). *Elmdale fm.*—Yellowish to bluish shales, with thin beds of alternating ls. including 2 or 3 thicker ones. Thickness 130 ft. Underlies Neva ls. and overlies Americus ls.

L. C. Wooster, 1905 (The Carbf. rock system of eastern Kans.). *Elmdale beds*, 150 ft. thick, overlie Americus ls. and shales and underlie Crusher Hill alternating shales and lss. They include a friable Fusulina ls. 24 ft. above base; the Neva and Cottonwood lss. and intervening beds; and, at top, 12 ft. of sh.

A. J. Smith, 1905 (Kans. Acad. Sci. Trans., vol. 19, pp. 150–154). *Elmdale fm.* underlies Neva ls. and overlies Americus ls. [This definition of Elmdale was followed for many years.]

N. W. Bass, 1929 (Kans. Geol. Surv. Bull. 12, pp. 38, 52). As defined by Prosser and subsequently used in Kans., the *Elmdale sh.* included a series of beds of sh. and ls. above Americus ls. and below Neva ls., with a total thickness of 130 ft. The strata btw. same limiting beds are but little less than 130 ft. thick in Cowley Co., Kans., but lower third of this thickness combined with Americus (?) ls. is herein called *Foraker ls., thus restricting Elmdale sh.* to strata btw. Foraker and Neva lss., having a total thickness of about 80 ft. The lowermost third of Elmdale fm. as thus defined is mostly sh. and is succeeded by 20 ft. of thin-bedded gray ls., of which the uppermost 2 to 3 ft. is deep buff and soft, the whole 20 ft. constituting the Red Eagle ls. memb.

R. C. Moore, 1929 (Kans. Geol. Surv. Bull. 12, p. 50, footnote). The section E. of Elmdale exhibits clearly all subdivisions of Elmdale sh. differentiated and named by Condra in Nebr. (Nebr. Geol. Surv. Bull. 1, 2d ser., p. 84, 1927), with Americus ls. at base and Neva ls. at top. The Foraker probably includes equivalents of Americus ls., Stine sh., Houchen Creek ls., Hughes Creek sh., and Long Creek ls. In view of known remarkable lateral persistence of minor strat. units from Nebr. to central Kans., it is likely detailed strat. work will afford basis for definite determination of relations of type Foraker to Americus and Elmdale.

See 1932 entry under *Admire sh.*, for later definitions of boundaries.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 50 and 251), dropped *Elmdale sh.* from his revised classification, treating its many subdivisions as fms. (See Kans. Nebr. chart compiled by M. G. Wilmarth, 1936.) The U. S. Geol. Survey has not yet had occasion to consider these innovations for its publications.

Named for exposures E. of Elmdale, Chase Co., Kans.

Elm Grove limestone member (of Washington formation).

Permian: Northern West Virginia (Panhandle) and southeastern Ohio.

G. P. Grimsley, 1907 (W. Va. Geol. Surv. Rept. Ohio, Brooke, and Hancock Counties, p. 68). *Elm Grove ls.*—Deep-blue or black ls., 2½ to 10 ft. thick. Underlies Waynesburg ss. and overlies Cassville plant sh. Exposed near Elm Grove and E. from that town, in Ohio Co., W. Va.

W. Stout, 1918 (Ohio Geol. Surv., 4th ser., Bull. 21). *Elm Grove ls.* is of fresh-water origin.

Elmo limestone member. (In Sumner group.)

Permian: Central Kansas (Dickinson County).

C. O. Dunbar, 1924 (Am. Jour. Sci., 5th, vol. 7, pp. 176, 178–208). *Elmo ls. memb.*—Chalky, light-gray, argill., thin-bedded ls., in layers ½ inch to 4 inches thick, containing fossil insects and land plants. It is the conspicuous calc. zone in a section dominantly made up of shales. Thickness 5½ ft. Overlain, on Insect Hill, by 9 ft. of light-gray sh. and harsh shaly ls., and underlain with sharp and irregular contact, by "stump bed," consisting of black sh. containing land plants and, at base, bone cgl. Occurs in midst of Wellington sh., probably 250 to 300 ft. above base. Named for occurrence about 3 mi. S. and ½ mi. E. of village of Elmo, Dickinson County, where it caps Insect Hill.

Elmont limestone. (In Wabaunsee group.)

Pennsylvanian: Eastern Kansas and southeastern Nebraska.

J. W. Beede, 1898 (Kans. Acad. Sci. Trans., vol. 15, p. 30). *Elmont ls.*—Very fossiliferous, white or gray argill. ls., 1 to 2 ft. thick, found on top of hills near Elmont [Shawnee Co.] and to N. Included in Upper Coal Measures of Shawnee Co. [From statement on p. 28 appears to underlie Willard sh. and overlie Auburn sh.]

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 66, 68, 71). Elmont ls. of Beede is one bed of the unit which Kirk may have meant to call Emporia ls. It is "Preston" ls. of Condra and Bengston. If Emporia is to be retained it should apply to ls. btw. Willard sh. and Auburn sh., and that definition is adopted in this rept. Emporia has priority over Beede's Elmont ls. [This discards *Elmont ls.*]

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 10). Preston ("Emporia") ls. fm. underlies Willard sh. fm., overlies Auburn sh. fm., and is divided into (descending): *Elmont ls.*, 2 to 5 ft. thick; Harveyville sh., 3 to 7 ft. thick; and Reading ls., 3± ft. thick.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 226). According to Beede's section *Elmont ls.* occurs btw. Auburn sh. below and Willard sh. above. It appears from study of type sections that the Elmont is="upper Emporia" of authors. In southern Kans. the Elmont is dense, hard, dark-blue ls. very like Reading ls., but it commonly bears much more closely spaced vertical joints and is typically a single massive bed that weathers light bluish. Is traced from Nebr. across Kans. to northern Okla. where it has been included in upper part of Stonebreaker ls. Thickness 1 to 15 ft.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Elm Point limestone.

Devonian: Manitoba.

E. M. Kindle, 1914 (Canada Geol. Surv. Summ. Rept. 1912, p. 251).

Elmtree slates.

Silurian: New Brunswick.

G. A. Young, 1911 (Canada Geol. Surv. Mem. 18, p. 43).

Elmwood beds.

Silurian: Central New York (Onondaga County).

B. Smith, 1929 (N. Y. State Mus. Bull. 281, pp. 26, 27–31). *Elmwood beds.*—Underlies, with sharp contact, Clark Reservation ls. and grades into underlying

Olney ls., all included in Manlius group. Is divided into (descending): (1) *Elmwood C*, upper water lime, consisting of 4± ft. of drab water lime usually very soft, barren in Onondaga Co.; (2) *Elmwood B*, bluish black ls., which disappears to W.; (3) *Elmwood C*, lower water lime, consisting of 6± ft. of drab water lime nearly or quite barren, sometimes hard in lower part, but chiefly fairly soft. Type section at Sweet's quarry, about ½ mi. NE. of Onondaga Hill and in belt btw. St. Agnes Cemetery and Elmwood Park.

B. Smith, 1935 (N. Y. State Mus. Bull. 300, p. 18). [See 1935 entry under *Manlius ls.*]

El Pasan series.

A term employed by C. R. Keyes to cover the Ord. lss. of western Tex. and southern N. Mex., which were formerly all included in El Paso ls., but which are now divided into Montoya ls. (above) and El Paso ls. restricted (below). He also applies the name to supposedly contemp. deposits in other States.

El Paso limestone.

Lower Ordovician: Western Texas and southern New Mexico.

G. B. Richardson, 1904 (Univ. Tex. Min. Surv. Bull. 9, p. 29). *El Paso ls.*—Mainly massive gray fossiliferous ls., locally aren. at base and containing throughout bands of chert irregularly distributed. Of variable hardness. Ranges in color from drab and buff, with locally reddish and bluish streaks, to prevailing gray. Thickness 1,200 ft. Comprises all of Ord. in Franklin Mtns. Underlies Sil. ls. In places overlies Camb. Bliss ss. and in other places rests on pre-Camb. rocks.

G. B. Richardson, 1908 (Am. Jour. Sci., 4th, vol. 25, pp. 476, 477–479), restricted *El Paso ls.* to lss. of Lower Ord. age, and named the lss. of Upper and Middle Ord. age the *Montoya ls.* He described El Paso ls. as thus restricted as gray, chiefly mag. ls., usually massive but locally thin-bedded; lower 100 ft. characteristically aren. and weathers brownish. Thickness 750 ft. in Van Horn quad. and 1,000 ft. in El Paso quad. Not sharply separated from Montoya ls. In El Paso quad. overlies Bliss ss. with apparent conformity, where that fm. is present; where it is absent the El Paso rests on pre-Camb. In Van Horn quad. it overlies Van Horn ss. (Camb.).

Of Beekmantown and Chazy age. May possibly include beds of Upper Camb. age.

Named for exposures in Franklin and Hueco Mtns, El Paso quad., Tex.

El Portal stage.

Pleistocene: Eastern California (Yosemite region).

F. E. Matthes, 1929 (Sci., n. s., vol. 70, pp. 75–76). Three stages of glaciation are recognized in Sierra Nevada; the youngest is properly correlated with Wisconsin stage; to the next older, which probably corresponds to Illinoian stage, the name *El Portal stage* is here applied; and to the oldest the name *Glacier Point stage* is here applied. The ice of El Portal stage was much more extensive than the ice of Wisconsin stage, reaching 10 mi. farther down Merced Canyon and terminating a short distance below El Portal, the entrance to Yosemite Park. Frontal moraines are lacking there, but the lateral moraines can readily be traced to vicinity of El Portal, and beyond that place begin the remnants of a long valley train of outwash material that must have extended from the front of the glacier. [See also F. E. Matthes, U. S. G. S. P. P. 160, 1930.]

El Reno formation.

Permian: Western Oklahoma.

C. M. Becker, 1929 (A. A. P. G. Bull., vol. 13, p. 955). *El Reno fm.* proposed for beds of Chickasha-Duncan time, to include all beds from top of Hennessey sh. to base of lower memb. of Whitehorse ss.

C. M. Becker, 1930 (A. A. P. G. Bull., vol. 14, pp. 37–56). At a conference of 10 geologists, who had detailed the areas in Wichita Mtns region here described, it was decided to suggest the name *El Reno fm.* to include the 575 to 650 ft. section (of Chickasha-Duncan ss.) from top of Hennessey sh. to base of Whitehorse ss. That the Chickasha-Duncan grades laterally into Dog Creek, Blaine, and Flower-Pot and has same time equiv. is now recognized by every field geologist who has detailed the entire region.

Probably named for El Reno, Canadian Co.

Elsinore metamorphic series.

Triassic: Southern California (Riverside County).

P. H. Dudley, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, p. 223). *Elsinore series*, large thickness of metamorphics in area btw. towns of Riverside and San Jacinto and Corona and Elsinore. Oldest rock in area.

P. H. Dudley, 1935 (Calif. Jour. Mines and Geol., vol. 31, No. 4, pp. 493-496). The name *Elsinore metamorphic series* has been chosen to include all metamorphic rocks in Perris-Elsinore area. Includes meta-sediments and meta-volcanics, ranging from coarsely crystalline gneisses and schists to slates, granulites, lss., banded cherts and altered andesitic volcanics. Thoroughly recrystallized. Color varies from dark brown to almost bluish black. Intruded by various plutonic bodies and by Temescal dacite porphyry. Are oldest rocks in Perris-Elsinore region. Uncon. overlain by Alberhill clays (Tert.). No fossils. Correlated, on lithology, with metamorphics of Santa Ana Range and Cuyamaca region. [On map assigned to Triassic.]

Elsinore sand.

A subsurface oil sand, of middle Mio. age, in North Dome of Kettleman Hills, southern Calif., where it is said to lie above Temblor fm. and in Monterey sh. (See H. V. Dodd and E. J. Kaplow, 1933, Calif. Div. Oil and Gas, Calif. Oil Fields, vol. 18, No. 4, pl. 1, where it is shown as lying at 1,875± ft. depth.)

†Elstone formation.

Eocene: Southern Texas (Medina County).

R. A. Liddle, 1921 (Univ. Tex. Bull. 1860, p. 75, map, and columnar section). *Elstone fm.*—Impure gray and yellow-gray, medium coarse-grained ls., moderately soft glauconitic ls.; argill. and aren.; fossiliferous. Thickness 30 to 40 ft. Lower fm. of Midway group in Medina Co. Underlies Squirrel Creek fm. and uncon. overlies Escondido fm. (Upper Cret.). Occurs in bed of Hondo River ¼ mi. above the bridge at Elstone.

G. H. Chadwick, 1929 (Geol. Soc. Am. Bull., vol. 40, p. 117). [See 1929 entry under *Squirrel Creek fm.*]

Julia Gardner (personal communication, July 1930). The so-called "Elstone fm." and "Squirrel Creek fm." are lithologic facies and do not maintain a uniform strat. position in the Midway.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 539, 550, 556). *Elstone ls. lentil* was named by Liddle. It is a white, hard, massive, fossiliferous ls. at top of Pisgah memb. of Kincaid fm. in southern Tex. Typically exposed near Elstone, Medina Co.

El Torre syenite.

Age (?): Mexico.

S. F. Emmons, 1910 (Econ. Geol., vol. 5, p. 324).

Elvins group.

Upper Cambrian: Southeastern Missouri.

E. O. Ulrich and H. F. Bain, 1905 (U. S. G. S. Bull. 260, p. 234, and Bull. 267, pp. 12, 17, 23-26). *Elvins fm.*—Shales, shaly lss., and more or less earthy dolomites, 0 to 120 ft. thick, intervening btw. shaly top of underlying Bonneterre ls. and cherty lss. of Potosi group above. In vicinity of Elvins and Flat Rock base of Elvins is marked by zone, 6 to 10 ft. thick, consisting mainly of indurated platy sh., at bottom and top of which is a layer, a few inches thick, largely made up of lenticular pebbles, usually arranged edgewise, in subcrystalline limy matrix, and btw. the layers one or more smaller lenses of cgl. This "cgl. zone" was included in the Potosi by Nason, which writers believe to have been a mistake, and prefer to make it the lower and greater part of a distinct fm. for which the name *Elvins fm.* is proposed. The Elvins is=basal part of Potosi ls. and=Potosi slates and cgls. of Nason. It rests uncon. on Bonneterre ls., the most appropriate and probably the only strictly available designation for the ls. beneath the cgl. of Elvins fm. Contact with overlying Potosi [restricted] is at least locally uncon. In N. part of St. Francois Co. drill holes frequently pass through 160 to 250 ft. of shales and chertless ls., thus indicating a greater thickness for the fm. than is found in section measured at Elvins. However, it is at present not possible to say how much of these shaly beds underlies the cgl. layers and thus belong to Bonneterre fm.

E. R. Buckley, 1907 (Mo. Bur. Geol. and Mines vol. 10, 2d ser., *separate*), in a table, divided Elvins fm. into (descending) Doe Run, Derby, and Davis, but did not define the subdivisions.

E. R. Buckley, 1909 (Mo. Bur. Geol. and Mines vol. 9, pt. 1), divided *Elvins fm. of Ulrich* into (descending) Doe Run, Derby, and Davis fms., and restricted Potosi fm. to overlying 300 ft. of siliceous cherty and drusy dol.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pp. 623, 629). Bonneterre dol. is followed, *apparently without break*, by *Elvins fm.*, which begins with a sh. and ends with an earthy mag. ls. There is an important uncon. btw. Elvins fm. and overlying Potosi dol.

See also under *Bonneterre dol.* and *Davis fm.* This name is now used as a group name, to include Doe Run dol., Derby dol., and Davis fm.

Named for exposures at Elvins, St. Francois Co.

Elwren sandstone. (In Chester group.)

Mississippian: Southwestern Indiana and northern Kentucky.

C. A. Malott, 1919 (Ind. Univ. Studies, vol. 6, No. 40, pp. 7–20). *Elwren ss.*—One or more members of ss. and frequently considerable thicknesses of sh. In region of "American Bottoms" it consists below of a ss. from a few ft. up to 30 ft. thick, and above of a gray-blue sh. with a maroon streak extending up to overlying Beech Creek ls. Rests on Reelsville ls. Named for exposures in vicinity of Elwren, Monroe Co., Ind., in cuts of Illinois Central Ry. To N. and E. of area mapped the Elwren ss. has unusual thickness and occupies position of several of the lower units which had been eroded away previous to its deposition.

Ely greenstone.

Pre-Cambrian (Keewatin): Northeastern Minnesota (Vermilion district).

C. R. Van Hise and J. M. Clements, 1901 (U. S. G. S. 21st Ann. Rept., pt. 3, pp. 401–409, map). *Ely greenstone.*—An ellipsoidally parted basic igneous and largely volcanic rock. Basal fm. of Vermilion series. Overlain by Soudan fm. Typical exposures are under and adjacent to town of Ely.

Ely limestone.

Pennsylvanian: Eastern Nevada (Ely region).

A. C. Lawson, 1906 (Univ. Calif. Pub., Bull. Dept. Geol., vol. 4, No. 14, p. 295). *Ely ls.*—Regularly stratified, thick-bedded, more or less cherty ls., 1,500 ft. thick, underlying Arcturus shaly ls. Basal Carbf. fm. in Robinson mining dist. [Ely quad.]. Fossils. Overlies White Pine sh., of supposed Dev. age.

A. C. Spencer, 1917 (U. S. G. S. P. P. 96, pp. 26, 27, map). *Ely ls.* is herein given a considerably greater thickness than that assigned to it by Lawson. This arises from discovery that "Ruth" ls. as mapped by him lies much lower in section than he supposed, and in fact is same as Ely ls. The discovery of abundant fossils in overlying Arcturus ls. has made it possible to outline distribution of the fm., and here again the geol. map is different from Lawson's. The Ely is fully 2,000 ft. thick and perhaps 2,500 ft. It consists of gray or bluish dense ls. in well-defined massive beds from a few ft. to nearly 50 ft. thick. The massive beds are separated by partings of shaly ls. or by mere seams. Chert nodules are prominent feature of certain of the lss. Locally there is, S. of Lane, a 30-foot bed of gray clay sh. 200± ft. above base. Fossils (Penn.) listed. The fm. covers a greater area in Ely quad. than any other fm.

†Elysian moraine.

Pleistocene (Wisconsin stage): Southeastern Minnesota.

Name applied in early Minn. repts to morainal deposits which F. Leverett (U. S. G. S. P. P. 161, 1932) considers to be "only a spur formed in a recess in the ice harbor of the Gary moraine." Named for occurrence at Elysian, LeSueur Co.

Ely Springs dolomite.

Upper Ordovician: Eastern Nevada (Pioche region).

L. G. Westgate and A. Knopf, 1932 (U. S. G. S. P. P. 171). *Ely Springs dol.*—Dol. or dolomitic ls., usually dark-gray dol. weathering smoky brown, in beds of variable thickness up to 5 ft. Some beds are laminated. Is cherty at a number of levels. In upper part are some thick beds of gray dol. Total thickness 675 ft. Fossils (listed) are Upper Ord., approx. of Richmond age, according to E. Kirk. Overlies, apparently conformably, Eureka qtzite, and is conformably overlain by dol. carrying Sil. (Niagaran) fossils, according to E. Kirk. Named for exposures in Ely Springs Range.

†Embar formation.

†Embar group.

Permian and Lower Triassic: Western and central Wyoming.

N. H. Darton, June, 1906 (Geol. Owl Creek Mtns, Wyo.: 59th Cong., 1st sess., S. Doc. 219, p. 17). *Embar fm.*—A prominent series of ls. and chert beds lying btw. Tensleep ss. (below) and Chugwater red beds (above). Thickness 200 to 250 ft. Consists of (descending): (1) Yellowish sss. and cherty beds [in 1 place mentions a ls.], 100 to 200 ft.; (2) ls., 30 to 50 ft., "constitutes greater part of upper memb. of fm. throughout its course," [but further along is statement this ls. is overlain by 100 to 200 ft. of sss., etc.]; (3) cherty sh., 100 ft. or more; (4) ls. and sh. alternating, 25 ft. or more.

N. H. Darton, Nov. 17, 1906 (U. S. G. S. P. P. 51, p. 35), stated that *Embar fm.* was named for Embar post office on Owl Creek, a short distance S. of which the fm. is extensively developed.

D. D. Condit, Dec. 4, 1916 (U. S. G. S. P. P. 98, pp. 263–270), divided Embar fm. of Darton in Dinwoody Canyon, Wind River Mtns, into 2 fms., the names for which were selected by E. Blackwelder, namely, Dinwoody fm. (Triassic), new name, and Park City fm. (Perm. and Penn.), the latter beds being identified by Blackwelder (U. S. G. S. Bull. 470, 1911, pp. 452–481) with typical Park City fm. of Utah. He reported the type Dinwoody (200 ft. of pale-green to white clay and shaly ls., weathering brown and containing pelecypod shells) as overlain by 150± ft. of typical Chugwater redbeds, and both the Dinwoody and Park City as grading eastward into the much thicker deposit of Chugwater redbeds of Bighorn Mtns. In some subsequent repts *Embar group* was used to include Dinwoody and Park City fms., the term *Embar* being in common use among oil geologists and drillers. Later work proved that the beds that had been called Park City fm. in western Wyo., are, in fact, the same as Phosphoria fm. and equiv. to only upper part of Park City fm. of Utah, and for several years the equiv. of Embar fm. of Darton was divided into Dinwoody fm. and Phosphoria fm.

In 1934 (A. A. P. G. Bull., vol. 18, No. 12, pp. 1670–1671) H. D. Thomas abandoned Embar fm., as it "has been superseded by Phosphoria and Dinwoody;" and the U. S. Geol. Survey now considers *Embar* discarded as the name of a geologic unit.

Embarrass granite.

Pre-Cambrian (post-Keweenawan): Northeastern Minnesota (Mesabi district).

C. K. Leith, 1903 (U. S. G. S. Mon. 43, p. 186). *Embarrass granite.*—Pink hornblende granite, usually of coarse grain. Intrusive into Upper Huronian in E. part of Giants Range. Named for its lithologic similarity to granite exposed at Embarrass Station on Duluth & Iron Range R. R. just N. of Mesabi Range.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52). The intrusive *Embarrass granite,* of Keweenawan age, forms core of extreme E. end of Giants Range. The rest of Giants Range is formed by Giants Range granite, of lower or middle Huronian age. Is younger than Duluth gabbro and the diabase.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), assigned *Embarrass granite* to *Killarney revolution* (*post-Keweenawan pre-Cambrian*).

†Emerald series.

Upper or Middle Cambrian: Southeastern Arizona (Tombstone district).

W. P. Blake, 1902 (Tombstone and its mines). *Emerald series* includes the heavy qtzites of Ajax Mtn. [Appears to underlie his Luck-Sure series.]

†Emerald limestone.

Upper or Middle Cambrian: Southeastern Arizona (Tombstone district).

J. A. Church, 1903 (Am. Inst. Min. Engrs. Trans., vol. 33, pp. 3–37). *Emerald ls.*—Thin lss. interleaved with finer shales. At some localities it is made up of thicker and purer lss. with thicker beds of qtzite. Thickness 420 ft. Underlies Lucky Cuss ls. and overlies Ajax qtzite.

Emerald dolomite member (of Ajax limestone).

Lower Ordovician: Central northern Utah (Tintic district).

G. F. Loughlin, 1919 (U. S. G. S. P. P. 107). *Emerald dol. memb.*—Cream-white, almost pure dol., for most part fine-grained but containing small patches and veinlets of coarser grain. Thickness 30 to 40 ft. Lies 90± ft. above base of Ajax ls. Named for Emerald mine. Continuously exposed from Mammoth to Eureka.

Emery sandstone member (of Mancos shale).

Upper Cretaceous: Central eastern Utah (Wasatch Plateau and Book Cliffs).

E. M. Spieker and J. B. Reeside, Jr., 1925 (Geol. Soc. Am. Bull., vol. 36, p. 439). *Emery ss. memb.*—Brown ss., 0 to 800 ft. thick, lying 600 ft. below top of Mancos sh. at S. end of Wasatch Plateau and 1,100 ft. below top to N. of Emery. Named for exposures SW. of town of Emery.

Emigrant formation.

Upper and Middle (?) Cambrian: Southwestern Nevada.

H. W. Turner, 1902 (Am. Geol., vol. 29, pp. 261–272). *Emigrant fm.*—Thin-bedded lss. and reddish slates with some layers of black chert. Thickness not stated. Conformably underlies Palmetto fm. and uncon. overlies Silver Peak fm. Finely developed to S. of Emigrant Pass, in N. part of Silver Peak Range, Esmeralda Co.

Emigration formation.

Lower Triassic: Central northern Utah (central Wasatch Mountains).

A. A. L. Mathews, 1931 (Oberlin Coll. Lab. Bull., n. s., No. 1). *Emigration fm.*—Chiefly light-colored thin-bedded platy friable calc. sss. with some beds of light-blue to olive-drab sandy lss.; at or near base is a dark-blue thick-bedded hard, very resistant ls. that weathers very light gray or dirty white, which forms cliffs as high as 100 ft. Thickness 1,000+ ft. Is upper part of Thaynes ls. Underlies (conformably) Ankareh fm. and conformably overlies Pinecrest fm. (lower part of Thaynes ls.). Named for Emigration Creek, E. of Salt Lake City, which it cuts across N. and NE. of Pinecrest Hotel.

Emily member (of Crow Wing formation).

Huronian (upper): Central Minnesota (Crow Wing, Aitkin, and Cass Counties).

C. Zapffe, 1930 (Lake Superior Min. Inst. Proc., vol. 28, pp. 101–106). *Emily memb.*—Lower memb. of Crow Wing fm. Underlies Cuyuna memb. of the Crow Wing and conformably overlies Aitkin fm. Consists of some green but largely dark-colored slaty rocks, probably few if any volcanics, and many scattering lenses of iron-bearing rocks, which are only slightly magnetic or nonmagnetic. Black graphitic slates are abundant in lower part. Green slates and green schistose rocks are more and more abundant as one approaches the upper horizons of Emily memb. It is convenient to consider lower part of the Crow Wing as a separate memb. and it is called *Emily*. Is distributed along W. and S. borders of Aitkin fm. and can be traced through middle-west part of Aitkin Co., then NW. through NE. part of Crow Wing Co., and into Cass Co. Named for occurrence at village of Emily, Crow Wing Co.

See also under *Cuyuna memb.*

Eminence dolomite.

Upper Cambrian: Southeastern and central (?) Missouri.

E. R. Buckley, 1908 (Am. Min. Cong. Rept., Proc. 10th Ann. sess., p. 286), gave, in table of Mo. fms., the following downward succession: Roubidoux; Gasconade; uncon.; Proctor; *Eminence;* Potosi; uncon.; Elvins (with Doe Run at top).

E. R. Buckley, 1909 (Mo. Bur. Geol. and Mines vol. 9, pt. 1, p. 58). In SE. part of State Dr. E. O. Ulrich has recognized above Potosi fm. a cherty memb. which he has named [unpublished] *Eminence fm.* Writer is unfamiliar with this fm. It does not occur in southern, western, and eastern parts of Ozark region, which have been the special fields of study of writer.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27, pp. 629–633). *Eminence chert.*—Very cherty dol. that rests, apparently uncon., on the Potosi or overlaps that fm. and then usually comes in contact with pre-Cámb. porphyry. Above it is limited by base of Proctor dol. Thickness in Shannon Co. not less than 200 ft. Widely distributed in Mo. Well displayed in valleys of Carter and Reynolds Counties. Also comes to surface in some of deep valleys near the Osage, in N. part of Camden and S. part of Morgan Counties.

Wallace Lee, 1914, suggested *Eminence fm.* may include Proctor fm. (See 1914 entry under *Proctor dol.*)

H. A. Buehler, 1917 (Am. Inst. Min. Engrs. Bull. 130, pp. 1699–1718). *Eminence,* 150 ft. thick, underlies Proctor and overlies Potosi. [Same definition given by C. L. Dake, 1918 (Mo. Bur. Geol. and Mines vol. 15, 2d ser.).]

E. B. Branson, 1918 (Univ. Mo. Bull., vol. 19, No. 15). *Eminence fm.,* 0 to 300 ft. thick, consists mainly of compact medium- to coarse-grained, sometimes oolitic cherty dol.; chert mostly light and porous, but some layers are white and dense. Occurs in SE. part of State, on E. flank of Ozarks. Uncon. underlies Gasconade fm. and overlies Potosi fm. Further investigation may show that Eminence is same as Proctor fm., 0 to 60 ft. thick, of W. flank of Ozarks.

M. E. Wilson, 1922 (Mo. Bur. Geol. and Mines vol. 16, 2d ser.). *Eminence fm.*—Very cherty dol., few ft. to 200± ft. Uncon. underlies Proctor fm. and uncon. overlies Potosi dol. Typically exposed in Shannon, Carter, Reynolds, and parts of Jefferson, Franklin, Washington, and Ste. Genevieve Counties, and doubtfully present in Camden and Morgan Counties, but thus far not identified in other parts of State.

Named for exposures at Eminence, Shannon Co.

Emmet moraine.

Pleistocene (Wisconsin stage): Southeastern Michigan. Shown on moraine map (fig. 7) in U. S. G. S. Detroit folio (No. 205), p. 9, also on moraine map (pl. 32) in U. S. G. S. Mon. 53. Named for Emmet, St. Clair Co.

Emmett formation.

Pleistocene: Southwestern Idaho (Gem County).

V. R. D. Kirkham, 1928 (Idaho Bur. Mines and Geol. Pam. 29, p. 1). Several hundred ft. of almost unconsolidated but distinctly stratified sands and clays which are tentatively called *Emmett fm.,* and which have their origin in deltas, fans, and alluvial flood plains of Pleist. age. [Derivation of name not stated. May be from town of Emmett, Gem Co.]

V. R. D. Kirkham, 1931 (Jour. Geol., vol. 39, No. 3, p. 198). *Emmett* was first proposed as a term to include part of what was originally called *Idaho fm.*

Emmitsburg facies.

Upper Triassic: Western Maryland.

G. E. Dorsey, 1919 (Geol. Soc. Am. Bull., vol. 30, pp. 155–156). *Emmitsburg facies.*—Westernmost facies of Newark system in Md. Predominantly soft red to purple sh. weathering into cubes. In places micaceous.

Probably named for occurrence at or near Emmitsburg or Emmitsburg Junction, Frederick Co.

Emmons Peak quartzite.

Pre-Cambrian: Northeastern Utah and northwestern Colorado.

H. E. Wood, 2d, 1934 (Bull. Am. Mus. Nat. Hist., vol. 67, p. 244). *Emmons Peak qtzite* proposed to replace preoccupied name "Uinta qtzite" of Powell, from peak of that name, which is an appropriate term geographically and geologically, since it is a high peak carved in that fm., as well as sentimentally, since it bears the name of an original student of the fm. [Emmons Peak is shown on King's 40th Par. Surv. map, at 40°42′ N. lat. and 110°18′ W. long., and with 13,694 ft. elev., within Uinta Mtns.]

†*Emory sandstone.*

Pennsylvanian: Southeastern Tennessee.

J. M. Safford and J. B. Killebrew, 1900 (Elements of geol. of Tenn., p. 153). *Emory ss.*—Great ss., forming top stratum of Tracy City Measures in water gaps of Big Emory River at Harriman, Roane Co.

Same as Rockcastle ss., older name.

Emperador limestone.

Miocene: Panama Canal Zone.

D. F. MacDonald, 1913 (Geol. Soc. Am. Bull., vol. 24, p. 709).

Empire formation.

Miocene: Southwestern Oregon (Port Orford and Coos Bay quadrangles and neighboring regions).

J. S. Diller, 1896 (U. S. G. S. 17th Ann. Rept., pt. 1, p. 475). The Mio. rocks of Coos Bay are well exposed on beach 3 mi. SW. of Empire City, btw. Pigeon Point and Fossil Point. They are so well characterized at this locality by their fossil contents and position with reference to adjoining rocks that we designate them *Empire beds*. [Fossils listed.] Assigned to Mio. on Dall's identification of fossils. Uncon. overlain by Plio. marine beds at "Fossil Rock." Uncon. underlain by Arago beds.

J. S. Diller, 1901 (U. S. G. S. Coos Bay folio, No. 73). *Empire fm.* consists of massive sss., white sh. of Mio. age similar to Monterey sh. of Calif., and, below the white sh., darker sh. Contains marine Mio. fossils. Uncon. underlies Coos cgl. and uncon. overlies Arago fm.

J. S. Diller, 1902 (U. S. G. S. Bull. 196, pp. 30–31). At Cape Blanco [Port Orford quad.] *Empire beds* (*Cape Blanco beds*) are 600 ft. thick, and consist of (descending): Argill. sands with some calc. nodules, 75 ft.; cgl., 25 ft.; light-gray sand beds, 50 ft.; yellowish ss., 30 ft.; tuff, 20 ft.; yellowish ss., 400 ft. Uncon. underlie Elk River beds (Pleist.) and uncon. overlie Cret. (?) crushed gray ss.

H. V. Howe, 1922 (Univ. Calif. Pub. Bull. Dept. Geol. Sci., vol. 14, No. 3, pp. 86–91), gave thickness of Empire fm. at South Slough, Coos Bay, as 1,100± ft. and assigned the fm. to lower Plio.

L. G. Hertlein and C. H. Crickmay, 1925 (Am. Phil. Soc. Proc., vol. 64, No. 2, pp. 264–270), assigned Empire fm. to middle Mio., after reviewing fossils and Howe's evidence.

H. G. Schenck, 1928 (Univ. Calif. Pub. Bull. Dept. Geol. Sci., vol. 18, No. 1, opp. p. 4). Empire fm. is Plio. according to B. L. Clark and H. V. Howe, and Mio. according to Dall and others.

Empire shale.

Pre-Cambrian (Belt series): Western central Montana.

C. D. Walcott, 1899 (Geol. Soc. Am. Bull., vol. 10, pp. 199–215). *Empire shales.*—Greenish-gray, massively bedded banded siliceous shales, 600 ft. thick. Underlie Helena ls. and overlie Spokane shales. Type localities are on ridge N. of Empire [2 mi. W. of Marysville] and in canyon walls just below Marysville.

Empire limestone.

Oligocene: Panama.

E. Howe, 1908 (Am. Jour. Sci., 4th, vol. 26, p. 224).

Empire Gulch rhyolite.

Tertiary: Leadville region, Colorado.

W. Cross, 1886 (U. S. G. S. Mon. 12, p. 351). White, very fine-grained, but with many clear and sharp quartz crystals. Named for occurrence on S. side of Empire Gulch, S. of Leadville.

Emporia limestone. (In Wabaunsee group.)

Pennsylvanian: Eastern Kansas, southeastern Nebraska, northwestern Missouri, and southwestern Iowa.

M. Z. Kirk, 1896 (Kans. Univ. Geol. Surv. vol. 1, pp. 72–85). *Emporia ls.*—Ls., quarried at Emporia and to NE. and disappearing under river near Emporia water works. Separated from overlying Americus ls. by an extensive bed of sh. and from underlying Wyckoff ls. by a bed of sh. 40 to 50 ft. thick.

The definition of Emporia ls. as overlain by Admire sh. and underlain by Willard sh. was followed by Kans. Geol. Survey and U. S. Geol. Survey for many years.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 61–91). Kans. Geol. Surv. applies *Emporia ls.* to beds underlying Admire sh. and overlying Willard sh. The Willard sh. and so-called Emporia ls. have been difficult to work out. The beds called by these names in Kans. need redefining in order to establish a basis for correlation in Nebr. I have studied the exposures in vicinity of Wyckoff, Chicago Mound, and Emporia. *Emporia,* if it is retained, should apply to No. 3 of the Nemaha beds of SE. Nebr., because Kirk seems to have meant to apply it to this unit, and because Haworth and Moore have, in effect, defined it as such. This name has priority over Beede's Elmont ls: This unit (No. 3) underlies Willard sh. and overlies Auburn sh., top bed of Humphrey sh. memb. of Wabaunsee fm. [This definition of Emporia ls. was adopted by R. C. Moore in 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3) and by Moore and Condra in their Oct. 1932 revised chart of Penn. rocks of Kans. In these 1932 repts Admire sh. was restricted to uppermost part of Admire sh. of previous repts.]

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 10), discarded *Emporia* for *Preston.* He stated: *Preston ("Emporia") ls. fm.*, 9 to 11 ft. thick, underlies Willard sh. fm., overlies Auburn sh. fm., and includes (descending): Elmont ls., 2 to 5 ft. thick; Harveyville sh., 3 to 7 ft. thick; and Reading ls., 3± ft. thick.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 223). It is impossible to determine to which of 3 or more lss. exposed near Emporia Kirk intended to apply this name. Judging from localities cited by him it appears that he considered as identical beds that are actually 75 ft. or more apart. [On p. 226:] It appears from study of type sections that the Elmont is="upper Emporia" of authors. [Moore discarded *Emporia ls.* from his revised classification as published in this bull. See p. 49, where he shows it as replaced by (descending) Elmont ls., Harveyville sh., and Reading ls., which he treated as fms.]

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

†Emporia blue limestone.

Pennsylvanian: Northeastern Kansas.

A. J. Smith, 1903 (Kans. Acad. Sci. Trans., vol. 18, p. 100). *Emporia blue ls.*—Hard blue ls., 3 ft. thick, with 6-inch layer at top that makes a good flagstone extensively used in Emporia. In Lyon Co. separated from underlying Burlingame ls. by 44½ ft. of shales with two thin lss. [Humphrey sh. of A. J. Smith 1905 rept] and separated from overlying Emporia ls. by about 64 ft. of shales with some thin lss. and one coal bed [Olpe sh. restricted of A. J. Smith 1905 rept].

Preoccupied. Discarded by A. J. Smith in 1905 (Kans. Acad. Sci. Trans., vol. 19, pp. 150–154) and replaced by *Reading blue ls.*

Named for Emporia, Lyon Co.

†Emporia reservoir shales.

Pennsylvanian: Eastern Kansas.

L. C. Wooster, 1905 (The Carbf. rock system of eastern Kans.). *Emporia reservoir shales.*—Aren. shales, 77 ft. thick, carrying 6-inch coal bed at top. Overlie Emporia buff lss. and underlie Admire shales and lss. [In same publication Wooster used *Emporia beds* to cover all rocks btw. top of Burlingame ls. and top of his Emporia reservoir shales, making three different uses of *Emporia.*]

Preoccupied. Lower part of Admire sh., as *Admire* was used for many years.

Probably named for Emporia.

Emrick sand.

A subsurface sand forming basal part of Ellis fm. (Upper Jurassic) in central northern Mont. (Great Falls-Conrad region). Named for man who drilled the well in Bannatyne oil field. Sometimes called "Ellis sand."

Encinas quartz porphyry.

Age (?): Mexico (Sonora).

N. L. Taliaferro, 1933 (Jour. Geol., vol. 41, No. 1, p. 33).

†Encrinal limestone.

A descriptive term—derived from presence of encrinites (fossil crinoids)—applied in early N. Y. repts to a ls. later named *Tichenor ls.;* also, according to Hartnagel (1912), to lss. at other horizons within Hamilton fm., and to Becraft ls.; also to Menteth ls. (See G. A. Cooper, 1930 entry under *Moscow sh. memb.*)

†Encrinital limestone.

A descriptive term applied in early repts on Mississippi Valley to *Burlington ls.* Derived from predominance of fossil crinoids. In some early repts the Keokuk ls. was included, and in others the name was restricted to lower memb. of the Burlington.

Endeavor granite.

Name applied by C. C. Wang (Geol. Soc. China Bull., vol. 11, No. 4, pp. 426–428, 1932) to a pre-Camb. granite in Wis. (area not stated).

Endee shale.

Triassic (?): Northeastern New Mexico.

C. R. Keyes, 1905 (Am. Jour. Sci., 4th, vol. 20, p. 424). *Endee shales*, 300 ft. thick, underlie Amarillo sss., uncon. overlie Cimarron shales (=Moencopie shales), and are correlated with Shinarump shales of western N. Mex. [Derivation of name not given.]

Endicott sand series.

Series of subsurface Penn. sss. and interbedded strata in central northern Okla. corresponding to upper part of Nelagoney fm. Thickness 30 to 200± ft.

Endicott diorite.

Devonian or Carboniferous: New Hampshire (Belknap Mountains). See 1936 entry (D. Modell) under *White Mtn magma series*. Exposed on Endicott Hill.

Enfield shale member (of Portage formation).

Upper Devonian: Southern central New York (Ithaca region).

H. S. Williams, 1906 (Sci. n. s., vol. 24, pp. 365–372). Nunda fm. [Portage fm. of U. S. Geol. Survey and N. Y. State Survey] of Ithaca region divided into (descending): *Enfield sh. memb.*, 550 to 800 ft.; Ithaca sh. memb., 80 to 300 ft.; Sherburne flagstone memb., 188 to 260 ft. The Enfield is overlain by Cayuta sh. memb. of Chemung fm. Typically exposed at town of Enfield [W. of Ithaca, Tompkins Co.].

The above definition was followed by W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369) and by G. H. Chadwick, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, p. 352).

Enfield facies subgroup.

Upper Devonian: Southern central New York (Ithaca region).

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, pt. 1, p. 201). *Enfield facies subgroup* (of Ithaca-Enfield facies group), divided into (descending) Van Etten memb., Grimes (?) ss. memb., and Hatch ss. memb. Overlies Ithaca facies sub-group and underlies Chautauquan series.

Engadine dolomite.

Silurian (Niagaran): Michigan (eastern part of Upper Peninsula).

R. A. Smith, 1916 (Mich. Geol. Surv. Pub. 21, p. 151). *Engadine dol.*—Very massive, hard, very crystalline dol., distinctly bluish or mottled and streaked with blue. Also characterized by numerous drusy cavities more or less completely filled with crystals of dol. or pearl spar. Thickness 54 to 95 ft. Top memb. of "Niagara" in Mich. Overlies Manistique series. Named for exposures at and around Engadine, Mackinac Co.

G. M. Ehlers, 1920 (Mich. Acad. Sci. 21st Rept., pp. 87–90), stated that *Engadine fm.* contains strata of Guelph and of pre-Guelph age, and suggests that *Racine*, the older name, be used to replace *Engadine*.

A. F. Foerste, 1924 (Univ. Mich. Contr. Mus. Geol., vol. 2), applied *Racine fm.* to fm. overlying Manistique fm.

W. A. VerWiebe, 1928 (Mich. Acad. Sci., Arts, and Lett. Papers, vol. 8, p. 330), applied *Engadine fm.*, to beds overlying Manistique fm.

R. B. Newcombe, 1933 (Mich. Geol. Surv. Pub. 38, geol. ser. 32, pp. 34, 35, 37). *Engadine dol.*—Top div. of Niagaran in Mich. Underlies Salina fm. (but contact has not been seen in Mich.) and overlies Manistique fm. Is probably = lower part of Guelph of Ont. and N. Y., and is about = Lockport of N. Y. and Ont. and the Racine of Wis.

Engle coal group. (In Vermejo formation.)

Upper Cretaceous: Eastern Colorado (Elmoro region).

R. C. Hills, 1899 (U. S. G. S. Elmoro folio, No. 58), applied *Engle group* to 100 ft. of sh., shaly ss., and coal beds immediately overlying Trinidad ss. These beds are basal part of Vermejo fm. of present terminology. They were described as separated from overlying Sopris group by 35 to 40 ft. of sh.

Engle shale.

Ordovician (?): North-central Kansas.

J. S. Barwick, 1928 (A. A. P. G. Bull., vol. 12, No. 2, p. 184). *Engle sh.*—Unit No. 4 encountered in wells in Salina Basin. Not exposed. Light-colored fine-grained sh., generally of bluish-gray or greenish-gray cast; in places a small amount of dolomitic lime or fine-grained quartz sand silt. Thickness 60 to 100 ft. where overlain by Younkin fm. (unit No. 3). Overlies Urschel lime (unit No. 5). Lithology and position indicate it correlates approx. with Sylvan sh. of Okla. and Maquoketa sh. of Iowa and Mo. Named for Marland Oil Co.'s Engle No. 1 well, sec. 12, T. 14 S., R. 1 E., Dickinson Co., where it lies at 2,876 to 2,962 ft. depth.

Englevale channel sandstone.

Pennsylvanian: Southeastern Kansas (Crawford County).

W. G. Pierce and W. H. Courtier, 1935 (A. A. P. G. Bull., vol. 19, No. 7, pp. 1061–1064). *Englevale channel ss.*—Usually light-brown with reddish-brown specks, micaceous, somewhat massive and cross-bedded. Locally middle part may be darker and lower part slightly shaly. Thickness 0 to 50 ft. Areal distribution is linear, trending N.-NW. from Arma for 9 mi., to Crawford Co. line, the limit of field work. Is younger than Fort Scott ls., which it cuts, and may possibly be younger than lower part of Labette sh. So far as seen its upper limit is gradational into lower part of Labette sh., and its base cuts into Fort Scott ls. and in places rests on upper part of Cherokee sh. Best exposed in vicinity of Englevale, along N.-S. road on E. side of town and along E.-W. road ½ mi. N. of town.

Englewood limestone.

Mississippian (Kinderhook): Western South Dakota (Black Hills) and northeastern Wyoming.

N. H. Darton, 1901 (U. S. G. S. 21st Ann. Rept., pt. 4, p. 509). *Englewood ls.*—Pink slabby ls., 20 to 30 [25 to 60] ft. thick, underlying Pahasapa ls. and overlying Deadwood fm. (Camb.). Merges rapidly into Pahasapa ls., with occasionally a few ft. of impure buff ls. intervening. Name suggested by T. A. Jaggar, from Englewood, in northern Black Hills, where it is extensively exposed. In northern Black Hills a mass of buff ls. of Sil. age [Upper Ord. Whitewood ls.] intervenes btw. Englewood ls. and Deadwood fm.

English Head formation.

Ordovician: Anticosti Island.

C. Schuchert and W. H. Twenhofel, 1910 (Geol. Soc. Am. Bull., vol. 21, p. 695).

English River sandstone member (of Hannibal shale).

Mississippian: Southeastern Iowa and (?) central western Illinois (Pike County.)

H. F. Bain, 1895 (Am. Geol., vol. 15, p. 322). *English River grits.*—Fine-grained buff to white ss. or gritstone, 0 to 20 ft. thick, underlying Wassonville ls. and overlying Maple Mill sh.; all included in Kinderhook.

W. H. Schoewe, 1924 (Iowa Geol. Surv. vol. 29), defined *English River gritstone memb. of Kinderhook series* as separated from overlying Wassonville ls. memb. by an oolitic ls. ledge memb. 2 to 3 ft. thick.

R. C. Moore, 1928 (Mo. Bur. Geol. and Mines vol. 21, 2d ser., pp. 21, 22, 23, 49, 56–59). *English River ss. memb. of Hannibal fm.*—Massive fine-grained soft drab ss., weathering buff, with occasional thin intercalated layers of sh. Upper 2 ft. filled with casts of fossils, most abundant being *Chonopectus fischeri*. Has commonly been called *Chonopectus* ss. Thickness at Prospect Hill, Burlington, Des Moines Co., Iowa, 22½ ft. Older than McKerney ls. memb. of Hannibal fm. and younger than Maple Mill sh. memb. of Hannibal.

L. R. Laudon, 1931 (Iowa Geol. Surv., vol. 35, pp. 341–387+). *English River fm.* underlies (uncon.) Hampton fm. and overlies (conformably) Maple Mill fm. in SE. Iowa, all of which are in Kinderhook series.

R. C. Moore, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 245), assigned this ss. to Kinderhook.

Named for exposures along English River in Washington Co., Iowa.

Englishtown sand. (In Matawan group.)

Upper Cretaceous: New Jersey Coastal Plain.

H. B. Kümmel, 1907 (N. J. Geol. Surv. Pal., vol. 4, p. 17, footnote). The term *Columbus* as here used has been found to conflict with its prior use in Ohio for a Dev. fm., and in this rept the term *Englishtown sand* will be used instead, as the fm. is well developed near that place in Monmouth Co. [See under †*Columbus sand.*]

Enid formation.

Permian: Western Oklahoma and Kansas (?), and Panhandle of Texas.

C. N. Gould, 1905 (U. S. G. S. W. S. P. 148, pp. 39–44, map). *Enid fm.* includes all red beds from base of Perm. to lowermost gyp. ledge on E. slope of Gypsum Hills. Top of fm. is not a plane, since the gyp. beds which mark its uppermost limits are more or less lenticular when traced long distances. Is chiefly brick-red clay shales, with some interbedded ledges of red and whitish ss. Thickness 1,200 to 1,500 ft. Includes Harper, Salt Plain, Cedar Hills, and greater part of Flowerpot memb. of Cragin's first paper and Kingfisher and Glass Mtn fms. of his second paper. Underlies Blaine fm. and overlies Wellington fm.

F. Aurin, 1917 (Okla. Geol. Surv. Bull. 30, p. 24). It can readily be seen that *Enid fm.* is a color distinction and not a constant strat. unit. In some places it includes more than in others. It is a name applied to part of lower Perm. Red Beds, and does not include the nonred Perm. even though it is of same age as lower part of Enid.

C. N. Gould, 1925 (Okla. Geol. Surv. Bull. 35, p. 88). *Enid fm.* is exposed in all or parts of Murray, Garvin, Stephens, McClain, Cleveland, Oklahoma, Pottawatomie, Canadian, Logan, Lincoln, Kingfisher, Blaine, Major, Garfield, Noble, Payne, Kay, Grant, Woodward, Alfalfa, Harper, and Woods Counties. Recent work in SW. Okla. has led to subdivision of upper part of rocks of that area heretofore mapped as Enid into Chickasha and Duncan fms.; also to conclusion that lower part of typical Enid (Enid, Garfield Co.) is there represented by upper part of rocks mapped as Clear Fork and Wichita fms. on 1926 Okla. geol. map. Base of Enid is believed by Aurin and Clark to be top of Wellington fm. of Kans. There are several unsolved problems connected with relations of Enid. In SW. Okla. it includes equivalents of Chickasha, Duncan, Clear Fork, and possibly part of Wichita. In Kans. the equiv. fms. are Harper, Salt Plains, Cedar Hills, and a part at least of Flowerpot sh.

C. N. Gould, 1926 (Jour. Geol., vol. 34, No. 5, pp. 416–421). *Enid group.*—The Enid fm. as originally described included all Oklahoma Perm. red beds below base of Blaine gyp. It has been divided into following fms. (descending): Chickasha fm., Duncan ss., Hennessey sh., Garber ss., Wellington fm., and Stillwater fm.

The Enid and Double Mountain overlap each other, the Duncan and Chickasha being represented in both. *Enid* appears to have had little usage in recent years.

Named for Enid, Garfield Co., Okla.

†Enochkin formation.

Middle and Upper Jurassic: Alaska (Iniskin Bay).

T. W. Stanton and G. C. Martin, 1905 (Geol. Soc. Am. Bull., vol. 16, p. 397). *Enochkin fm.*—Shales and sss., with some cgl. beds, typically exposed on E. shore of Enochkin [Iniskin] Bay. Thickness 1,500 to 2,500 ft. Is Middle Jurassic. Overlies Lower Jurassic tuffs and sss. and underlies Naknek fm. (Upper Jurassic).

Later work resulted in dividing these rocks into 2 fms., Chinitna sh. (Upper Jurassic) and Tuxedni ss. (Middle Jurassic).

Ensenada shale.

Cretaceous: Puerto Rico.

G. J. Mitchell, 1922 (N. Y. Acad. Sci., Scientific survey of Porto Rico and Virgin Islands, vol. 1, pt. 3, p. 252).

†Enterprise green marl. (In Claiborne group.)

Eocene (middle): Southeastern Mississippi.

O. Meyer, 1885 (Am. Jour. Sci., 3d, vol. 30, p. 435). [*Enterprise* (?) used in Miss. column of table opp. *Claibornian*. No definition.]

E. N. Lowe, 1915 (Miss. Geol. Surv. Bull. 12, pp. 76–77). *Enterprise green marl.*—Light-gray to dark-green marl, the color determined by relative proportions of glauconite or greensand. Highly fossiliferous. Thickness 12 ft. Basal memb. of Lisbon fm.

Conflicts with Enterprise sh. (Perm., Kans.), the older name. The marl is now included in Winona sand, basal memb. of Lisbon fm. in Miss.

Named for exposures at town of Enterprise, Clarke Co.

Enterprise shale. (In Sumner group.)

Permian: Central Kansas, northern Oklahoma, and southeastern Nebraska.

J. W. Beede, 1909 (Kans. Acad. Sci. Trans., vol. 21, pt. 2, p. 253). *Enterprise shales.*—Shales, with some thin lss. near top; 44 ft. thick; overlying Luta ls. and underlying Herington ls. All included in Marion stage.

In 1927 †Marion fm. was abandoned by both Kans. Geol. Survey and U. S. Geol. Survey, and *Enterprise sh.* was elevated to rank of a fm. within Sumner group.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., p. 13), divided Enterprise sh. into 3 members (descending): Paddock sh., Krider ls., and Odell sh.

R. C. Moore, 1936 (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 12), discarded *Enterprise*, raised Odell sh. to rank of a fm., and combined Condra's Krider ls. and Paddock sh. with overlying Herington ls. into a newly named fm. (Nolans ls.). These changes have not yet been considered by U. S. Geol. Survey for its publications.

Named for Enterprise, Dickinson Co., Kans.

†Enterprise sandstone. (In Boggy shale.)

Pennsylvanian: Central eastern Oklahoma (Muskogee County).

S. W. Lowman, 1932 (Summaries and abstracts of technical papers presented before Tulsa Geological Society 1932, unpaged; paper dated Dec. 19, 1932). The Salt sand of Okmulgee underground is to be correlated with the massive ss. 300 ft. above base of the Boggy in Rattlesnake Mtn, just NW. of Warner [Muskogee Co.]. This has been called *Enterprise ss.* (a manuscript name), from a locality on N. side of McAlester basin. [The town of Enterprise is in Haskell Co.]

This name being preoccupied in several senses, and the ss. having been found, by tracing, to be same as Bluejacket ss., it was called *Bluejacket* by C. W. Wilson, Jr., in 1935 (A. A. P. G. Bull., vol. 19, No. 4, pp. 504–520). Wilson treated the Bluejacket as top memb. of Savanna ss., but it is now treated by U. S. Geol. Survey as basal memb. of Boggy sh., and *Enterprise ss.* has been discarded. (See C. H. Dane and T. A. Hendricks, A. A. P. G. Bull., vol. 20, No. 3, 1936, pp. 312–314.)

Entiat physiographic stage.

Pleistocene: Central Washington (Cascade Range).

B. Willis, 1903 (U. S. G. S. P. P. 19). *Entiat physiographic stage.*—Earlier Glacial epoch. Type loc., basin of the Entiat and foot spurs of Chelan Range.

Entrada sandstone. (In San Rafael group.)

Upper Jurassic: Southeastern, southern and northeastern Utah, northwestern New Mexico, and western and central Colorado to east side of Front Range.

J. Gilluly and J. B. Reeside, Jr., 1926 (U. S. G. S. Press Bull. 6064, March 30, 1926; name adopted at joint conference of J. Gilluly, J. B. Reeside, Jr., R. C. Moore, and

H. E. Gregory, from area specially studied by Messrs. Gilluly and Reeside). *Entrada ss.*—Thin-bedded red sh. and ss. at base; heavy, massive, red-brown, earthy ss. above, which weathers into rounded forms and steep cliffs. Thickness 265 to 844 ft. Conformably overlies Carmel fm. and uncon. underlies Curtis fm. Belongs to San Rafael group.

Named for strong development of fm. on Entrada Point, in N. part of San Rafael Swell.

For further details see U. S. G. S. P. P. 150, 1928 (by J. Gilluly and J. B. Reeside, Jr.), and U. S. G. S. P. P. 183, 1936 (by A. A. Baker, C. H. Dane, and J. B. Reeside, Jr.).

Enumclaw volcanic series.

Miocene (upper): Western Washington (Puget Sound region).

C. E. Weaver, 1916 (Wash. Geol. Surv. Bull. 13, p. 84). Along W. slopes of Cascade Mtns there are extensive deposits of andesitic lavas and interbedded tuffs and clays. The older Eocene deposits pass beneath these lavas along W. margin of foothills of the Cascades. Well exposed from Enumclaw to Cedar Lake, in [SW. part of] King Co., and name *Enumclaw volcanic series* is provisionally applied to them. They may be W. extension of Keechelus volcanic series. Rest uncon. on older qtzites, schists, and granodiorites (Snoqualmie granodiorite), also on Eocene and Olig. sediments in E. part of Puget Sound Basin. Assigned to upper Mio. Probably in part= Keechelus fm.

†Eobiotic era.

A part of Proterozoic era of U. S. Geol. Survey. For definition see U. S. G. S. Bull. 769, p. 27.

Eocene epoch (or series).

Oldest epoch (and the rocks) of the Tertiary period. For definition see U. S. G. S. Bull. 769, p. 54.

Eogene.

A term employed by European geologists to include the Oligocene and Eocene series of American geologists.

†Eolian limestone.

Ordovician and Cambrian: Southwestern Vermont (Bennington and Rutland Counties).

E. Hitchcock, 1861 (Rept. Geol. Vt., vol. 1, pp. 396–419). *Eolian ls.*—White and gray ls., both nonmagnesian and dolomites. Thickness 2,000+ ft. Includes some sparry ls., clay sl., talcose schist, talcose ls., etc. Same as Berkshire ls. and Stockbridge ls. of Mass. and Dorset ls. of Vt. (Elem. geol. of E. and C. H. Hitchcock, 1860). The name *Eolian ls.* is more appropriate for this fm. than *Stockbridge ls.*, because only a part of fm. is developed in that town, and that is in an inferior condition to this. Named for Mount Eolus (Dorset Mtn) [in Pawlet quad.], of which it composes greater part. [Gave a detailed section of beds on Dorset Mtn, in Dorset Twp, Bennington Co., SW. Vt.] May be Sil. or may be Dev.

E. Hitchcock, 1862 (Geol. Me., Prel. Rept., vol. 2, pp. 245–259), used Eolian ls. in Maine, and in same year (Maine Bd. Agric. 7th Ann. Rept.) he called the ls. in Maine *Taconic (Eolian) ls.* and *Stockbridge ls.*

C. H. Hitchcock, 1866, also 1867. [See 1866 entry under *Dorset ls.*]

J. E. Wolff, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 331–338). Eolian ls. of Vt. geol. repts includes Centre Rutland ls. and West Rutland ls. (which are of "Trenton-Chazy-Calciferous" age) and Rutland ls. (which is of Lower Camb. age).

T. N. Dale, 1893 (U. S. G. S. 13th Ann. Rept., pt. 2, pl. 97). In SW. Vt. at least 470 ft. of lower part of Stockbridge ls. is Camb.

T. N. Dale, 1894 (U. S. G. S. 14th Ann. Rept., pt. 2, pl. 67, pp. 533–543). Stockbridge ls. (=Eolian ls. of Hitchcock) is 1,000–1,400 ft. thick in Rutland-Danby Ridge-Clarendon, Vt., and includes Lower Sil. [Ord.], upper and middle Camb.(?), and 470 ft. of lower Camb. Overlies Vermont fm.

T. N. Dale, 1904 (Am. Jour. Sci., 4th, vol. 17, pp. 185–190). Stockbridge ls. is present in valleys in Rutland Co., Vt. Upper part is of Chazy and Trenton age; lower part is Camb.

H. M. Seely, 1910 (7th Rept. Vt. State Geol., pp. 257–313). "Eolian ls." of Hitchcock (type loc. of which was Dorset Mtn, at that time renamed *Mount Eolus*) includes beds of Trenton, Black River, Chazy, and Beekmantown age.

F. A. Burt, 1929 (16th Rept. Vt. State Geol., pp. 68–84). Stockbridge ls. of Bennington area, Vt., is 1,200± ft. thick, and consists of bluish crystalline lss. and dolomites; near bottom ls., schist, and qtzite layers are interbedded. Underlies Berkshire schist and overlies Vermont fm.

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), showed Stockbridge ls. of southern Vt. as containing beds of Chazy, Beekmantown, Tribes Hill, Little Falls, and Upper Camb. age.

Replaced by Stockbridge ls., which has many years priority and is the name now applied to this ls. in southern Vt.

Eolian limestone member (of Pueblo formation).

Pennsylvanian: Central northern Texas.

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, pp. 24, 31, 171–173, pl. 2, and table 2). *Eolian ls. memb.*—Blue or bluish-gray hard crystalline ls., weathering in large rectangular yellowish-brown blocks. Average thickness is but 1 ft., and it does not form a prominent or persistent escarpment. It may be= Stockwether ls. of Drake. Is separated from underlying Saddle Creek ls. by 50 to 60 ft. of sh. and from overlying Camp Colorado ls. by 75 to 125 ft. of sh.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 103). *Eolian ls.*, in Pueblo fm., named for exposures near Eolian, Stephens Co.

†Eo-lignitic.

A term applied by A. Heilprin, 1882 (Phila. Acad. Nat. Sci. Proc. 1881, pp. 158–159), to the pre-Claiborne Eocene (Wilcox and Midway) deposits of the eastern and southern coastal States.

Eolus granite.

Pre-Cambrian: Southwestern Colorado.

W. Cross and E. Howe, 1905 (U. S. G. S. Needle Mtns folio, No. 131). *Eolus granite.*—Coarse pink hornblende-biotite granite. Occupies about one-third of quad., and composes Mount Eolus. Intrudes Archean schists and Uncompahgre fm. (Algonkian), and is uncon. overlain by Ignacio qtzite [Upper Camb.].

The terms "Algonkian system" and "Archean system" were discarded by U. S. Geol. Survey in 1934. For 1935 Colo. geol. map this fm. was included in Front Range granite group and assigned to pre-Camb.

†Eomorphic era.

A part of Proterozoic era of U. S. Geol. Survey. For definition see U. S. G. S. Bull. 769, p. 27.

†Eozoic era.

As originally defined applied to all pre-Paleozoic time. In later usages it has been applied: (1) To all Camb. and pre-Paleozoic time; (2) to pre-Paleozoic time only; (3) to only the period formerly called "Algonkian period;" (4) to Huronian, Laurentian, and Keewatin time; (5) to a part only of the so-called "Algonkian period;" and (6) to a hypothetical pre-Keewatin interval. For definition see U. S. G. S. Bull. 769, pp. 27–30.

†Eparchean.

A term applied in some early repts to part of the pre-Camb. rocks, including Keweenawan, Huronian, and others. (See U. S. G. S. Bull. 360, 1909, pp. 87, 745.)

Eparchean interval.

A term applied by A. C. Lawson to the period of granitic intrusion believed to have immediately preceded the upper Huronian. (See U. S. G. S. Bull. 360, 1909, pp. 38, 322–323, 371, 382.)

Ephraim conglomerate. (In Gannett group.)

Cretaceous (?): Southeastern Idaho.

G. R. Mansfield and P. V. Roundy, 1916 (U. S. G. S. P. P. 98, pp. 76, 82). *Ephraim cgl.*—Red cgl. with minor amounts of ss. and some thin bands of gray to purplish ls. Thickness varies, but is 1,000± ft. at type loc. Forms most of mass known as Red Mtn in NE. part of Montpelier quad. Named for Ephraim Valley, sec. 36, T. 10 S., R. 45 E. Boise meridian, which lies in the fm. Is basal fm. of Gannett group. Underlies Peterson ls. and overlies Stump ss. May be Jurassic.

Epicene series.

A term proposed by C. R. Keyes for "early or preglacial Quat. deposits" of N. Mex. (See Iowa Acad. Sci. Proc., vol. 22, p. 262, 1915.)

Epperson sand.

A subsurface sand in Lee fm. (of Pottsville group) of Knox Co., SE. Ky.

Epworth dolomite.

Pre-Cambrian: Arctic Canada.

J. J. O'Neill, 1924 (Canadian Arctic Expedition, 1913–18, vol. 11, pt. A, p. 21).

Equity quartz latite. (In Potosi volcanic series.)

Miocene: Southwestern Colorado (Creede district).

W. H. Emmons and E. S. Larsen, 1923 (U. S. G. S. Bull. 718). *Equity quartz latite.*—Entirely massive rock, and in large part at least a single great flow, forming top fm. of Alboroto group (of Potosi volcanic series). Thickness 0 to 1,000 ft. Overlies, rather regularly, the Campbell Mtn rhyolite, and therefore occupies about same position in section as Phoenix Park quartz latite, from which it differs chiefly in its more massive character and, slightly, in its composition, which is somewhat nearer that of a rhyolite. The two latites have not been found in contact, but are believed to be very closely related and to represent different phases of same period of eruptive activity. Named for development near Equity mine.

†Equus beds.

A paleontologic name applied to Pleist. deposits containing *Equus* remains. Replaced by different geographic names in different areas: In Kans. by *McPherson fm.;* in western Tex. by *Tule fm.* (also called "Rock Creek beds," but that name is preoccupied); in Nebr. and adjacent States the name "Sheridan fm." has been used, but that name also is preoccupied. The U. S. Geol. Survey in general calls the beds containing *Equus* remains the *Equus zone*, but *McPherson fm.* and *Tule fm.* are also in good standing in their respective regions.

Eramosa member.

Term applied by M. Y. Williams, 1919 (Canada Geol. Surv. Mem. 111, No. 91 geol. ser.), to what he called top memb. of Lockport dol. in Ontario Peninsula. Overlain conformably by Guelph dol. (which he treated as distinct fm.) and underlain by unnamed dol., which separated his Eramosa memb. from underlying Gasport dol. memb.

Erian period or group.

See under *Erie group.*

Ericson sandstone. (In Mesaverde group.)

Upper Cretaceous: Southwestern Wyoming (Baxter Basin, Sweetwater County).

J. D. Sears, 1926 (U. S. G. S. Bull. 781, p. 20, pl. 5). [See under *Almond fm.*]

Erie group.

Erie series.

Upper and Middle Devonian: New York.

E. Emmons, 1842 (Geol. N. Y., pt. 2, div. 4, geol. 2d dist., pp. 100, 429). *Erie group.*—Named for Lake Erie, the valley of which is excavated out of Ludlowville shales, shaly sss., etc., which compose it. Includes Chemung and Ithaca shales and grits, Genesee sl., Tully ls., and Hamilton and Marcellus shales. Is top group of New York system. Overlies Helderberg series, which includes at top Schoharie grit and overlying Helderberg [Onondaga] ls. Underlies Old Red ss.

L. Vanuxem, 1842 (Geol. N. Y., pt. 3). *Erie div.*—Includes Chemung group at top and Marcellus shales at base. [Used in this sense by James Hall (1843), W. W. Mather (1843), and other geologists.]

J. S. Newberry, 1874 (Am. Ass. Adv. Sci. Proc., vol. 22, pp. 185–196). The Portage and Chemung form an indivisible mass of mechanical sediments, of which both fossils and lithological characters contrast strongly with underlying Hamilton and is evidently the record of a new era in geol. history of continent. This new *group* I have called the *Erie*, and I think it will be found to belong, both by its fossils and its physical relations, rather with the Carbf. than the Dev. system.

In 1879 T. Sterry Hunt included in his *Erian or Devonian* all beds btw. top of Catskill and base of Oriskany.

J. M. Clarke and C. Schuchert, 1899 (Sci., pp. 874–878). *Erian period or group.*—The "Erie div." comprised the fms. from top of Onondaga ls. to top of the Chemung. We propose to save the term to N. Y. nomenclature by reviving it with a restricted meaning—to include the rocks btw. Tully ls. and Onondaga ls. [This definition has been generally followed, except that in 1910 Schuchert (Geol. Soc. Am. Bull., vol. 20, p. 541) included the Onondaga, as did G. H. Ashley, 1923 (Eng. and Min. Jour.-Press, vol. 115, pp. 1106–1108), who proposed that it be called *Erie series*.]

The U. S. Geol. Survey does not use *Erian* or *Erie* in its classification. The present N. Y. State Survey includes in its Erian the beds below Tully ls. and above Onondaga ls. (See W. Goldring, N. Y. State Mus. Hdb. 10, 1931, p. 370.)

†Erie clay.

Pleistocene: Ontario, Ohio, New York.

W. E. Logan, 1863 (Canada Geol. Surv. Repts. 1843–63, pp. 887, 896–907). *Erie clay.*—The lower of the two divisions of stratified clays which overlie the boulder fm. or glacial drift of western Canada [Ontario]. Is sometimes associated with beds of gravel and sand. When moist is of blue color, with thin grey bands. Is commonly more or less calc. and always holds boulders and pebbles (of Paleozoic, Laurentian, and Huronian rocks) in greater or less abundance. Thickness more than 200 ft. No fossils yet found. With few interruptions runs along N. shore of Lake Erie from Long Point westward to Detroit River, and appears to underlie whole country btw. this part of the lake and the main body of Lake Huron. Also occurs at Owen Sound and along Nottawasaga River, also along shores of Lake Ontario, and as far E. as Brockville. Is uncon. overlain by Saugeen clay. The Erie and Saugeen clays and sands of western Canada apparently belong to a distinct basin, and are in part at least of fresh-water origin, so that their relations to lower and upper divisions of the stratified drift of eastern Canada and Vt. cannot yet be determined.

J. W. Spencer, 1888 (Am. Geol., vol. 2, pp. 294–297). *Erie clay* is best represented in the Lake region. It is a well-stratified, generally stoneless blue clay derived from the older drift. It also includes some stony stratified clays. Rests on Upper Drift or Till and is overlain by Saugen [Saugeen].

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 222). In Ontario the boulder clays are superimposed by the Erie clay, which in turn is overlain by the Saugeen clay and sands.

The name "Erie clay" was introduced into northern Ohio by J. S. Newberry, in 1870, and for many years was applied to the blue clays, 0 to 280 ft. thick, "overlying the glacial drift and underlying sands of variable thickness." The upper part was described by Newberry (Ohio Geol. Surv. vol. 2, pt. 1, 1874) as consisting of fine laminated clay without pebbles and corresponding closely to Saugeen clay, and the lower part as consisting of tough blue unstratified clay. According to Frank Leverett (unpublished letter dated Jan. 10, 1928) "the ordinary glacial till of Wisconsin age seems to be the main deposit that has been called Erie clay in Ohio."

†Erie shale.

Upper Devonian: Northern Ohio.

J. S. Newberry, 1870 (Ohio Geol. Surv. Rept. Prog. 1869, p. 20). *Erie sh.*—Bluish or greenish shales, 400 ft. thick in northern Ohio; absent in central Ohio. Topmost fm. of Dev. in northern Ohio. Overlain by black bituminous Cleveland sh. and underlain by Huron sh.

Preoccupied. Replaced by *Chagrin sh.*

Named for exposures on shores of Lake Erie from mouth of the Vermillion to Dunkirk.

†Erie limestone.

Pennsylvanian: Eastern Kansas.

E. Haworth and M. Z. Kirk, 1894 (Kans. Univ. Quart., vol. 2, pp. 108, 118). *Erie ls.*—System of lss., few ft. to 60 ft. thick, overlying Laneville shales and underlying Chanute shales. [Some later repts have called the beds *Erie or Triple ls. system.*]

According to R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), †Erie ls. of Haworth extended from top of Dennis ls. down to base of Hertha ls.

Named for Erie, Neosho Co.

Erin shale.

Carboniferous (probably early Pennsylvanian): Eastern Alabama (Clay County).

C. Butts, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14, p. 217). *Erin sh.*—Black carbonaceous sh. or sl. exposed in vicinity of Erin, Clay Co. Weathers gray or dirty white. Thickness tentatively estimated as 2,000 ft. Contains fossil plants of Carbf. (probably Penn.) age. Heretofore included in Talladega sl.

C. F. Park, Jr., 1935 (Wash. Acad. Sci. Jour., vol. 25, No. 6, pp. 278–279). It has been stated by C. Butts that C. W. Hayes considered Erin sh. to be an infolded bed in Talladega sh. Butts' notes, however, indicate a fault along SE. contact of Erin sh. and Talladega sl., but he stated that Hayes's interpretation seems equally probable. (Personal communication Jan. 1935.) C. W. Hayes and D. White concluded, after field study, that Erin sh. is uncon. with Talladega sl. (U. S. G. S. Bull. 340, 1908, p. 38.) Miss Jonas has recently described and mapped (Am. Jour. Sci., 5th, vol. 24, 1932, p. 243) Erin sh. as a fenster in Talladega sl. but does not discuss it in detail. There is sufficient evidence to indicate a fault btw. Talladega fm. and Erin sh. and to justify suggestion that Talladega fm. has been thrust over Erin sh., which is thought to have been exposed by erosion of the thin overthrust plate, thus forming a window. The assignment of part of Talladega sl. and other crystalline rocks in eastern Ala. to Carbf., on supposition that Erin sh. is a lenticular mass originally deposited in the Talladega, is believed to be unwarranted.

Erindale member.

Ordovician (Richmond): Ontario.

W. S. Dyer, 1925 (Ont. Dept. Mines 32d Ann. Rept., pt. 7, p. 121).

Ermont formation.

Devonian: Southwestern Montana (Argenta, Beaverhead County).

P. J. Shenon, 1931 (Mont. Bur. Mines and Geol. Bull. 6). *Ermont fm.*—In vicinity of Ermont mine, Argenta dist., it rests conformably on Tilden fm. (Camb.) and consists of (descending): (1) Poor exposures, but probably bluish gray ls., 230 ft., Dev. fossils in dense bluish-gray ls. bed at base; (2) poor outcrop, but probably gray sh., 100 ft.; (3) dense light-gray massive ls., 30 ft.; (4) sill of dark-green andesite porphyry, 80 ft.; (5) dark-colored mag. ls. with buff-colored patches which may be due to alteration, 248 ft.; (6) black shaly ls. similar to basal beds, 80 ft.; (7) sill of dark-green andesite porphyry, 228 ft.; (8) black shaly mag. ls., with sugary appearance, in beds mostly less than 6 inches thick, a bed 2 ft. thick with twiglike bodies lying 10 ft. above base. Color contrast clearly marks division line btw. Ermont and underlying Tilden fm. Top of Ermont is not definite but was fixed at a cherty horizon in rocks that resemble the overlying Madison ls., Madison fossils being found a short distance above this cherty horizon. Correlates fairly well with Jefferson fm. of Threeforks region, although no sh. beds corresponding in position with Threeforks sh. are present in Argenta dist.

Erskine moraine.

Pleistocene (Wisconsin stage): Northwestern Minnesota.

F. Leverett, 1932 (U. S. G. S. P. P. 161, pp. 115–117). Well developed in vicinity of Erskine, Polk Co.

Ervay tongue (of Phosphoria formation).

Permian: Northwestern Wyoming (Owl Creek and Wind River Mountains).

H. D. Thomas, 1934 (A. A. P. G. Bull., vol. 18, No. 12, pp. 1664, 1666). *Ervay tongue of Phosphoria fm.*—The uppermost lss. of Phosphoria fm., which extend E. and S. from Wind River and Owl Creek Mtns as a fairly widespread tongue. Crops out a few hundred ft. W. of Ervay, a post-office in Natrona Co., near N. end of Rattlesnake Hills, Natrona Co., and also at such scattered localities as Ferris Mtns, Green Mtns, and Alcova. Thickness 9 to 16 ft. The tongue is not as well exposed near Ervay as on the head of Casper Creek near Garfield Peak, about 15 mi. S. of Ervay, where it forms the dip-slope of a prominent hogback. Type section is on Casper Creek. [Fossils of the tongue are listed.] Underlies Dinwoody fm. and grades laterally into Freezeout tongue of Chugwater fm.

Ervine Creek limestone. (In Deer Creek limestone.)

Pennsylvanian: Southeastern Nebraska, southwestern Iowa, northwestern Missouri, and northeastern Kansas.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 40, 43, 49, 50). *Ervine Creek ls.* is top unit in Deer Creek ls. It is 24 to 28 ft. thick in SE. Nebr., 22½ ft. thick in SW. Iowa, 16 ft. thick at Forbes, Mo., and 12 ft. thick in Kansas Valley E. of Topeka, Kans. Its thickest and best-known development is near Louisville, Nebr. Overlies Mission Creek sh. and underlies Jones Point sh., the basal bed of Calhoun sh. Named for Ervine Creek, NE. of Union, Nebr.

R. C. Moore and G. E. Condra, 1932 (Oct. 1932 revised classification chart of Penn. rocks of Kans. and Nebr.), excluded from Calhoun sh. the Jones Point sh. and the overlying ls. and included them in Deer Creek ls.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 11), transferred Jones Point sh. and overlying ls. to Calhoun sh., leaving his Ervine Creek ls. the top bed of Deer Creek ls. This classification was adopted by R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 48), but on pp. 187–194 he proposed to redefine Ervine Creek ls., Jones Point sh., and Sheldon ls. on a cyclothem basis. (See 1936 entry under *Sheldon ls.*)

For Condra's latest interpretation of strat. position of this ls. see 1937 entry under *Topeka ls.*

Erving hornblende schist.

Carboniferous: Western central Massachusetts.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 60, 72–74, and map). *Erving hornblende schist.*—A thick mass of fissile, rather fine-grained hornblende schist, which is in middle of Quabin qtzite in Northfield, but sinks lower farther S., and in middle of State it forms the basal memb. In many places it passes into a gray tremolite-actinolite schist. It appears to represent a calc. band in the original Paxton schist. Named for occurrence at Erving.

Erwin quartzite.

Lower Cambrian: Southwestern Virginia, western North Carolina, and eastern Tennessee.

A. Keith, 1903 (U. S. G. S. Cranberry folio, No. 90, p. 5 and columnar section). *Erwin qtzite.*—White ss. and qtzite, 500 to 700 ft. thick, of very uniform appearance. The strata are composed of fine white sand, more or less cemented by secondary silica. Layers very massive and show scarcely any sh. partings. Between the qtzite and overlying Shady ls. are a few ft. of sandy sh. and thin ss., in which are found a few Lower Camb. fossils of the *Olenellus* fauna. Scolithus borings are common in the qtzites. Overlies Hampton sh.

Named for exposures near Erwin, Unicoi Co., Tenn.

Escabrosa limestone.

Mississippian (lower): Southeastern Arizona (Bisbee region).

F. L. Ransome, 1904 (U. S. G. S. P. P. 21). *Escabrosa ls.*—Characteristic rocks are rather thick-bedded, nearly white to dark-gray, granular lss. made up largely of fragments of crinoid stems. Lower 100 ft. is usually in beds 10 to 15 ft. thick; above that in beds 1 to 5 ft. with occasional occurrences of more massive strata. As a whole it is a pure nonmagnesian ls. containing practically no aren. sediments anl only occasional irregular bunches and nodules of chert, usually in upper part. General appearance of fm. is white or light gray, but some dark-gray beds occur, particularly near top. Thickness 800± ft. Rests, apparently conformably, on Martin ls. and is conformably overlain by Naco ls. Named for conspicuous exposures on Escabrosa Ridge, Bisbee quad.

Escamela limestone.

Cretaceous: Mexico (Guerrero).

C. E. Hall, 1903 (Soc. cient. Ant. Alzate Mem. y rev., t. 13, p. 328). *Escamela ls.*, in Washita div. of Comanche series, at and in vicinity of town of Iguala.

Escanaba limestone.

Middle Ordovician: Michigan (Upper Peninsula).

A. C. Lane, 1909 (Mich. Geol. Surv. Rept. 1908, p. 47). *Escanaba ls.*—Local name suggested by A. W. Grabau for Trenton ls. of Mich., because neither at top nor bottom do the dividing lines exactly agree in time with the Trenton of N. Y. But it is entirely unlikely that the dividing lines are exactly the same at the two ends of the State, that is, on the Escanaba and St. Mary's Rivers, where alone it has been or can be studied.

A. C. Lane, 1910 (Jour. Geol., vol. 18, btw. pp. 393 and 430). Trenton ls. of Mich. includes equivalents of Chazy, Birdseye, Black River, and Trenton of N. Y. So Grabau would suggest a local name like *Escanaba*. While *Escanaba ls.* is a more euphonious term, my impression is it would be better to use Trenton in a broad sense and introduce *Escanaba* as applicable to some accurately defined subdivision.

Escondido formation. (Of Navarro group.)

Upper Cretaceous (Gulf series): Southern Texas.

E. T. Dumble 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 227–229, 230). *Escondido beds.*—Lower part ss. with indurated glauconitic layer containing small oysters and other fossil forms; upper part friable and hard sss. alternating with blue, buff, brown, and green clays and sandy clays, the sss. in places highly calc. and containing beds of oyster shells. Thickness 3,300 ft. Top fm. of Eagle Pass div. Overlies Coal series [Olmos fm.] of Eagle Pass div. and underlies Webb Bluff Tertiary.

According to L. W. Stephenson, 1928 (Am. Jour. Sci., 5th, vol. 16, p. 492), the Escondido fm. of Rio Grande region overlies Olmos fm.; the Escondido of Anacacho Mtn region rests uncon. on Anacacho ls. The Escondido of Medina River region is separated from underlying Taylor marl by Corsicana marl. The Escondido is top fm. of Upper Cret. in southern Tex., and is uncon. overlain by Midway fm.

Named for exposures on Escondido River below Eagle Pass, Maverick Co.

†Escondido series.

Miocene (?): Southern California (Los Angeles County).

O. H. Hershey, April 1902 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 3, pl. 1, map). [*Escondido series* and *Escondido lava* are titles of two blocks on the map, lying btw. Rosamond series below and Tejon (?) ss. above.]

O. H. Hershey, 1902 (Am. Geol., vol. 29, pp. 349–372). *Escondido series.*—Marine sediments and contemp. interbedded lava flows of Eocene (?) age occurring near head of Escondido Canyon [Los Angeles Co.]. Type section is in Tick Canyon. Slightly younger than Rosamond series.

W. S. W. Kew, 1924 (U. S. G. S. Bull. 753, pp. 38, 52). Hershey's "Escondido series" is tentatively correlated with Sespe fm., and mapped as *Sespe (?) fm.* No fossils found. Is overlain uncon. by Mint Canyon fm. Name is preoccupied.

E. C. Simpson, 1934 (Calif. Dept. Nat. Res. Div. Mines, Calif. Jour. Mines and Geol., vol. 30, No. 4, pp. 391–395, and 401, in rept. on Elizabeth Lake quad., which includes part of Escondido Canyon). *Escondido fm.* is probably middle Mio. and = Topanga fm., instead of same as Sespe (?) fm. of Kew. The Escondido accumulated subaerially; the Topanga contains abundant middle Mio. marine fossils. The two fms. closely resemble each other lithologically. So it is thought best to retain "Escondido fm." In quads to S. and W. the Escondido is overlain uncon. by Mint Canyon fm. (late Mio.).

R. P. Sharp, 1935 (Pan-Am. Geol., vol. 63, No. 4, p. 314). *Vasquez series* is here suggested to replace "Escondido series," preoccupied.

Escuminac beds.

Upper Devonian: Quebec (Escuminac Bay).

E. M. Kindle, 1930 (Canada Geol. Surv. Dept. Mines Summ. Rept. 1928, pt. C, pp. 82C–84C, pl. opp. p. 82C). Gray ss. and sh., carrying Upper Dev. fishes and ferns, discon. underlying Bonaventure cgl. (Carbf.) and overlying Fleurant cgl. in Escuminac Bay section, Gaspe Peninsula, on N. shore of Chaleur Bay, opp. Dalhousie, N. B. Highest Upper Dev. in section.

Eshamy granite.

Mesozoic (?): Southeastern Alaska (Prince William Sound region).

U. S. Grant and D. F. Higgins, 1910 (U. S. G. S. Bull. 443, pp. 34–35, 46). *Eshamy granite.*—Pinkish gray, medium-grained; granitoid texture. Practically surrounds Granite Bay and occupies nearly all of neck of land btw. Granite and Eshamy Bays. Cuts Valdez group.

Eska conglomerate.

Miocene (?): Central southern Alaska (Cook Inlet region).

G. C. Martin and F. J. Katz, 1912 (U. S. G. S. Bull. 500, pp. 15, 52–54). *Eska cgl.*—Predominantly coarse cgl. in massive plates interbedded with some coarse ss. Thickness, 3,000± ft. Overlies, without observed uncon., Chickaloon fm. and uncon. underlies basaltic lavas, breccias, and tuffs of Plio. (?) age. Extends W. from valley of Eska Creek, for which it is named. No determinable fossils, but regarded as certainly Tert. and probably Mio.

Eskota beds.

Permian: Central northern Texas.

J. W. Beede and W. P. Bentley, 1921 (Univ. Tex. Bull. 1850, pp. 16, 22, 29, 51, 53). *Eskota or Greer beds.*—A series (65 ft. thick in Coke Co.) of soft, evenly bedded clayey fine-grained sss. and fine sandy shales provisionally referred to Greer stage. As a rule the sss. and shales are dark red. Locally they are leached to a buffish or greenish shade, and occasionlly there are persistent light-colored beds. In this fm. are many heavy gyp. beds. Throughout its extent in Coke Co. only 1 thin sheet of ls. has been seen, and that is of a very peculiar crystalline texture, locally found to be very sandy. It is correlated by Wrather with the dol. in Eskota gyp. It is reasonably certain that the gypsums of Double Mtn fm. correspond in general way to those of Greer fm., and the succession is similar in Okla. and central Tex., as Wrather pointed out. Wrather tentatively refers the ls. or dol. in these gypsums to Eskota dol. Overlies, probably conformably but with sharp division line, San Angelo fm., and underlies Quartermaster (?) fm.

Probably named for Eskota, Fisher Co.

Eskota dolomite.

Eskota gypsum.

Permian: Central northern Texas.

A. M. Lloyd and W. C. Thompson, 1929 (A. A. P. G. Bull., vol. 13, pl. 10, p. 953). *Eskota dol. gyp.*—Massive gyp. beds, 10 to 20 ft. thick, underlain by thin dol. Has not been followed farther than central Fisher Co. Lies 120 ft. above Childress dol. and gyp., and is older than Croton gyp.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 180). *Eskota gyp.* is a memb. in Whitehorse-Cloud Chief interval.

Probably named for Eskota, Fisher Co.

Eskridge shale.

Pennsylvanian: Eastern Kansas, southeastern Nebraska, and central northern Oklahoma.

J. W. Beede, 1902 (Kans. Univ. Sci. Bull., vol. 1, p. 181). *Eskridge sh.*—Name suggested by C. S. Prosser, in unpublished ms., for 30± ft. of shales overlying Neva ls. and underlying Cottonwood ls.

Top fm. of Wabaunsee group as used in Kans. for many years, but Kans. and Nebr. Surveys have recently greatly restricted Wabaunsee group. (See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.) Some geologists, including R. C. Moore, 1936, assign this fm. to Perm. This change in Perm.-Penn. bdy has not been considered by U. S. Geol. Survey for its publications.

Named for exposures near Eskridge, Wabaunsee Co., Kans.

Esmeralda formation.

Miocene (upper): Southwestern and central Nevada and Inyo County, California.

H. W. Turner, 1900 (Am. Geol., vol. 25, pp. 168–170; U. S. G. S. 21st Ann. Rept., pt. 2, pp. 197–208). *Esmeralda fm.*—Fresh-water lake deposit, consisting of sss., shales, and lacustral marls, with local development of breccia and cgl. on large scale; rhyolitic and basaltic lavas and tuffs at top in some places; also layers of rhyolitic and andesitic tuff lower down in fm. Thickness 14,800 ft. Overlain by rhyolitic and andesitic eruptive rocks. Named for development in Esmeralda Co., Nev. [before the county was subdivided].

S. H. Ball, 1907 (U. S. G. S. Bull. 308), mapped *Siebert lake beds* (now abandoned for Esmeralda fm., the older name) in Inyo Co., eastern Calif.

†Esopus millstones.

Silurian: Eastern New York (Ulster County).

W. W. Mather, 1840 (N. Y. Geol. Surv. 4th Rept., pp. 246–250). Shawangunk grit extends N. from Shawangunk Mtn nearly to Kingston, N. Y., where the firm coarse grits have long been quarried for millstones, known on the market as *Esopus millstones*, from name of township and village of Kingston during War of Revolution. [According to N. H. Darton (personal communication) the †Esopus millstones are older than Esopus grit, and were quarried from Shawangunk cgl. The present village of Esopus is about 10 mi. S. of Kingston, Ulster Co.]

Esopus slate.

See under *Esopus grit.*

Esopus grit.
Esopus shale. } (In Oriskany group.)

Lower Devonian: Eastern New York, northern New Jersey, and northeastern Pennsylvania.

L. Vanuxem, 1842 (Geol. N. Y., pt. 3, pp. 127–130). *Cauda-galli grit.*—Fine-grained, calc. and argill ss., usually drab and brownish. Underlies Schoharie grit and overlies Oriskany ss.

From 1842 until 1894 this fm. was called "Cauda-galli grit" and "Cocktail grit."

J. Hall, 1867 (N. Y. Nat. Hist. Geol. Survey N. Y., vol. 4, pp. 1–3). *Cauda-galli grit.*—Usually occurs as aren. sh. or sh. The rock itself is usually dark or nearly black slaty grit, weathering grayish or brownish gray, with strong lines of jointing. *Fucoides cauda-galli* in upper beds.

N. H. Darton, 1894 (N. Y. State Geol. 13th Ann. Rept., pp. 209–210, 244–245, 302). *Esopus shales* (*Cauda-galli grit*).—The shales and slates which have been known as "Cauda-galli grit" attain max. development in N. Y. about Catskill and Kingston; thinning gradually to 70 ft. at Schoharie; 40 ft. near Jordansville, N. of Richfield Springs; 3 ft. at Columbia, NW. of Richfield Springs; and are entirely absent at Litchfield, 8 mi. farther W. This rock expands greatly in N. J. Thickness at Clarksville [Albany Co., N. Y.], 110 ft.; in Ulster Co., 200 to 300 ft. In order to have a locality designation for Cauda-galli grit, *the State Geologist* [*James Hall*] *has suggested Esopus sl.*, from Esopus settlement, of which the portion now known as Kingston is largely on this fm.; and Esopus Creek, along which, for some mi. above Saugerties [Ulster Co.], the slates are particularly well exposed. Is in greater part a fine-grained aren. deposit of dark-gray color, with more or less completely developed slaty cleavage. About Schoharie and westward to its termination it is moderately hard, sandy sh., dark gray or buff to light olive, but E. and S., with increasing thickness, the color becomes darker, the texture harder, and slaty cleavage is general. In Helderburg Mtns and westward the shales constitute a slope btw. shelves of Onondaga ls. above and Oriskany ss. below, but from S. part of Albany Co. southward it constitutes high rough ridges.

H. Ries, 1897 (N. Y. State Geol. 15th Ann. Rept., vol. 1), gave thickness of 750± ft. for *Esopus sl.* in Orange Co., N. Y.

F. J. H. Merrill, 1898 (N. Y. State Mus. Bull. 4, pp. 137–180). Only fossil known in Cauda Galli grit is *Spirophyton caudæ galli*, which occurs also in underlying Oriskany ss. [He treated *Cauda Galli grit* as top fm. of his Oriskany group, and Oriskany ss. as basal fm. of that group. For views of other geologists regarding the group classification of Esopus grit see under *Oriskany group.*]

C. S. Prosser, 1899 (N. Y. State Geol. 18th Ann. Rept., pp. 63–67), gave thickness of *Esopus sh.* at Schoharie and vicinity as 121 ft. (instead of 70 ft., as reported by Darton). G. Van Ingen and P. E. Clark, 1903 (N. Y. State Mus. Bull. 69, pp. 1176–1227), reported 300 to 325 ft. of *Esopus grit* in vicinity of Rondout, N. Y.

The U. S. Geol. Survey includes Esopus grit (and Esopus sh.) in Oriskany group. (See under *Oriskany group.*) The present N. Y. State Survey includes Esopus grit in its *Oriskanian*, but calls the underlying fm. *Oriskany ss.* (See W. Goldring, N. Y. State Mus. Hdb. 10, 1931, p. 370.)

Espanola granite.

Pre-Cambrian: Western Ontario.

T. T. Quirke, 1917 (Canada Geol. Surv. Mem. 102, p. 33).

Espanola graywacke.

Pre-Cambrian (Huronian): Western Ontario.

See under *Bruce series.*

Espanola limestone.

Pre-Cambrian (Huronian): Western Ontario.

See under *Bruce series.*

Esperanza trachyte.

Tertiary (middle or late): Northwestern Arizona (Oatman district).

F. L. Ransome, 1923 (U. S. G. S. Bull. 743). *Esperanza trachyte.*—Dense lilac-gray to brown volcanic flows of latitic trachyte, with some breccia. Thickness 0 to 1,000± ft. Younger than Alcyone trachyte. Overlain by Oatman andesite. Named for Esperanza Canyon.

Espina breccia.

Tertiary (upper? Miocene): Southwestern Nevada (Goldfield district).

F. L. Ransome, 1909 (U. S. G. S. P. P. 66, pp. 28, 69, etc.). *Espina breccia.*—Breccia and tuff, 200± ft. thick, which show rough, nearly horizontal bedding. Mostly greatly altered, so that original character is in part doubtful. May be a part of Siebert [Esmeralda] fm., but definite correlation is not at present possible. [Forms Espina Hill; see map.]

Esplanade sandstone member (of Supai formation).

Permian: Northern Arizona (Grand Canyon).

D. White, 1929 (Carnegie Inst. Wash. Pub. 405, p. 11). *Esplanade ss. memb.*—A group of hard sss. at top of Supai fm., which form shelf known as the "Esplanade." Underlies Hermit sh.

Esquias formation.

Upper Cretaceous: Honduras.

C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 354).

Essex limestone.

Silurian (pre-Niagaran): Northeastern Illinois (Will and Kankakee Counties).

T. E. Savage, 1912 (Ill. Acad. Sci. Trans., vol. 4, p. 100). *Essex ls.*—Small remnants of fossiliferous lss. of early Sil. (pre-Clinton) age, 0 to 10 ft. thick, uncon. overlying Maquoketa sh. in Will and Kankakee Counties. Believed to be younger than Edgewood fm. and to belong near top of Alexandrian series. Upper 1½ ft.

yellowish-brown mag. ls. with small nodules and masses of chert; lower 8½ ft. yellowish-brown thin-bedded mag. ls.

T. E. Savage, 1913 (Ill. Geol. Surv. Bull. 23). *Essex ls.* underlies Sexton Creek ls. with possible break in deposition. Is thought to be a distinct fm., but later studies may show it should be treated as a memb. of the Sexton Creek or as a memb. of underlying Edgewood ls.

T. E. Savage, 1913 (Geol. Soc. Am. Bull., vol. 24, pp. 111–112), divided his Alexandrian series into (descending) Sexton Creek (Brassfield) ls., *Essex ls.*, Edgewood ls., and Girardeau ls., and stated "the several fms. are uncon. among themselves."

T. E. Savage, 1914 (Am. Jour. Sci., 4th, vol. 38, pp. 28–37). *Essex ls.* of Will Co., NE. Ill., represents a horizon of the Edgewood a little higher than Channahon ls., and is overlain by brown, almost barren mag. ls. corresponding to Bowling Green memb. of the Edgewood.

A. H. Sutton, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 270–274). *Essex ls. memb.* is probably at or near top of Edgewood ls.

Named for Essex, Kankakee Co.

Estancia basalt.

Quaternary: Mexico.

R. H. Palmer, 1926 (Pan-Am. Geol., vol. 45, p. 128).

Estelle quartz diorite.

Late Jurassic (?): Southern California (Riverside County).

P. H. Dudley, 1935 (Calif. Jour. Mines and Geol., vol. 31, No. 4, map, pp. 491, 502). Late Jurassic (?) intrusive occurring in first valley E. of Estelle Mtn, Riverside Co.

Estes system.

Pre-Cambrian: Western South Dakota (Black Hills).

J. J. Runner, 1934 (Am. Jour. Sci., 5th, vol. 28, pp. 354–372). The pre-Camb. rocks of Black Hills, S. Dak., are here divided into (descending): Lead system, Estes system, and Nemo system. The Estes consists of (1) very thick qtzite, sl. iron fm., and arkosic grits, underlain by (2) cgl., qtzite, ls., and sl. Underlies Lead system with possible uncon. and rests uncon. on Nemo system. Well exposed along Estes Creek.

Estevan formation.

Eocene (?): Saskatchewan and Alberta.

N. B. Davis, 1918 (Canada Dept. Mines, Mines Branch, Rept. clay resources southern Saskatchewan, p. 9). Included in Fort Union beds (Eocene).

All subsequent repts assign this fm. to Cret.

Esther granite.

Paleozoic (?): Southeastern Alaska (Prince William Sound region).

U. S. Grant and D. F. Higgins, 1910 (U. S. G. S. Bull. 443, pp. 39–41, 46). *Esther granite.*—Gneissic granite. Occupies greater part of Esther Island, at S. end of Port Wells. Probably oldest granite of Prince William Sound. Cuts Valdez group.

Estill clay.

Silurian (Niagaran): East-central Kentucky.

A. F. Foerste, 1905 (Ky. Geol. Surv. Bull. 6, p. 145) and 1906 (Ky. Geol. Surv. Bull. 7, pp. 10, 59). *Estill clay.*—Clay, 65 to 120 ft. thick, overlying Waco ls. and forming top memb. of Alger fm. (of Niagaran age). Overlain uncon. by Dev. ls.

In 1931 (Ky. Geol. Surv., ser. 6, vol. 36, pp. 172, 173) Foerste assigned this clay to Clinton epoch.

A. F. Foerste, 1935 (Denison Univ. Bull., Jour. Sci. Lab., vol. 30, p. 132). Type exposure of *Estill clay* is NE. of Estill Springs, Estill Co., N. of Irvine, where it is 56 ft. thick.

Etchegoin formation (narrow sense).

Pliocene: Southern California.

F. M. Anderson, 1905 (Calif. Acad. Sci. Proc., 3d ser., vol. 2, pp. 178–192). [Name applied to lower two-thirds of Etchegoin fm. See description under *Etchegoin fm.*]

W. P. Woodring, 1934 (U. S. G. S. geol. map and structure sections of Kettleman Hills), restricted *Etchegoin*, under the name *Etchegoin ss.*, to lower two-thirds of Etchegoin fm. as originally defined and used in previous publications, and adopted *San Joaquin fm.* for upper part, previously called *San Joaquin clays*.

This restricted unit is now known as *Etchegoin fm.*

†Etchegoin formation (broad sense).

Pliocene: Southern California (Sunset, Midway, Coalinga, Mount Diablo, and Salinas Valley districts).

F. M. Anderson, 1905 (Calif. Acad. Sci. Proc., 3d ser., vol. 2, pp. 178–192). *Etchegoin beds*.—Divided into Etchegoin sands, which compose lower two-thirds of fm., and San Joaquin clays, which compose upper one-third. The *Etchegoin sands* consist of unconsolidated sands and gravels in many places characterized by blue or bluish gray color. They vary in thickness from 1,200 to 2,500 ft. Are commonly coarse in texture and often pebbly, forming beds of cgl. One fossil horizon occurs near bottom and another some distance above. [Fossils listed.] The *San Joaquin clays* are about 1,500 ft. thick. At a distance they present a banded appearance, from the zones of color seen in the different strata, some of which have a width of 200 or 300 ft. The clays are conformably overlain by fresh-water Tulare fm. The Etchegoin beds overlie in turn all older fms. of region, resting upon each respectively with a distinct noncon. The next older rocks are the Coalinga beds.

R. Arnold and R. Anderson, 1908 (U. S. G. S. Bull. 357, pp. 46–55). In accordance with Mr. [F. M.] Anderson's statements and on basis of reasons stated below the Etchegoin fm. is mapped and described in present paper as the succession of slightly consolidated beds of sand, gravel, and clay, interbedded with occasional indurated beds, occurring on summit and flanks of Anticline Ridge and on SE. end of Joaquin Ridge N. of Coalinga, above base of the hill-forming ss. beds (referred to for convenience as *Glycymeris* zone), and below the beds described as Paso Robles fm. Strata in other parts of Coalinga dist. are referred to Etchegoin fm. on basis of paleontologic correlation with the beds on Anticline Ridge. The *Glycymeris* zone is underlain by clay that is classed in Jacalitos fm., and is overlain by a thick succession of bluish gray sand beds interbedded with dark-gray sand. An uncon. occurs below the *Glycymeris* zone in the synclinal basin N. of White Creek. Although in most places the Etchegoin appears to rest conformably on Jacalitos fm., in other places it overlaps the Jacalitos. It is overlain by Tulare fm., with possible uncon. Thickness over 3,600 ft. in S. part of dist., 1,700 ft. in oil field N. of Coalinga, 1,100 ft. in White Creek basin. [Fossils listed. The fm. includes marine, brackish, and fresh-water deposits.]

The broad usage of *Etchegoin* has been discontinued by U. S. Geol. Survey, and *Etchegoin fm.* has been adopted for the beds called *Etchegoin sands*, and *San Joaquin fm.* has been adopted for the beds called *San Joaquin clays* in original definition of Etchegoin fm.

Named for exposures in vicinity of Etchegoin ranch, 20 mi. NE. of Coalinga, in NW¼ sec. 1, T. 19 S., R. 15 E., Fresno Co.

Etchegoin sands.

Pliocene: Southern California.

F. M. Anderson, 1905 (Calif. Acad. Sci. Proc., 3d ser., vol. 2, pp. 178–192), applied this name to lower two-thirds of Etchegoin fm. (See under *Etchegoin fm.*)

Etcheminian series.

Etcheminian group.

Lower Cambrian: Newfoundland, Nova Scotia, and New Brunswick.

G. F. Matthew, 1888 (Am. Geol., vol. 2, p. 1). *Etcheminian series*, Camb., Canada.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4), applied *Etcheminian series* to lower part of Lower Camb. of Newfoundland, the upper part of Lower Camb. being named *Hanfordian series*. He divided his Etcheminian series into (descending) Smith Point, Brigus, and Bonavista fms., and listed fossils from each fm.

Etheline volcanics.

Tertiary: British Columbia.

J. D. MacKenzie, 1914 (Canada Geol. Surv. Summ. Rept. 1913, p. 47).

Etholen conglomerate.

Lower Cretaceous (Comanche series): Western Texas (El Paso County).

J. A. Taff, 1891 (Tex. Geol. Surv. 2d Ann. Rept., pp. 723, 736). *Etholen bed.*—Consists of (descending): Lenticular bed of gyp., 0 to 90 ft.; massive bowlder breccia and cgl. made of Carbf. ls. and chert, 240 ft. Overlies Malone bed and underlies Yucca bed; all included in Washita div.

C. L. Baker, 1927 (Univ. Tex. Bull. 2745, pp. 7–40). *Etholen cgl.*—Consists of 250 ft. of cgl. alone on N. flank of Quitman Mtns. Includes beds of ls., ss., sh., and marl. Is lowest group of Trinity found uncon. overlying Perm. and older rocks, although it possibly may not be oldest Trinity in Malone Mtns. Is probably = Campagrande fm. of Richardson. Occurs in Etholen Knobs, just NW. of Etholen section house, and in nearby small hills S. of the railway. Grades into overlying Cox ss.

Etna sandstone.

Pennsylvanian: Central Tennessee (Grundy County).

J. J. Stevenson, 1904 (Geol. Soc. Am. Bull., vol. 15, pp. 125, 201+). *Etna ss.*—Underlies Cashie coal bed and overlies Etna coal bed. On W. side of basin extends N. to middle Tenn.; on E. side to probably 50 mi. N. from New River in W. Va. Is same as Cliff ss. and Lower Etna cgl. of Safford in Tenn. [Safford used *Cliff Rock (Lower Cgl. of Etna Mines).*]

J. J. Stevenson, 1912 (Am. Phil. Soc. Proc., vol. 51, p. 460). *Etna ss.*—Varies in texture, as does the younger Bonair ss. Is often fine-grained and without pebbles when the Bonair is very coarse, and very coarse when the Bonair is not coarse. Can be recognized over nearly as great an area as Bonair ss., which can be traced from northern W. Va. and northern Tenn. almost continuously into Ala. Included in New River fm.

Etna quartz monzonite porphyry.

Post-Carboniferous: Central Colorado (Monarch-Tomichi region).

R. D. Crawford, 1913 (Colo. Geol. Surv. Bull. 4, p. 80). Characterized by numerous large orthoclase phenocrysts.

Eubanks sand.

A subsurface sand occupying interval btw. 2,927 and 2,936 ft. depth in Richland gas field, NE. La. According to D. Gordon (A. A. P. G. Bull., vol. 15, No. 8, 1931) it lies at horizon of upper part of lower part of Glen Rose, of Trinity group.

†Euchee phase.

Miocene (probably upper): Northwestern Florida.

L. C. Johnson, 1893 (Sci., vol. 21, pp. 90–91). *Euchee phase of the younger Miocene.*—Near Euchee Ana it consists of a sandy ferruginous clay, calc. in spots, having innumerable shells and casts of the small *Mactra congesta*. This is a counterpart of topmost layers at Alum Bluff. Estuary deposit. Underlies Alaqua phase.

According to studies of Julia Gardner these beds are probably Choctawhatchee fm. (upper and middle Miocene) and younger than "Alaqua phase."

Named for development at Eucheeanna, Walton Co.

Euclid sandstone lentil (in Bedford shale).

Devonian or Mississippian: Northern Ohio.

W. F. Morse and A. F. Foerste, 1909 (Jour. Geol., vol. 17, p. 166). Sss., in regular layers, at about same horizon in Bedford fm., along Euclid Creek. Known to trade as Euclid stone, and the division has been appropriately named *Euclid lentil* by C. S. Prosser in ms. [Defined by C. S. Prosser (Ohio Geol. Surv., 4th ser., Bull. 15, pp. 24, 26, 51, 1912) as *Euclid ss. lentil of Bedford sh.*, consisting of 19 to 20 ft. of sss. in lower part of Bedford; separated from underlying Cleveland sh. by 5 to 14 ft. of argill. bluish-gray sh. forming basal part of Bedford.]

Named for Euclid Creek, E. of Cleveland.

Euclid moraine.

Pleistocene (late Wisconsin): Northern Ohio and northwestern Pennsylvania. Oldest moraine of Lake Escarpment morainic system. Named for Euclid, Ohio. (See U. S. G. S. Mon. 41.)

Eudora limestone.

Pennsylvanian: Eastern Kansas.

J. Bennett, 1896 (Univ. Geol. Surv. Kans., vol. 1, p. 113), casually used, in one place, *upper Eudora ls.*, but did not define it nor locate it in his section. On p. 136 of same vol. E. Haworth stated: We must conclude that *Eudora ls.*, as shown by Bennett in chap. VI and pl. VI, is nearly 100 ft. below the thin ls. at the dam, and therefore that Garnett ls. is also; for we have satisfactory evidence the two are the same. [Pl. VI does not show Eudora ls. but does show *Garnett ls.*]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 131). †*Eudora ls.* of Bennett (Kans. Univ. Geol. Surv., vol. 1, p. 113, 1896) is Stanton ls. of modern usage at Eudora, and is abandoned.

Eudora shale.

Pennsylvanian: Southeastern Nebraska and northeastern Kansas.

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, 2d ser., pp. 12, 26, 27, 31, 34). *Eudora sh.*, in lower part of Stanton ls. memb., consists of alternating thin beds of bluish to black sh. and bluish lss. Total thickness 9± ft. Underlies Stoner ls. and overlies Meadow ls. as here redefined. Named for good exposures E. of Eudora, Kans.

Foregoing definition was used by R. C. Moore, C. O. Dunbar, G. E. Condra, and others.

In Kans. Geol. Surv. Bull. 21, pt. 1, May 15, 1935, pp. 76–79, N. D. Newell defined *Eudora sh. memb. of Stanton ls.* of Johnson and Miami Counties, NE. Kans., as consisting of 4 to 11 ft. of black carbonaceous sh., overlain by Olathe ls. memb. and underlain by Captain Creek ls. memb. (See also Newell, Jour. Geol., vol. 44, No. 1, 1936, pp. 23–31, and Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.)

†Eufaula sands.

Upper Cretaceous: Southwestern Alabama and northeastern Mississippi.

E. A. Smith, 1888 (Ala. Geol. Surv. Rept. Prog. 1884–88 geographic map of Ala.). [*Eufaula* (*Ripley*) is applied to uppermost Cret. fm. of Ala. on this map, the name †*Demopolis* (*Rotten ls.*) being applied to underlying fm. There is no description or definition.]

W. H. Dall and G. D. Harris, 1891 (U. S. G. S. Bull. 84, p. 166), used "Eufaula sands" for the Cret. beds overlying †Tombigbee chalk and underlying †Lignitic in Miss.

Replaced by Ripley fm., older name.

Presumably named for exposures at Eufaula, Barbour Co., Ala., where Ripley fm. is well developed.

Eugene formation.

Oligocene: Northwestern Oregon (Eugene region).

W. D. Smith, 1924 (Econ. Geol., vol. 19, No. 5, p. 462). At Eugene the principal fm. is *Eugene fm.*, which consists largely of tuffaceous shales and sss. of Olig. age, in a monoclinal attitude, intruded by basalt dikes and sills. [In table on p. 458 he stated that *Eugene fm.* is = Astoria and Yaquina fms.]

W. D. Smith, 1925 (Oreg. Univ. Commonwealth Rev., vol. 7, No. 4, pp. 149–156). A considerable thickness of sh. of Olig. age in upper end of Willamette Valley we have called *Eugene fm.* It is in part marine, but with it are associated more or less volcanic ash or tuff. As the tuffaceous material is not especially coarse, it may have come from a considerable distance (Cascades), being blown by winds and later water-sorted along the shore. There are some terrestrial deposits associated with this, indicating a change from marine to land conditions, perhaps several fluctuations from one to the other.

W. D. Smith, 1926 (Oreg. Univ. Commonwealth Rev., vol. 8, p. 269), assigned Eugene fm. to middle Olig.

H. G. Schenck, 1927 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 16, No. 12, pp. 453, 459). *Eugene fm.*—Marine ss., sandy sh., cgl., and tuff, cut by basaltic dikes and sills. Typically exposed in city of Eugene. Fossils listed. Assigned to middle Olig. Younger than Fisher fm. [Thickness not stated.]

H. G. Schenck, 1928 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 16, No. 12). *Eugene fm.* has total thickness of perhaps 5,000 ft.

R. W. Chaney and E. I. Sanborn, 1933 (Carnegie Inst. Wash. Pub. 439), assigned Eugene fm. to middle part of lower Olig.

Euphemia dolomite.

Silurian (Niagaran): Southwestern Ohio.

A. F. Foerste, 1917 (Ohio Jour. Sci., vol. 17, pp. 187, 201, 202). *Euphemia dol.*—The very porous Mottled Zone of Prosser (Jour. Geol., 1916, pp. 334–365). Was identified by Orton with his West Union fm. of more southern counties in Ohio. Cannot be identified W. of New Paris nor S. of Cedarville. Overlies Laurel ls. and is regarded as inaugurating the dolomitic series herein named *Durbin fm.*, which includes (descending) Cedarville dol., Springfield dol., and Euphemia dol. Type loc. of Euphemia dol. is at quarry described by Prosser as Lewisburg stone quarry, 1 mi. NW. of Lewisburg; Euphemia is ½ mi. NW. of Lewisburg and a little nearer the quarry.

A. F. Foerste, 1923 (Denison Univ. Bull., Sci. Lab. Jour., vol. 20, pp. 43–49). *Euphemia dol.* is West Union bed of Orton in Clinton Co. and northward. Underlies Springfield dol.

A. F. Foerste, 1935 (Denison Univ. Bull., Jour. Sci. Lab., vol. 30, pp. 136–137). *Euphemia dol.* is of Lockport age. [On p. 154 he stated that at Springfield, Ohio, *Euphemia dol.* is 8 ft. thick and is overlain by typical Springfield dol. and underlain by Massie clay. Thicknesses given at other places range from 2.6 ft. (at New Paris) to 7.2 ft. at Cedarville and S. of Covington. Not identified S. of Cedarville. Foerste's *Springfield dol.* appears to be only a part of *Springfield ls.* of Orton.]

Eureka quartzite.

Ordovician (Middle): Northern Nevada, western Utah, and Inyo County, California.

A. Hague, 1883 (U. S. G. S. 3d Ann. Rept., pp. 253, 262). *Eureka qtzite.*—Compact vitreous qtzite; white and blue, passing into reddish tints at base; indistinctly bedded. Thickness 500 ft. Uncon. overlain by Lone Mountain ls. and underlain by Pogonip ls. Named for development at Eureka, Nev. [See E. Kirk, 1932, below.]

This fm. was mapped by S. H. Ball (U. S. G. S. Bull. 308, 1907) in Inyo Co., Calif.

E. Kirk, 1932 (Am. Jour. Sci., 5th, vol. 26, pp. 27–43). Recent observations show that Eureka qtzite may have been essentially a continental deposit. The widespread occurrence of cross-bedding, ripple marks, and sun cracks clearly indicates shallow water and emergent conditions over large areas. It may well be that except for marginal zone along W. border of its area the Eureka was subject to only partial and intermittent marine transgression. The Pinyon Range, Nev., is its northern known limit. There it is 400± ft. thick. Southern known limit is in S. part of Las Vegas quad., Nev., where it is 20 ft. thick. To W., in Amargosa Range, it is 800 ft. thick, in Kawich Range, 1,200 to 1,500 ft., in Monitor Range, 400± ft., while in Toquima Range it is absent. Eastern known limit is in Dugway Mtns, Utah (300 ft.), and Fish Springs Mtns and Confusion Ranges, Utah. It appears to be absent in Stansbury Mtns, Utah, but is represented in Frisco dist., SW. Utah, by Morehouse qtzite, 2,000 ft. thick. The Eureka qtzite as heretofore understood included 3 divisions: (1) At top 0 to 3± ft. of saccharoidal ss., which is now known to be of Upper Ord. (probably Maysville) age, and to be uncon. on (2), the main mass of the Eureka, which consists of dense, white, vitreous qtzite; the basal beds (3) vary from sandy calc. argillites, cross bedded, to massive, brownish, cross bedded sss., some lss., dol., etc., in places containing Black River (Middle Ord.) fossils. *It is here proposed, with the approval of*

U. S. Geol. Survey, to transfer to overlying Lone Mtn ls., the few ft. of Upper Ord. saccharoidal ss. at top, and to designate the exposures on SW. slope of Lone Mtn as the type section of the fm., because here it is completely exposed, together with overlying Lone Mtn ls. and underlying Pogonip ls., while it is not exposed at Eureka, although it is poorly exposed in Eureka region. The Lone Mtn section is 18± mi. NW. of Eureka, and was known to Hague, who named the fm. Recent work has shown that basal part of Eureka qtzite about 30 mi. SW. of Eureka grades laterally into sss., calc. beds, and lss.

†Eureka shale.

Devonian (?): Northern Arkansas.

J. C. Branner and F. W. Simonds, 1891 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 4, pp. xiii, 26–27). [According to p. xiii the fm. was named by Branner; the description is by Simonds.] *Eureka sh.*—Very black argill. sh., with marked tendency to break into prismatic blocks. Lithologically resembles Fayetteville sh. but is older. Same as "Black sh." of Dr. Safford in Tenn. Thickness in Washington Co., Ark., 10 to 12 ft. Oldest outcropping fm. in Washington Co. Underlies Boone chert and cherty ls.

E. O. Ulrich, 1904 (U. S. G. S. P. P. 24, correlation chart). ***Typical Eureka sh.*** underlies St. Joe ls., overlies Sylamore fm., and is=Noel sh.

A. H. Purdue and H. D. Miser, 1916 (U. S. G. S. Eureka Springs-Harrison folio, No. 202, correlation chart). Chattanooga sh. underlies St. Joe ls. memb. of Boone ls., overlies Clifty ls., and is divided into black clay sh. (which is=typical Eureka sh.) underlain by Sylamore ss. memb.

Named for Eureka Springs, Carroll Co.

†Eureka limestone.

Pennsylvanian: Southeastern Kansas.

E. Haworth, 1898 (Kans. Univ. Geol. Surv. vol. 3, pp. 67, 73). *Eureka ls.* proposed by G. I. Adams for ls. which serves as a protector and assists in production of permanent escarpment extending from Madison [in directions described in detail] to S. line of State. Overlies what seems to be equiv. of Osage shales [really a higher sh., the Scranton]. Same as Burlingame ls. [older name].

Preoccupied. Same as Burlingame ls., according to R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 215).

Named for Eureka, Greenwood Co.

†Eureka limestone.

Lower Ordovician and Upper, Middle, and Lower Cambrian: Central northern Utah (Tintic district).

G. W. Tower, Jr., and G. O. Smith, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, p. 622). *Eureka ls.*—Dolomitic, cherty, and shaly ls., with several beds of clay sl. near base. Thickness 4,000 ft. Underlies Godiva ls. and overlies Robinson qtzite. [A footnote on p. 620 says that in Tintic folio the Eureka ls. will be named *Mammoth fm.*, in order to avoid duplication of names, and it was so named. Later, however, (U. S. G. S. P. P. 107, 1919), it was divided into 9 fms. (of Lower Ord. and Upper, Middle and Lower Camb. age) and *Mammoth ls.* was abandoned.]

†Eureka beds.

Pennsylvanian: Eastern Kansas.

L. C. Wooster, 1905 (The Carbf. rock system of eastern Kans.). *Eureka beds* introduced [reason not stated] to include Topeka ls., Severy shales, Howard ls., Burlingame shales, and Burlingame ls.

Preoccupied and conflicts with established classification.

Probably named for Eureka, Greenwood Co.

Eureka rhyolite. (In Silverton volcanic series.)

Tertiary (Miocene): Southwestern Colorado.

W. Cross and E. Howe, 1905 (U. S. G. S. Silverton folio, No. 120). *Eureka rhyolite.*—Massive flows, dikes, and well-bedded tuffs, former greatly predominating. Much of rock can be called a flow breccia. Thickness thin to 2,000 ft. Uncon. underlies Burns latite complex and uncon. overlies Picayune andesite. [Mapped around town of Eureka, Silverton quad.]

Eureka fire clay.

A fire clay, 10 ft. thick, lying 100 ft. above Eureka coal in NE. Mo. Named for Eureka shaft.

Eureka Divide type.

Name applied by L. V. Pirsson (U. S. G. S. 20th Ann. Rept., pt. 3, pp. 326–327, 546–547, 1900) to a series of dikes of analcite basalt on Eureka Divide, btw. Bandbox Mtn and Steamboat Mtn, Little Belt Mtns, Mont.

Eurepticau.

A term used by H. M. Seely (7th Rept. Vt. State Geol., 1910) "to indicate the great interval existing in the rocks of western Vt.—the geological gap reaching up from top of the Utica to bottom of Pleistocene."

†Eurypterus beds.

A paleontologic name applied in some repts to Rondout ls. of N. Y.

Eutaw formation.

Upper Cretaceous: Western Georgia, Alabama, eastern and northern Mississippi, and western Tennessee.

E. W. Hilgard, 1860 (Rept. Geol. and Agric. Miss., pp. 3, 61–68). *Eutaw group.*—Bluish, black, or reddish laminated clays, often lignitic, alternating with and usually overlain by noneffervescent sands, mostly, though not always, poor in mica and of gray or yellow tint. Contains beds of lignite, and very rarely other fossils. Lowest Cret. fm. in Miss. Underlies Tombigbee sand group. Overlies Carbf.

Later studies revealed that Coffee sand of J. M. Safford is lithologically like but younger than Eutaw group of E. W. Hilgard, and that in northern Miss. it is underlain by a sand lithologically like Tombigbee sand of Ala. and forming the upward extension of that sand. The Coffee sand and Tombigbee sand were therefore for many years treated by U. S. Geol. Survey and Miss. Geol. Survey as members of *Eutaw fm.* (See L. W. Stephenson, Ga. Geol. Surv. Bull. 26, pl. 5, 1911; Wash. Acad. Sci. Jour., vol. 7, No. 9, 1917; U. S. G. S. W. S. P. 576, 1928.) Further studies, however, led Stephenson to opinion that Coffee sand should be treated as a distinct fm., and in March, 1936, it was decided to remove it from Eutaw fm. It grades laterally into basal part of Selma chalk, but is lithologically distinct.

In central and western Ala. the Eutaw fm. as now defined is overlain by Selma chalk, with which it intertongues. In eastern Ala. and western Ga. it is overlain by Ripley fm. In NE. Miss. it is overlain in places by Selma chalk, and in other places by Coffee sand. In western Tenn. it is everywhere separated from Selma chalk by Coffee sand. In western Tenn. it is in places underlain by Tuscaloosa fm. and in other places it rests on Paleozoic rocks; in Miss. and Ala. it is underlain by Tuscaloosa fm.

Named for Eutaw, Greene Co., Ala.

Evacuation Creek member *(of Green River formation).*

Eocene: Northeastern Utah (Uinta Basin) and northwestern Colorado (Garfield and Rio Blanco Counties).

W. H. Bradley, 1931 (U. S. G. S. P. P. 168). *Evacuation Creek memb.*—Barren sh. and marlstone that weathers brown or brownish gray. Locally the sh. is sandy and locally thin beds of soft claystone occur. Thickness 530 to 840 ft.; latter figure in vicinity of Piceance Creek, Rio Blanco Co., Colo. Top memb. of Green River fm. in S. part of Uinta Basin. Overlies Parachute Creek memb. Named for excellent exposures on Evacuation Creek, Utah.

Evans granite.

Pre-Cambrian (?): Central northern Colorado (Georgetown region).

J. Underhill, 1906 (Univ. Colo. Studies, vol. 3, No. 4, p. 272; also Colo. Sci. Soc. Proc., vol. 8, pp. 103–122). *Evans granite.*—Occupies a small area in W. part of Evergreen [Denver Mtn Parks] quad. Strongly resembles Central City granite and very likely is same petrographic unit.

Probably named for Mount Evans, Clear Creek Co.

Evans Creek coal series.

Eocene: Western central Washington (Puget Sound region).

B. Willis, 1886 (U. S. 10th Census, vol. 15, pls. 81, 84). Puget Sound coal measures divided into (descending): (1) *Evans Creek coal series,* 10,260 ft., including coals 24 to 127; (2) sh. and sss., 400 to 500 ft.; (3) *Wilkeson [coal] series,* 1,260 ft., including coals 11 to 20; (4) sh. and sss. and coals 10 and 11, 300–900 ft.; (5) lower series, including coals 1 to 9, 980 ft. The *Carbon River [coal] series,* 1,180 ft. thick, probably lies btw. coals 10 and 11.

Evans Gulch porphyry.

Eocene: Northern central Colorado (Leadville district).

S. F. Emmons, J. D. Irving, and G. F. Loughlin, 1927 (U. S. G. S. P. P. 148). *Evans Gulch porphyry.*—A gray porphyry, of fine, almost even-grained texture, containing less quartz and more biotite than Mount Zion porphyry. Belongs to Gray porphyry group. Named for exposures in Evans Gulch, E. of Leadville.

Evans Landing facies.

Name applied by P. B. Stockdale (Ind. Dept. Cons., Div. Geol., Pub. 98, pp. 76, 167, etc., 1931) to a lithologic development of his Carwood fm. in a part of southern Ind.

Evanston formation.

Eocene or Upper Cretaceous: Southwestern Wyoming.

L. Lesquereux, 1876 (U. S. Geol. and Geog. Surv. Terr. Bull. 5, 2d ser., pp. 244–248). *Evanston group* (upper Eo. or lower Mio.), may represent merely an upper memb. of Lower Lignitic (Eo.), which it overlies. Separated from Green River group (upper Mio.) by *Carbon group* (*middle Mio.*). [Latter name doubtless applies to Wasatch group, Eo.]

C. A. White, 1879 (U. S. Geol. and Geog. Surv. Terr. 11th Ann. Rept., pp. 240–241). *Evanston coal series* underlies Wasatch and overlies Bear River.

A. C. Veatch, 1906 (U. S. G. S. Bull. 285, p. 332). *Evanston fm.*—Gray and yellow clays, with irregular ss. beds containing Almy coal and several minor coal beds. Characterized by plants which are distinctive of upper Laramie beds, and by invertebrates which are common to the Laramie and Fort Union. Thickness 1,500 ft. Of Eo. or Upper Cret. age. Underlies Wasatch and rests on Bear River and Jurassic beds. Exposed from Evanston for 10 mi. N. The coal mined at Evanston is in this fm. Is same as "Evanston coal series" of C. A. White, 1879.

A. C. Veatch, 1907 (U. S. G. S. P. P. 56), gave thickness of *Evanston fm.* (*"Upper Laramie"*) as 1,600± ft. and stated that it rests on Bear River and Beckwith fms.

†Evanston coal series.

See 1879 entry under *Evanston fm.*

†Evanstonian series.

A term applied by C. [R.] Keyes (Pan-Am. Geol., vol. 41, 1924, pp. 36, 65–66) to Evanston fm.

Evansville sandstone bed. (In Wellington formation.)

Permian: Central northern Oklahoma (Logan and Lincoln Counties).

J. M. Patterson, 1933 (A. A. P. G. Bull., vol. 17, No. 3, pp. 243, 251, etc.). The name *Evansville ss. bed* is proposed for a ss. bed in Iconium memb. of Wellington fm. that has heretofore been called by some geologists the *Bu-Vi-Bar bed,* because it is well developed near a dry hole drilled by Bu-Vi-Bar Oil Co. close to town of Evansville. Lies lower in section than Lowrie ss. bed. Bed has been traced from S. line of Logan Co. to N. line of T. 16 N., R. 1 W. It is massive ss., cross-bedded, friable, reddish brown, and averages about 25 ft. in thickness. Top of bed is exposed ¾ mi. E. of Evansville, with approx. elev. of 1,120 ft., but is better exposed as conspicuous ledges S. of there, at locality 500 ft. N. of SW. cor. of sec. 25, T. 15 N., R. 1 W., Logan Co., at elev. 1,062± ft. Latter exposure shows top of the ss. and base of overlying sh.

†Everett schist.

Ordovician: Southwestern Massachusetts and northwestern Connecticut.

W. H. Hobbs, 1893 (Jour. Geol., vol. 1, pp. 717–736, 780–802). *Everett schist.*—The upper schist horizon of Mount Washington. Overlies Egremont ls. Is top fm. of Mount Washington series. Named for fact it has its max. thickness within area of Mount Everett, Mass. Is a porphyritic rock not easily distinguished from Riga schist, from which it differs chiefly in absence of macroscopic garnets and staurolites. Correlated with Greylock schist of NW. Mass.

Is same as Berkshire schist. See B. K. Emerson, 1917 (U. S. G. S. Bull. 597 and map).

†Everglades limestone.

Pleistocene: Southeastern Florida.

W. H. Dall, 1892 (U. S. G. S. Bull. 84, pp. 101, 154, 157, 325). The deposit upon which the Everglades immediately rest, in this part at all events, is a recent organic ls. probably based on the Tert. rocks, which farther N. are elevated above the sea. For it we may provisionally adopt the name *Everglades ls.* It is the rock forming about the margin and underlying the basin of the Everglades of Fla.; the deposits lately formed and apparently now forming in region of Everglades. They are partly organic and partly chemical in origin. To latter fact may perhaps be ascribed the exceptionally crystalline character which some of Everglades ls. exhibits and which, so far, has not been duplicated elsewhere in State. [According to table on p. 157 it underlies white sand and overlies †Vermetus rock.]

Replaced by Miami oolite and Anastasia fm. (both Pleist.) and Caloosahatchee marl (Plio.).

Evergreen amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name locally in use many years. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. The fm. belongs in Central Mine group, since it lies above cgl. No. 8, in Evergreen mine, N. of Evergreen Bluff, Ontonagon Co. The mineralized part is the Evergreen lode.

Evergreen flow.

Includes Evergreen amygdaloid and underlying trap.

Everona limestone.

Lower Ordovician: Northeastern Virginia.

A. I. Jonas, 1927 (Geol. Soc. Am. Bull., vol. 38, p. 842). *Everona ls.*—A narrow belt of blue slaty ls. exposed from Mitchells Ford, on Rapidan River, to SW. of Rivanna River near Charlottesville. Named for small village in Orange Co., where the ls. is exposed in a small quarry N. of Mountain Run. The ls. is blue, crystalline, with slaty partings, closely crumpled, with breaks cemented by secondary white calcite, and is interbedded with thin, blue, only slightly calc. slates, which form a considerable part of fm. Probably of same age as Frederick ls. of Md., which Bassler concludes is probably Chazy. Is believed to be in fault contact with Wissahickon schist.

Eversole chert.

Middle Devonian: Central Ohio.

C. R. Stauffer, 1909 (Ohio Geol. Surv. Bull. 10, pp. 72–74). *Eversole chert.*—Layers of gray chert alternating with layers of subcrystalline gray or brown ls.; 8 ft. thick. Forms zone D of Columbus ls.

Named for Eversole Run, Delaware Co.

Everton limestone.

Lower Ordovician: Southern Missouri and northern Arkansas.

A. H. Purdue, 1907 (Geol. Soc. Am. Bull., vol. 18, pp. 251–256). *Everton ls.*—Named by E. O. Ulrich, from Everton, Boone Co., Ark. Absent over W. and extreme N. parts of Ark. Uncon. underlies Upper St. Peter of Ulrich [St. Peter ss. of present usage] (which in places was deposited in hollows in Everton ls.) and uncon. overlies Lower St. Peter of Ulrich [later named Kings River ss. memb.].

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27). *Everton ls.* uncon. underlies St. Peter ss. and uncon. overlies Yellville fm. [The Yellville of this 1911 rept applied to Powell ls. only, according to A. H. Purdue and H. D. Miser, 1916 publication cited below.]

A. H. Purdue and H. D. Miser, 1916 (U. S. G. S. Eureka Springs-Harrison folio, No. 202). *Everton ls.* consists of 3 subdivisions: (1) Sneeds Creek ls. lentil at base; (2) Kings River ss. memb.; and (3) a fine-grained nonmag. ls. interbedded with ss., which forms bulk of fm. in Harrison quad. and a small part of it in Eureka Springs quad.

C. L. Dake, 1921 (Univ. Mo. School Mines and Met. vol. 6, No. 1). In Mo. *Everton ls.* consists of 2 members: (1) a basal group of dominantly sandy beds with some interbedded lss., and (2) an upper ls. The lower memb. is 20 to 55 ft. thick; the upper memb. 0 to 55 ft. thick. Rests uncon. on Powell ls. or older beds. (See also under *†St. Peter group.*)

E. T. McKnight, 1935 (U. S. G. S. Bull. 853). *Everton fm.* of Yellville quad., northern Ark., is 0 to 400 ft. thick. It underlies the unfossiliferous Jasper ls. (0 to 50 ft. thick) and farther E. in Ark. uncon. overlies Black Rock fm., of Beekmantown age. It is possible later work may show that Jasper ls. really belongs to Everton fm. The Jasper is uncon. overlain by true St. Peter ss. The Everton as here interpreted includes the so-called Joachim ls., the so-called St. Peter ss. (here named *Newton ss. memb. of Everton fm.*), and the so-called Everton ls. (0 to 190 ft. thick) of Eureka Springs-Harrison folio. [See under *Black Rock fm.*]

J. Bridge, March 1937 (personal communication). *Everton* belongs with the Chazy. In fact some consider it post-Chazy.

Ewing limestone member (of Conemaugh formation).

Pennsylvanian: Southeastern Ohio and northern West Virginia.

E. Orton, 1878 (Ohio Geol. Surv., vol. 3, pp. 889, 890, 897, and pls. opp. pp. 889, 900, 912). *Ewing ls.*—Ferruginous ls., 5 ft. thick, in Coal Measures, about 80 ft. above Cambridge ls. and 40 ft. below Ames ls. Extends from Sunday Creek Valley southward to Ohio River.

Named for Ewing Site, in Sunday Creek Valley, in Hocking or Perry Co.

Excelsior formation.

Middle Triassic: Southwestern Nevada (Tonopah and Hawthorne quadrangles).

S. W. Muller and H. G. Ferguson, 1936 (Geol. Soc. Am. Bull., vol. 47, pp. 241–252). *Excelsior fm.*—Dominantly effusive and pyroclastic rocks, with subordinate sediments. The lavas range from andesite through quartz latite to rhyolite. Is cut by intrusives that are probably of same age as the lavas. Thickness 12,000 ft. In Pilot and Excelsior Ranges 8,000 ft. of fm. consists of massively bedded cherts, which microscope shows to be extremely fine-grained water-laid tuff cemented and largely replaced by silica. Interbedded with the cherts are dark tuffaceous slates, a little impure ss., and some lava and breccia. The cherts are present in other ranges but are subordinate. In places lenticular lss. occur; these have yielded some Middle Triassic fossils. Overlies Candelaria fm. (Lower Triassic), probably with uncon., but contact not seen. Underlies Luning fm. (Upper Triassic) with marked erosion uncon. Named for Excelsior Mtns, where fm. is well exposed in Gold Range min. dist., about 6 mi. SW. of Mina.

Exeter diorite.

Post-Carboniferous: Southeastern New Hampshire (Rockingham County).

C. H. Hitchcock, 1870 (2d Ann. Rept. Geol. N. H., map and p. 32). *Exeter syenites.*—Syenitic rocks, of probable Laurentian age, exposed along Boston & Maine R. R. btw. Mass. and Maine, especially in towns of Exeter and Dover (SE. N. H.). They form, apparently, an anticlinal mass overlaid by Merrimack slates.

C. H. Hitchcock, 1877 (Geol. N. H., pt. 2, btw. pp. 658 and 675), used *Exeter sienite and diorite.*

F. J. Katz, 1917 (U. S. G. S. P. P. 108, p. 176). *Exeter diorite.*—Generally even, medium-grained light- to medium-gray hornblende-biotite diorite or quartz diorite. Intrudes Kittery qtzite and Eliot sl. Occurs in Exeter, Newmarket, Durham, Madbury, Dover, and Rollinsford Twps, in Rockingham and Strafford Counties. Is post-Carbf. Named for occurrence in Exeter Twp, Rockingham Co.

Exeter syenite.

See *Exeter diorite.*

Exeter sandstone.

Jurassic (?): Northeastern New Mexico and Panhandle of Oklahoma (Cimarron County).

W. T. Lee, 1902 (Jour. Geol., vol. 10, pp. 45–46). *Exeter ss.*—Firm, hard, and rather coarse but even-laminated sss., pink to white. Consists of (descending): (1) Massive white ss., 35 ft.; (2) loose-textured and readily weathered ss.; (3) massive chalky white ss., cross bedded and cavernous weathering, 15 ft.; (4) soft shaly ss., 2 ft.; (5) massive evenly laminated ss., ranging from red at base to white at top, 15 ft. Thickness of fm. 75 ft. near Exeter P. O., where it is overlain conformably by Morrison fm. and rests uncon. on Red Beds. [The P. O. was formerly spelled *Exter.* The town is now called Johnson.]

T. W. Stanton, 1905 (Jour. Geol., vol. 13, pp. 664–665). *Exter ss.*—Massive white or pinkish ss. which Mr. Lee has described as Exter ss. varies greatly in thickness. Max. observed was 80 ft. Is in places separated from overlying Morrison fm. by 40 to 50 ft. of gyp. and gypsiferous sh. Rests on Red Beds with striking angular uncon.

J. T. Duce, 1924 (Colo. Geol. Surv. Bull. 27, pt. 3, pp. 79–93), stated that in SE. Colo. the Exeter ss. appears as a thin lentil btw. the Morrison and the Lykins fm.

E. P. Rothrock, 1925 (Okla. Geol. Surv. Bull. 34, p. 36). *Exeter ss.* underlies Morrison fm. either discon. or uncon. It overlies the red beds and wedges out to E. in Cimarron Valley before reaching Okla.

R. K. DeFord, 1927 (Okla. Geol. Surv. Press Bull. May 3, 1927). *Exeter ss.* outcrops in T. 6 N., R. 1 E. and T. 5 N., R. 1 E., Cimarron Co., Okla., where it underlies Morrison fm. (consisting of sss., variegated shales, ls.) and rests with angular uncon. on unnamed variegated shales, which are absent in places. Lee described the uncon. but did not mention the brilliantly variegated shales which in places are present beneath the uncon. and above the Triassic red shales.

R. K. DeFord, 1927 (A. A. P. G. Bull., vol. 11, No. 7, pp. 753–755). *Exeter ss.*, massive ss., underlies Morrison fm. in Cimarron Co., Okla., and rests with angular uncon. on variegated shales which were mapped as Morrison fm. in Okla. Geol. Surv. Bull. 34, but which are probably Triassic.

N. H. Darton, 1929 (U. S. G. S. Bull. 794, p. 306). One ss. which lies considerably below middle of Morrison fm. in canyon of Cimarron River in NE. part of Union Co., N. Mex., has been called *Exeter ss.* by Lee. I am confident it is same bed that appears continuously in SW. part of Union Co. and E. part of San Miguel Co. in middle of Morrison fm. but here increased somewhat in thickness. In places the underlying sh. or clay is absent and the ss. rests uncon. on Triassic "Red Beds" (Dockum group), with some local discordances of dip as described by Lee. Near center of R. 34 E. the surface of "Red Beds" slopes down to W., and 80 ft. of what seems to be typical Morrison massive clay lies btw. the white ss. (Exeter) and the eroded surface of the "Red Beds."

B. H. Parker, 1930 (Kans. Geol. Soc. 4th Ann. Field Conf., p. 132), and 1933 (Jour. Geol., vol. 41, No. 1, pp. 40–43), introduced *Sheep Pen Canyon fm.* for 0–68 ft. of ss., of Triassic (?) age, in Union Co., NE. N. Mex., which he stated overlies Sloan Canyon fm. and underlies Exeter ss., "with which it has been confused."

C. W. Sanders, 1934 (A. A. P. G. Bull., vol. 18, No. 7, p. 866). Writer believes *Exeter ss.* is a ss. lentil in lower part of Morrison fm.

B. H. Parker, 1934 (A. A. P. G. Bull., vol. 18, No. 11, pp. 1544–1546). In Cimarron Valley, N. Mex., Morrison fm. rests on Todilto (?) fm. (0 to 15 ft. thick), which rests on *Exeter ss.* (0 to 80 ft. thick), which in places lies on Sheep Pen ss., in places on the older Sloan Canyon fm., and in places on the still older Dockum group. The Sloan Canyon has been mistaken, by some geologists, for Morrison fm., which has resulted in inclusion of Exeter ss. in the Morrison.

The U. S. Geol. Survey still treats Exeter ss. as a distinct fm., older than Morrison.

†Exogyra arietina clay.

†Exogyra arietina marl.

Paleontologic names for Lower Cret. beds in Tex. that were later named *Del Rio clay.*

†Exogyra ponderosa marl.

Paleontologic name for Upper Cret. beds in eastern Tex. that were later named *Taylor marl.* The Brownstown marl of Veatch (which in Ark. includes Ozan fm.) has also been called "Exogyra ponderosa marl."

†Exogyra texana clay.

Paleontologic name for Lower Cret. beds in Tex. later named *Walnut clay.*

Extension formation.

Upper Cretaceous: British Columbia.

C. H. Clapp, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 97).

Extension breccia (intrusive).

Tertiary: Central Nevada (Tonopah district).

T. B. Nolan, 1930 (Univ. Nev. Bull., vol. 24, No. 4, p. 17). *Extension breccia.*—Name has been locally used in Tonopah dist. for an intrusive mass of breccia whose relations are best exposed in Tonopah Extension mine; and, as it is desirable to distinguish this mass, the name is retained here. In previous mapping this fm. has probably been included in either Tonopah fm. or "Montana breccia." Max. thickness probably in neighborhood of 1,000 ft. Is younger than Mizpah trachyte, for it includes fragments of that rock, and is intruded by West End rhyolite. Probably formed in same general period of volcanic activity as Tonopah fm. and its associated flows.

†Exter sandstone.

Same as *Exeter ss.*, the spelling used in original definition and most subsequent repts, although the correct spelling of the town (in Union Co., N. Mex.) for which it was named is said to be *Exter.* The town, however, is now known as *Johnson.*

Fabre series.

Pre-Cambrian: Quebec.

R. Harvie, Jr., 1911 (Quebec Dept. Colonization, Mines, and Fisheries, Mines Branch, pp. 9, 15).

Factoryville moraine.

Pleistocene (Wisconsin stage). NE. N. Y. (Essex Co.). Named for Factoryville. See N. Y. State Mus. Bull. 187, 1916.

Fagundas conglomerate.

Term applied by J. F. Carll (2d Pa. Geol. Surv. Rept. I, pp. 38–40, 1875) to the coarse cgl. that appears in hill tops at Fagundas, Warren Co., NW. Pa., which is said to be same as Olean cgl. memb. of Pottsville fm.

Fairfax formation.

Pennsylvanian (Conemaugh): Northeastern West Virginia and western Maryland.

N. H. Darton and J. A. Taff, 1896 (U. S. G. S. Piedmont folio, No. 28). *Fairfax fm.*—Lower half has thin and impure ss. beds interstratified with thicker beds of sh. and contains two thin and poor coal beds. Upper half is clay sh. and minor bands of sandy sh., with a bed of ss. (20 ft. thick) nearly 20 ft. below top and an 18-inch coal bed 40 to 50 ft. below top. Upper limit of fm. is base of Elkgarden coal or 14-foot bed. Thickness about 300 ft. Underlies Elkgarden fm. and overlies Bayard fm. Exposed around Fairfax, Grant Co., W. Va.

Fairfax limestone.

Pennsylvanian: Northern West Virginia.

D. B. Reger, 1923 (W. Va. Geol. Surv. Tucker Co. Rept. pp. 130, 149, 156). *Fairfax ls.*—Hard gray ls., 2 ft. thick, visible near summit of Fairfax Knob, Grant Co. Lies about 5 ft. beneath Pittsburgh coal and about 3 ft. above Morantown coal. A fresh-water deposit near top of Conemaugh series.

Fairfax.

Eocene: Western Washington (Puget Sound region).

See under *Melmont*.

Fairfield slate.

Upper Ordovician: New York.

L. Vanuxem, 1842 (Geol. N. Y., pt. 3, pp. 56–60), stated that Utica sl. is *Fairfield sl. of repts,* but compiler has been unable to find any previous use of *Fairfield*. W. W. Mather also stated (Geol. N. Y., vol. 1, p. 367, 1843) that Fairfield sl. is a synonym of Utica sl.

Fairfield member. (In Cuyahoga formation.)

Mississippian: South-central Ohio.

J. E. Hyde, 1915 (Jour. Geol., vol. 23, pp. 656, 657, 671). *Fairfield memb.*—Alternating sss. and shales; the sss. typically coarse, reddish, yellowish, brown or bluish gray, sometimes pebbly and commonly in massive members, 20 to 60 ft. thick, with intervening shaly members of similar thickness; the sh. strata formed of thin interbedded sss. and shales, the former likely to be very coarse even where thin. Thickness 200 to 330 ft. Included in Cuyahoga fm. of Fairfield and Hocking Counties. Overlies Lithopolis memb., and underlies Black Hand memb. [restricted use of Black Hand].

Named for development in Fairfield Co.

Fairfield coal group. (In Mesaverde group.)

Name locally applied to basal 900 ft. of Williams Fork fm. (Upper Cret.) in Meeker, Axial, and Monument Butte quads., NW. Colo. Underlies Twenty-mile ss. memb. and overlies Trout Creek ss. memb. of Iles fm. Named for Fairfield mine, Meeker quad. (See U. S. G. S. Bull. 812C, by E. T. Hancock and J. B. Eby, 1930, pp. 206, 288–230, etc.)

Fairhaven diatomaceous earth member (of Calvert formation).

Miocene: Eastern Maryland.

G. B. Shattuck, 1904 (Md. Geol. Surv. Miocene vol., p. lxxii). *Fairhaven diatomaceous earth memb.*—Characterized by presence of large proportion of diatoms embedded in a very finely divided quartz matrix. Only small amount of calc. material. Consists of (descending) 20 ft. of diatomaceous earth; 1 ft. white sand locally indurated to ss.; and 2 to 6 ft. of brownish sand. Named for Fairhaven, Anne Arundel Co.

Fairlee granite gneiss.

Cambrian: Northeastern Vermont (Orange County).

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), listed this name in Camb. of eastern Vt., but without definition. Probably named for Fairlee Twp, McCube quad., Orange Co., or some of the geographic Fairlee features within that Twp.

J. B. Hadley (letter dated April 23, 1936). In my opinion, and in opinion of M. Billings, the fm. referred to, but not described, by Foyles and Richardson is *quartz monzonite,* and I am calling it *Fairlee quartz monzonite* in rept. in preparation.

Fairmont shale member (of Hennessey shale).

Permian: Central northern Oklahoma.

F. L. Aurin, H. G. Officer, and C. N. Gould, 1926 (A. A. P. G. Bull., vol. 10, pp. 786–799). *Fairmont sh. memb.*—The lower 250 ft. of Hennessey sh., consisting largely of deep-red clay sh., not conspicuously laminated, but blocky and breaking with a characteristic conchoidal fracture. Has scattered thin white or greenish bands or streaks, rarely more than a few inches thick. Is composed of alternating hard and soft layers. Underlies Bison banded memb. of Hennessey sh. Named for exposures near Fairmont, Garfield Co.

J. M. Patterson, 1933 (A. A. P. G. Bull., vol. 17, No. 3, pp. 253–254). Since the beds lying above redefined top of Garber fm. are predominantly red sh. for several hundred ft., it is proposed that Fairmont memb. of Hennessey fm. include the beds btw. top of redefined Garber fm. and base of Bison banded memb. of the Hennessey. Part of the Fairmont as thus redefined was mapped as Garber by Aurin, Officer, and Gould. At least 200 ft. of lower part of Fairmont shales are exposed above the Garber in Logan Co. The Fairmont is at least 90 percent. sh., with thin beds and lenses of fine ss. throughout. The sh. is red, blocky, nonlaminated, sandy, and contains dolomitic concretions; sun cracks locally. Lenses of ss. like underlying Garber ss. occur in basal 50 ft. of the Fairmont. The sss. above basal 50 ft. are finer grained than any ss. in Stillwater, Wellington, and Garber fms.; are reddish brown to gray, thin, cross-bedded, lenticular, and rarely more than 5 ft. thick. Thin dolomitic cgls. are generally found at bases of the sss.

J. C. Ross, 1933 (A. A. P. G. Bull., vol. 17, No. 3, p. 255). [See under *Garber ss.*]

Fairmont morainic system.

Pleistocene (Wisconsin stage): Southern Minnesota and northern Iowa.

F. Leverett, 1932 (U. S. G. S. P. P. 161, pp. 90–93). Composed of unnamed members. The town of Fairmont, Martin Co., Minn., stands on this morainic system, which may blend with Gary morainic system in SW. Minn.

†Fairmount gneiss.

Pre-Cambrian: Southeastern Pennsylvania.

T. D. Rand, 1887 (2d Pa. Geol. Surv. Ann. Rept. 1886, pp. 1601–1603). *Fairmount gneiss.*—Fine-grained orthoclase-albite-muscovite gneiss which forms hill at Fairmount. Differs from all other gneisses in vicinity in containing numerous veins or beds of granite, generally very coarse. Has been quarried at Fairmount. Is overlain by mica schists and hornblende schists.

Is a part of Wissahickon fm.

Fairmount limestone member (of Fairview formation).

Upper Ordovician: Southwestern Ohio, southeastern Indiana, and northern Kentucky.

J. M. Nickles, 1902 (Cincinnati Soc. Nat. Hist. Jour., vol. 20, p. 78). *Fairmount or Dekayia aspera beds.*—Alternating thin-bedded bluish lss. and bluish, pale yellowish, or brownish shales, 80 ft. thick. Overlain by Bellevue or *Monticulipora molesta* beds and underlain by Mount Hope or *Amplexopora septosa* beds.

Upper memb. of Fairview fm.

Named for Fairmount, a part of Cincinnati, Ohio.

Fairmount limestone. (In McLeansboro formation.)

Pennsylvanian: Central eastern Illinois (Vermilion County).

E. F. Lines, 1912 (Ill. Geol. Surv. Bull. 17, pp. 59, 75). *"Fairmount" ls.*—Important Penn. ls. outcropping over area of less than 2 sq. mi. near Fairmount, Vermilion Co. Used in manufacture of portland cement. Included in McLeansboro fm. [Used by E. F. Lines in quotation marks and probably is economic term only.]

J. E. Lamar and H. B. Willman, 1934 (Ill. Geol. Surv. Bull. 61, pp. 129–138). La Salle fm. includes the 16 to 20-foot ls. in Vermilion Co. called *Fairmount ls.*

†Fairmount slate.

Upper Cambrian: Northwestern Georgia (Gordon County).

H. K. Shearer, 1918 (Ga. Geol. Surv. Bull. 34, map opp. p. 43). [*Conasauga (Fairmount) sl.* is name used on map. In text the rocks are called "the green sl. belt of Conasauga fm."] Although Conasauga fm. is areally one of most important of Paleozoic area of Ga., the green sl. deposits are confined to comparatively small belt along E. border of outcrop of fm. In the slate-bearing area of the fm. no younger fms. are present. On account of folding and faulting it is impossible to say whether the sl. beds represent top or bottom of Conasauga fm.

Preoccupied by other uses of Fairmount.

Named for development about Fairmount, Gordon Co.

Fairport chalky shale member (of Carlile shale).

Upper Cretaceous: North-central Kansas.

W. W. Rubey and N. W. Bass, 1925 (Kans. Geol. Surv. Bull. 10, pp. 16, 40). *Fairport chalky sh. memb. of Carlile sh.*—Chalky sh. and thin beds of chalk, 85 ft. thick, forming basal memb. of Carlile sh. in Russell Co. Replaces "Ostrea shales" of Logan. Underlies Blue Hill sh. memb. and overlies Greenhorn ls. Named for exposures a few mi. S. and W. of Fairport, Russell Co.

Fairview diorite.

Tertiary: Central southern Colorado (Silver Cliff-Rosita Hills region).

W. Cross. 1896 (U. S. G. S. 17th Ann. Rept., pt. 2, p. 291). *Fairview diorite.*—Dikes and irregular masses. Named for Mount Fairview.

Fairview formation. (In Maysville group.)

Upper Ordovician: Southwestern Ohio, southeastern Indiana, and north central Kentucky.

R. S. Bassler, 1906 (U. S. Nat. Mus. Proc., vol. 30, p. 10). *Fairview fm.*—Name proposed to include J. M. Nickles' divisions *Mount Hope* and *Fairmount.* About 100 ft. thick. Overlain by McMillan fm. and underlain by Eden.

Lower fm. of Maysville group.

Named for Fairview Heights, Cincinnati, Ohio.

†Fairview formation.

Lower Cambrian: Alberta and British Columbia.

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804, pp. 2, 5). *Fairview fm.*—Gray qtzitic sss., 1,000+ ft. thick on E. slope of Fairview Mtn. Base not seen. Underlies Lake Louise fm. Type loc. is NE. slope of Fairview Mtn.

C. D. Walcott, 1917 (Smithsonian Misc. Coll., vol. 67, No. 1, Pub. 2444), discarded this preoccupied name, and included the beds in a fm. which he named *Fort Mtn,* of which they form upper part. See under *Fort Mtn ss.*

†Fairview shale.

Upper Devonian: Colorado (Pitkin region).

J. M. Hill, 1909 (U. S. G. S. Bull. 380, pp. 24, 35–36). *"Fairview" sh.,* local name for a mottled yellow sh., 40 ft. thick, separated from overlying buff "buckskin ls." by 10 ft. of mottled red sh. and from underlying "Parting" qtzite by 18 ft. of gray dol. Crops out in Quartz Creek dist. The ore of Fairview mine (7½ mi. a little W. of N. of Pitkin) usually lies in upper part of the dol. just beneath "Fairview" sh.

R. D. Crawford and P. G. Worcester, 1916 (Colo. Geol. Surv. Bull. 10). The lss. locally called "Buckskin lss." in Gold Brick dist. are underlain by 10 to 15 ft. of brownish-gray aren. shales and shaly lss., thin-bedded and ripple-marked, which are locally called *Fairview sh.,* because they form the hanging wall in Fairview mine. They are separated from underlying white or red qtzite, locally called parting qtzite (but which is believed to lie stratigraphically lower than so-called "Parting" qtzite of Leadville dist.), by 1 ft. of qtzite underlain by 35 ft. of massive blue-gray or dark-gray sandy dolomitic ls.

Lies in lower part of Chaffee fm.

Fajardo shales.

Cretaceous: Puerto Rico.

C. P. Berkey, 1915 (N. Y. Acad. Sci. Annals, vol. 26, p. 61). Assigned to early Cret. (?).

Recent (1931 and 1933) repts by H. A. Meyerhoff assign this fm. to *Cret.*

Falkirk dolomite.

Silurian (Cayugan): Western New York.

G. H. Chadwick, 1917 (Geol. Soc. Am. Bull., vol. 28, pp. 173–174). *Falkirk dol.*—Brownish and bituminous; below massive and often producing waterfalls. Thickness 30 feet. Underlies Scajaquada dark shales and blocky waterlimes, and overlies O-atka beds. Is a part of the Bertie [ls. memb. of Salina fm.].

Derivation of name not stated.

Fall Creek conglomerate lentil (of Chemung formation).

Upper Devonian: Northeastern Pennsylvania (Bradford County) and central southern New York? (Ithaca? region).

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. G_5, pp. 74–79, 82, 98, 100, 236). *Fall Creek cgl.*—Rather coarse, very hard yellow sandrock, full of shells in lower layers. Contains many fragments of coaly material derived from carbonized plants. Bottom layer is mass of shells. Type loc., Fall's Creek, in Bradford Co. Same as Cascade ss. and Panama cgl.

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Final Rept., vol. 2, p. 1556). Mr. Sherwood's claim to have identified *Fall Creek cgl.* through southern counties of N. Y. with Venango third oil sand rock is hardly worth consideration.

H. S. Williams, 1906 (Sci., n. s., vol. 24, pp. 365–372). *Fall Creek cgl. lentil*, top memb. of Chemung fm. at Ithaca, N. Y., is interpreted to be=cgl. of that name in Bradford and Tioga Counties, Pa. Thickness 0 to 10 ft. Overlies Wellsburg ss. memb. of Chemung.

H. S. Williams, 1906 (Jour. Geol., vol. 14, p. 579). *Fall Creek cgl. lentil*, 0 to 10 ft. thick; top memb. of Chemung fm. at Ithaca, N. Y.

H. S. Williams, 1907 (Am. Ass. Adv. Sci. Proc., vol. 56, pp. 265–267) and 1909 (U. S. G. S. Watkins Glen-Catatonk folio, No. 169). A thin band of cgl. in top of Chemung fm. at Ithaca, N. Y., is supposed to be same as Fall Creek cgl. of Bradford Co., Pa. It overlies *Leptostrophia* zone, top bed of Wellsburg ss. memb. of Chemung.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369), included Fall Creek cgl. in Chemung of central N. Y. On p. 406 she stated: Wellsburg ss., typically exposed at Wellsburg, Chemung Co., contains near top a 10-foot lentil of cgl., the *Fall Creek cgl.*

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60, p. 323). In Tioga Co., Pa., the Dunkirk sh. includes *Fall Creek cgl.*, which rests on true Chemung and belongs in Canadaway group.

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, p. 593). It looks to writer as if Fall Creek cgl. is below Luthers Mills coquinite, perhaps 50 ft. lower. I. C. White's correlation of it with Cascade ss. is perhaps nearer the truth than is usually supposed.

Fallis member (of Wellington formation).

Permian: Central northern Oklahoma (Logan and Lincoln Counties).

J. M. Patterson, 1933 (A. A. P. G. Bull., vol. 17, No. 3, pp. 243, 248+). *Fallis memb. of Wellington fm.*—Basal 240 ft. of Wellington fm. in Logan and Lincoln Counties. At least 90 percent is ss., friable, micaceous, reddish brown. Includes red sh. lenses with max. thickness of 20 ft. Fossil wood and imperfect barite rosettes locally. Base is in places marked by bed of dolomitic cgl. 2± ft. thick, which forms ledges in T. 15 N., R. 2 E. Tops of the shales are generally marked by dolomitic cgls. The sh. increases to N., and W. of Stillwater probably 50 percent of it is sh. Overlies Stillwater fm. Named for town of Fallis, sec. 29, T. 15 N., R. 2 E., Lincoln Co. The P. O. of Fallis is about 40 ft. above base of the ss. Contact with overlying Iconium memb. of Wellington is shown 1½ mi. E. of Iconium, 50 ft. E. of SW. cor. of sec. 12, T. 16 N., R. 1 E., Logan Co., at 1,109± ft. elev.

Fall River sandstone.

Pennsylvanian: Southeastern Kansas.

Robt. Hay, 1887 (Kans. Acad. Sci. Trans., vol. 10, p. 7 and cross section). *Fall River ss.*—Massive ss., 85 ft. thick, toward top of section in Wilson Co. Overlain by 150 ft. of sh., ss., and ls., with alluvium and gravel at top. Separated from underlying Dun ls. by 145 ft. of sh., ls., and ss.

Named for Fall River, Greenwood Co.

There is no other record of this name. According to R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 124), Dun ls. of Hay included Plattsburg, Vilas, and Stanton fms.

Fall River sandstone. (In Inyan Kara group.)

Lower Cretaceous: Western South Dakota (Black Hills region), northeastern Wyoming, and (in wells) southeastern Montana.

W. L. Russell, 1927 (Am. Jour. Sci., 5th, vol. 14, p. 402). It has been shown by writer elsewhere (S. Dak. State Geol. and Nat. Hist. Surv. Bull. 14, 1927, in press) that so-called Dakota ss. of Black Hills region is in reality older than true Dakota, and it will be called *Fall River fm.* in this paper. Overlies Fuson fm. and underlies Graneros sh. [Type loc. not stated.]

W. L. Russell, 1928 (Econ. Geol., vol. 23, No. 2, pp. 136–137). The so-called Dakota ss. of Black Hills region is here renamed *Fall River fm.* According to fossil plants identified by E. W. Berry it is much older than typical Dakota ss. of eastern Nebr. It consists of 75 ft. of sss. and interbedded shales underlying Graneros sh. and overlying Fuson sh. Type loc. is at Evans quarry, on Fall River, below Hot Springs, Fall River Co., S. Dak.

W. W. Rubey, 1930 (U. S. G. S. P. P. 165A, p. 5). *Fall River ss.* is so-called Dakota ss. of previous repts on Black Hills region. It is top fm. of Inyan Kara group, of Lower Cret. age, and named for exposures along Inyan Kara Creek in NE. part of Moorcroft quad., Wyo. Conformably underlies Graneros sh. and overlies Fuson fm. Continental except upper 20 ft., which contains marine fossils.

Falls formation.

Lower Ordovician (Chazy): Central southern Oklahoma (Arbuckle and Wichita Mountains).

E. O. Ulrich in 1928, at N. Y. meeting of Geol. Soc. Am., exhibited a ms. chart (which he did not publish) in which he divided Simpson fm. of Okla. into (descending) Bromide, Criner, Tulip Creek, McLish, *Falls*, Nebo, and Joins Ranch. In Feb. 1930 (U. S. Nat. Mus. Proc., vol. 76, art. 21, p. 73) Ulrich published the following as his subdivisions of Simpson fm. (descending) Bromide, Criner, Tulip Creek, *Falls*, McLish, Oil Creek, and Joins. C. E. Decker, however, in Dec. 1930 (A. A. P. G. Bull., vol. 14, No. 12, p. 1495), published Ulrich's 1928 list, as "reported by Dr. Chas. N. Gould."

C. E. Decker, 1930 (A. A. P. G. Bull., vol. 14, No. 12, pp. 1498–1505), divided Simpson fm. into (descending): Bromide (of Trenton and Black River age); Tulip Creek (of Black River? age); McLish (of Chazy age, and *same as Falls, abandoned*); Oil Creek (of Chazy age); Joins (of Chazy age); and basal cgl. (of Beekmantown? age).

C. E. Decker and C. A. Merritt, 1931 (Okla. Geol. Surv. Bull. 55, pp. 12, 98). *Falls Creek* is approx. = McLish to E. and has been discarded. [See under *McLish fm.* On p. 28 they say: Because of interlocking of faunas, that which was temporarily called *Falls fm.* has now been included in the McLish.]

E. O. Ulrich, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 105). *Falls fm.* is older than McLish. [See this entry under *McLish fm.*]

C. E. Decker, 1933. See this entry under *Simpson fm.*

Named for exposures on Falls Creek, in Murray Co., sec. 33, T. 1 S., R. 2 E.

†Falls sandstone.

A name that has locally been applied to Homewood ss. memb. in southern W. Va., because it forms the falls in Kanawha River.

Falls City limestone. (In Admire shale.)

Pennsylvanian: Southeastern Nebraska and eastern Kansas.

G. E. Condra and N. A. Bengston, 1915 (Nebr. Acad. Sci. Pub., vol. 9, No. 2, pp. 9, 17, 30). *Falls City ls.*—Usually one massive bed, brownish mottled, soft, resinous; hardens on exposure. Thickness 3 ft. to 6 ft. 4 in. Lies 18 to 37 ft. above Aspinwall ls.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser.), named the beds overlying Falls City ls. and underlying Americus ls. the *West Branch sh.*, and the beds underlying Falls City ls. the *Aspinwall sh.;* but in 1932 he discarded Aspinwall sh. and named the beds immediately below Falls City ls. the *Hawxby sh.* On p. 82 of 1927 rept. cited Condra stated type loc. of Falls City ls. to be in Lehmer quarry, sec. 32, 2½ mi. S. and 1½ mi. W. of Falls City, Richardson Co.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), transferred all beds above Brownville ls. to Perm. (See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.)

Falls City shale.

Eocene (Jackson): Southeastern Texas (Fayette, Gonzales, Karnes, and Atascosa Counties).

A. C. Ellisor, 1933 (A. A. P. G. Bull., vol. 17, No. 11, pp. 1302, 1314, etc.). *Falls City sh.*—Series of chocolate-colored bentonitic shales and carbonaceous shales with thin lenses of sand, in places fossiliferous. As *Textularia hockleyensis* is found in these shales it is advisable to name them so as to differentiate them from the McElroy. The sh. also carries typical Whitsett species. Is a lower zone of Whitsett fm. as here defined. Type loc. is W. of Falls City, in bed of San Antonio River, forming the falls of the river. Occurs in Fayette, Gonzales, Karnes, and Atascosa Counties. Overlies Dilworth sand (basal Whitsett) and underlies Stone's Switch sand.

†Falls Creek formation.

Lower Ordovician (Chazy): Central southern Oklahoma (Arbuckle and Wichita Mountains).

See under *McLish fm.*

Falls Mills limestone. (In Hinton formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Tazewell County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 295, 338). *Falls Mills ls.*—Yellow, shaly ls., 0 to 5 ft. thick, with marine fossils. Underlies Falls Mills sh. and overlies Upper Fivemile sh.; all members of Hinton group [fm.]. Type loc. along Bluestone River slightly NW. of Falls Mills, Tazewell Co., Va. Also observed in Summers Co., W. Va.

Falls Mills sandstone. (In Hinton formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Tazewell County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 295, 335). *Falls Mills ss.*—Greenish-gray ss., usually massive and fairly coarse, but in places shaly; 25 to 50 ft. thick. Underlies Lower Pluto sh. and overlies Falls Mills sh.; all members of Hinton group [fm.]. Noted in Mercer and Summers Counties, W. Va. Type loc. is in edge of Tazewell Co., Va., just W. of Falls Mills Station, where it makes falls across Bluestone River.

Falls Mills shale. (In Hinton formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Tazewell County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 295, 336). *Falls Mills sh.*—A calc. or red, sandy and variegated deposit, 3 to 50 ft. thick; lenticular ss. in lower part; marine fossils. Underlies Falls Mills ss. and overlies Falls Mills ls.; all members of Hinton group [fm.]. Type loc. along Bluestone River slightly NW. of Falls Mills, Tazewell Co., Va. Also observed in Mercer and Summers Counties, W. Va.

Falmouth formation.

Pleistocene: Jamaica.

R. T. Hill, 1899 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 34, pp. 101-102)

Falmouth moraine.

Pleistocene: Southeastern Massachusetts (Barnstable County).

N. S. Shaler, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, pp. 553–556).

Named for occurrence in town of Plymouth, Barnstable Co. Is of Wisconsin age. Present on Cape Cod.

Falmouth pegmatite.

Pre-Carboniferous (?): Southwestern Maine.

F. J. Katz, 1917 (U. S. G. S. P. P. 108, p. 175). *Falmouth pegmatite.*—Normal medium to very coarse-grained pegmatite, occurring as dikes. With it is associated a fine-grained white or light-gray garnetiferous aplite. Intrudes Berwick gneiss. Assigned to pre-Carbf. (?). Named for exposures in Falmouth Twp, Cumberland Co.

On 1933 geol. map of Maine, by A. Keith, these rocks appear to be included in pre-Camb.

†False Dove limestone.

See under *Ward ls.*

Famine series.

Devonian: Quebec.

B. R. MacKay, 1921 (Canada Geol. Surv. Mem. 127, pp. 12, 31).

Fanney rhyolite.

Tertiary: Mogollon district, New Mexico.

H. G. Ferguson, 1927 (U. S. G. S. Bull. 787). The only rock in Mogollon dist. in which spherulitic texture is prominent. Thickness 0 to 1,200 ft. Older than Last Chance andesite and younger than Mineral Creek andesite.

Named for prominent outcrops in vicinity of Fanney mine, on Fanney Hill.

Fant meta-andesite.

Middle Jurassic: Northern California (Taylorsville region).

J. S. Diller, 1908 (U. S. G. S. Bull. 353). *Fant meta-andesite.*—Altered andesitic flows and tuff cgl., of greenish to reddish brown color. Thickness more than 150 ft. Is younger than Hardgrave ss. and older than Thompson ls.

Named for an unidentified locality near Taylorsville.

This fm. has been classified as Lower Jurassic, but according to C. H. Crickmay, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, pp. 80–81), it is Middle Jurassic, and he calls the fm. *Fant volcanics.*

Fant tuff member (of Catahoula tuff).

Tertiary (lower Miocene or Oligocene): Southwestern Texas Coastal Plain.

T. L. Bailey, 1926 (Univ. Tex. Bull. 2645, pp. 46, 65, 66–80, 178–179). *Fant memb. of Gueydan fm.*—Essentially a number of beds of indurated creamy-white mudflow tuff, which commonly shows sun cracks, interstratified with friable grayish-white air-deposited tuffs and greenish-gray or purplish-pink fluviatile clays and sandy clays. Thickness 12 to 255+ ft. Basal memb. of Gueydan fm. Grades into overlying Soledad memb. of Gueydan fm., and rests on Frio fm. and on Fayette fm. with probable discon. and overlap. Named for numerous exposures near Fant City, northern Live Oak Co. Assigned to Olig., as it grades laterally into Catahoula ss.

The Gueydan fm. is same as Catahoula tuff, and "Gueydan" has been discarded. The fm. is of either Olig. or lower Mio. age. The U. S. Geol. Survey and the Tex. Geol. Survey (as recorded in Univ. Tex. Bull. 3232, 1933) include Fant tuff in Catahoula, but A. C. Ellisor, 1933 (A. A. P. G. Bull., vol. 17, No. 11), includes it in underlying Frio clay.

Farallon Grande breccia.

Oligocene: Cuba.

S. Taber, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 4, p. 581).

Fargo limestone.

Pennsylvanian: Southeastern Nebraska and southwestern Iowa.

G. E. Condra and N. A. Bengston, 1915 (Nebr. Acad. Sci. Pub., vol. 9, No. 2, pp. 15, 26, 27). *Fargo ls.*—Exposed btw. Weeping Water Valley and Walnut Creek, from 4 mi. NW. of Fargo to near Rulo, and in spur S. of Rulo. Makes prominent cliff in valley side near Fargo, the type loc. One-half mi. N. of Fargo it consists of: (1) Bluish, massive, brittle ls., 1½ to 2 ft. thick, which makes a natural riprap along river bank; (2) dark-blue, carbonaceous, clayey to sandy sh., 5 ft.; (3) ls., 4 ft., in 3 beds. Separated from overlying Preston [Emporia] ls. by 14 to 34 ft. of sh. and from underlying Burlingame ls. by 11 to 29 ft. of sh.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 63, 66, 67). *"Fargo" ls.* of Condra and Bengston is Wakarusa ls., which has priority.

Fargo moraine.

Pleistocene: Northwestern New York (Jefferson County).

A. F. Buddington, 1934 (N. Y. State Mus. Bull. 296, pp. 43–44). Extends NE. and SW. through Fargo, Antwerp quad., Jefferson Co.

Farias beds.

Upper Cretaceous: Southwestern Texas (Maverick County).

F. M. Getzendaner, 1931 (Tex. Univ. Bur. Econ. Geol., Min. Res. of Tex., p. 130). *Farias beds* is name provisionally suggested for a series of beds not described in existing literature. Known only from Humble Oil & Refining Co. No. 1 Sullivan and No. 1 City Nat. Bank, the latter in Dimmit Co. Thickness 0 to 900 ft. Top 200 ft. very glauconitic, with nonlignitic sandy shales and impure sss.; middle 400 ft. very lignitic, but containing marine fauna; basal 325 ft. very micaceous calc. sandy shales with a prolific microfauna of basal Navarro. [In section of Maverick Co. these beds are placed below Olmos fm. and above San Miguel fm. Derivation of name not stated.]

Farland.

Name applied by C. [R.] Keyes (Pan-Am. Geol., vol. 46, 1926) to 75 ft. of lss. in upper part of Kootenai fm. of Mont. Derivation of name not stated.

Farley limestone bed. (In Lansing ? formation.)

Pennsylvanian: Northwestern Missouri, eastern Kansas, and southeastern Nebraska.

H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines vol. 13, 2d ser., pp. 29, 155). *Farley ls. bed.*—Ranges from a thin layer of calc. sh. to a bed of ls. 10 ft. thick, seemingly disappearing to NE. Divides Lane sh. memb. of Lansing fm. into two parts, the overlying beds being aren. and the underlying beds chiefly argill. Is bed No. 100 of Broadhead's section. Named for exposures near Farley, Platte Co., Mo.

R. C. Moore, 1931 (Kans. Geol. Soc. 5th Ann. Field Conf. correlation chart), named the sh. overlying Farley ls. the *Bonner Springs sh.* and the sh. underlying it the *Island Creek sh.*, and included all of them in Kansas City group.

According to N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21), the Lane sh. of Hinds and Greene is younger than true Lane sh. and corresponds to upper part of Wyandotte ls. and overlying Bonner Springs sh. of Moore and Newell; and Farley ls. is upper memb. of their Wyandotte ls. This classification is followed by R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 45, 120, 122). Moore draws top of Kansas City group at top of Bonner Springs sh. These changed definitions have not yet been considered by U. S. Geol. Survey for its publications.

Farmington sandstone member (of Kirtland shale).

Upper Cretaceous: Southwestern Colorado and northwestern New Mexico.

C. M. Bauer, 1916 (U. S. G. S. P. P. 98K). *Farmington ss. memb. of Kirtland sh.*—Brown resistant ss., varying in thickness up to 455 ft., where it forms bluff on San Juan River. To S. it is gradually replaced by lenses of sh. Where thickest it lies 271 ft. above base of Kirtland and 110 ft. below top of Kirtland. Farther S. it is 20 ft. thick, lies 40 ft. below top of the Kirtland and 830 ft. above base of Kirtland, and still farther S. it is represented only by isolated ss. lenses in the Kirtland.

J. B. Reeside, Jr., 1924 (U. S. G. S. P. P. 134). *Farmington ss. memb.* is 0 to 480 ft. thick, and of fluviatile origin. Is well exposed near Farmington, San Juan Co., N. Mex.

Farmington shale. (In McLeansboro formation.)

Pennsylvanian: Central western Illinois (Fulton County).

T. E. Savage, 1927 (Am. Jour. Sci., 5th, vol. 14, p. 309), applied *Farmington sh.* to that part of McLeansboro fm. of Fulton Co. underlying Lonsdale ls. and overlying coal No. 7. Thickness and derivation of name not stated, but probably named for the town in Fulton Co.

Farm Ridge moraine.

Pleistocene (Wisconsin stage): Northeastern Illinois. See F. Leverett, 1899 (U. S. G. S. Mon. 38, pp. 260–261). *Farm Ridge* of La Salle Co. is same as *Grand Ridge*. Named for Farm Ridge P. O., La Salle Co. Now said to be same as Chatsworth moraine.

Farnham limestone.

Ordovician: Quebec.

R. W. Ells, 1896 (Canada Geol. Surv., n. s., vol. 7, pp. 17J, 25J to 27J). Included in Trenton.

Farrer non-coal-bearing member (of Price River formation).

Upper Cretaceous: Central eastern Utah (Book Cliffs).

D. J. Fisher, 1935 (U. S. G. S. Bull. 852). Top memb. of Price River fm. btw. Sunnyside and Colo. State line. Somber-colored sss. and greenish tinged gray sh., 410 to 1,095 ft. thick. Overlies Neslen coal-bearing memb. Contains fresh-water fossils. Named for local mine in Coal Canyon. Has been traced eastward into Colo., where it seems approx.="undiff. part of Mesaverde" of W. T. Lee in Grand Mesa.

Far Rockaway gravels.

Tertiary: Southeastern New York (Long Island).

J. B. Woodworth, 1901 (N. Y. State Mus. Bull. 48, pl. 1, map). Yellow gravels overlying Cret. clays and sands and underlying Pleist. gravels in Oyster Bay and Hempstead quads. Assigned to pre-Pleist. [On 1901 geol. map of N. Y., by F. J. H. Merrill, these gravels were assigned to Neocene.]

Fashing clays.

Eocene (Jackson): Southeastern Texas (Karnes County).

A. C. Ellisor, 1933 (A. A. P. G. Bull., vol. 17, No. 11, pp. 1302, 1315, etc.). *Fashing clays.*—Fossiliferous bentonitic green clays, weathering to heavy sticky clay. Typically exposed in creeks around town of Fashing. Crop out from Frio River to W. part of Karnes Co. Thickness 110 ft. in vicinity of Whitsett; absent (on surface and in wells) in W. part of Karnes Co. Overlies Calliham sand and underlies Olmos sand, all zones in Whitsett fm. as here defined.

Faulconer limestone member (of Perryville formation).

Middle Ordovician: Central Kentucky.

A. F. Foerste, 1912 (Denison Univ. Sci. Lab. Bull. 17, pp. 23, 32, 131, 132). Farther eastward, especially btw. Danville and Harrodsburg, along the railroad, this lower part of the Perryville [memb. of Lexington ls.] is even more richly supplied with silicified fossils, and the rock is whiter and less distinguishable from the so-called dove-colored lss. at the top [of the Perryville]. Should any separate designation for the lower layers with the silicified fossils be desirable, the term *Faulconer ls.* will serve.

A. M. Miller, 1913 (Ky. Geol. Surv., 4th ser., vol. 1, pt. 1, pp. 317–342). *Faulconer memb.* of Perryville is a gastropod horizon, 5 to 8 ft. thick, underlying Salvisa memb. of Perryville and overlying Flanagan.

A. F. Foerste, 1913 (Ky. Geol. Surv., 4th ser., vol. 1, pt. 1, pp. 389, 429–430). *Faulconer memb.* of Perryville bed is 20 to 25 ft. thick; consists of fine-grained ls., grayish or bluish brown, usually containing many gastropods and underlain locally by coarser-grained gray ls. Is overlain by Salvisa memb. and underlain by Woodburn bed, the top memb. of the Flanagan.

Named for Faulconer, Boyle Co.

Faxon limestone.

Pre-Cambrian: Northern New York (Adirondacks).

H. L. Alling, 1918 (N. Y. State Mus. Bull. 199). *Faxon ls.*—Sometimes pure ls., but more frequently siliceous. Thickness 0 to 20 ft. Included in Grenville series. Caps "Dixon" schist. Underlies Swede Pond qtzite. Type loc. Faxon Pond, Warren Co.

H. L. Alling, 1919 (Am. Jour. Sci., 4th, vol. 48, pp. 52–53). *Faxon ls.* is most erratic memb. of Grenville series. At type loc., along shore of Faxon Pond, near Graphite, Warren Co., it lies above "Dixon" schist (preoccupied name), but it is absent at Hague and at mines in South Bay dist., along shore of Lake Champlain. It seems to be confined to interior of area. About 3½ miles W.-NW. of Pottersville it is represented by two beds of paramphibolite separated by a stratum of ls., and appears to be replacing Swede Pond qtzite by progressive overlap. At some localities it seems to depart from its normal position and to occur within the "Dixon" graphite schist and even beneath it as well. It may be same as Chesterfield ls. of Geo. W. Smith property, S. of Clintonville.

Fayette breccia.

Middle Devonian: Northeastern Iowa.

W J McGee, 1884 (10th Census, vol. 10, Rept. on Building stones, pp. 262–263). *Fayette breccia.*—Bed consisting of angular fragments of compact, brittle ls. embedded in matrix of similar material. Occurs at Fayette [Fayette Co.], Quasqueton [Buchanan Co.], and elsewhere.

W. H. Norton, 1894 (Iowa Acad. Sci. Proc., vol. 1, pt. 4, pp. 22–24). Fayette breccia of McGee includes (descending): (1) Fragments, fossiliferous and shaly, involving several life zones of Cedar Valley ls.; (2) fragmental masses of tough gray crystalline or semicrystalline heavy-bedded ls., which should be separated from Cedar Valley ls.; (3) fragments of hard drab unfossiliferous [fossiliferous?] ls. of finest grain, often thinly bedded, the *Gyroceras* beds, here named *Upper Davenport beds;* (4) buff or brown matrix, fragments small, unfossiliferous, named *Lower Davenport beds.* Overlies Kenwood beds.

W. H. Norton, 1895 (Iowa Geol. Surv. vol. 4). Fayette breccia of McGee includes Upper Davenport beds (*Gyroceras* beds) and Lower Davenport beds, the 2 top members of Wapsipinicon ls., which is overlain by Cedar Valley ls.

S. Calvin, 1898 (Iowa Geol. Surv. vol. 8). *Fayette breccia* includes (descending): (1) *Spirifer pennatus* beds, 8 to 12 ft.; (2) barren bed, 10 to 15 ft.; (3) *Gyroceras* beds, 5 ft.; (4) true brecciated beds, 15 to 20 ft. Is top part of Wapsipinicon stage and younger than Independence sh. of Wapsipinicon.

T. E. Savage, 1905 (Iowa Geol. Surv. vol. 15). *Fayette breccia,* 33 ft. thick, consists of diverse lss. brecciated. Is top memb. of Wapsipinicon stage and in Benton Co. uncon. overlies Coggon beds of Wapsipinicon stage. Includes Upper Davenport and Lower Davenport.

W. H. Norton, 1921 (Iowa Geol. Surv. vol. 27, p. 413). Wapsipinicon brecciated beds include (descending) *Spirifer pennatus* beds, Upper Davenport, Lower Davenport, Independence, Otis (Cedar Valley phase), Otis (Vinton phase), Coggon phase, and Bertram. [These are described under the following headings: Upper Davenport breccia, Lower Davenport breccia, Independence breccia, Otis breccia, and Bertram breccia.]

Named for Fayette, Fayette Co.

Fayette sandstone. (Of Jackson age.)

Eocene: Eastern and southern Texas and northwestern Louisiana.

E. T. Dumble and R. A. F. Penrose, Jr., 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. xxxiii, 17, 47, 57, 58, 63). *Fayette beds.*—Sands, sss., clays, and lignites, more or less calc., 300 to 400 ft. thick, overlying uppermost fossiliferous stratum of Marine

Tert. (siliceous and glauconitic sands and white, brown, and black clays with lignite) and underlying Quat. Coast clays, on Brazos, Colorado and Rio Grande. [As thus defined includes, at base, Yegua fm.]

E. T. Dumble, 1893 (Brown coal and lignite of Texas, pp. 124, 154). *Fayette div.*—Gray sss. interstratified with gray clays and gray sands, 20 to 200 ft. thick. Uncon. underlies Lapara beds, and overlies Yegua div., originally included in Fayette.

E. T. Dumble, 1894 (Jour. Geol., vol. 2, pp. 549, 552). *Fayette sands* restricted to series of sands (coarse and angular) and sss. with some clays, which contain large amount of opaline and chalcedonic materials, overlying Yegua clays and underlying Frio clays.

A. Deussen, 1924 (U. S. G. S. P. P. 126). *Fayette ss.*, 800 ft. thick, underlies Frio clay and overlies Yegua fm. in coastal plain of Tex. W. of Brazos River.

E. T. Dumble, 1924 (A. A. P. G. Bull., vol. 8, No. 4, pp. 424–436). *Fayette* of type section uncon. underlies Frio group and overlies Yegua fm. The upper 500+ ft. is of Jackson age, and is here named *Whitsett beds*. The lower part, or true Fayette, is 150± ft. thick, is uncon. overlain and overlapped by Whitsett beds, and is of Claiborne age. These lower beds are here named *Lipan beds*. Their separation from the Jackson is made necessary by uncon. at their top.

T. L. Bailey, 1926 (Univ. Tex. Bull. 2645). *Fayette fm.* is 135+ ft. thick. in SW. coastal plain of Tex. Is largely sss., but includes clay and sh. Conformably underlies Frio fm. and overlies Yegua clay. Is basal fm. of Jackson group.

M. A. Hanna, 1929 (A. A. P. G. Bull., vol. 13, p. 384). Age assigned to *Fayette ss.* in literature has ranged from Lower Claiborne (Eocene) to Mio. Work of Deussen, Matson, and Berry, and later work by Bailey (Univ. Tex. Bull. 2645, 1926), seems sufficient definitely to allocate the Fayette, or, to quote Deussen, "the Fayette ss. lies above Jackson fm., is overlain by Catahoula." Bailey's Gueydan is approx.=Deussen's Catahoula. Miss Alva C. Ellisor has stated to writer that she has verified this position of Fayette on the surface, and the work of the writer has verified it in subsurface. It is in sense of Upper Jackson that Fayette is used in this note.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, p. 681). *Fayette* is employed as a fm. name for Tex. strata btw. Yegua below and Catahoula or Frio above, and *Jackson* as a group name to designate all Eo. strata above the Claiborne. [In this publication Frio was referred to Olig., thus making *Fayette* and *Jackson* equiv.] Whitsett is upper memb. of Fayette fm. (Jackson, Eocene).

A. C. Ellisor, 1933 (A. A. P. G. Bull., vol. 17, No. 11, p. 1302). Jackson group divided into (descending) Whitsett fm., McElroy fm., and Caddell fm., which are=Fayette of U. S. G. S.

A. Deussen, 1934 (A. A. P. G. Bull., vol. 18, No. 4, p. 501). Jackson group is here divided into (descending) Whitsett, McElroy, and Caddell, following 1933 classification of Miss Ellisor; and, also following Miss Ellisor, *Fayette* is abandoned and *Whitsett* is substituted.

W. L. Goldston and G. D. Stevens, 1934 (A. A. P. G. Bull., vol. 18, No. 12, p. 1639). Fayette is divided into (descending): (1) Fayette (Whitsett); (2) McElroy; and (3) Caddell.

A. Deussen, and E. W. K. Andrau, 1936 (A. A. P. G. Bull., vol. 20, No. 5, p. 540). Jackson group, following Miss Ellisor, is here divided into Whitsett fm. (substituted for *Fayette*, which is abandoned), McElroy fm., and Caddell fm.

The U. S. Geol. Survey's present definition of *Fayette ss.* (of Jackson age) includes in the fm. all beds in eastern Tex. below Frio clay and above Yegua fm.

Named for Fayette Co., Tex., but F. B. Plummer states (Univ. Tex. Bull. 3232, 1933, p. 681): The section exposed at Lipan Hills, as described by Dumble in his final [1924] description of the Fayette is now regarded as the type section of the Fayette fm.

A. C. Ellisor, 1936 (Gulf Coast oil fields, A. A. P. G., p. 474). As U. S. G. S. has used the name *Fayette* as synonymous with the name *Jackson* and is using Fayette to include all Jackson sediments, F. B. Plummer of Bur. of Econ. Geol., Univ. of Tex., suggested dropping the name Fayette for the upper, third fm. of Jackson group. As the name is now applied as a group name it can not be delimited as a fm. The name Whitsett has been selected for former Fayette of the writer.

†Fayette sandstone.

Pennsylvanian: Southern West Virginia and southwestern Virginia.

M. R. Campbell and W. C. Mendenhall, 1896 (U. S. G. S. 17th Ann. Rept., pt. 2, pp. 487, 497). *Fayette ss.*—Massive cliff-making cgl., practically without bedding planes, reaching its greatest development at Nuttall, where it is 110 ft. thick and overlain by soft ss. or sandy sh., which makes no showing in outcrop, but which is a portion of the Fayette, as shown at type loc. and at other points down the river. Total thickness of fm. 180 to 220 ft. At Gaymont the fm. is composed of two plates of coarse ss. or cgl., the lower somewhat more massive than the upper, the interval btw. being composed of soft ss. and sandy sh. Underlies Kanawha fm. and overlies Sewell fm.

Preoccupied. Replaced by Nuttall ss., which is treated as a lentil in Sewell fm.

Named for Fayette Station, Fayette Co., W. Va.

Fayette gas sand.

Local economic term for a gas sand in Fayette dist., NW. Ala. Believed by M. J. Munn to lie at horizon of Black Creek coal group of Pottsville fm. (Penn.).

Fayetteville shale.

Mississippian (Chester): Northern Arkansas and northeastern and central eastern Oklahoma.

F. W. Simonds, 1891 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 4, pp. 26, 42–49). *Fayetteville sh.*—Chiefly black but also bluish and even yellowish-brown sh. Thickness 150 to 175 ft. In Washington Co., Ark., underlies Batesville ss. and overlies Wyman ss. [In this rept. Simonds gave following downward succession of fms: Archimedes [Pitkin] ls.; Marshall sh., 0 to 80 ft.; Batesville ss., 10 to 60 ft.; Fayetteville sh., 150 to 175 ft.; Wyman ss., 2 to 9 ft.; Boone chert and cherty ls.]

G. I. Adams and E. O. Ulrich, 1904 (U. S. G. S. P. P. 24), corrected the miscorrelations made in above rept., and described the following as correct strat. succession (downward): Pitkin ("Archimedes") ls.; Wedington ss. underlain by Fayetteville sh. (=Marshall sh. of Simonds); true Batesville ss. (=ss. exposed at type loc. of Wyman ss.); Moorefield sh. (mistaken for Fayetteville sh. by Simonds); and Boone ls.; and stated that Wedington ss. seems to be the ss. called Batesville by Simonds.

G. I. Adams and E. O. Ulrich, 1905 (U. S. G. S. Fayetteville folio, No. 119) treated Wedington ss. as a memb. near top (in places at top) of Fayetteville sh., and this is still the approved definition. In Okla. this ss. lies near middle of Fayetteville sh.; in Ark. it lies 0 to 70 ft. below top of the Fayetteville.

Named for Fayetteville, Washington Co., Ark., in valley of West Fork of White River.

Federal Hill beds. (In Patapsco formation.)

Lower Cretaceous: Northeastern Maryland.

L. F. Ward, 1905 (U. S. G. S. Mon. 48, pp. 566–569, 598). *Federal Hill beds.*—Plastic or aren. clays, 50 ft. thick, forming basal part of Patapsco fm. at Federal Hill, in Baltimore.

Felch schist.

Pre-Cambrian (middle and lower Huronian): Northwestern Michigan (Felch Mountain and Calumet districts).

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, pp. 303, 307). *Felch schist.*—Schists, more than 200 ft. thick, lying btw. Randville dol. below and Vulcan fm. above. They do not outcrop in Felch Mtn dist., but have been pierced by many drill holes. Are exposed, however, at Calumet, where they have identical characters of schist here named *Felch schist.* They are chiefly fine-grained mica schists containing garnet and tourmaline. Near contact with Vulcan fm. they become more siliceous and more ferruginous. Were called "Mansfield schists" by Smyth and correlated with slates at Mansfield and Michigamme Mtn. But slates at Mansfield are older than any in Felch Mtn dist. The fm. is therefore named for typical development at Felch Mtn. Assigned to upper Huronian.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), assigned *Felch schist* to middle and lower Huronian.

†Felch Mountain iron-bearing series.

A term applied by C. R. Van Hise in 1892 (U. S. G. S. Bull. 86, p. 195, and U. S. G. S. Mon. 19, p. 473) to the lower Huronian rocks of Felch Mtn dist., Mich. Later, upper and lower Huronian were found to be present there, and in 1909 (U. S. G. S. Bull. 360, pp. 317–318, by C. R. Van Hise and C. K. Leith) the "Lower Felch Mountain" was said to correspond to lower Huronian and the "Upper Felch Mountain" to upper Huronian.

Felix siltstone.

Miocene (middle): Southern California (Kettleman Hills).

H. V. Dodd and E. J. Kaplow, 1933 (Calif. Oil Fields, Calif. Dept. Nat. Res., Div. Oil and Gas, vol. 18, No. 4, pls. 1, 2). *Felix siltstone,* 50± ft. thick in wells in North Dome, Kettleman Hills. Overlies Whepley sh. and is overlain by a considerable thickness of fine gray sands. Contains abundant Sporbo at base. Included in Temblor. Occurs in Felix, Huffman, and other areas [leases] in North Dome, lying at 2,885± ft. depth.

†fence-post limestone.

Upper Cretaceous: North central Kansas.

See under †*Downs ls.*

Fennell formation.

Cambrian or pre-Cambrian: British Columbia. W. L. Uglow, 1922 (Canada Geol. Surv. Summ. Rept. 1921, pt. A, p. 77).

Fentress shale division. (In Lee formation.)

Pennsylvanian: Northern Tennessee (Fentress and Pickett Counties).

L. C. Glenn, 1925 (Tenn. Geol. Surv. Bull. 33B, pp. 276, 384, 385). *Fentress sh. div.*—Name proposed for the part of Lee fm., in Fentress and Pickett Counties, beneath Rockcastle ss. Consists mainly of shales (fine clay shales and sandy shales), but may contain some beds of ss. and usually has two coal horizons, one just above its base and the other not over a score or two of ft. below its top. The shales change locally along the bedding into shaly ss. Thickness of the div. may be as much as 175 ft. Laid down on irregular erosional surface of Pennington fm. (Miss.). Upper part has been cut away locally at least. [Type loc. not stated, but presumably the beds were named for their development in Fentress Co.]

Fergus Falls moraine.

Pleistocene (Wisconsin stage): Western Minnesota and South Dakota.

W. Upham, 1888 (Minn. Geol. and Nat. Hist. Surv., vol. 2, pp. 545, 549, 570, 605, 625, 653). Named for occurrence at Fergus Falls, Minn.

F. Leverett, 1932 (U. S. G. S. P. P. 161). The Fergus Falls moraine is a part of Bigstone morainic system.

Ferguson gypsum member (of Blaine gypsum).

Permian: Western Oklahoma.

C. N. Gould, 1902 (Okla. Geol. Surv. 2d Bien. Rept., pp. 42, 47). *Ferguson gyp. memb. of Blaine div.*—Almost pure white to dirty brown gyp. forming basal memb. of Blaine div. Overlain by red sh. Older than Medicine Lodge gyp.

N. Evans (1931) suggests abandoning Ferguson. (See 1931 entry under *Medicine Lodge gyp. memb.*)

Named for Ferguson, Blaine Co.

†Fernandan system.

Pre-Cambrian (Llano series). Central Texas.

T. B. Comstock and E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. lvi, 267–276). *Fernandan system.*—Consists of (descending): (1) Important calc. series; (2) slaty schists, largely chloritic but as a rule not foliated; (3) carbonaceous schists; (4) magnetite, sometimes with hematite, 50 ft.; (5) fine-grained quartz rock; (6) thick series of mica schists; (7) tough hornblendic schists probably of detrital origin. Nos. 6 and 7 named *Valley Spring series;* Nos. 2 to 5 inclusive named *Iron Mtn series;* No. 1 named *Click series.* Overlies Burnetan system and underlies Texan system.

Now included in Llano series, which is divided into Packsaddle schist (dark-colored) and Valley Spring gneiss (light-colored gneisses and schists).

Named for San Fernando Creek, Llano Co.

Fernando group.

Pliocene and lower Pleistocene: Southern California (Los Angeles and Ventura Counties).

G. H. Eldridge and R. Arnold, 1907 (U. S. G. S. Bull. 309). *Fernando fm.*—A variable series of cgls., sss., and aren. clays; thickness 1,500 to 6,000 ft. and possibly several thousand ft. more. *Fernando* is term applied by Homer Hamlin a number of years ago, on unpublished maps, to include the siliceous sh. skirting the sides of San Fernando Valley, Los Angeles Co., which is general equiv. of all post-Modelo and pre-Saugus beds in Santa Clara province. Uncon. overlies Modelo fm. in Santa Clara dist. and Puente fm. in Puente Hills region and Los Angeles dist. Uncon. underlies Pleist. sand and gravel.

W. S. W. Kew, 1924 (U. S. G. S. Bull. 753). *Fernando group.*—Restricted to post-Mio. beds and divided into two fms., Saugus fm. (2,000 ft. thick) above and Pico fm. (4,000 ft. thick) below. Both of these fms. are present at Fernando type loc., and are separated by an uncon. Is uncon. overlain by Pleist. terrace deposits and rests uncon. on Modelo fm. Fossils indicate it is of lower Plio., upper Plio., and lower Pleist. age.

Fern Glen limestone. (Of Osage group.)

Mississippian: Eastern Missouri and southwestern Illinois.

S. Weller, 1906 (St. Louis Acad. Sci. Trans., vol. 16, p. 438). *Fern Glen fm.*—Red ls., with greenish blotches; chert band at top and some chert scattered through it; 8½ ft. thick; containing Kinderhook fossils and underlain by 6 ft. of probably softer red calc. sh., which is not exposed but which probably belongs to Fern Glen fm. and is separated from underlying Bushberg ss. by 4 ft. of hard, somewhat crystalline yellow or gray ls. The Fern Glen is overlain by crystalline greenish gray ls. which probably belongs to Burlington ls.

S. Weller, 1909 (Geol. Soc. Am. Bull., vol. 20, pp. 265, 269, 322). *Fern Glen fm.*—Near Fern Glen Station, 20 mi. W. of St. Louis, central eastern Mo., consists of (descending): (1) Greenish calc. shales with much chert, 14 ft.; transition beds to overlying Burlington ls., but contains same fauna as beds 2 and 3, below; (2) red calc. shales, with 6-inch persistent chert band at top, 12 ft.; (3) hard, red, crystalline ls., with many crinoid stems and other fossils, 14 ft. Rests on [so-called] Chouteau ls. Included in Kinderhook. Lithologically and faunally closely resembles St. Joe marble.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 29), assigned Fern Glen to Osage group, and defined it as underlying Lower Burlington, as younger than Chouteau ls., and as uncon. overlying his Sulphur Springs fm.

The Mo. Geol. Surv. 1922 and 1926 geol. maps of Mo. assigned Fern Glen to Osage group.

S. Weller, 1926 (Jour. Geol., vol. 34, pp. 320–335). Fern Glen is a manifestation of the very lowest Burlington.

S. Weller and S. St. Clair, 1928 (Mo. Bur. Geol. and Mines vol. 22, 2d ser., table opp. p. 30, p. 155), assigned Fern Glen to Osage group, but stated (p. 166): A consideration of all data would seem to indicate that it would not do serious violence to facts to consider the Fern Glen as earliest memb. of Osage div., but faunas do seem to indicate that it is older than any of typical Burlington, and if it is transferred from Kinderhook to Osage it may be necessary to transfer some portion of upper Chouteau ls. also to the Osage.

R. C. Moore, 1928 (Mo. Bur. Geol. and Mines vol. 21, 2d ser., opp. p. 282), showed Fern Glen of eastern Mo. as uncon. on Bushberg ss., the uncon. representing Chouteau ls. and most of underlying Hannibal sh. In 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 245) Moore showed Fern Glen of Mo. and Ill. as uncon. on Glen Park fm.

The present generally accepted classification of Fern Glen assigns it to Osage group, but not to Burlington ls.

Fernian series.

Name introduced by C. [R.] Keyes (Pan-Am. Geol., vol. 46, p. 217, 1926) to replace *Fernie fm.* of Alberta.

Fernie formation.

A name applied by Canada Geol. Surv. to Jurassic beds in southern Alberta and British Columbia that are approx.=Ellis fm. of Mont. (See W. W. Leach, Geol. Surv. Canada Summ. Rept. 1902–3, p. 169A; D. B. Dowling, Geol. Soc. Am. Bull., vol. 17, p. 298, 1906; Canada Geol. Surv. rept on Cascade coal basin, Alberta, p. 8, 1907; P. S. Warren, Am. Jour. Sci., 5th. vol. 27, pp. 56–70, 1934.)

Fernow rhyolite.

Tertiary (post-Eocene?): Central northern Utah (Tintic district).

G. W. Tower, Jr., and G. O. Smith, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, pl. 74), mapped Packard rhyolite and *Fernow rhyolite* (flows and sheets) in Tintic dist.

G. O. Smith, 1900 (U. S. G. S. Tintic folio, No. 65). *Fernow rhyolite* occurs in several small areas in S. part of Tintic dist. Is like Packard rhyolite but rather more glassy. Probably erupted from a different vent than Packard rhyolite but at about same time and under similar conditions.

Named for Fernow Canyon, in S. part of Tintic dist.

Fern Ridge tuffs.

Late Tertiary (?): Central northern Oregon.

See under *Stayton lavas*. Derivation of name not stated. There is a town of this name in Clackamas Co.

Fernvale limestone. }
Fernvale formation. } (In Richmond group.)

Upper Ordovician: Western Tennessee, northern Arkansas, southeastern Missouri, and southwestern Illinois.

C. W. Hayes and E. O. Ulrich, 1903 (U. S. G. S. Columbia folio, No. 95, p. 2). *Fernvale fm.*—Soft green and chocolate shales, including one or more layers of coarsely crystalline, occasionally flesh-colored ls., usually with greenish specks, the lower layer not infrequently conglomeratic and highly phosphatic. In some areas lower part of fm. is composed of 5 or 6 ft. of strongly ferruginous, often vermilion-red ls. Thickness 0 to 40 ft. Uncon. overlies Leipers fm. and uncon. underlies Clifton ls. (Sil.). Top fm. of Richmond group.

To W., in Tenn., the Arnheim (†Warren) ls. intervenes btw. Fernvale fm. and Leipers fm., and Brassfield ls. overlies the Fernvale. In northern Ark. the Fernvale uncon. underlies Cason sh. and uncon. overlies Kimmswick ls. In Mo. and SW. Ill. the Fernvale underlies Maquoketa sh. and uncon. overlies Kimmswick ls. In Tenn. the Fernvale is called *Fernvale fm.;* in Mo., Ark., and Ill. it is called *Fernvale ls.*

Named for Fernvale, Williamson Co., Tenn.

†Ferriferous limestone.

A descriptive term applied in early Pa. and W. Va. repts to *Vanport ls. memb.* of Allegheny fm.

Ferris formation.

Eocene and Upper Cretaceous: Central southern Wyoming (Carbon County).

C. F. Bowen, 1918 (U. S. G. S. P. P. 108, pp. 228, 230, etc.). *Ferris fm.*—Light-colored, dark-gray, and carbonaceous sh.; buff to brown ss., in places extremely cross-bedded and showing great irregularity of deposition; and numerous coal beds. Pockets, lenses, and thin beds of cgl. composed of pebbles of older rocks are distributed through a zone 1,000± ft. thick at base. The fm. contains fresh-water invertebrates, land plants, and vertebrate bones. The shells and plants, which occur chiefly above the cgl. zone, are regarded as of Fort Union age. The vertebrates (consisting of bones of turtles, indeterminable fragments of ceratopsians, and a few specimens of Triceratops) were found only in the cgl. zone. Fm. tentatively classified as Tert. (?). Thickness 6,500± ft. Uncon. underlies Hanna fm. (Eo.) and overlies, without proof of uncon., Medicine Bow fm. (Upper Cret.). Best exposed from old Ferris ranch, on North Platte River, E. to top of hill N. of "Middle Ditch" at its junction with "Big Ditch." Is=lower part of "Upper Laramie" of Veatch.

Triceratops-bearing beds are now assigned to Upper Cret. by U. S. Geol. Survey.

Ferron sandstone member (of Mancos shale).

Upper Cretaceous: Central eastern Utah (Carbon, Emery, Sevier, and Grand Counties).

C. T. Lupton, 1914 (U. S. G. S. Bull. 541, p. 128). *Ferron ss. memb. of Mancos sh.*—Sand and sandy material, 50 to 100 ft. thick, containing in places fossiliferous concretions. More resistant than underlying and overlying rocks. Forms a hogback in Green River field and can be definitely correlated with alternating ss., sh., and coal beds in vicinity and S. of Ferron, in Castle Valley, from which it takes its name. *Lies 2,500± ft. below top of Mancos sh. and 400± ft. above Dakota ss.* [Dakota ? now]. [In Wasatch Plateau the Ferron has been found to be 800 ft. thick in places.]

Ferron Point formation.

Middle Devonian: Northeastern Michigan (Thunder Bay region).

A. S. Warthin, Jr., and G. A. Cooper, 1935 (Wash. Acad. Sci. Jour., vol. 25, No. 12, pp. 524–525). *Ferron Point fm.*—Green to bluish clays, interbedded with argill. lss., all carrying abundant fossils. Thickness 35± ft. Is basal fm. of Long Lake stage. Underlies calc. sh. of Genshaw fm. and overlies Rockport ls., base of Traverse group of Alpena region. Type loc., Rockport quarry, Rockport, Alpena Co. [Dr. Cooper stated, orally, that Ferron Point is 1 mi. due N. of the big dump at N. end of Rockport quarry.]

†Ferruginous sandstone.

A term used in early Mo. repts for the Miss. ss. later named *Aux Vases ss.*

Fiborn limestone.

Silurian (Niagaran): Michigan (eastern part of Upper Peninsula).

R. A. Smith, 1916 (Mich. Geol. Surv. Pub. 21, p. 153). *Fiborn ls.*—Ls., mainly massive, low in magnesia, of buff to grayish buff color, dense grained to lithographic, with small disseminated crystals of calcite. Thickness 18 to 30 ft. Underlies Manistique series and overlies Hendricks series, all included in Niagara. Named for exposures in Fiborn quarry, Mackinac Co.

R. B. Newcombe, 1933 (Mich. Geol. Surv. Pub. 38). [See 1933 entry under *Burnt Bluff fm.*]

†Fickett series.

Mississippian, Devonian, and Silurian (?): Northern central Alaska (John River region).

F. C. Schrader, 1902 (Geol. Soc. Am. Bull., vol. 13, p. 242). *Fickett series.*—Ranges from chloritic schists or phyllites on S. through ls., slates, ss., qtzites and grit to hard cgl. on N. To S. rests uncon. on Skajit fm.; to N. it seems to be in fault contact with Stuver series and Lisburne fm. To W. it seems to overlie Lisburne fm. and possibly extends beneath Mesozoic. Lower Carbf. fossils near base. May include rocks younger than Lower Carbf.

Named for river called Fickett River in early repts but now known as John River.

Includes Noatak fm. (Miss.), also Middle and Upper Dev. and Sil. (?) rocks.

Fidalgo formation.

Triassic (?): Northwestern Washington (San Juan Islands).

R. D. McLellan, 1927 (Univ. Wash. Pub. Geol., vol. 2, pp. 142–146). *Fidalgo fm.*—A number of intrusive masses of serpentinized dunite. Occurs on Fidalgo Head and at several localities in SE. part of Fidalgo Island. Composes Burrows, Young, Allan, Saddlebag, Dot, and Hat islands, and Williamson Rocks, and forms major part of Cypress Island. Consists of 3 distinct rock types, which are invariably associated with each other: (1) Coarse-grained dunite, (2) fine-grained dunite, (3) both of which are cut by thin stringers of serpentinized pyroxenite. Intrudes Leech River group. Assigned to Triassic (?).

Fiddle limestone.

Upper Devonian: Alberta (Jasper Park).

P. E. Raymond, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 294–296, 300). *Fiddle ls.*—Ls. with a good deal of clay scattered through it, although some layers are pure. Layers of it, standing on end, form a massive gateway in Fiddle Creek ½ mi. above the road. Best exposed along road S. of Disaster Point, near the old lime kilns and along ridge that faces valley of Rocky River. Thickness 300 ft. Fossils. Overlies Coronach sh. and underlies Kiln sh., Upper Dev.

†Fiddler's Green limestone.

Silurian: Western New York (Onondaga County).

T. C. Hopkins, 1914 (N. Y. State Mus. Bull. 171, p. 12). *Fiddler's Green ls.*—Thin-bedded dolomitic ls., 20 to 40 ft. thick, occurring in upper part (25 to 63 ft. below top) of *Camillus beds or group* in Syracuse quad.

Fido sandstone.

Mississippian: Southwestern Virginia.

C. Butts, 1927 (Va. Geol. Surv. Bull. 27). *Fido ss.*—Coarse, friable, brown to reddish ss. about 50 ft. thick. Underlies Cove Creek ls. and overlies lss. of Gasper age. Probably corresponds to Hardinsburg ss. of Ky. Known to extend from a point 5 mi. W.-SW. of Gate City to road btw. Lindell and Holston River in Abingdon quad. and probably extends nearly entire length of Mississippian trough SE. of Clinch Mtn. Named for exposures in vicinity of Fido, Scott Co.

Fieldian series.

Cambrian and Ordovician (?): Canada.

P. S. Warren, 1929 (Canadian Field-Nat., vol. 43, p. 24).

Fields sand.

A subsurface sand, of early Penn. (Cherokee) age, in central eastern Okla. In Morris pool, Okmulgee Co., it is 10 ft. thick, lies at 1,800 ft. depth, the Lyons-Quinn sand lying at 2,000 ft., the so-called Glenn sand at 1,725 ft., and the Morris sand at 1,600 ft.

†Fierro limestone.

Permian, Pennsylvanian, and Mississippian: Southwestern New Mexico (Silver City region).

S. Paige, 1916 (U. S. G. S. Silver City folio, No. 199). *Fierro ls.*—Gray to blue fossiliferous ls. having max. thickness of 800± ft. Contains Penn. and Miss. faunas, which suggests an uncon. btw. upper and lower parts, but even in well-exposed sections no separation can be made by lithologic differences. Includes beds ranging from light gray to dark blue or purplish. West of Silver City upper half is chiefly light gray or light blue, and lower half is darker blue except where whitened, probably by intrusions. The beds are characteristically cherty except in lower 100 ft. The chert is either black or white; near base some red chert. Rests on Percha sh. (Dev.) with apparent conformity. Is uncon. overlain by Beartooth qtzite (Cret.). Named for town of Fierro, in NE. part of Silver City quad. Fossils listed. Girty says faunas are early Miss. and early Penn. The older fauna is correlated with that of Lake Valley ls. and the younger fauna with that of Magdalena group.

Abandoned in 1933, having been subdivided into (descending) Abo redbeds (Perm.); Magdalena group (Penn.), consisting of Syrena fm. above and Oswaldo fm. below; and Lake Valley ls. (Miss.).

Fife gabbro.

Cretaceous (?): Southern British Columbia.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, map 9, 118° to 118°30', near 49th Par.) and 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2). *Fife gabbro;* deep green to greenish black; occurs at Fife railway station. Cret. (?).

Figuera formation.

Cretaceous: Puerto Rico.

H. A. Meyerhoff, 1931 (N. Y. Acad. Sci., Scientific survey of Porto Rico and Virgin Islands, vol. 2, pt. 3, p. 284).

Fincher sand.

A subsurface sand, lying 95 ft. below top of Marble Falls ls. in central northern Tex.

Finis shale member (of Graham formation).

Pennsylvanian: Central northern Texas (Brazos River region).

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31; Univ. Tex. Bull. 2132, pp. 127–128). *Finis sh. memb. of Graham fm.*—Sandy sh. with interbedded ss. comprising basal portion of Graham fm. Thickness 45 to 100 or more ft. Rests on Home Creek ls. memb. of Caddo Creek fm. Underlies Jacksboro ls. memb. of Graham fm. (of Canyon group).

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 104), transferred Jacksboro ls. and Finis sh. to underlying Caddo Creek fm., and stated that Home Creek ls. includes Jacksboro ls. But F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501), and F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534), drew base of Graham fm. at top of Home Creek ls. (which is where the bdy is at present drawn by U. S. Geol. Survey), and divided lower part of Graham fm. in Palo Pinto Co. into following members (descending): Bunger ls., 6 ft.; Gonzales Creek sh., 116 ft.; Eastland ss., 10 to 15 ft.; and Finis sh., 50 ft.

Named for Finis, Jack Co.

Finlay limestone. (In Fredericksburg group.)

Lower Cretaceous (Comanche series): Western Texas.

G. B. Richardson, 1904 (Univ. Tex. Min. Surv. Bull. 9, p. 47). *Finlay fm.*—Almost entirely massive gray nonmag. ls., but locally containing thin beds of brown ss. At least 300 ft. exposed in Finlay Mtn region, but top not found. Top fm. of Fredericksburg group. Overlies Cox fm. and underlies residual soil and wash.

C. L. Baker, 1927 (Univ. Tex. Bull. 2745), transferred this fm. to Trinity group. [According to P. B. King (1937 communication) the fossils collected by Baker did not come from Finlay ls.]

The U. S. Geol. Survey now classifies this fm. as belonging to Fredericksburg group.

Named for Finlay Mtns, El Paso Co.

†Finley limestone.

Lower Ordovician (Beekmantown): Southwestern Missouri.

E. M. Shepard, 1904 (Bradley Geol. Field Sta. Drury Coll., Bull. 1, pt. 1, p. 42). *Finley ls.*—Ls., 150 ft. thick; the First Mag. ls. overlain by Black River and Birds Eye ls. and underlain by Marshfield ss.

H. F. Bain and E. O. Ulrich, 1905 (U. S. G. S. Bull. 260, p. 234, and Bull. 267, p. 12), correlated Finley ls. with Jefferson City dol.

The 1922 geol. map of Mo. shows surface fms. of Finley Creek, Christian Co., to be Mississippian rocks and Jefferson City dol.

J. Bridge, 1930 (personal communication), stated that Finley ls. of Shepard is either Cotter dol. or Powell dol.

Finley Knob shale member.

Mississippian: Southern Indiana.

P. B. Stockdale, 1931 (Ind. Dept. Cons., Div. Geol., Pub. 98, pp. 77, 100, 111, 116, 148, 151, 152, 153, 154, 158, 162–163). *Finley Knob sh. memb. of Carwood fm* — Argill. to sandy sh., gray to drab or buff, with numerous bryozoans and some crinoids, 5 to 16 ft. thick. Top bed of Carwood fm. At Finley Knob, NW¼ sec. 5, T. 2 N., R. 6 E., 6 mi. W. of Vienna, Scott Co., it consists of 13 to 15 ft. of sandy sh., gray to drab, with many bryozoans and crinoidal ls. patches in lower part. Underlies Floyds Knob ls. and is underlain by massive ss. of Carwood fm.

Finnie sandstone. (In Tradewater formation.)

Pennsylvanian: Western Kentucky and southeastern Illinois (?).

L. C. Glenn, 1912 (Ky. Geol. Surv. Bull. 17, pp. 13, 14, 23, 24). *Finnie ss.*—Ss., 0 to 50 ft. thick, in Tradewater fm., in interval btw. coals Nos. 2 and 3, Owen's coal No. 2 lying about 16 ft. below it. Lower part contains irregular shaly lenses, coal streaks, and sh. breccia or cgl.; upper part, gently cross-bedded, of alternating white and purplish laminae, medium grained.

Named for Finnie Bluff, on road N. of Milfordtown, Union Co., Ky.

Finnie Bluff sandstone.

A name applied by some Ky. geologists to *Finnie ss.* of other geologists.

†First Pentamerus limestone.

Silurian (Niagaran): New York.

T. A. Conrad, 1840 (Am. Jour. Sci., 1st, vol. 38, pp. 89–90). First Pentamerus ls. underlies Rochester sh. and overlies green sl. and iron ore; is characterized by *Pentamerus oblongus*.

Same as †Pentamerus ls. of 1839 rept.

Fish Creek sandstone member (of Greene formation).

Permian: Southwestern Pennsylvania, eastern Ohio, and northern West Virginia.

J. J. Stevenson, 1876 (2d Pa. Geol. Surv. Rept. K, p. 42). *Fish Creek ss.*—Shaly, massive ss., 40 to 100 ft. thick. On Fish Creek, in SW. part of Greene Co., Pa., it is conspicuous for miles. Overlies Dunkard coal and lies about 36 to 40 ft. below Nineveh coal. Included in Greene County group [Greene fm.].

I. C. White, 1891 (U. S. G. S. Bull. 65, pp. 22, 33). *Fish Creek ss.*—Very massive ss., lying 135 to 150 ft. below Nineveh coal, and 100 ft. below Nineveh ls. Makes the great cliffs along waters of Fish Creek, in Springhill Twp, Greene Co., Pa. Is very conspicuous in region of Deep Valley, Pa., where it forms cliffs 25 to 30 ft. high.

†Fish Creek beds.

Upper Cretaceous: Central southern Montana (Sweetgrass County).

E. Douglass, 1902 (Am. Phil. Soc. Proc., vol. 41, pp. 207–221). In area E. of Crazy Mtns and S. of Big Snowy Mtns, in basin of Musselshell River, Mont., the Niobrara is overlain (uncon. at Fish Creek) by beds that I believe belong to Belly River fm., but until they are certainly correlated I give them the name *Fish Creek beds*. They are best exposed btw. Fish and Mud Creeks, a few mi. from where latter empties into Musselshell River. They consist of rather soft sandy clay with hard, almost black concretions and hard ss. layers containing in some places plant impressions. These beds are probably of fresh or brackish water origin. They are overlain by a series of shales and hard laminated sss. (the latter containing some fossil leaves, and the shales numerous plant fragments) which I am uncertain whether to place in *Fish Creek series* or in overlying Fort Pierre shales, but for present I am including them in Fish Creek series.

These beds are considered by U. S. Geol. Survey geologists to correspond to Judith River fm.

Fish Creek shale. (In Greene formation.)

Permian: Northern West Virginia.

R. V. Hennen and D. B. Reger, 1913 (W. Va. Geol. Surv. Rept. Marion, Monongalia, and Taylor Counties, p. 183). *Fish Creek fire clay sh.*—Fire clay sh., 5 to 8 ft. thick. Underlies Fish Creek coal and lies higher in section than Rush Run ss. Named for association with Fish Creek coal.

Fish Creek argillite.

Paleozoic (?): Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 80; map). *Fish Creek argillite.*—Chiefly black carbonaceous argillites and interbedded bands of argillite and dark-colored qtzite; the argillites are greatly crumpled and show considerable variation in strike and dip. Thickness 1,500± ft. Intruded by large mass of dark-gray diorite. Separated from Red Top ls. and Lead Point argillite by a fault that follows along Fish Creek. Occupies about 2 sq. mi. in NE. corner of Stevens Co.; extends into B. C., and is part of Pend Oreille group.

Fisher latite-andesite.

Miocene (?): Southwestern Colorado.

E. S. Larsen, 1917 (Colo. Geol. Surv. Bull. 13, pp. 20, 23–33). *Fisher quartz latite.*—Overlies Piedra fm. of Potosi volcanic series and underlies Hinsdale volcanic series.

W. H. Emmons and E. S. Larsen, 1923 (U. S. G. S. Bull. 718). *Fisher quartz latite* is 0 to 3,000+ ft. thick in Platoro-Summitville dist., where it underlies Hinsdale volcanic series and overlies Piedra fm. of Potosi volcanic series. In Creede dist. it is 0 to 100 ft. thick, the Hinsdale volcanic series is absent, and the Fisher is separated from Piedra deposits by 0 to 2,000± ft. of lake beds named *Creede fm.* The Fisher was named for exposures in vicinity of Fisher Mtn, Creede quad.

W. Cross and E. S. Larsen, 1935 (U. S. G. S. Bull. 843), changed name to *Fisher latite-andesite.*

Fisher formation.

Oligocene: Northwestern Oregon (Eugene district).

H. G. Schenck, 1927 (Calif. Univ. Pub. Dept. Geol. Sci. Bull., vol. 16, No. 12, pp. 451, 459). *Fisher fm.*—A non-marine fm. overlying the Eocene sss. Composed of volcanic rocks, such as aggl. and tuff, and terrestrial clays, sands, and gravels. Estimated thickness 1,500 ft. Typically exposed in vicinity of Coyote Creek (sec. 12, T. 18 S., R. 5 W.), about 8 mi. W. of Eugene, and near Fisher Butte, ¼ mi. W. of Oak Hill. No fossils mentioned. Assigned to the lower Olig. Older than Eugene fm.

R. W. Chaney and E. I. Sanborn, 1933 (Carnegie Inst. Wash. Pub. 439). Flora of Fisher fm. is upper Eocene to lower Olig., with balance of evidence in favor of Eocene.

Fisherville coral reef. (In Waynesville limestone.)

Upper Ordovician: North-central Kentucky.

A. F. Foerste, 1909 (Denison Univ. Sci. Lab. Bull. 14, p. 291). *Fisherville coral reef* is in lower part of Waynesville bed of Richmond fm.

Named for Fisherville, Jefferson Co. Extends from Henry Co. to NW. edge of Nelson Co.

Fish Haven dolomite.

Upper Ordovician (Richmond): Northeastern and western (Gold Hill district) Utah and southern Idaho.

G. B. Richardson, 1913 (Am. Jour. Sci., 4th, vol. 36, pp. 407, 409). *Fish Haven dol.*—Medium-bedded bluish dol., 500 ft. thick. Underlies Laketown dol. and overlies (uncon.?) Swan Peak qtzite.

Named for exposures on Fish Haven Creek, Bear Lake Co., Idaho.

Fish House clay.

Pleistocene: Southern New Jersey.

R. D. Salisbury, 1895 (N. J. Geol. Surv. Ann. Rept. State Geol. 1894). Age of *Fish House clays* has been in dispute. At Fish House, on Delaware River [about 5 mi. N. of Camden, Camden Co.], they rest on Pensauken, so it is certain they are post-Pensauken.

L. Woolman, 1897 (N. J. Geol. Surv. Ann. Rept. State Geol. 1896, p. 201). *Fish House clay.*—Black or blue clay worked for many years. Thickness 5½ ft. at Fish House, 25 ft. at Delair. [For strat. position of this clay see 1897 entry under †*Fish House beds.*] Writer believes it belongs to Pensauken fm., but leaves determination of exact equivalency to Prof. Salisbury, who is still working on the fm.

H. B. Kümmel and G. N. Knapp, 1904 (N. J. Geol. Surv. vol. 6). *Pensauken fm.* consists (descending): (1) Gravel, etc.; (2) few ft. of clayey loam, usually with well-marked line of pebbles at base; (3) *Fish House clays* 27 or 28 ft. (of limited extent and in places uncon. on white Cret. clay); (4) ironstone a few inches; (5) coarse yellow sand.

R. D. Salisbury and G. N. Knapp, 1917 (N. J. Geol. Surv. vol. 8). Pensauken fm. includes the clays at Fish House.

†Fish House beds.

Pleistocene: Southern New Jersey.

L. Woolman, 1897 (N. J. Geol. Surv. Ann. Rept. State Geol. 1896, pp. 201+). *Fish House beds.*—Under this name we would include (descending): (1) Orange yellow clay bed, thin; (2) *Fish House clay*, blue or black clay 5½ ft. thick at Fish House; (3) orange yellow clay, 0–1 ft.; (4) ironstone crust, ½ ft.; (5) laminated and cross-bedded coarse-yellow sands and medium-coarse yellow gravels, 12½ ft. At Fish House rests uncon. on Raritan fm. Author believes these beds are Pensauken fm.

Same as Pensauken fm., as explained under *Fish House clay.*

Fishkill limestone.

Ordovician and Cambrian: Southeastern New York (Dutchess County).

J. M. Clarke, 1909 (N. Y. State Mus. Bull. 133, pp. 12–18). *Fishkill ls.*—A belt of hard ls., highly metamorphosed, weathering grayish white, but showing buff-colored markings on fresh surfaces. Outcrops in town of Fishkill, NW. of road from Fishkill Village to Matteawan, btw. it and Glenham gneiss belt, and extends 2 mi. roughly parallel with outcrop of the gneiss. Can not be traced beyond road from Fishkill Village to Wappingers Falls. Contains lowest Ordovicic and latest Camb. fossils. Rests on Poughquag qtzite. Overlain by slates of Trenton or later age. Areal survey by C. E. Gordon.

C. E. Gordon, 1910 (N. Y. State Mus. Bull. 140, pp. 16–20). The Wappinger ls. occurs within Poughkeepsie quad. in two well-defined masses, the composite Wappinger Creek belt and the *Fishkill ls.*

C. E. Gordon, 1911 (N. Y. State Mus. Bull. 148, pp. 48, 70). The eastern belt of Wappinger ls. is known as *Fishkill ls.*, as it lies chiefly in town of old Fishkill. Includes Trenton, Beekmantown, and Lower Camb. fossils.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 30). Another extensive area of Barnegat ls. (=Wappinger ls.), of Cambric and Ordovicic age, is developed just N. of Fishkill Mtns. These rocks, called *Fishkill ls.*, are in part strat. equiv. of Wappinger ls.

See also under *Barnegat ls.*

Fishpot limestone member (of Monongahela formation).

Pennsylvanian: Western Pennsylvania and Maryland, northern West Virginia, and eastern Ohio.

J. J. Stevenson, 1876 (2d Pa. Geol. Surv. Rept. K). *Fishpot ls.*—Separated from overlying Sewickley coal by 10 ft. of ss., and from underlying Redstone coal by 25 ft. of ss. or sandy sh. Thickness at mouth of Fishpot Run, in southern Washington Co., Pa., 30 ft.; at W. Va. line it is thin.

Fishpot sandstone. (In Monongahela formation.)

Pennsylvanian: Eastern Ohio.

R. E. Lamborn, 1930 (Ohio Geol. Surv., 4th ser., Bull. 35, pp. 29, 32, 181, 234, 235–236). At some localities along belt of outcrops of Monongahela series of eastern

Ohio is a thin ss. lying btw. Fishpot and Sewickley coals, which W. Stout, chief of Geol. Surv. of Ohio, suggests be named *Fishpot ss.* The strat. position of this ss. is a few ft. below Sewickley coal, which suggests correlation with Lower Sewickley ss. of W. Va. In Jefferson Co., O., the type of rock usually found on this horizon is aren. sh. [In detailed sections given in this bull. Lamborn applied *Fishpot* to sh. and ss. ranging in thickness from 6 in. to 18 ft. 2 in. and lying 12 ft. 1 in. to 36 ft. 8 in. above Fishpot ls.]

†Fish Tooth sandstone.

A name locally applied, at Salt Creek, Wyo., to a ss. about 400 ft. above base of Steele sh.

Fitch formation.

Silurian (middle): Northwestern New Hampshire (Ammonoosuc River region).

M. Billings and A. B. Cleaves, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, Feb. 28, p. 196, and Am. Jour. Sci., 5th, vol. 25, No. 146, Feb., p. 149). Ten fossil forms have been identified in material from *Fitch fm.*, and we confirm Schuchert's opinion that this fm. is middle Sil. Overlies West Bath sl. (pre-Sil.) and underlies Littleton fm. (Lower Dev.). [In 1934 Billings replaced *West Bath sl.* with *Partridge sl.*]

M. Billings, 1934 (Sci., Jan. 19, vol. 79, No. 2038, pp. 55–56). *Fitch fm.* (*middle Sil.*).—Calc. sh., calc. ss., aren. dol., arkose, qtz cgl.; 700 ft. thick. In Fitch fm. the calc. shales have become biotite calcite schists and the aren. dolomites now consist of actinolite, pyroxene, plagioclase, and quartz. It underlies Littleton fm. (Lower Dev.) and overlies Clough cgl. (middle or lower Sil.).

M. Billings, 1934 (Am. Jour. Sci., 5th, vol. 28, Dec., pp. 412+). *Fitch fm.* is named for [G. E.] Fitch farm. 2 mi. NW. of Littleton, N. H. Thickness 400–700 ft. Grades into underlying Clough cgl. Contains Niagaran fossils. [See also Billings' Geology of Littleton and Moosilauke quads., N. H., a 1935 publication.]

Fitchburg granite.

Late Carboniferous or post-Carboniferous: Central Massachusetts and central southern New Hampshire.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 231–233 and map). The deep-seated central portion of central batholith, uninfluenced by the cover, is a medium-grained muscovite-biotite granite, which may be taken as the normal constituent of the batholith, and is called the *Fitchburg granite.* Crosses Fitchburg, Mass.

Fitch Hill granite gneiss.

Silurian (?): Northwestern New Hampshire (Ammonoosuc River region).

F. H. Lahee, 1913 (Am. Jour. Sci., 4th, vol. 36, pp. 231–250; map). *Fitch Hill granite gneiss.*—Metamorphosed igneous rock, pre-Sil. [?]. Intrudes Lyman schist [Sil.] and uncon. underlies Sil. (Niagaran) sediments. Called "chlorite," "chloritic rock," etc., by Hitchcock. [Probably named for proximity to same hill as that for which the arkose was named.]

M. Billings, 1935 (letter dated Aug. 27). Lahee's Fitch Hill granite gneiss is precisely same as our Highlandcroft granodiorite. It belongs to Highlandcroft magma series, which is late Ord. (?).

Fitch Hill arkose.

Silurian (Niagaran): Northwestern New Hampshire (Ammonoosuc River region).

F. H. Lahee, 1913 (Am. Jour. Sci., 4th, vol. 36, pp. 231–250). The thick mass (200–300 ft.) of arkose forming Fitch Hill, NW. of town of Lisbon, is here called *Fitch Hill arkose*, to distinguish it from basal arkose of basal series of the Sil. Lies 150± ft. higher in the series than sl. and ls. carrying Niagaran fossils. [This appears to be a part of Fitch fm. of Billings and Cleaves.]

Fite limestone.

Upper (?) Ordovician: Central eastern Oklahoma (Cherokee and Adair Counties).

I. H. Cram, 1930 (Okla. Geol. Surv. Bull. 40QQ, pp. 20–22). *Fite ls.*—Hard, light-gray, sublithographic ls. attaining thickness of 8 ft. where protected from pre-

Chattanoogan erosion by Fernvale ls. Blotches of crystalline calcite are almost invariably present in the sublithographic matrix, and often near middle there is a lens of brownish fine-grained dolomitic ls. The fm. occurs only in anticlinal area just NE. of Tahlequah. It is not present in Barren Fork area. It was included in Tyner fm. by Taff in Tahlequah folio, but because it is so distinct, and because it is absent at type loc. of Tyner, it is here named *Fite ls.*, from excellent exposures on estate of Dr. Fite in sec. 11, T. 17 N., R. 22 E. It uncon. overlies Tyner fm. [as here restricted] and is uncon. overlain by Fernvale ls. (Upper Ord.) or by Chattanooga sh. The Fernvale was also included in Tyner fm. by Taff. Underground in Okla. an occasional bed of ss. occurs btw. Fite and Fernvale lss. Fossils are now identified by E. O. Ulrich as pre-Fernvale Richmond.

I. H. Cram, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, p. 286). The best, though inconclusive, evidence indicates that the Fite is Bromide (Black River-Trenton) in age, instead of Richmond, as meager fauna collected at outcrop suggests.

Fitzgerald limestones.

Silurian: Northwest Territory and Mackenzie.

A. E. Cameron, 1918 (Canada Geol. Surv. Summ. Rept. 1917, pt. C, p. 25).

Fitzhugh sands.

C. E. Jamison, 1912 (Wyo. State Geol., ser. B, Bull. 4), stated that Wall Creek ss. of Salt Creek oil field, Wyo., was formerly called "First Fitzhugh sand," and that a sand lying 220 ft. lower was called "Second Fitzhugh sand." These sands both occur in upper part of Frontier fm.

Fitzwilliam granite.

Late Carboniferous or post-Carboniferous: Southwestern New Hampshire and extreme central northern Massachusetts.

C. H. Hitchcock, 1873 (Am. Ass. Adv. Sci. Proc., vol. 21, pp. 134–135), stated that Laurentian included *Fitzwilliam granite.*

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, p. 238 and map). *Fitzwilliam granite.*—Light-gray muscovite-biotite granite, of even, fine grain. It just enters Mass. from Fitzwilliam, N. H. Assigned to late Carbf. or post-Carbf.

Five Islands volcanics.

Triassic: New Brunswick and Nova Scotia.

S. Powers, 1915 (Geol. Soc. Am. Bull., vol. 26, p. 93).

Fivemile shale. (In Hinton formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Tazewell County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 295–296, 338–340). *Upper Fivemile sh.*—Gray or green and calc. deposit, with marine fossils; occasionally red and variegated, with lenticular ss.; thickness 15 to 43 ft.; underlies Falls Mills ls. and overlies Fivemile coal. *Lower Fivemile sh.*—Green and sandy, with marine and plant fossils; thickness 10 to 20 ft.; underlies Fivemile coal and rests on Tallery ss. All members of Hinton group [fm.]. Type loc. of both shales is on Fivemile Creek, along Princeton-Narrows road, 4.5 mi. SE. of Princeton, Mercer Co., W. Va. The upper sh. also observed in Summers Co. and in Tazewell Co., Va. The lower sh. observed in Mercer and Summers Counties.

Five Point limestone. (In Admire shale.)

Pennsylvanian: Kansas and Nebraska.

R. C. Moore and G. E. Condra (Oct. 1932 revised classification chart of Penn. rocks of Kans. and Nebr.). [*Five Point ls.* is shown as underlying Stine sh. and overlying West Branch sh., all included in Admire sh. Derivation of name not stated.]

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 5). *Five Point ls.* was named for exposures in Five Point Valley, Richardson Co., Nebr. Has been traced S. through Kans. to Okla., and is recognized by Kans. Surv.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), transferred all beds above Brownville ls. to Perm. (See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.)

E. C. Reed (Asst. State Geol. Nebr.), 1936 (letter dated Oct. 16). Type loc. of *Five Point ls.* is Five Point Creek, near Five Point School, sec. 25, T. 1 N., R. 15 E., Richardson Co., Nebr., 2 mi. S. and 4½ mi. W. of Falls City.

Flades clay.

Silurian (Niagaran): East-central Kentucky.

A. F. Foerste, 1905 (Ky. Geol. Surv. Bull. 6, p. 145) and 1906 (Ky. Geol. Surv. Bull. 7, pp. 10, 18, 60). *Flades clay*.—Name to include Waco ls. and Estill clay [members of Alger fm.] where Waco ls. cannot be distinguished from overlying Estill clay but where thick basal layer of Waco ls. can be recognized.

Named for Flades Creek, E. of Crab Orchard, Lincoln Co.

Flag Spring limestone. (In Conemaugh formation.)

Pennsylvanian: Gallia County, Ohio.

E. Orton, 1878 (Ohio Geol. Surv., vol. 3, pp. 889–890). *Flag Spring ls*.—Fossiliferous blue ls. in northern Gallia Co., about midway btw. Shawnee and Cambridge lss. Occurs at exact horizon of Banda iron ore, which replaces it throughout several twps.

Named for well-known locality in Walnut Twp, Gallia Co.

Flag Spring trachyte.

Tertiary (middle or late): Northwestern Arizona (Oatman district).

F. L. Ransome, 1923 (U. S. G. S. Bull. 743). Compact, fine-grained red brown lava flow closely resembling Esperanza trachyte. Thickness 0 to 250± ft. Overlies Gold Road latite. Well exposed in cliffs along Cottonwood Canyon, and named for Flag Spring, in the canyon.

Flagstaff limestone.

Eocene: Central eastern Utah (Wasatch Plateau).

E. M. Spieker and J. B. Reeside, Jr., 1925 (Geol. Soc. Am. Bull., vol. 36, pp. 150–151, 448). *Flagstaff ls. memb. of Wasatch fm*.—A remarkable memb. of fresh-water ls., 200 to 1,000 ft. thick, lying 1,000 ft. below top of Wasatch fm. and 1,200 to 2,000 ft. above base of Wasatch in Wasatch Plateau, Utah. [Named for fact it is prominent in Flagstaff Peak.]

These beds are now treated as a distinct fm. by U. S. Geol. Survey.

Flagstaff limestone.

Miners' local term for a part or all of Madison ls., of lower Miss. age, in Little Cottonwood dist., central northern Utah.

Flambeau quartzite.

Pre-Cambrian (Huronian): Northwestern Wisconsin (Rusk County).

W. O. Hotchkiss et al, 1915 (Wis. Geol. Nat. Hist. Surv. Bull. 44, econ. ser. 19, p. 50). *Flambeau qtzite*.—Varies from a predominant reddish brown to pale yellowish gray. Chiefly quartz grains, as a rule well cemented. Is vitreous, but interstices are not completely filled. Lowest qtzite beds seen are in a number of places marked by thin beds of cgl., 3 to 10 ft. thick, extending through 40 ft. of beds. Thickness 2,000 to 2,500 ft. No other beds found in contact with it. Believed to be older than Barron qtzite and to be upper or middle Huronian.

Probably named for exposures at Flambeau or on Flambeau River, Rusk Co.

†Flaming Gorge group.

Upper Jurassic: Northeastern Utah (Uinta Mountains) and northwestern Colorado.

J. W. Powell, 1876 (Geology of eastern portion of Uinta Mtns, pp. 41, 51, 146, 151). *Flaming Gorge group*.—In descending order: (1) Bad-land sss. of lacustrine origin; (2) mid-group lss., marine, more or less aren.; (3) massive ss., 400 to 600 ft., which to S. is represented by bad-land ss. with clay and gyp.; (4) *White Cliff ls*., marine ls. 10 to 200 ft. thick. Named for Flaming Gorge, on S. side of Green River [at mouth of Henrys Fork], Utah [in Uinta Co.].

A. R. Schultz, 1920 (U. S. G. S. Bull. 702, table opp. p. 24), showed Flaming Gorge group of Powell = Beckwith and Twin Creek fms. of SW. Wyo.

A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1936 (U. S. G. S. P. P. 183, chart opp. p. 33), showed Flaming Gorge group of Powell and of G. K. Gilbert's Henry Mtns rept = (descending) Morrison, Summerville, Curtis, Entrada, and Carmel fms. (all Upper Jurassic).

Flanagan limestone.

Middle Ordovician (Trenton): Central Kentucky.

M. R. Campbell, 1898 (U. S. G. S. Richmond folio, No. 46, p. 2). *Flanagan chert.*—Thin-bedded gray ls. and calc. sh. containing bands of chert; thickness 0 to 40 ft. Overlain by Winchester ls. and underlain by Lexington ls. Named for exposures at Flanagan Station, Clark Co.

A. M. Miller, 1905 (Ky. Geol. Surv. Bull. 2, pp. 8–23). The Flanagan chert of Campbell is a cherty horizon at top of Bigby substage of Lexington stage. It does not represent a constant time unit of deposition, but is due to a particular phase of weathering.

G. C. Matson, 1909 (U. S. G. S. W. S. P. 233). *Flanagan chert memb.*—Gray crystalline ls., usually lighter colored and more cherty than underlying ls. Thickness 75 ft. Is top memb. of Lexington ls.

A. M. Miller, 1913 (Ky. Geol. Surv., 4th ser., vol. 1, pt. 1, pp. 317–342). *Flanagan,* 55 ft. thick, divided into Woodburn above and Brannon below. Underlies Perryville and overlies Bigby fm. [named *Benson bed* by Foerste in 1913].

W. C. Phalen, 1917 (Ky. Geol. Surv. rept. on phosphate rocks of central Ky.). *Flanagan ls.* divided into Woodburn phosphatic memb. (30 to 40 ft. thick) above and Brannon cherty memb. (13 to 15 ft. thick) below. [This is present accepted definition of U. S. Geol. Survey.]

Flat Creek beds.

Tertiary: Canada (Yukon).

R. G. McConnell, 1905 (Canada Geol. Surv. Ann. Rept., vol. 14, pt. B, p. 24).

Flat Gap limestone member (of Olive Hill formation).

Lower Devonian (Helderbergian): Western Tennessee.

C. O. Dunbar, 1918 (Am. Jour. Sci., 4th, vol. 46, p. 738). *Flat Gap memb.*—Heavy-bedded coarsely crystalline or granular ls. of white or pinkish color, very sparingly fossiliferous. Thickness 0 to 53 ft. Top memb. of Olive Hill fm. Uncon. underlies Birdsong sh. and overlies Bear Branch memb. of Olive Hill fm. [Type loc. not stated.]

Flathead quartzite.

Middle Cambrian: Montana and northwestern Wyoming.

A. C. Peale, 1893 (U. S. G. S. Bull. 110). *Flathead qtzite.*—Remarkably persistent qtzite or ss., which has long been recognized in Rocky Mtn region as lying in most cases at base of Paleozoic section. Is usually qtzitic. In some places there are interlaminated beds of reddish or reddish brown sss. in which cementing material is partly an iron oxide. Thickness 125 ft. In places rests on Belt series and in places on Archean schists or gneisses. No fossils. Is overlain by Flathead shales, from which it is in places separated by a layer of eruptive rock. The *Flathead qtzite* and *Flathead shales* comprise *Flathead fm.*

Named for exposures in Flathead Pass, in NE. corner of Threeforks quad., Mont.

†Flathead formation.

†Flathead shales.

Middle Cambrian: Montana and northwestern Wyoming.

A. C. Peale, 1893 (U. S. G. S. Bull. 110). *Flathead fm.*—Divided into *Flathead shales* above and *Flathead qtzite* below. The shales are soft, green, shaly beds interlaminated with thin beds of glauconitic ls.; toward base are beds of very dark reddish-brown and green ss. Thickness of the shales 290 ft. Overlain by Trilobite ls., the basal memb. of Gallatin fm. [For description of the qtzite see *Flathead qtzite.*]

The use of *Flathead* in 3 senses being objectionable, the name has for many years been restricted to the qtzite, and the so-called "Flathead shales" have been combined with the overlying trilobite-bearing lss. and *Obolella*-bearing shales (originally included in Gallatin fm.) into a fm. named *Gros Ventre fm.*

Named for exposures in Flathead Pass, in NE. corner of Threeforks quad., Mont.

Flatiron andesites.

Age (?): Northern California (Lassen National Park).

H. Williams, 1932 (Calif. Univ. Pub., Bull. Dept. Geol. Sci., vol. 21, No. 8, pp. 214–376, map). *Flatiron andesites.*—Pyroxene andesite, 1,700+ ft. thick. Occurs on Flatiron Ridge. Extends from White Mtn to head of Warner Valley. Believed to be younger than Twin Lakes andesites.

Flat Lick sandstone. (In Pottsville group.)

Pennsylvanian: Southeastern Kentucky (Knox County).

W. R. Jillson and J. M. Hodge, 1919 (Ky. Dept. Geol. and Forestry, ser. 5, Bull. 3, pp. 1, 2, 3, 9–10, 34). *Flat Lick ss.*—A strong ss., 50 to 75 ft. thick, underlying Lily coal, and prominent in cliffs along river near Artemus; also forms base of Flat Lick plateau. Named because it is well exposed by the doming at Flat Lick, Knox Co. Included in Upper Pottsville.

Flat Rock stone.

Silurian: Indiana.

See *Greensburg or Flat Rock stone.*

Flat Rock dolomite member (of Detroit River dolomite).

Lower Devonian: Southeastern Michigan (Wayne County) and western Ontario.

W. H. Sherzer and A. W. Grabau, 1909 (Geol. Soc. Am. Bull., vol. 19, p. 541). *Flat Rock dol.*—Hard, porous, compact gray dolomitic calcilutite, 47 ft. thick. Fossils. Oldest memb. of Upper Monroe [Detroit River dol.]. Underlies Anderdon ls. Discon. overlies Sylvania ss. [On later pages (553–556) thickness of 40 to 150+ ft. is given.]

Named for exposures at Flat Rock, Wayne Co.

Flat Rock sand.

See under *Robinson sand.*

Flat Run sand.

Drillers' term; SW. Pa.; probably at same horizon as Gordon sand, and of Catskill age. Is younger than McDonald sand and older than Campbells Run sand. In W. Va. the name has been applied to a sand that may be older than Gordon sand.

Flat-top sandstone.

Pennsylvanian: Southeastern Oklahoma.

H. M. Chance, 1890 (Am. Inst. Min. Engrs. Trans., vol. 18, pp. 653–661). *"Flat-top ss."*—M-ssive ss., 100 ft. thick, which caps Roundtop and Long Mtn in Grady Basin, and forms Adams Ridge. Lies 600 ft. above Grady group of coals and 550 ft. below McAlester coal in Choctaw coal field.

Flattop schist.

Pre-Cambrian: Western North Carolina.

A. Keith, 1903 (U. S. G. S. Cranberry folio, No. 90, p. 4). *Flattop schist.*—Black, dark blue, bluish-green, and greenish gray very fine-grained schists (composed of quartz, feldspar, and mica of secondary origin), which weather to yellowish gray or greenish gray. Commonly marked by light-gray bands more feldspathic than rest of rock, being made up of quartz and feldspar grains of varying sizes with a little fine muscovite. Other portions of the schist contain porphyritic crystals of feldspar and amygdules, which show its volcanic nature. Grades into older Montezuma schist. Is pre-Camb. (Algonkian?).

Named for Flattop Mtn, Cranberry quad., in Watauga Co.

Flat-top limestone.

Devonian or Mississippian (?): Western Colorado.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, pp. 281, 292). *Flat-top ls.*—Drab lithographic unfossiliferous dol., 150 ft. thick, underlying Leadville ls. and uncon. overlying Ouray ls. in Colo. May be of Kinderhookian age. Named for Flat-top Mtn, N. of Glenwood Springs.

E. Kirk, 1931 (Am. Jour. Sci., 5th, vol. 22, p. 229). Flattop dol. of Keyes is hard to identify. It was probably taken from one of older Territorial Survey publications and might be either Dev. or Miss.

Flattop Mountain sandstone. (In Pottsville group.)

Pennsylvanian: Southern West Virginia.

I. C. White, 1908 (W. Va. Geol. Surv. vol. 2A, p. 13). Pocahontas group divided into (descending): (1) *Flat Top Mtn ss.;* (2) Pocahontas coals Nos. 6, 5, 4, 3, 2, and 1, with intervening sss. and shales; and (3) Pocahontas sss.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, p. 217). *Flattop Mtn ss.,* top memb. of Pocahontas group or Lower Pottsville series, rests on sh. here named *Rift sh.* Is generally massive to current bedded, medium grained to coarse, micaceous, bluish gray to brown, 22 to 50 ft. thick. Named for Flattop Mtn, 2 mi. NW. of Pocahontas, Va.

Flat Top Mountain sandstone. (In Pottsville group.)

Pennsylvanian: Northeastern Kentucky.

J. B. Hoeing, 1913 (Ky. Geol. Surv., 4th ser., vol. 1, pt. 1, p. 81). *Flat Top Mtn ss.*—Top memb. of Lower Pottsville or Pocahontas group in upper Big Sandy Valley and headwaters of North Fork of Kentucky River.

†Flatwoods clay.

Eocene (lower): Western Tennessee, northeastern Mississippi, and southwestern Alabama.

E. W. Hilgard, 1860 (Rept. Geol. and Agric. Miss., pp. 110–111, 275). *Flatwoods clay.*—Hard gray or whitish clay, sometimes laminated but more usually of massy cleavage, with tendency to conchoidal or nodular forms, which are conspicuous in most outcrops found on whitened hillsides in the Flatwoods. Shows little tendency to disintegrate by atmospheric agencies alone. Is a phase of Northern Lignitic fm.

Same as Porters Creek clay, of Midway group.

Named for low, flat land, covering several counties in NE. Miss., resembling broad bottom of large river and generally known as the "Flatwoods country."

†Flatwoods group.

Eocene: Western Tennessee.

J. B. Killebrew and J. M. Safford, 1874 (Resources of Tenn., p. 44). *Flatwoods group.*—Sands and clays, 200 to 300 ft. thick, underlying LaGrange group and overlying Ripley group (Cret.). In geol. rept. of Tenn. was called "Porter's Creek group," because a heavy bed of laminated clay, 100 ft. thick, occurs on Porter's Creek.

Includes Porters Creek clay and Clayton fm. of present nomenclature, or all of Midway group.

†Flatwoods shale.

Upper and Middle Cambrian: Eastern Alabama.

E. A. Smith, 1890 (Ala. Geol. Surv. Rept. on Cahaba coal field, p. 148, map, and structure section opp. p. 162). [See under †Coosa sh.]

Named for level, badly drained lands in valley region of eastern Ala. which are generally known as "Flatwoods."

Flaxman formation.

Pleistocene (Wisconsin): Northern Alaska (Canning River region).

E. D. Leffingwell, 1919 (U. S. G. S. P. P. 109, pp. 103, 142, map). *Flaxman fm.*—Foreign glacial till, possibly containing glacial ice, scattered along Arctic coast line of America. Well exposed on Flaxman Island. From its youth it must be ascribed to last advance of continental ice—the Wisconsin.

Flaxville gravel.

Miocene (upper) or Pliocene: Northern Montana and adjacent parts of Saskatchewan and Alberta.

A. J. Collier, 1917 (Wash. Acad. Sci. Jour., vol. 7, pp. 194–195). *Flaxville fm.*—Brownish to ash-gray, silt, sand, and gravel, and white marl, from a few ft. to 100 ft. thick. Generally noncoherent but locally cemented with calcite, and forms prominent outcrops, often marked by cross-bedding. The gravel is characterized by material from Rocky Mtns. Is found on four extensive plateaus ranging in elevation from 2,700 ft. S. of Redstone, to 3,200 ft. in W. side of Boundary Plateau. Fragments of vertebrate fossils from the fm. at 27 localities (in wells, railroad cuts, badger holes, and natural exposures) pronounced by J. W. Gidley to be not older than Mio. nor younger than lower Plio.

A. J. Collier and W. T. Thom, Jr., 1918 (U. S. G. S. P. P. 108J, pp. 179–184). *Flaxville gravel.*—Named for town of Flaxville, Mont., on Scobey branch of Great Northern Ry. Deposited in Mio. or early Plio. time. [Lists fossils.] Caps a series of even-topped plateaus ranging in altitude from 2,600± ft. at its E. end, a few mi. S. of Redstone, to 3,200 ft. in W. front of Boundary Plateau in Cherry Creek quad. Is from a few ft. to 100 ft. thick. Rests on eroded surfaces of Fort Union, Lance, and Bearpaw fms. [Mapped over area extending from E. of 105° to W. of 110°, both N. and S. of 49° par.] Generally composed of yellowish to ash-gray gravel, clay, and sand, but in some places contains beds of white marl and volcanic ash. The gravel consists of well-rounded pebbles from less than 1 in. to 1 ft. or more diam., of qtzite and argillite derived from Rocky Mtns. Pebbles of ls. from same source may have been dissolved and the lime redeposited as cementing material and beds of marl. Materials mostly noncoherent and easily excavated by well diggers, though beds of hard ss. and cgl. cemented with calcite from 1 ft. to several ft. thick are encountered in most wells. In places thoroughly cemented with calcite and forms prominently outcropping ledges of ss. and cgl. In railway cuts W. of Flaxville, where best collection of fossils was made, about half of exposed material is gravel and remainder clay and sand, with about 1 ft. of marl or concretionary calcite. Bedding irregular.

Fleener facies.

Name applied by P. B. Stockdale (Ind. Dept. Cons., Div. Geol., Pub. 98, pp. 77, 184, etc., 1931) to a local facies of his Carwood fm. of southern Ind.

†Fleming clay.

†Fleming group.

Miocene (upper) and Pliocene (?): Eastern Texas and northwestern Louisiana.

W. Kennedy, 1892 (Tex. Geol. Surv. 3d Ann. Rept., pp. 45, 62). *Fleming beds.*—Clays and sands or sandy clays, dark blue, pale blue, brown, red, yellow, and pale green, thinly laminated and partially stratified and massive. Thickness 260 ft. Overlies Fayette sands and sss. and underlies Quat. clays.

A. Deussen, 1914 (U. S. G. S. W. S. P. 335). *Fleming clay* consists of 200 to 500 ft. of gray, white, and bluish white, bedded, calc. clays with numerous small concretions of lime and some lenses of sand, underlying Dewitt fm. and uncon. overlying Catahoula ss. Assigned to basal Mio.

E. T. Dumble, 1915 (Geol. Soc. Am. Bull., vol. 26, pp. 447–475). *Fleming beds* include all sediments btw. Corrigan sands and Lafayette or Reynosa sands btw. Sabine and Navasota rivers. Is=Lagarto, Lapara, and possibly Oakville. Thickness 1,500± ft.

G. C. Matson, 1916 (U. S. G. S. P. P. 98), divided Fleming clay of eastern Tex. into Pascagoula clay (above) and Hattiesburg clay (below).

J. A. Udden, C. L. Baker, and E. Böse, 1916 (Univ. Tex. Bull. 44, pp. 81, 88–89). *Fleming beds* (Mio. and Plio.) overlie Corrigan or Catahoula and are=Lagarto, Lapara, and Oakville. Thickness, 1,500± ft.

W. Kennedy, 1917 (SW. Ass. Pet. Geol. Bull., vol. 1, pp. 36–37). It is probable that some, if not all, of Lagarto clays, Lapara sands, and Oakville sands may be correlated with some of various phases of *Fleming beds*.

A. Deussen and L. L. Lane, 1925 (A. A. P. G. Bull., vol. 9, pp. 1031–1052). *Fleming fm.* immediately underlies Lafayette fm. and overlies Catahoula ss. Thickness, 1,100 to 2,600 ft. Is=Lagarto clays, Lapara sands, and Oakville ss. of region W. of Brazos River.

C. W. Cooke and J. Gardner, 1930 (personal statement). *Fleming clay* is of upper Mio. and possibly lower Plio. age; is=Pascagoula clay; and is younger than Oakville ss. and Hattiesburg clay.

The U. S. Geol. Survey discarded this name from its classification in 1932.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 727), applied *Fleming group* to the Mio. and Plio. beds btw. Catahoula fm. and Goliad fm., and divided the group into Lagarto fm. [restricted] and Oakville fm.

Named for Fleming, Tyler Co.

Fleurant conglomerate.

Upper Devonian: Quebec (Gaspe Peninsula).

E. M. Kindle, 1930 (Canada Geol. Surv. Dept. Mines Summ. Rept. 1928, pt. C, pp. 82C–84C, pl. opp. p. 82C). Boulder cgl., 45 ft. thick, underlying Escuminac beds and overlying 450 ft. of barren coffee-colored sh. Type loc. Fleurant Point; also seen at Mushroom rock and ⅛ mi. SE. of Englishman Creek.

Flint moraine.

Pleistocene (Wisconsin stage): Southeastern Michigan. Shown on moraine map (pl. 32) in U. S. G. S. Mon. 53. Named for Flint, Genesee Co.

†Flint Creek beds.

Tertiary (middle Miocene?): Central western Montana (Philipsburg region).

E. Douglass, 1903 (Carnegie Mus. Annals, vol. 2, pp. 153–154). *Flint Creek beds* are typically exposed in a line of bluffs 100 to 150 or more ft. exposed high on W. side of valley of Flint Creek, beginning about 1 mi. N. of village of New Chicago and extending southward several miles. [Fossils listed. In 1908 (Carnegie Mus. Annals, vol. 4, Nos. 3 and 4, pp. 256–266) Douglass assigned these beds to upper Mio.]

H. F. Osborn, 1909 (U. S. G. S. Bull. 361, pp. 65, 114). "Flint Creek beds" are middle Mio.

H. F. Osborn, 1918 (Am. Mus. Nat. Hist. Mem, n. s., vol. 2, pt. 1, pp. 9, 16), assigned "Flint Creek beds" to middle Mio. on p. 9, but on p. 16 stated that they are "probably lower Plio."

†Flint Hills division.

Permian: Central Kansas.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, pp. 3, 6–9). *Flint Hills div.*—Lower div. of Big Blue series. Divided into Chase lss. above (265 ft. thick) and Neosho shales below (130 ft. thick). Overlain by Sumner div.

Not used in later classifications of Kans. Geol. Survey.

Named for Flint Hills, Cowley and Butler Counties.

Flint Ridge limestone. (In Allegheny? formation.)

Pennsylvanian: Central Ohio.

E. B. Andrews, 1870 (Ohio Geol. Surv. Rept. Prog. 1869, pp. 86, 91–93) and 1871 (Ohio Geol. Surv. Rept. Prog. 1870, pp. 89, 94–95). *Flint Ridge ls.*—Highly fossiliferous ls. in Coal Measures at Flint Ridge. Dark blue, almost black, thin bedded, and contains some iron; 12 to 14 ft. thick. Supposed=Putnam Hill ls. [On p. 93 is called "The Flint Ridge Putnam Hill ls."] At Flint Ridge is separated from underlying Flint Ridge cannel coal by 4 ft. of blue clay sh., 4 inches of bituminous coal, and 5 inches of bituminous sl. Overlain by iron ore. In Hopewell Twp, Muskingum Co., it partakes more of nature of a highly calc. sh.

Named for Flint Ridge, Licking Co.

W. Stout, 1927 (Ohio Geol. Surv., 4th ser., Bull. 31, p. 170), stated that Flint Ridge ls. is in upper part of Pottsville fm.

Flint Ridge flint. (In Allegheny formation.)

Pennsylvanian: Central Ohio

E. B. Andrews, 1871 (Ohio Geol. Surv. Rept. Prog. 1870, pl. opp. p. 242). *Flint Ridge flint.*—[Name applied, in cross-country section of 2d geol. dist. of Ohio, to flint occurring in Lower Coal Measures at a considerably higher horizon than Putnam Hill ls. (supposed equiv. of Flint Ridge ls.). According to E. Orton, 1878

(Ohio Geol. Surv., vol. 3, p. 894), the Putnam Hill ls. of Flint Ridge, Licking Co., is *replaced by 6 to 8 ft. of fossiliferous flint.*]

Named for Flint Ridge, 2½ mi. SE. of Newark, Licking Co.

Flint Ridge shale. (In Pottsville formation.)

Pennsylvanian: Central Ohio.

C. L. Herrick, 1887 (Denison Univ. Sci. Lab. vol. 2, pt. 1, pp. 10–12). *Flint Ridge sh.*—Thin layer of black sh. immediately over the coal at Flint Ridge, and about 100 ft. below summit of ridge.

Named for Flint Ridge, Licking Co.

Flint Ridge clay. (In Pottsville formation.)

Name for many years applied to the clay, 1 to 7 ft. thick, underlying Flint Ridge coal in Vinton Co., Ohio.

Flint Ridge flint.

Pennsylvanian: Eastern Kentucky (Breathitt County).

W. C. Morse, 1931 (Ky. Geol. Surv., ser. 6, vol. 36, pp. 296, 305). *Flint Ridge flint.*—A 3-foot bed of yellow, non-fossiliferous flint, lying 30 ft. below top of Flint Ridge at head of Leatherwood Branch of South Quicksand Creek, Troublesome quad., and near 1,500-foot contour line; it also lies 550 ft., by barometer, above Magoffin beds, and 370 ft. above Lost Creek ls. Loose dolomitic or leached ls. blocks associated with the flint are very fossiliferous. The Flint Ridge flint has not been recognized outside of this area.

†Flint River lower zone.

†Flint River upper zone.

Oligocene (middle): Southwestern Georgia.

Terms that have been applied (C. J. Maury, Am. Jour. Sci., 4th, vol. 48, pp. 209–215, 1919) to a single faunal zone characterizing Glendon fm., according to C. W. Cooke.

Named for exposures on Flint River.

Flint River formation. (Of Vicksburg group.)

Oligocene (middle): Northwestern Florida, southeastern Alabama, southern Georgia, and southwestern South Carolina.

C. W. Cooke, 1935 (A. A. P. G. Bull., vol. 19, No. 8, pp. 1170–1171). My 1923 tentative correlation of the chert beds of Ga. and SE. Ala. with Glendon ls. now appears doubtful, and these beds, which are present in northern Fla., SE. Ala., Ga., and SW. So. Car., are here given the tentative name *Flint River fm.*, from exposures on Flint River btw. Red Bluff, 7 mi. above Bainbridge, SW. Ga., to Hales Landing, 7 mi. below Bainbridge. Their fauna appears to be more closely related to Chickasawhay marl memb. of Byram marl of SE. Miss. than to Glendon ls. In S. C. the fm. is present in Allendale Co. only.

C. W. Cooke, 1936 (U. S. G. S. Bull. 867, on Coastal Plain of S. C.). In S. C. *Flint River fm.* occurs only in narrow strip bordering Savannah River in Allendale Co. from vicinity of Johnsons Landing to Cohens Bluff. The beds consist chiefly of broken lumps of yellow vitreous chert in reddish yellow sand. Few fossils. These beds are tentatively correlated with the upper or Chickasawhay memb. of Byram marl of Miss. and SW. Ala., and so far as now known they are the sole representative of Vicksburg group in SE. Ala., Ga., and S. C.

Florena shale member (of Garrison shale).

Permian: Eastern Kansas and southeastern Nebraska.

C. S. Prosser, 1902 (Jour. Geol., vol. 10, p. 712). *Florena shales.*—Yellowish fossiliferous shales, 2 to 13 ft. thick, heretofore called "Cottonwood shales" (preoccupied). Underlies Neosho memb. and forms lower part of Garrison fm. Overlies Cottonwood ls.

Adopted by U. S. Geol. Survey as lower memb. of Garrison fm. Overlain by Neosho sh. memb. of Garrison and underlain by Cottonwood ls.

See also under *Beattie fm.* and under *Garrison sh.*, which R. C. Moore discarded in 1936.

Named for exposures in quarries near Florena, Marshall Co., Kans.

Florence flint. (In Chase group.)

Permian: Eastern Kansas, central northern Oklahoma and southeastern Nebraska.

C. S. Prosser, 1895 (Jour. Geol., vol. 3, pp. 771–786, 798). *Florence flint.*—Two beds, each 10 ft. thick, of massive fossiliferous ls. with prominent layers of flint, separated by 2 ft. of white cellular ls. Included in middle of Chase fm. Underlain by 31 ft. of yellowish, chocolate, and greenish shales and overlain by buff shaly ls.

C. S. Prosser, 1902 (Jour. Geol., vol. 10, p. 714). *Florence flint* is overlain by Fort Riley ls. and underlain by Matfield shales.

Named for Florence, Marion Co., Kans.

†Florence limestone. (In Chase group.)

Permian: Central Kansas.

C. S. Prosser, 1895 (Jour. Geol., vol. 3, pp. 771–786, 798). *Fort Riley or Florence ls.*—Massive buff ls., 5 or more ft. thick. Separated from overlying Marion flint by 22 ft. of buff shaly lss. overlain by 62 ft. of varicolored sh. with thin ls. layers, and separated from underlying Florence flint by 15 ft. of buff shaly lss.

In 1902 (Jour. Geol. vol. 10) Prosser redefined *Fort Riley ls.*, to include at base the 15 ft. of shaly lss. and at top the 22 ft. of buff shaly lss., both of which he had excluded in his original definition. He also stated that Fort Riley ls. (40 ft. thick) rested on Florence flint and was separated from overlying Marion flint by Doyle sh.; that *Florence ls.* is Fort Riley main ledge; and that Florence ls. is abandoned.

In succeeding years Prosser's 1902 definition of Fort Riley ls. was adopted generally, *Florence ls.* fell into disuse, and *Florence flint* was name applied to the fm. underlying Fort Riley ls. In 1936 (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 12) R. C. Moore revised the terminology of the Perm. rocks of Kans. by (1) restricting *Fort Riley ls.* to the original 5-foot massive ledge; (2) introducing *Oketo sh.* for underlying 5 ft. of shaly ls.; (3) applying *Florence ls.* to underlying 30 ft. of beds bearing the symbol of flinty ls. and apparently corresponding to *Florence flint* of previous repts. He called the beds immediately overlying his Fort Riley ls. the *Holmesville sh.*, and the beds immediately underlying his Florence ls. the *Blue Springs sh.*

Named for Florence, Marion Co.

Florence gravel.

Pleistocene: Northwestern Illinois (Stephenson County).

O. H. Hershey, 1895 (Am. Geol., vol. 15, pp. 7–12). *Florence gravel.*—Blue-gray loose aggl. of small gravel and sand, a few ft. thick, underlying Valley loess and comprising basal memb. of Columbia fm. Regarded as northern representative of Port Hudson memb. of Columbia fm. [In 1897 Hershey treated this as basal memb. of his Florencia fm.]

Named for Florence Twp, Stephenson Co., but "typical localities are in banks of Yellow and Crane's Creeks, a few mi. W. and S. of Freeport."

Florencia formation.

Pleistocene: Northwestern Illinois.

O. H. Hershey, 1897 (Am. Jour. Sci., 4th, vol. 4, pp. 90–98). *Florencia fm.*—Consists of two members: (1) A series of dark blue-green silt, light brownish-gray sand, and dark-brown carbonaceous clay or muck, everywhere resting on irregular surface of (2), a moderately coarse subangular gravel, called *Florence gravel* in earlier rept and *Florencia gravel* in this rept. The fm. lies uncon. on Kansan drift and is overlain, with perfect conformity, by basal memb. of Iowan loess. The name Florencia is derived from Florence Twp, Stephenson Co., and is slightly modified because of common use of name Florence in Europe and America.

F. C. Baker, 1920 (Univ. Ill. Bull., vol. 17, pp. 294–296), stated that Kansan drift of Hershey in rept cited above is correlated by Leverett (U. S. G. S. Mon. 38, p. 167) with Illinoian drift, and that *Florencia fm.* of Hershey therefore falls into Sangamon interglacial stage.

Florida gravel.

Pleistocene: Southwestern Colorado.

W. W. Atwood and K. F. Mather, 1932 (U. S. G. S. P. P. 166). *Florida gravel.*—Gravel deposited by streams after melting of ice of Cerro glacial stage. Thickness 10 to 50 feet. Materials range from coarse sand and grit to large cobbles and bowlders. Caps Florida Mesa and other extensive mesas.

†Floridian series.

†Floridian group.

Pliocene (lower): Southwestern Florida.

A. Heilprin, 1887 (Wagner Free Inst. Sci. Trans., vol. 1, pp. 28–32, 64A–64B, May, 1887). I would propose to designate the Pliocene series of the Caloosahatchie as the "Floridian," by this name indicating the region where the fm. has its furthest, and, as far as we know, only development. What its precise equiv. among the trans-Atlantic fms., if any such exist, may be, still remains to be determined. Thus far I have been unable to discover any whose fauna can be strictly, or even approx., correlated with the present one. Consists of highly fossiliferous deposits extending from a short distance above Daniels practically without intermission to Fort Thompson, a distance along the river of 10 to 12 mi. Appears in most places as a partially indurated marl or earthy ls. of yellowish buff or white color, and either largely destitute of organic remains or so densely charged with them as to constitute a pure shell rock. Thickness 2½ to 8 ft. Overlain by post-Plio. *Venus cancella* bed. Referred to basal Plio.

Replaced by Caloosahatchee marl, introduced in September 1887 and a better-established name.

Named for development on W. coast of Fla.

†*Floridian* epoch.

A term introduced by W. H. Dall (Wagner Free Inst. Sci. Trans., vol. 3, pt. 2, pp. 201–216, 1892) for *Pliocene*. "As peninsula of Florida has preserved an unbroken record of this [Plio.] era, it would seem appropriate to apply to it the name of *Floridian epoch*, and slightly modifying Prof. Hilgard's [Heilprin?] use of the term, to refer all deposits of similar paleontologic contents to a single assemblage in the system under the name of *Floridian group*." "Includes Lafayette group and Floridian group (Caloosahatchie beds)."

Florissant lake beds.

Miocene (upper): Eastern Colorado (Pikes Peak region).

W. Cross, 1894 (U. S. G. S. Pikes Peak folio, No. 7). *Florissant lake beds.*—Almost wholly volcanic ashes, which were probably showered upon waters of the lake forming soft and crumbling tuffs and mud shales. Predominantly andesitic, with detritus of basalt and rhyolite. Thickness 50 ft. Older than Alnwick and High Park lake beds.

Named for Florissant, Teller Co.

Flower-pot shale. (In Cimarron group.)

Permian: Central southern Kansas and western Oklahoma.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, pp. 3, 24–27). *Flower-pot shales.*—Chiefly highly gypsiferous varicolored clays, 150 ft. thick, overlying Cedar Hills sss. and underlying Cave Creek gypsums. Included in Salt Fork div.

Named for Flower-pot Mound, Barber Co., Kans.

Floyd shale.

Mississippian: Northwestern Georgia, northeastern and northern central Alabama, and southern Tennessee.

C. W. Hayes, 1891 (Geol. Soc. Am. Bull., vol. 2, p. 143). *Floyd sh.*—Shales, 2,500 ft. thick, overlying Fort Payne chert and underlying Oxmoor [Hartselle] ss.

Floyd sh. as above defined is now known to constitute only a small part of the black sh. unit to which this name was evidently intended to apply, since part of the sh. underlies Hartselle ss. and part of it overlies the Hartselle. According to C. Butts it includes beds equiv. to Ste. Genevieve ls. and overlying fms. of Chester group of Miss. Valley region up to top of Palestine ss., or up to base of Parkwood fm. of Ala., except in N. part of Shades Valley, where it extends up to base of the Penn. and includes shales contemp. with the Parkwood. The Hartselle as now restricted is treated as a distinct fm. in some areas, where it underlies Bangor ls. restricted, and as a memb. of Floyd sh. in other areas. (See C. Butts, Ala. Geol. Surv. Spec. Rept. No. 14, 1926.)

Named for development in Floyd Co., Ga.

Floyd limestone.

Upper Devonian: Central northern Iowa.

A. O. Thomas, 1912 (Sci., n. s., vol. 36, pp. 569–570). A new substage, tentatively called *Floyd ls.,* is added at base of Lime Creek stage. Uncon. overlies Cedar Valley stage in Floyd Co. [The Nora ls. of Thomas, to which this ls. may correspond, has been referred by C. L. and M. A. Fenton to Cedar Valley ls.]

Floyds Knob formation. (In Borden group.)

Mississippian: Southeastern Indiana.

P. B. Stockdale, 1929 (Ohio Jour. Sci., vol. 29, No. 4, p. 170). [See under *Borden group.*]

P. B. Stockdale, 1930 (Ind. Acad. Sci. Proc., vol. 39, pp. 213–214). Study of Borden rocks throughout unglaciated area of southern Ind. and incidental observation in adjacent parts of Ky., revealed a persistent unit in upper part of Borden group which has served as vital key to subdividing the rocks and to properly associating uppermost Borden fms. with overlying Harrodsburg and Salem lss. The name *Floyds Knob fm.* is being suggested for this fm. It exhibits several lithologic facies, the most common being ls. that is itself of differing traits from place to place. For this ls. facies the name *Goss Mill ls. facies* is being suggested. Thickness is commonly 3 to 4 ft., but at a few places it is as much as 8 ft. or more. Various Ind. workers have referred to the different ls. facies of Floyds Knob fm. as "Stevens Creek ls.," although the name has never been formally proposed in the literature. Preemption of the term by Stevens Creek slates of S. Car. and confusion in interpretation of different beds which have been referred to same horizon in N. part of unglaciated area, preclude continuation of "Stevens Creek." Floyds Knob fm. will be fully described in rept. for publication by Ind. Dept. Cons. Div. of Geol.

P. B. Stockdale, 1931 (Geol. Soc. Am. Bull., vol. 42, No. 3, pp. 708–710). *Floyds Knob fm.* is key unit in subdividing the upper Borden rocks and correlating the units of southern Ind. with those of adjacent parts of Ky. It exhibits several lithologic facies. The most common is ls., which varies markedly from place to place. Throughout S. half of unglaciated Ind. outcrop belt, and in adjacent parts of Jefferson Co., Ky., the fm. varies from fairly pure crinoidal, oolitic, or crystalline rock to ferruginous siliceous ls. Average thickness 3 to 4 ft. In Jefferson Co., Ky., and in adjoining regions the fm. is the one described by C. Butts (Ky. Geol. Surv., ser. 4, vol. 3, 1915, pp. 157–158, and Ky. Geol. Surv., ser. 6, vol. 7, 1922, p. 73) as the "layer of oolite" at "base of the Warsaw." Locally in So. Ind. the fm. is ss. North of T. 6 N., Ind., the fm. is a peculiar mixture of calc., ferruginous cherty, shaly rock. Extending upward from this locally, and involving the basal portion of overlying Edwardsville fm., are the prominent bioherms of Edwardsville fm., mainly in Monroe and Morgan Counties, Ind. Overlies Carwood fm.

P. B. Stockdale, 1931 (Ind. Dept. Cons., Div. Geol., Pub. 98, pp. 54, 76, 193–219). *Floyds Knob fm.*—Variable ls., 1 to 6 ft. thick. Parts are finely granular, crystalline, light gray; in places it is crinoidal; in some places it is oolitic; again it is impure, sandy, buff to chocolate colored. This ls., which is an excellent key fm., has often been spoken of as the "Stevens Creek ls." by Ind. workers, although the name has never been definitely proposed. For Jefferson Co., Ky., Butts erroneously referred to it as the "oolitic ls." at the "base of the Warsaw." No name has been specifically proposed for it in the literature. Most Ind. workers entirely overlooked it. Locally, especially in northern region, the calc. condition continued well into Edwardsville time. This dominantly calc. interval comprises

Floyds Knob fm. [Describes and names several local *facies* of the fm.] At some exposures a single characteristic dominates the fm.; at others another trait is predominant; whereas at still others a combination characterizes the zone. [See also under *Stevens Creek ls.* and *Stobo ls.*, by both of which names the ls. has been known.] Named for Floyds Knob, ¾ mi. E. of post office of same name, 3 mi. NW. of New Albany, Ind., where the fm. is overlain by heavy angular ss. bed and underlain by soft, massive siltstone of Carwood fm. [On p. 265 he gives thickness of Floyds Knob fm. slightly W. of old Stobo post office as 15 ft.]

Fluffy sand.

A term that has been applied (C. P. Berkey, N. Y. State Mus. Bull. 146, 1911) to deposits in SE. N. Y. classified as Mio.

Flume dolomite.

Middle Devonian: Alberta (Jasper Park).

P. E. Raymond, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 295, 300). *Flume dol.*, 400 to 1,800 ft. thick. Overlies Mons dol. (Lower Ord.) and underlies Perdrix sh. (Upper Dev.). [Appears to be a nongeographic name, a stream having excavated a narrow flume along the strike of the ls. in cliffs on Roche Miette.]

Fly Creek limestone.

Upper Cretaceous: Central southern Montana.

J. F. Kemp and P. Billingsly, 1921 (Geol. Soc. Am. Bull., vol. 32, p. 474, in chart). [No description or definition, but shown as=Greenhorn ls. in cross section from Greenhorn to Hardin, Mont., to Porcupine.]

Foix oil zone.

Name applied to 180 to 185 ft. of sandy shales and interbedded sands, shales, and shells, the basal 20–40 ft. of which consists of sticky brown sh., in Santa Fe Springs field, Los Angeles Co., Calif. It directly overlies Bell oil zone. Named for Foix No. 1 well, which yields oil at depth of 3,500 ft.

†Folley limestone.

Lower Ordovician (Chazy): Central eastern Missouri.

C. R. Keyes, 1898 (Iowa Acad. Sci. Proc., vol. 5, pp. 59, 61). *Folley ls.*—Light-yellow, rather heavily bedded mag. ls. containing few fossils, but locally containing thin sh. and sandy beds. Thickness 65 ft. Underlies Bryant ls. and overlies Cap-au-Gres ss.

Same as Joachim ls., older name.

Named for *Foley*, Lincoln Co.

Fond du Lac sandstone.

Pre-Cambrian (Keweenawan?): Northeastern Minnesota (St. Louis County).

N. H. Winchell, 1899 (Minn. Geol. Nat. Hist. Surv. Final Rept., vol. 4, p. 567). *Fond du Lac ss.*—Exposed on both banks of St. Louis River from Fond du Lac westward to point at which it is replaced by the quartzose pebbly cgl. that lies nonconformably on Thomson slates. Is about contemp. with some of Manitou flows of Keweenawan. Upper strata are almost free from the shaly red sediment that characterizes lower portion. The rock thus gradually becomes a pinkish and finally a nearly white sandrock well known as building stone at Hinckley and on Kettle River. Lower part consists of fine red cgls., red shales, and sss.

W. Upham, 1901 (Minn. Geol. Nat. Hist. Surv. Final Rept., vol. 6, Atlas, pl. 37, map, and text describing pl. 56), placed *Fond du Lac ss.*, 157 ft. thick, below Hinckley ss. (381 ft. thick) and above Potsdam red qtzite. "To these sss., therefore, the name Potsdam is also extended. They are of the date of the waning stages of the Keweenawan."

C. R. Stauffer, 1927 (Geol. Soc. Am. Bull., vol. 38, pp. 469–475). The best Minn. outcrop of Red Clastic Series, free from glacial debris, is that along St. Louis River at Fond du Lac, where measured thickness lies somewhere btw. 412 ft., as given by Winchell, and 730 ft. as given by Thwaites.

Fond du Lac moraine.

Pleistocene (Wisconsin stage): Northeastern Minnesota and northwestern Wisconsin.

F. Leverett, 1928 (U. S. G. S. P. P. 154). Waterlaid moraine. At N. end connects with Highland morainic system and at S. end connects with Nickerson morainic system. Named for Fond du Lac, St. Louis Co., Minn.

Fond du Lac brownstone.

Commercial term for stone of Keweenawan (?) age quarried at Fond du Lac, *Minn*.

Fontana shale

Pennsylvanian: Eastern Kansas, northwestern Missouri, and southwestern Iowa.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 85, 91, 97). *Fontana sh.*—Basal memb. of Cherryvale fm. Underlies Block ls. and overlies Winterset ls.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pp. 19, 36–37). *Fontana sh.*—Argill. or calc. sh., greenish gray or buff, 5 to 25 ft. thick, comprising basal fm. of Kansas City group as restricted by R. C. Moore. Overlies Winterset memb. of Dennis ls. and underlies Block ls. Type exposures near Fontana, Miami Co., Kans., in road cuts at NE. cor. sec. 11, T. 18 S., R. 23 E., and at middle of W. side of NW¼, sec. 36, T. 18 S., R. 23 E.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), stated that Newell is author of this name.

Foothills series.

Tertiary (?): Alberta.

J. A. Allan and R. L. Rutherford, 1934 (Alberta Research Council Rept. 30, p. 34).

Foraker limestone. (In Wabaunsee group, Kansas.)

Foraker limestone member (of Sand Creek formation, Oklahoma).

Pennsylvanian: Central northern and central Oklahoma and southern Kansas.

K. C. Heald, 1916 (U. S. G. S. Bull. 641, pp. 21, 25). *Foraker ls.*—Chiefly ls., but much of rock is so soft and thin-bedded as to give no outcrop. Some soft sh. is present. The heavy ls. can easily be recognized by the large number of Fusulinas which it contains, the rock in places being fairly jammed with them. Another distinguishing mark is great abundance of chert concretions it contains. The fresh surface of the chert is generally light blue gray, and the concretions usually include fossils which show white against the bluish background. Most common fossil in the chert is *Fusulina secalica*. Thickness 74± ft. The ls. forms the rim of Ekler Canyon, and is prominent along line of bluffs in E. part of Foraker quad. It lies 18 ft. below Red Eagle ls. and is underlain by sh. A ss. which occurs 28± ft. below the Foraker is a good horizon marker.

N. W. Bass, 1929 (Kans. Geol. Surv. Bull. 12, pp. 45+). Thick-bedded ls. containing chert and minor proportion of sh. and shaly ls., with thickness of 50 ft., constitutes *Foraker ls.* in Cowley Co., Kans. Lowermost bed of fm. is Americus(?) ls. memb. It is separated from upper thick-bedded ls. memb. by 10 to 13 ft. of soft sh. The Foraker overlies Admire sh. and underlies Elmdale sh. as here restricted. The beds above Americus(?) ls. were formerly included in Elmdale sh.

R. C. Moore, 1929 (Kans. Geol. Surv. Bull. 12, pp. 45, 50, footnotes). (See under *Americus ls. memb.*)

In Okla. is top memb. of Sand Creek fm.; in Kans. is treated by U. S. Geol. Survey as a fm. in Wabaunsee group.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 8), carried this name into NW. Mo. and SE. Nebr.; called it *Foraker ls. fm.* (45 to 50 ft. thick); defined it as underlying his Johnson sh. fm. and overlying his Hamlin sh. fm.; and divided it into (descending): Long Creek ls., Hughes Creek sh., and Americus ls. (See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.)

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), transferred this ls. to Perm. This change in Perm.-Penn. bdy has not been considered by U. S. Geol. Survey for its publications.

Named for Foraker, Osage Co., Okla.

†Forbes limestone. (In Shawnee formation.)

Pennsylvanian: Northwestern Missouri, southwestern Iowa, and southeastern Nebraska.

C. R. Keyes, June, 1898 (Am. Geol., vol. 21, p. 349). *Forbes ls.*—Thick ls., top exposed in top of bluffs of Missouri and Nodaway rivers, near town of Forbes, Holt Co., Mo., being highest heavy ls. in Missourian series until capping Cottonwood ls. is reached.

J. A. Gallaher (Mo. Geol. Surv. 5th Bien. Rept., p. 56, 1898) mentioned *Forbes ls.*, but did not define it.

In Mo. the name *Forbes ls.* was for many years applied to the beds beneath Calhoun sh. and above Tecumseh sh., or to Deer Creek ls. memb. of present nomenclature.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., p. 49). The *upper unit* of Deer Creek ls. has been called *Forbes ls.* in Mo., Iowa, and Nebr. Writer is of opinion this name should be retained for this unit, but U. S. Geol. Survey holds that it would be preferable to select some other name. Replaced by *Ervine Creek ls.*

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 181). †*Forbes ls.* of Gallaher, is poorly defined designation of ls. at Forbes, Holt Co., Mo., recognizable from description as = Deer Creek.

Ford sandstone.

Pennsylvanian: Central southern Iowa.

H. Hinds, 1909 (Iowa Geol. Surv. vol. 19, pp. 99, 131, 178). *Ford ss.*—Heavy ss. overlying Ford-Runnels coal in Polk and Warren Counties. On N. side of river is represented by sss. and sandy shales. Included in Des Moines stage.

Probably named for Ford, Warren Co.

Fordham gneiss.

Pre-Cambrian: Southeastern New York.

F. J. H. Merrill, 1890 (Am. Jour. Sci., 3d, vol. 39, pp. 388–389). Thinly bedded gray qtzite gneiss, containing little feldspar, its beds varying from almost pure quartz to a mixture of quartz and biotite or hornblende. Occasionally layers of pure biotite schist an inch or two thick are intercalated with white, coarsely granular qtzite. Forms anticlinal ridge of Fordham Heights, which borders E. shore of Harlem River, from which it is proposed to call it *Fordham gneiss.* In a few places it varies widely from the normal type, through presence of hornblende and garnet and an increase in feldspar and mica. Intercalated at a great many localities are hornblendic and augitic strata, usually a few ft. thick, which resemble diorites and diabases, are granular, and may have originally been eruptive rocks, but whatever their origin they are now metamorphic and may be called amphibolites and pyroxenites. The Fordham gneiss overlies Yonkers gneiss and underlies Inwood ls., from which it is in a few places separated by 5 to 10 or more ft. of thinly bedded qtzite [later named *Lowerre qtzite*]. Thickness undet., but is at least 200 ft. Included in Manhattan group, which is believed to be metamorphosed Paleozoic. [The Yonkers gneiss is now known to intrude the Fordham.]

F. J. H. Merrill, 1898 (N. Y. State Mus. 15th Ann. Rept., vol. 1, pp. 21–31). *Fordham gneiss* is certainly pre-Camb., and if it is sedimentary it may be called *Algonkian.* Overlain by Lowerre qtzite, of probable Camb. age. [Lowerre is now classified as pre-Camb.]

F. J. H. Merrill, 1902 (U. S. G. S. New York City folio, No. 83). *Fordham gneiss.*—Gray thin-banded gneiss; some bands highly quartzose, some composed largely of biotite, some consist of pegmatite or granite which seems to have been injected parallel to regular banding of the gneiss. The rock is thoroughly gneissoid. Is certainly pre-Camb. If of sed. origin it may be called Algonkian. Is oldest rock in dist. Overlain by qtzite that is called *Poughquag qtzite* because of probable equivalence to Poughquag qtzite (Camb.) of Dutchess Co. [This qtzite is now classified as pre-Camb. and is called *Lowerre qtzite.*]

C. P. Berkey, 1907 (N. Y. State Mus. Bull. 107, pp. 361–378). *Fordham gneiss* of Harlem quad. (folio 83) is not different in position or significance or general character from same gneiss series of Tarrytown quad., with which it is continuous; and writer sees no essential point of difference btw. these and the basal gneisses of West Point quad., from which they are separated by only a belt of later lss. and schists occupying the synclinal fold of lower Croton valley. In northern Highlands interbedded lss. and qtzites and schistose graphitic beds are common, whereas in southern localities the lss. at least are not so frequently seen. No subdivision of the gneiss at present seems possible. There is no natural strat. break. Because of abundance and regularity of igneous injections and close folding and frequent faulting, it is not even clear as to order of superposition of constituent members.

C. P. Berkey, 1911 (N. Y. State Mus. Bull. 146, pp. 47–57). *Fordham gneiss* is chiefly sed. and consists of granitic and quartzose banded gneisses and schists of very complex development. Included in Grenville series. [Referred to "interbedded lss." as "associated with Fordham gneisses;" and included Fordham gneiss, the interbedded ls., and the intrusives in Grenville series.]

C. P. Berkey and J. R. Healy, 1912 (Columbia Univ. Contr., vol. 20, pp. 1907–1912). *Fordham gneiss series* (pre-Camb.) includes metamorphosed ancient sediments and igneous intrusives, some of which are very extensive. Includes Yonkers gneiss, Ravenswood granodiorite, and banded black and white gneisses, black mica schists, thin beds of very impure serpentinous ls., qtzite schist, quartzose gneisses, and graphitic schists, forming a unit through which and into which the igneous masses have been injected. Believed to be very old pre-Camb. and a local representative of Grenville series of Adirondacks and Canada.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 19). *Fordham gneiss*, a complex sed. series of conformable and interbedded gneisses, schists, qtzites, and lss. Constitutes oldest and lowest fm. in SE. N. Y. May be=Grenville series of Adirondacks and Canada.

J. F. Kemp, 1912 (Int. Geol. Cong., 11th sess., Stockholm, Compt. rend., vol. 1, pp. 702–711). *Fordham gneiss* is=Grenville series of northern area. Sedimentary character established by discovery in it of coarsely crystalline marbles.

C. P. Berkey and Marion Rice, 1921 (N. Y. State Mus. Bull. 225, 226, p. 140). Pre-Camb. rocks of N. Y. City and Westchester Co. divided as follows (descending) :

Post-Grenville (very old pre-Cambrian).	Basic dikes.	Later igneous.
	Pegmatites.	
	Yonkers gneissoid granite.	
	Pegmatites.	
	Ravenswood granodiorite.	
	Injection granites and pegmatites.	Laurentian (?).
	Fordham gneiss, in part (injection gneiss).	
	Occasional basic injections.	Earliest igneous.
	Staten Island serpentine.	
	Stevens Point serpentine.	
	The Hornblende schists.	
Later Grenville (sedimentary).	Manhattan schist.	
	Inwood ls.	
	Lowerre qtzite.	
Older Grenville (sedimentary).	Interbedded lss. and schists.	
	Fordham gneiss, in part (paragneiss).	

Keewatin apparently not represented.

H. L. Alling, 1924 (Am. Jour. Sci., 5th, vol. 8, pp. 27–29). *Fordham gneiss* is a syntectic—sed. and igneous. In West Point quad. Berkey assigns the Fordham in part to the Grenville, in part to the Laurentian, and in part to the Algoman. This means that origin has been deciphered. The dark-green hornblende (amphibolitic) portion is regarded as a metamorphosed sed. rock of Grenville age, the igneous portion assigned to Laurentian and Algoman, respectively. Writer thinks name Fordham should be limited to the bands believed to be sedimentary. But until agreement is reached he suggests the hyphenated terms *Fordham-Grenville, Fordham-Laurentian,* and *Fordham-Algoman*.

E. B. Knopf and A. I. Jonas, 1929 (U. S. Geol. Bull. 799). Manhattan schist correlates with Wissahickon fm.; Inwood ls. with Cockeysville marble; Lowerre qtzite with Setters fm.; and the paragneiss parts of Fordham gneiss with Baltimore gneiss. The injection-gneiss parts of Fordham gneiss are of post-Manhattan but pre-Camb. age. The Wissahickon, Cockeysville, and Setters are classified as Algonkian and Baltimore gneiss as Archean.

The terms "Algonkian system" and "Archean system" have now been discarded, and the Fordham is classified simply as pre-Camb.

Fordyce Knob sandstone facies.

Name applied by P. B. Stockdale (Ind. Dept. Cons., Div. Geol., Pub. 98, pp. 76, 197, etc., 1931) to a lithologic development of his Floyds Knob fm. in a part of southern Ind.

Forelle limestone.

Permian: Southeastern Wyoming and northeastern Colorado.

N. H. Darton, 1908 (Geol. Soc. Am. Bull., vol. 19, pp. 430, etc.). *Forelle ls.*—Heavy-bedded pure ls., locally gypsiferous and thin bedded. In places contains Carbf fossils, but for which the Forelle and underlying Satanka sh. might be regarded as part of Chugwater fm. (Perm. or Triassic). Thickness 4 to 20 ft. May possibly represent Embar fm. Underlies Chugwater fm. (red) and overlies Satanka sh. (red). Named for R. R. station a few mi. S. of Laramie.

H. D. Thomas, 1934 (A. A. P. G. Bull., vol. 18, No. 12, p. 1666). *Forelle ls.* seems to be an extended tongue of Phosphoria fm., and consequently may be considered as *Forelle ls. tongue of the Phosphoria.* It underlies red beds here named *Freezeout tongue of Chugwater fm.* and overlies Satanka sh.

Foreman formation.

Upper Jurassic: Northern California (Taylorsville region).

J. S. Diller, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 370–394). *Foreman beds.*—Sixteen hundred ft. of slates and sss. with several beds of cgl. Plants identified by Prof. Fontaine as "clearly Mesozoic and most probably Rhaetic." Regarded as older than Hardgrave ss. and younger than Trail beds. [Later proved to be much younger than Hardgrave ss.]

J. S. Diller, 1908 (U. S. G. S. Bull. 353). *Foreman fm.*—A succession of sh., ss., and cgl. in which the sediment is for most part derived from rocks which are not clearly volcanic. Shales often slaty and with pencil structure, and range in color from dark carbonaceous with traces of leaves through gray, which predominates, to shades and tints of red and yellow. Most of sss. are very fine, decidedly shaly, and of reddish brown and gray colors. The cgl. is less abundant than the sh. and ss. Overlies, probably uncon., Hinchman ss., and in places uncon. overlaps Mormon ss. and even Robinson and Peale fms. Fauna determined to be not earlier than Middle Jurassic.

Named for exposures at Foreman and in Foreman's Ravine, NE. of Taylorsville, Plumas Co.

Foreman argillite.

Upper Jurassic: Northern California (Mount Jura).

C. H. Crickmay, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 81, and No. 5, pp. 895–903). *Forman argillite.*—Named by Diller, 1892. Consists of light-gray argillite composed of fine volcanic waste. Thickness 350 ft. [Diller gave thickness of his *Foreman* fm. as 1,600 to 2,500 ft., and his lithology differed.] Fossils listed. Of early Upper Jurassic age. Occurs at Taylor's Diggings, in S. fork of Forman [Foreman] Ravine, and elsewhere.

Foremost formation.

Upper Cretaceous: Southern Alberta, Canada.

D. B. Dowling, 1917 (Canada Geol. Surv. Mem. 93, p. 37). Shales and shaly silts, with many coal or carbonaceous beds and with subordinate amounts of ss., underlying Pale beds and overlying Pakowki fm. in southern Alberta. The beds are chiefly brackish water lagoonal deposits, and of Judith River age. Top memb. is Taber coal; basal memb. is Verdigris ss. Thickness 400± ft. Named for exposures in Chin Coulee, near town of Foremost.

Corresponds to lower third of Judith River fm. of Mont.

Forest conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan (Ontonagon County).

S. H. Broughton, 1863 (Remarks on mining interest and details of geology of Ontonagon County, pam. of 24 pp. and map, Phila., 1863, map and p. 19). A belt of cgl., 86 ft. wide, exposed 500 ft. N. of old Forest mine is termed *Forest cgl.* Distinguished by varied character of enclosed pebbles, among which occur ls. and ss.; a coarse gravelly appearance; and a tendency to disintegrate on exposure. Older than Minesota cgl., from which it is separated by 2,540 ft. of traps.

Same as Bohemia cgl. of Bohemian Range group.

Forest amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name locally in use many years. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. The fm. belongs in Central Mine group. Is younger than Lake amygdaloid. The mineralized part is the Forest lode. Probably named for occurrence in old Forest mine, in Ontonagon Co.

Forest flow.

Includes Forest amygdaloid and the underlying trap.

Forest clay.

Forest sands.

Miocene: South Trinidad.

G. W. Halse, 1935 (Inst. Pet. Tech. Jour., vol. 21, No. 145, pp. 940–951).

Forest Rock.

A term formerly applied by miners to the White porphyry of Leadville dist., Colo. So called from profusion of deposits of dendritic oxide of manganese on its surface.

Forest City sand rock. (In Shawnee formation.)

Pennsylvanian: Northwestern Missouri.

J. A. Gallaher, 1898 (Mo. Bur. Geol. and Mines Bien. Rept., pp. 55, 57). ***Forest City sand rock,*** alternating with clay sh. Underlies Forest City ls. and overlies Curzon's ls. Included in Perm.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., p. 101), named subdivisions of Topeka ls. memb. of Shawnee fm. at Forest City, Mo. (descending): Coal Creek ls., 3½± ft.; Holt sh., 1 ft. 10 in.; DuBois ls., 1 ft. 1 in. to 1 ft. 2 in. [Forest City ls.]; Turner Creek sh., 4½ ft. to 6 ft. [Forest City sand rock of Gallaher]; and Curzen ls. 6± ft.

Named for Forest City, Holt Co.

Forest City limestone. (In Shawnee formation.)

Pennsylvanian: Northwestern Missouri.

J. A. Gallaher, 1898 (Mo. Bur. Geol. and Mines Bien. Rept., pp. 55, 57). ***Forest City ls.***—Overlies Forest City sand rock and underlies calc. shales at and near Forest City. Included in Perm.

G. E. Condra, 1927. (See 1927 entry under *Forest City sand rock.*)

Named for Forest City, Holt Co.

Forestdale marble.

Pre-Cambrian: Southwestern Vermont (Rutland County).

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 362, 394). ***Forestdale marble.***—Massive marble, greatly metamorphosed in most localities, with growth of many silicate minerals. Colors from white to light gray, buff, and cream mottled; usually weathers with marked reddish-brown surface. Minimum thickness (perhaps 200 ft.) is in dist. NE. of Brandon. Thickens to SE. of Brandon until it is nearly 2 or 3 times that figure; thins again to E. of Rutland. To N. it is fairly continuous to Canadian border. At Forestdale [Brandon quad.], 5 mi. NE. of Brandon, there is an excellent section from the upper graywacke cgl. of underlying Nickwaket graywacke up to basal cgl. of the uncon. overlying Camb. Is considered older than Moosalamoo phyllite.

Forest Grove formation. (In Chester group.)

Mississippian: Northeastern Mississippi (Tishomingo County).

W. C. Morse, 1928 (Jour. Geol., vol. 36, pp. 31–43). ***Forest Grove fm.***—Top fm. of Chester series in Tishomingo Co., Miss., and NW. Ala. Consists of Highland

Church ss. memb., 25 ft. thick, at top, underlain by 90± ft. of sh. and ss. that is nowhere completely exposed, but is believed to include clay, sandy shales, and shaly sss. Contains Chester fossils. Overlies Southward Bridge fm. Named for the school located on top of the fm. near old Mingo Village and Southward Bridge, Tishomingo Co., Miss.

W. C. Morse, 1930 (Miss. Geol. Surv. Bull. 23) gave many details of the fm. and stated that old Mingo village is at confluence of Bear Creek and Cedar Creek Valleys, which is in Ala., according to his map.

Forest Hill sand. (In Vicksburg group.)

Oligocene (lower): Southern Mississippi.

C. W. Cooke, 1918 (Wash. Acad. Sci. Jour., vol. 8, pp. 187, 191–193). *Forest Hill sand* introduced to replace preoccupied name "Madison sands" of Lowe. In type area consists chiefly of cross-bedded or laminated, more or less ferruginous, siliceous sand and some clay. West of type area the fm. becomes more argill. and contains lenses of lignite and lignitic clay. Thickness 50 to 70 ft. A shallow water or nonmarine deposit. Basal fm. of Vicksburg group in western Miss. Appears to rest conformably on Yazoo clay memb. of Jackson fm. Overlain conformably by Mint Spring calc. marl memb. of Marianna ls. Believed to be contemp. with marine Red Bluff clay.

Some geologists and paleontologists have included Forest Hill sand in upper Eocene Jackson fm., but according to studies of C. W. Cooke it is of Olig. age and more properly belongs to Vicksburg group, being of different lithology from Jackson. (See also *Red Bluff clay.*) Cooke says (A. A. P. G. Bull., vol. 19, No. 8, 1935) its Vicksburg age is proved because it overlies Red Bluff clay where the two interwedge.

Named for Forest Hill, 5½ mi. SW. of Jackson.

Forestville shale.

Mississippian: Michigan (Sanilac County).

C. H. Gordon, 1900 (Mich. Geol. Surv. vol. 7, pt. 3, p. 23). *Forestville shales.*—Blue shales, 100 to 200 ft. thick, forming upper part of Coldwater shales in Sanilac Co. Overlie Richmondville ss. [Probably named for exposures at Forestville, Sanilac Co.]

Forked Deer limestone.

Ordovician (Lower): Northeastern Tennessee (Morristown quadrangle).

G. M. Hall and H. C. Amick, 1934 (Tenn. Acad. Sci. Jour., vol. 9, No. 2, pp. 158–161). *Forked Deer ls.*—Approx. 185'10" of ls. and dol., including a few thin beds of sh. The ls. and dol. occur in about equal proportions and are interbedded. The sh. is mostly in thin partings. The ls. is predominantly "dove-like" and is the "brown rock" of the miners at Mascot, Tenn. It is less massively bedded than the dol. Chert is less conspicuous than in Copper Ridge and Nittany dolomites, and is almost entirely confined to the dol. Many beds are more or less brecciated. The fm. is in general lighter colored than underlying fms. Underlies Thorn Hill fm. and overlies Nittany dol., all of which belong to Knox dol. Is approx.=Jefferson City fm. of Ozark region. Section studied is along U. S. Highway 25 E, btw. Indian Creek and Bean Gap. The fm. is named for the creek in valley in which the highway is located.

†Fork Mountain slate.

Pennsylvanian: Southwestern Arkansas (Polk County).

A. H. Purdue, 1909 (Slates of Arkansas, Ark. Geol. Surv., pp. 30, 40) and 1914 (U. S. G. S. Bull. 586). *Fork Mtn sl.*—Gray to greenish and chocolate-colored slates, containing thin layers of qtzite in lower part; much jointed, but withstands weathering, and usually forms a bluff where it outcrops on mtn side. Thickness 0 to 125 ft. Overlies Arkansas novaculite and uncon. underlies Stanley sh.

H. D. Miser, 1917 (U. S. G. S. Bull. 660, p. 66). Some sh. at base of Stanley sh. has in places been altered to sl., to which the name "Fork Mtn sl." has been earlier applied. [This name has been discarded. The beds are only a local facies of Stanley sh.]

Named for Fork Mtn, Polk Co.

Fork Ridge sandstone member (of Mingo formation).

Pennsylvanian: Southeastern Kentucky and northeastern Tennessee.

G. H. Ashley and L. C. Glenn, 1906 (U. S. G. S. P. P. 49, pp. 31, 33, 39, 40). *Fork Ridge ss. memb.*—Cliff-making ss. in Mingo fm., lying about 40 ft. below Mingo coal. Thickness few ft. to 50 ft.

Named for Fork Ridge, Bell Co., Ky.

Forman argillite.

Upper Jurassic: Northern California (Mount Jura).

See *Foreman argillite.*

Forrest shale.

Lower Cretaceous: Southeastern Arizona.

C. [R.] Keyes, 1935 (Pan-Am. Geol., vol. 64, No. 2, pp. 129, 138, 139). *Forrest sh.*—The reddish shales forming lower half of Cinturan series (Cintura fm. of Ransome) in SE. Ariz. Thickness 800+ ft. Underlies Mexican ss. and overlies Comanche ls., top div. of Muralian series. Named for well-known Forrest ranch, a few mi. E. of Bisbee.

†Fort Adams or Ellisville phase.

See †*Ellisville phase.*

Fort Ancient division. (In Richmond group.)

Upper Ordovician: Southwestern Ohio.

A. F. Foerste, 1909 (Denison Univ. Sci. Lab. Bull. 14, p. 292). *Fort Ancient div.*—Lower part of Waynesville bed of Richmond fm., characterized by abundant presence of *Dalmanella jugosa*, with exclusion of all other Brachiopoda and corals considered characteristic of the Richmond. The assemblage of lamellibranchs suggests that Fort Ancient div. of Waynesville bed belongs with upper part of Arnheim rather than with Clarksville and Blanchester divisions of Waynesville bed.

Is treated by U. S. Geol. Survey as top beds of Arnheim fm. According to E. O. Ulrich and C. Butts the beds more appropriately belong to Arnheim than to Waynesville, from which they are separated by an uncon. Later repts of Foerste, however, describe an uncon. at base of his Fort Ancient div.

Named for Fort Ancient, Warren Co.

Fort Apache limestone. (In Supai formation.)

Permian: Southeastern Arizona (Fort Apache Indian Reservation).

A. A. Stoyanow, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 533–536). In his work on geol. of Ariz. Darton mentions "a thick memb. of ls. about 100 ft. below top of Supai fm." in Fort Apache Ind. Res. area, and stated that it carries Manzano fossils. This ls. is herein described as *Fort Apache ls.* It lies considerably above the Perm. plant-bearing beds (pink ss. and sh.) here named ***Kinishba beds of Supai fm.*** In Plateau wall there are 400± ft. of Supai beds above Fort Apache ls. The Fort Apache [memb.] consists of gray ls., 70 ft. thick at Kelly Butte (the flat top of which it forms), very fossiliferous [fossils listed], and lying 489 ft. above Kinishba beds, 20 ft. thick. The latter beds (which occur in basal part of Supai fm.) are named for occurrenee in walls of an old Indian pueblo, known as Kinishba, on bank of a dry wash SW. of White River settlement and NW. of Fort Apache, at foot of Kelly Butte.

Fort Atkinson limestone. (In Maquoketa group.)

Upper Ordovician: Northeastern Iowa and western Wisconsin.

S. Calvin, 1906 (Iowa Geol. Surv. vol. 16, pp. 60, 98). *Fort Atkinson ls.*—Heavy beds of yellow cherty dol. and associated ls., 40 ft. thick, constituting second fm. of Maquoketa stage [group]. Overlain by Brainard sh. (top fm. of Maquoketa stage) and underlain by Clermont sh., also of Maquoketa stage.

Named for exposures in quarry W. of old fort at town of Fort Atkinson, Winneshiek Co., Iowa.

†Fort Benton group.

A term applied in early repts on Rocky Mtn region to Upper Cret. deposits now generally called *Benton sh.*

†Fort Bridger series.

A name applied by H. Engelmann, 1876 (Engr. Rept. U. S. A., Rept. Expl. Great Basin Terr. Utah, made in 1859 by J. H. Simpson, p. 287), to *Bridger fm.* (Hayden, 1869).

Fort Cassin formation.

Lower Ordovician (Beekmantown): Northwestern Vermont (Addison County) and eastern New York.

See explanation under *Beekmantown group.*

Named for Fort Cassin, Port Henry quad., Addison Co., Vt.

Fort Creek shale.

Devonian: Mackenzie.

E. M. Kindle and T. O. Bosworth, 1921 (Canada Geol. Surv. Summ. Rept. 1920, pt. B, p. 47).

Fort Dodge gypsum.

Permian(?): Central northern Iowa.

W J McGee, 1884 (Rept. 10th Census, vol. 10, Rept. on building stones, pp. 257, 258). *Fort Dodge stage.*—Nearly pure, light-gray, regularly bedded gyp., 35 ft. thick. Rests uncon. on St. Louis and Lower Coal strata and is uncon. overlain by drift. Assigned to Lower Cret. Covers an area of 25 sq. mi. in vicinity of Fort Dodge, Webster Co. [Some authors regard this gyp. as of Perm. age.]

Forteau formation.

Lower Cambrian: Labrador.

C. Schuchert and C. O. Dunbar, 1934 (Geol. Soc. Am. Mem. 1, pp. 18, 21).

Fort Ellis beds.

Pliocene(?): Central southern Montana (Threeforks quadrangle).

W. H. Dall and G. D. Harris, 1892 (U. S. G. S. Bull. 84, p. 287). *Fort Ellis beds.*—In vicinity of Fort Ellis [near Bozeman] Peale (U. S. Geol. and Geog. Surv. Terr., 1873, pp. 112-113) described bluffs composed of Plio. sss., marls and cgls. 175 ft. thick, which are remnants of Plio. fms. that once spread over entire valley and formed bottom of vast lake that spread over what are now the valleys of Jefferson, Madison, and Gallatin Rivers, reaching to junction of the 3 streams.

Fort Erie moraine.

Pleistocene (Wisconsin stage): Southern Ontario. Shown on moraine map (fig. 8) in U. S. G. S. Niagara folio (No. 190), p. 17. Named for Fort Erie, Ont. Probably same as Buffalo moraine.

†Fort Gaines.

Eocene (lower): Southern Alabama and western Georgia.

E. A. Smith, 1888 (Ala. Geol. Surv. Rept. Prog. 1884–88, geographic map of Ala.). [On this map *Fort Gaines* is applied to rocks btw. the Midway above (probably only upper part of Midway group of present usage) and the Ripley below. As thus used the name applies to lower part of Midway fm. of eastern Ala. The Nanafalia fm. is also well exposed at Fort Gaines, Ga.]

Probably named for Fort Gaines, Clay Co., Ga., near Ala. line.

Fort Hall formation. (Of Thaynes group.)

Lower Triassic: Southeastern Idaho.

G. R. Mansfield, 1915 (Wash. Acad. Sci. Jour., vol. 5, p. 492). *Fort Hall fm.*—Middle fm. of Thaynes group in Fort Hall Ind. Res. Thickness 600 ft. Underlies Portneuf ls. and overlies Ross ls.

G. R. Mansfield, 1916 (Wash. Acad. Sci. Jour., vol. 6, pp. 32, 37). *Fort Hall fm.*—In descending order: (1) Yellow to grayish cherty and sandy lss. in thin beds, 600± ft.; (2) at two localities only a set of sandy and shaly gray lss. 50± ft. thick including an oolitic bed 6 to 10 ft. thick; (3) gray or yellowish siliceous dense ls. containing large pectinoids and irregular cherty nodules and streaks that weather with rough surface and project along bedding planes, 100± ft.; (4) soft and somewhat sugary yellow calc. ss., 50± ft. [Fossils listed.] Middle fm. of Thaynes group in Fort Hall Ind. Res. Underlies Portneuf ls. conformably and overlies Ross [Ross Fork] ls. conformably. Named for old Fort Hall, the site of which is in valley of Lincoln Creek, which appears on some maps as Fort Hall Creek. The fm. occupies a prominent ridge along N. side of valley.

†Fort Hays division or group.

Upper Cretaceous: Western Kansas.

B. F. Mudge, 1876 (U. S. Geol. and Geog. Surv. Terr. Bull. 2, pp. 218–221). *Fort Hays div. or group.*—Upper part massive ls. or yellow chalk 60 ft. thick; lower part varicolored shales and thin lss. 140 ft. thick. Included in Niobrara, but lower part may be=upper part of Benton. Underlies Niobrara proper and overlies Dakota group.

Includes lower part of Niobrara fm. and upper part of Benton sh.

Named for old Fort Hays, in western Kans.

Fort Hays limestone member (of Niobrara formation).

Upper Cretaceous: Western Kansas and eastern Colorado.

S. W. Williston, 1893 (Kans. Acad. Sci. Trans., vol. 13, pp. 108–109). The very characteristic heavy stratified chalk, or soft white ls., at base of this [Niobrara] fm., about 80 ft. thick, extends across the State, from near Mankato, Jewell Co., on N., to N. of Coolidge, in Hamilton or Greeley Co., on W. Its character and thickness, wherever seen, are so unmistakable that it is at once recognized. [Further on he speaks of "*the stratified, or Fort Hays beds,* as I will call them in Ness and Trego Counties," and states: "The divisional line btw. Benton and Niobrara I take at top of the stratified beds already mentioned, following Mudge, but I am not at all certain that it should not be placed below this, or even below the subjacent dark-blue sh."]

As above defined *Fort Hays ls.* was tentatively included in the Benton. In 1896, however, Cragin, also Williston, included it in the Niobrara, as its basal memb., underlying Smoky Hill chalk memb. This is commonly accepted definition. The ls. is top memb. of Fort Hays div. or group of Mudge.

In 1933 the U. S. Geol. Survey and Kans. Geol. Survey agreed to change the name to *Hays ls.*, "the name of the town having been changed from *Fort Hays* to *Hays*, and geologists working in Kans. having become accustomed to calling the ls. *Hays ls.*" (See A. A. P. G. Bull., vol. 18, 1934, p. 1494.) Later the Kans. Geol. Soc. reported that the beds were named for old Fort Hays, a well-known landmark in western Kans., and *Fort Hays ls. memb.* was therefore restored.

†Fort Knox sandstone.

Pennsylvanian: Southwestern Indiana.

J. Collett, 1874 (Ind. Geol. Surv. 5th Rept., p. 323). *Merom or Fort Knox ss.*—Coarse soft red and white ferriferous ss. 30 to 80 ft. thick, in Knox Co., Ind. Overlain by soil and drift; underlain by coal-bearing strata.

Same as Merom ss.

Named for Fort Knox, Knox Co.

Fort Littleton formation.

Upper Devonian: Eastern Pennsylvania.

B. Willard, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 8, pp. 1199, 1218, etc.). *Fort Littleton fm.*—Upper fm. of Portage group, divided into (descending): Parkhead memb., Trimmers Rock ss. memb., Losh Run [sh.] memb., Braillier memb., and Harrell memb. (redefined by exclusion of Burket sh). [Willard stated that Burket memb. is of nearly equal distribution to Harrell.] Named for Fort Littleton, a village in NE. part of Fulton Co. There is a sharp lithologic change (practically a break) at base of Harrell memb., accompanied by appearance of a plentiful Naples fauna.

Fort Logan beds.

Miocene (lower): Western central Montana (Meagher County).

E. Douglass, 1903 (Carnegie Mus. Annals, vol. 2, pp. 150–151). *Fort Logan beds.*—Heretofore called *Lower Deep River*, but fauna [listed] is different from Upper Deep River fauna and is considered to be upper Olig. Cope's collections of fossils all came from Upper Deep River, to which name Deep River is here restricted. Named for military post [in Meagher Co.] near which the beds are best exposed.

H. F. Osborn, 1909 (U. S. G. S. Bull. 361, pp. 65, 76, 112). Fauna of upper part of Deep River sequence is middle Mio. and of Fort Logan beds is lower Mio.

H. F. Osborn, 1918 (Am. Mus. Nat. Hist. Mem., n. s., vol. 2, pt. 1). [On p. 9 the Fort Logan beds are assigned to lower Mio., but on pp. 12 and 15 they are said to be upper Olig. or lower Mio.]

Fort Mountain sandstone.

Lower Cambrian: British Columbia and Alberta.

C. D. Walcott, 1917 (Smithsonian Misc. Coll., vol. 67, No. 1, Pub. 2444, pp. 4–6). *Fort Mtn fm.*—Consists of (descending): (1) Qtzitic ss. (called "Fairview fm." by author in 1908, but Fairview is preoccupied), 350 ft.; (2) coarse ss., 570 ft.; (3) siliceous sh., 44 ft.; (4) aren. qtzitic cgl., 360 ft. Since 1908, when upper part of this fm. was named "Fairview," the basal part of fm. has been found exposed at several places on E. side of Bow River Valley, where (on Fort Mtn, about 5 mi. NE. of Lake Louise station on Canadian Pacific R. R., Alberta) its basal cgl. is in contact with pre-Camb. shales. The fm. is overlain by Lake Louise sh.

†Fort Niobrara formation.

See 1909 and 1918 entries under †*Niobrara group* (Tert.).

Fort Payne chert.

Mississippian: Northern and eastern Alabama, northwestern Georgia, Tennessee, and northeastern Mississippi.

E. A. Smith, 1890 (Ala. Geol. Surv. Rept. on Cahaba coal field, pp. 155–156, section opp. p. 162, and map). *Fort Payne chert.*—The siliceous memb. of the Sub-Carbf., consisting of a great series of cherty lss. somewhat analogous to Knox. dol.; lower part more cherty than upper part in Tennessee Valley, but S. of the Tennessee the entire memb. shows, at least on surface, little else than chert. Usually very fossiliferous. Thickness not great. Probably represents both subdivisions of Siliceous group. Overlies Dev. black sh. and underlies Bangor ls. in some areas and Oxmoor ss. and shales in other areas.

As thus defined the Fort Payne chert included (according to E. A. Smith's 1894 rept) the rocks which in 1894 he differentiated into "Tuscumbia ls. (=upper part of Fort Payne chert)" and "Lauderdale cherty ls. (=lower part of Fort Payne chert)." In subsequent repts the noncherty beds equiv. to Tuscumbia ls. were, according to C. Butts, included in Bangor ls. of some areas, and the name Fort Payne was thus actually applied to beds of pre-Tuscumbia age. In 1910 (U. S. G. S. Bull. 400 and Folio 175) C. Butts definitely restricted the name *Fort Payne chert* to rocks of pre-Warsaw (=pre-Tuscumbia) age, and since then detailed work has proved that in Ky., western Tenn., and northern Ala. the Ste. Genevieve, St. Louis, and Warsaw lss. can be separated as fms., so that the name *Fort Payne chert* is now applied to pre-Warsaw rocks underlain by Chattanooga sh. In western Tenn. the Fort Payne is uncon. underlain by New Providence fm. or Ridgetop sh., both of post-Chattanooga age. According to E. O. Ulrich and C. Butts the Fort Payne contains fossils of Keokuk, lower Burlington, and Fern Glen age (comprising Osage group), and of late Kinderhook age. (See also C. Butts, 1926, Ala. Geol. Surv. Spec. Rept. No. 14.)

Named for development at Fort Payne, De Kalb Co., Ala.

Fort Peña formation.

Middle or Lower Ordovician: Southwestern Texas (Brewster County).

P. B. King, 1931 (A. A. P. G. Bull., vol. 15, No. 9, pp. 1066, 1070+). *Fort Peña fm.*—Chiefly alternations of thick-bedded ls. and bedded chert. The lss. are coarsely granular and in part sandy and pebbly, and crop out in conspicuous ledges several ft. thick. There are some thin partings of sh. In middle and upper parts considerable thicknesses of granular, purplish, reddish, and bluish chert, mostly in thin beds. In S. part of area, as in Garden Springs region, upper part is marked by a very massive chert memb. in beds 3 or 4 ft. thick. At base are 5 or 10 ft. of coarse massive cgl. composed of subrounded pebbles of chert, ls., and ss., from ¼ inch to 6 in. diam. Thickness 125 to 200 ft. Overlies Alsate sh. and grades into overlying Woods Hollow sh. Is chief ridge maker in Marathon succession below Caballos novaculite. Most of fauna suggests Black River (Middle Ord.), but occurrence here and there of primitive genera *Didymograptus* and *Tetragraptus* suggests that fm. is possibly Chazyan (Lower Ord.). Type loc. is on one of these ridges directly N. of old Fort Peña Colorada, Brewster Co.

†Fort Pierre group.

A term applied in early repts on Rocky Mtn region to Upper Cret. deposits long known as *Pierre sh.*

Fort Plain.

Middle Ordovician: Eastern New York (Mohawk Valley).

R. Ruedemann and G. H. Chadwick, 1935 (Sci., n. s., vol. 81, No. 2104, p. 400). *Fort Plain* introduced for uppermost Canajoharie or zone of *Climacograptus spinifer* in Mohawk Valley.

Fort Riley limestone. (In Chase group.)

Permian: Eastern Kansas, central northern Oklahoma, and southeastern Nebraska.

G. C. Swallow, 1866 (Kans. Geol. Surv. Prel. Rept., p. 14). *Fort Riley ls.*—Thick-bedded buff porous mag. ls., 8 to 10 ft. thick, forming bed No. 52 of geologic section of eastern Kans. Included in Lower Perm.

C. S. Prosser, 1895. [See 1st entry under *†Florence ls.*]

C. S. Prosser (1902) redefined Fort Riley ls. as explained in 1902 entry under *†Florence ls.*

R. C. Moore (1936) restricted Fort Riley ls. as explained in 1936 entry under *†Florence ls.* This restricted definition has not been considered by U. S. Geol. Survey for its publications.

Named for Fort Riley, Geary Co., Kans.

Fort St. John shales.

Upper Cretaceous: British Columbia.

G. M. Dawson, 1881 (Canada Geol. Surv. Rept. 1879–80, p. 15B). Partial synonym of Benton sh.

Fort Scott limestone (distinct formation in Kansas and Oklahoma).

Fort Scott limestone member (of Henrietta formation) in Missouri.

Pennsylvanian: Northwestern Missouri, eastern Kansas, and northeastern Oklahoma.

G. C. Swallow, 1866 (Kans. Geol. Surv. Prel. Rept., p. 25). *Fort Scott ls.*—Bluish-drab and brown, irregularly bedded fossiliferous ls., 8 to 18 ft. thick, forming top memb. of Fort Scott coal series and constituting bed No. 212 of geol. section of eastern Kans.

E. Haworth, 1896 (Univ. Kans. Geol. Surv. vol. 1, p. 42). *Fort Scott* is suitable as alternative designation for *Oswego ls.*, but should not include the upper heavy ls. which caps the hills on all sides of Fort Scott. Oswego ls. consists of (descending): (1) ls., 5 to 15 ft.; (2) black sh., 4 to 7 ft.; (3) ls., the "cement rock," 5 to 15 ft.

J. Bennett, 1896 (pp. 86 to 98, pl. 4 of book last cited). *Oswego or Fort Scott ls.* consists of (descending): (1) ls., 10 to 14 ft.; (2) clay and bituminous sh.; (3) ls. ("cement rock"), 4½ ft. [This definition of *Fort Scott ls.* is still in current use.]

The present commonly accepted definition of *Fort Scott ls.* in Mo. applies name to basal memb. of Henrietta fm., underlying Labette sh. memb. and overlying Cherokee sh. It includes at top the Fort Scott ls. of Swallow and at base the †*Fort Scott cement rock* of later repts, the two being separated by 5 to 20 or more ft. of sh., coal, and clay. In Kans. the Henrietta has for years been treated as a group by U. S. Geol. Survey, and Fort Scott ls. as a fm. In Okla. the Fort Scott ls. is also treated as a distinct fm. But R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), has discarded Pleasanton and Henrietta fms., and treats Fort Scott ls. as a fm. in his Marmaton group. These changes have not been considered by U. S. Geol. Survey for its publications.

See also under *Cherokee sh.*

Named for exposures at Fort Scott, Bourbon Co., Kans.

†Fort Scott coal series.

Pennsylvanian: Eastern Kansas.

G. C. Swallow, 1866 (Kans. Geol Surv. Prel. Rept., pp. 25–26): *Fort Scott coal series.*—Series of lss., shales, slates, sss., coals, and clays, 142 ft. 10 in. thick, including beds Nos. 212 to 223, inclusive, of geol. section of eastern Kans. Underlies Pawnee ls. series, overlies Fort Scott marble series, and includes Fort Scott ls. as top memb.

Includes lower part of Henrietta group and upper part of Cherokee sh.

†Fort Scott marble. (In Cherokee shale.)

Pennsylvanian: Eastern Kansas.

G. C. Swallow, 1866 (Kans. Geol. Surv. Prel. Rept., p. 26). *Fort Scott marble.*—Black marble, weathering brown, with numerous yellowish veins and crystallized shells; thickness 1½ ft. Constitutes bed No. 227 of geol. section of eastern Kans. Included in Fort Scott marble series.

†Fort Scott marble series. (In Cherokee shale.)

Pennsylvanian: Eastern Kansas.

G. C. Broadhead, 1866 (Kans. Geol. Surv. Prel. Rept., p. 26). *Fort Scott marble series.*—Series of lss., shales, and slates, 22 ft. 8 in. thick, including beds Nos. 224 to 230, inclusive, of geol. section of eastern Kans. Underlies Fort Scott coal series and overlies Lower coal series. Includes Fort Scott marble (bed No. 227).

†Fort Scott cement rock.

See under *Fort Scott ls. memb.*

†Fort Scott flagstones.

Trade name of ss. in Pleasanton group (Penn.), quarried near Fort Scott, Kans. Is younger than Fort Scott ls. See under †*Robinett flags.*

Fort Shafter gravel.

Pleistocene (late): Hawaii (Oahu Island).

C. K. Wentworth, 1926 (Bernice P. Bishop Mus. Bull. 30, pp. 62, 64, 65–71). There are 5 principal fms. in Salt Lake dist. The oldest is Koolau basalt, which is followed by the older parts of the reef ls. Next younger is *Fort Shafter gravel,* a coarse alluvial gravel, commonly made up of cobbles and boulders from 10 to 40 cm. diam. embedded in matrix of poorly sorted finer alluvium. Thickness of beds 2 to 10 ft. At many places the gravel rests on the basalt. It is deeply weathered; of Pleist. age; and the combined work of several streams draining this part of Koolau Range probably when sea stood about 40 ft. higher than now. Inner margin of Fort Shafter terrace in places stands 125 ft. or more above sea level. Most striking remnant of the terrace is that on which Fort Shafter military post is located, and which is here called Fort Shafter terrace. The lowest (oldest) tuff of Salt Lake region is interbedded with Fort Shafter gravels at a number of places. Over Fort Shafter terrace the upper tuff is

1 to 5 ft. thick and lies on the weathered and soil-covered surface of Fort Shafter gravel.

Not differentiated by H. T. Stearns, 1935 rept (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1).

†Fort Sill series.

Tertiary (?): Southwestern Oklahoma.

T. B. Comstock, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pp. 322, 324, 328). The ss. overlying the Perm. red clays (in SE. part of Wichita Range) is what Mr. Cummins calls *Fort Sill series*, and our observations make me think it may be Tert. It is persistent along S. base of the Wichitas for many miles westward, and in most places is overlain by thick deposits of Quat. gravels and boulders of local origin.

T. W. Vaughan, 1899 (Am. Geol., vol. 24, pp. 44–55). Comstock considered Fort Sill series of Cummins to be Tert. He does not give any reason for this opinion. The material resembles in lithologic character the Perm., composed of reddish argill. material. This fm. is still problematic, and we probably shall not be able to ascertain its relations until the area has been the subject of detailed investigation.

Abandoned because later workers are unable to identify the beds to which the name was applied.

Named for Fort Sill, Comanche Co.

Fort Sill formation.

Upper Cambrian: Arbuckle and Wichita Mountains, Oklahoma.

E. O. Ulrich, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 3, pp. 742–747). *Fort Sill fm.*—Basal unit of Arbuckle ls. in both Arbuckle and Wichita Mtns, Okla. Rests uncon. (locally overlaps) on *Honey Creek fm.*, and in Wichita Mtns is everywhere overlain by Signal Mtn fm. In Arbuckle Mtns, however, the Royer marble, 100 to 600 ft. thick, wedges in btw. Fort Sill and Signal Mtn fms. The Fort Sill is named for exposures in a small quarry on Fort Sill Military reservation on E. side of the highway btw. Fort Sill and Lawton (SE¼ sec. 8, T. 2 N., R. 11 W.), where only 40 ft. of fm. is exposed. A complete section of fm. is found about 6 mi. W. of Fort Sill and 1 mi. S. of Signal Mtn, in sec. 7, T. 2 N., R. 12 W., where 150 ft. of beds assigned to this fm. are exposed, as follows (descending): (1) 70 ft. of rather massive fine-grained gray to dove-colored ls.; sponge spicules abundant in zone near top; gastropod and trilobite zone in upper 50 ft.; (2) 34 ft. of thin-bedded, laminated fine-grained gray to dove-colored fossiliferous ls. in beds 2 to 6 inches thick, separated by thin sh. partings, with trilobite fragments throughout entire thickness; (3) 6 ft. of ls. similar to No. 12, with large trilobite fragments at base; (4) 40 ft. of ls. similar to above but with dove-colored varieties predominating; base irregular, marked by a thin green seam of weathered and redeposited material; fossils (chiefly trilobites) throughout. A much thicker bed (368 ft.) is exposed on N. side of Wichita Mtns, sec. 17, T. 4 N., R. 12 W. It is here divided into several faunal zones [described and named].

†Fort Smith formation.

Pennsylvanian (Allegheny): Western Arkansas coal field.

A. J. Collier, 1907 (U. S. G. S. Bull. 326, pp. 12, 18–20, and map). *Fort Smith fm.*—Thin and somewhat variable sss. with interbedded shales; sss. ripple-marked, the markings presenting considerable variety in size and form, and many beds are characterized by wavy cleavage approx. parallel to minor undulations of bedding planes. False bedding or cross-bedding unusual; shales nearly everywhere more or less aren. and resulting soils reddish or yellowish and sandy. Thickness 375 to 425 ft. Usually consists of (descending) hard sss. and shaly sss., 100 to 200 ft.; sh., 40 to 200 ft.; and at base, 20 to 50 ft. of hard, flaggy, ripple-marked ss., locally called "Tennessee ss." Coal beds in upper part. Overlies Spadra sh. and underlies Paris sh. Middle fm. of McAlester group.

Named for Fort Smith, Sebastian Co.

Has been discarded. See explanation under *McAlester fm.*

Fort Stanton shale.

Upper Cretaceous (Benton): Southern central New Mexico (Sierra Blanca region).

G. H. Hansen, 1931 (Geo. Wash. Univ. Bull., Summaries of doctoral theses 1925–28, p. 84). *Fort Stanton sh.*—Dark-gray to blue soft shales that carry near base a few thin beds of ls. and bentonite. Thickness 500 ft. Fossils [listed] collected by M. R. Campbell from this fm. near Fort Stanton Reservation are Benton, according to T. W. Stanton. Overlies Dakota (?) ss. and underlies Tucson ss.

Fort Thompson formation.

Pleistocene: Southern Florida (Palm Beach and neighboring counties).

E. H. Sellards, 1919 (Fla. Geol. Surv. 12th Ann. Rept., pp. 71–72, 75, 76, 118). *Fort Thompson beds.*—Alternating fresh- and brackish-water and marine shell marls and lss., typically exposed at Fort Thompson [just above LaBelle, Hendry Co.], just below Goodno's Landing. Relations to Miami oolite not determined. Underlies Coffee Mill Hammock marl.

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept.). *Fort Thompson fm.*—Here redefined to include Sellards' †Coffee Mill Hammock marl, a thin shell bed of marine origin containing a great profusion of *Chione cancellata*. The name "Coffee Mill Hammock marl" is not needed and is discarded. In type area the Fort Thompson fm. as here redefined lies uncon. on Caloosahatchee marl. Is overlain by peaty muck of Recent age. Thickness 0 to 10 ft.

Fortuna sand.

A series of subsurface sands which were in 1920 the principal producing sands in Cement oil field, Caddo Co., SW. Okla. They are correlated with part of Wellington fm. (Perm.).

Fort Union formation.

Eocene (early): North Dakota, northwestern South Dakota, Wyoming, Montana, northwestern Colorado.

F. B. Meek and F. V. Hayden, 1862 (Phila. Acad. Nat. Sci. Proc., vol. 13, p. 433). *Fort Union or Great Lignite group.*—Clay and sand, with round ferruginous concretions, numerous beds, seams, and local deposits of lignite, and great numbers of dicotyledonous leaves, stems, etc., of [listed] genera. Thickness 2,000+ ft. Overlies Fox Hills beds (Cret.) and underlies Wind River deposits. Occupies whole country around Fort Union and extends N. into British possessions unknown distances and southward to Fort Clark. Seen under White River group on North Platte River above Fort Laramie and on W. side of Wind River Mtns. Is probably Eocene.

F. V. Hayden, 1869 (U. S. Geol. Surv. Colo. and N. Mex. 3d Ann. Rept., pp. 89–92). *Fort Union group* extends along E. flanks of the mtns probably to Denver, Colo., and perhaps farther. The coal beds of Raton Hills, which I have called Raton Hills group, I suspect are also a portion of the great lignite group. The coal strata of Canyon City, which I have called Canyon City group, I have little doubt are also a fragment of the great lignite group.

In 1876 King and Hayden agreed to replace the descriptive term "Lignitic group" with the geographic name *Laramie group*. (See under *Laramie fm.* See also under †*Lignitic group* and *Laramie fm.* for early views regarding age and distribution of Fort Union fm.)

F. V. Hayden, 1876 (U. S. Geol. Terr. Bull. 5, pp. 405–411). Those who have worked from the S. and SW. toward the N. have been thoroughly impressed with Cret. age of Lignitic group, while those who have studied the deposits from the N. and NW. toward the interior basin received their first impressions they were of Tert. age.

F. B. Meek, 1876 (U. S. Geol. and Geog. Surv. Terr. Mon. 9, p. lix). The section of Fort Union group beds at Fort Union is as follows:

(1) ferruginous marl, with aren. concretions, the upper part being sometimes, for several ft. in thickness, composed of concretionary ss. forming ledges, 20–30. Most common fossil *Viviparus trochiformis*.

(2) drab indurated aren. clay, 20.

(3) impure lignite, with numerous crystals of selenite, 1.

(4) gray and drab indurated clay, with, at some localities, numerous impressions of leaves of dicotyledonous trees and of a species of fern, 50–70.

(5) impure lignite, with much silicified wood, 1½.

(6) gray indurated sand, with a slight mixture of clay. Contains numerous * * * (fossils) also many fragments and entire stumps of silicified trees, 30.

(7) impure lignite, ⅛ ft.

(8) yellowish-gray indurated clay, 2.

F. V. Hayden, 1878 (U. S. Geol. Surv. Terr. Mon. 7, pt. 2, p. iv), stated that his "Lignitic group" included Laramie and Fort Union, and that latter was probably identical with whole, or at least a part, of Wasatch group. (See quotation under *Laramie fm.*)

C. King, 1878 (U. S. Geol. Expl. 40th Par., vol. 1, pp. 351–354), stated that he had never visited Fort Union locality, but that "the correlation of the upper plant beds of Fort Union with the Wahsatch (my Vermilion Creek) seems the most prodigious strain."

In 1893 (U. S. G. S. Bull. 105) and 1896 (Am. Geol., vol. 18, pp. 201+) W. H. Weed divided *Fort Union or Lignitic group* of Hayden ("also called Laramie group by Hayden") near Livingston, Mont., into (descending): (1) *Fort Union fm.* (Eocene), 4,000 to 8,000 ft. of rather massive cross-bedded sss. with gray silty shales and local lenses of impure ls., "believed to be a distinct fm., corresponding in lithology, strat. position, and fossil contents to beds exposed along Missouri River at mouth of Yellowstone, so long known in geological literature as Fort Union beds," resting uncon. on (2), Livingston beds, 7,000± ft. of chiefly assorted and water-worn volcanic material, somber-colored sss., shales, and grits, which rest uncon. on (3), 1,000 ft. of massive, light-colored coal-bearing sss. and intercalated shales containing leaf remains and invertebrates and corresponding to Cret. Laramie fm. of King, Newberry, Emmons, and Cross. (The Livingston fm. was not assigned to either Eocene or Cret. by Weed.)

Later and more detailed work in Crazy Mtn region, Mont., by R. W. Stone and W. R. Calvert resulted in differentiating, in that region (Econ. Geol., vol. 5, pp. 551–557, 652–669, 741–764, 1910), the following fms. (descending): (1) *Fort Union fm.*, 4,000+ ft. thick, consisting of massive sss. and shales, with Lebo andesitic memb. at base, the latter 450 to 2,200 ft. thick and containing Fort Union (Eocene) fossils; (2) Lance fm. ("Ceratops beds"), 1,000 to 2,400 ft. of light-gray ss. and variegated sh.; (3) Lennep ss., 250 to 400 ft. of ss. with intercalated shales, which may correspond to Fox Hills ss.; (4) Bearpaw sh.; (5) Judith River fm.; (6) Claggett fm.; (7) Eagle ss.; (8) Colorado sh.; and (9) Kootenai fm. (Lower Cret.). They also ascertained that the andesitic Livingston fm. of Weed included equivalents of Lebo andesitic memb. of Fort Union fm. and all other fms. mentioned above down to top of Eagle ss., which was called *Laramie* by Weed.

Repts of different geologists published since 1910 have described and mapped the Fort Union fm. (Eocene) over large areas in Mont., N. Dak., S. Dak., and down into central Wyo. (See 1924 geol. map of Wyo., where Fort Union is shown resting on Lance fm. and overlain by Wasatch fm.) More recent work by J. B. Reeside, Jr., resulted in discovery that Wasatch fm. of 1924 Wyo. geol. map as mapped in southern Wyo. (where it was shown as resting on Lance fm.) included a representative of Fort Union fm., and that both Fort Union and Lance fms. are traceable into Yampa coal field of NW. Colo. A rept. on Yampa field by J. B. Eby and others describes the Fort Union of that area (called *post-"Laramie"* in earlier repts) as consisting of 1,345 ft. of sh. and ss., with coal near top and base, with a cgl. at base, and usually an indurated ferruginous platy ss. at top. These beds are uncon. overlain by Wasatch fm., and uncon. underlain by

Lance fm. (called "*Laramie*" in previous repts on the region), consisting of 1,020 ft. of ss., sh., and coal beds underlain by 500 ft. of sh. with small ss. lenses and coal bed near base. The Yampa coal field is southernmost area in which Fort Union and Lance fms. have been certainly identified. That the Fort Union fm. is of Eocene age, and that it underlies Wasatch fm. and overlies Lance fm. is definition now accepted by most if not all geologists.

Named for exposures at Old Fort Union, near mouth of Yellowstone River, later called Fort Buford and now town of Buford, N. Dak.

Fort Washington gneiss.

R. P. Stevens, 1867 (N. Y. Lyc., Nat. Hist. Annals, vol. 8, pp. 116–120). [On his "Section across New York [Manhattan] Island along southern shore of Spuyten Duyvel Creek and Harlem River" *Fort Washington gneiss* is applied to upturned body of gneiss along Hudson River. It is bounded on E. by King's Bridge ls. According to 1911 map of C. P. Berkey in N. Y. State Mus. Bull. 146, the Manhattan schist occurs in and around Fort Washington Park, and to E. Inwood ls. and Fordham gneiss occur.

Fort Washington.

Eocene: Southern Maryland (Prince Georges County).

T. A. Conrad, 1830 (Acad. Nat. Sci. Phila. Jour., vol. 6, pp. 205–217), listed fossils from Fort Washington and vicinity, but did not name the deposits.

A. Heilprin, 1884 (Phila. Acad. Nat. Sci. Jour., 2d ser., vol. 9, pt. 1, pp. 124–128), divided Eocene of Md. into (apparently descending): Upper Marlborough or Marlborough rock, Piscataway sands, and Fort Washington.

Probably is basal part of Aquia fm.

Fort Wayne moraine.

Pleistocene (Wisconsin stage): Northern Ohio and Indiana and southern Michigan. Shown on moraine map (fig. 8) of U. S. G. S. Columbus folio (No. 197), p. 12, 1915; also on moraine map (pl. 32) in U. S. G. S. Mon. 53, 1915. Named for Fort Wayne, Ind. Replaces "St. Marys" moraine of Gilbert.

Fort Worth limestone. (In Washita group.)

Lower Cretaceous (Comanche series): Eastern Texas, central southern and southeastern Oklahoma, and southwestern Arkansas.

R. T. Hill, 1889 (Tex. Geol. Surv. Bull. 4, pp. xiv, xxi, xxii). *Washita or Fort Worth ls.*—Comparatively massive, impure, chalky, sparsely fossiliferous ls., base and top compact; middle more disintegrated. Contains shell breccia and calc. marls in alternating strata. Has same general aspect upon weathering as Comanche Peak beds. Thickness 150+ ft. Overlies upper Caprotina ls. or Austin marble and underlies *Exogyra arietina* clays [Del Rio clay].

R. T. Hill, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 503–528). *Fort Worth ls.* of Tex.-Ark. region is overlain by Denison fm. and underlain by Duck Creek chalk. Included in Washita div. [group]. [This is present generally accepted definition of Fort Worth ls.]

R. T. Hill, 1894 (Geol. Soc. Am. Bull., vol. 5, pl. 13, pp. 318, 319). At Austin *Fort Worth beds* as originally defined underlie *Exogyra arietina* beds and overlie Caprina, the top div. of Fredericksburg group [and are=Georgetown ls.]. They include (descending) *Kingena wacoensis bed* (probably southern attenuation of Marietta bed of Denison section); *Gryphaea pitcheri* bed, 10 ft.; and Fort Worth ls. as name should be restricted.

R. T. Hill and T. W. Vaughan, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2). *Fort Worth ls.* of Edwards Plateau and Rio Grande Plain consists of 75± ft. of impure white ls. underlying Del Rio clay and overlying Edwards ls. [This broad definition corresponds to Georgetown ls., and Fort Worth ls. is no longer used in this area, where the unit described includes much more than typical Fort Worth ls.]

W. M. Winton and W. S. Adkins, 1919 (Univ. Tex. Bull. 1931), in rept on Tarrant Co. (typical Fort Worth ls.), advocated the transfer to Fort Worth ls. of the two upper members of Duck Creek fm., which they called Kingena memb. or *Duck*

Creek marl (top) and Scaphites memb. or *Duck Creek limy marl.* The underlying members (to which they restricted name *Duck Creek fm.*) they designated as Schloenbachia memb. or *Duck Creek marly lime* (above) and Desmoceras memb. or *Duck Creek ls.* (below). "The Duck Creek marl and limy marl are distinct from the overlying Fort Worth ls. and the underlying *Duck Creek ls.*, both lithologically and paleontologically, and have as much justification for ranking as a separate fm. as either of them. If they are to be placed with either it should be with Fort Worth ls., since the faunal changes are very abrupt at end of Duck Creek ls." [basal memb. of Duck Creek fm.].

Named for exposures at Fort Worth, Tarrant Co.

†Fortymile series.

†Fortymile group.

Paleozoic and pre-Cambrian: Central eastern Alaska (Fortymile Creek).

J. E. Spurr, 1898 (U. S. G. S. 18th Ann. Rept., pt. 3, pp. 145–155). *Fortymile series.*—Interbedded marbles, qtzites, and schists of various kinds—hornblendic, micaceous, garnetiferous, and sometimes graphitic. The marble beds occur throughout fm. and are its distinctive feature. The series is calc. at bottom and rather shaly at top. Intrusive rocks abundant; two sets of quartz veins. Folded, faulted, sheared. Overlies Birch Creek series, and appears to underlie Rampart series. Named for exposures along canyonlike valley of Fortymile Creek. Age undet.

These rocks were later called *Fortymile group*, but the name was finally discarded. In its type area it included part of Birch Creek schist (pre-Camb.) and also Paleozoic rocks.

Fortymile granite.

A term applied by J. E. Spurr (U. S. G. S. 18th Ann. Rept., pt. 3, pp. 135, 137, 1898) to the basal granite in Fortymile dist., Alaska, where it underlies Birch Creek schist.

Fossil Creek volcanics.

Middle Ordovician: Northeastern Alaska (Yukon-Tanana region).

J. B. Mertie, Jr., 1936 (U. S. G. S. Bull. 872). *Fossil Creek volcanics.*—Basic lavas, tuffs, breccias, and aggls. of greenstone habit, with a small proportion of granular basic intrusives. Lower part consists mainly of bedded lavas and interbedded pyroclastic rocks. Thickness probably 2,000+ ft. Typically exposed in White Mtns, about 50 mi. N. of Fairbanks, where they crop out just N. of Fossil Creek, in a belt 40± mi. long. Overlain by Tolovana ls. (Sil.), without observed structural uncon., but in reality there is a great discon. btw. them. Middle Ord. fossils. Included in †Tatalina group of Prindle.

Fossil Lake formation.

Pleistocene: Central southern Oregon.

W. D. Smith, 1926 (Oreg. Univ. Commonwealth Rev., vol. 8, pp. 207–214). *Fossil Lake fm.*—Lake silt, 8 to more than 10 ft. thick, containing Pleist. fossils. Type loc., Fossil Lake, N. part of Lake Co.

Fountain formation.

Pennsylvanian: Eastern Colorado.

W. Cross, 1894 (U. S. G. S. Pikes Peak folio, No. 7). *Fountain fm.*—Series of red sss., grits, and cgls., *a part of so-called "Red beds,"* found in typical development on Fountain Creek below Manitou Springs [in Colorado Springs quad.] and at head of same stream in NE. corner of Pikes Peak quad. The beds of upper exposures on Fountain Creek belong to basin of Manitou Park. They are chiefly coarse-grained, crumbling arkose sss., in heavy *banks* showing cross-bedding; are locally conglomeratic, mottled with gray and various light shades of red; near base and at intervals throughout the series are very dark-red or purplish layers of aren. sh. or fine-grained ss. Thickness near Woodland Park estimated at nearly 1,000 ft. The characteristics above noted are also found in lower 1,000 ft. of section of reddish sss. and grits to E. of Manitou Springs, referred by Hayden to upper Carbf., while the *finer grained* "Red beds" succeeding them, together with the strata of Manitou Park, were called "Triassic." In Garden Park the Fountain beds reach max. thickness of about 1,000 ft.; they are heavy bedded, with much feldspathic material derived from adjacent granite; the cgl. layers contain many pebbles of hard Algonkian qtzites, while a few ls. and chert pebbles were noted in lower part; dark sh. is less prominent than in Manitou Park. The Fountain beds rest uncon. on edges of entire Silurian section in Red ridge, at upper end of Garden Park; along S. end of Colorado Range they rest on Harding ss. While greater part of "Red beds" series E. of Colorado Range has been considered Triassic, no fossil or other definite evidence has as yet been found to show correctness of this conclusion. It is more probable lower part at least of these "Red beds" belong to Carbf. than that the whole complex is Triassic.

The geol. map of Colorado Springs folio (No. 203) shows that Fountain Creek cuts across Fountain fm. for 2 mi. to E. of Manitou Springs, and that about 2 mi. E. of latter place it cuts across Lyons ss. and Lykins fm. as described in that folio. From this it would appear that Lyons ss. and Lykins fm. of that folio were included in foregoing original definition of Fountain fm. But Cross distinctly states that his Fountain fm. is only a *part* of the "Red beds." The latter term was replaced by "Wyoming fm." in 1896, and still later was subdivided into Lykins, Lyons, and Fountain fms. There are also differences in the thicknesses. The Fountain of Colorado Springs quad. is 800 to 4,500 ft. thick, while Lyons ss. of that folio is 850 ft. thick, and Lykins fm. is 180 ft. thick. The author of Colorado Springs folio (G. I. Finlay) interpreted the Fountain fm. as originally defined to be=Fountain fm. plus lower part of Lyons ss. as mapped by him in Colorado Springs folio.

Fourmile sandstone member (of Nelagoney formation).

Pennsylvanian: Central northern Oklahoma (Osage County).

C. F. Bowen, 1918 (U. S. G. S. Bull. 686D, pp. 17-20). *Fourmile ss.*—Massive ss., about 25 ft. thick, overlain and underlain by some thinner sss. and interbedded red shales, the whole having a thickness of about 40 ft., but this varies considerably from place to place. The basal bed is distinguished from other sss. in this part of section by being coarse and gritty, but not conglomeratic. Rests on gray sh. A thin ls. lies 10 to 15 ft. below base of Fourmile ss. The Fourmile ss. lies 40± ft. below top of section in T. 24 N., R. 10 E., and 350± ft. above Birch Creek ls. Named for exposures on the point S. of Fourmile Creek in SW¼ sec. 30, T. 24 N., R. 10 E.

Fourmile limestone. (In Wreford limestone.)

Permian: Eastern Kansas, southeastern Nebraska, and northern Oklahoma.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., p. 31). Fourmile ls.—Basal memb. of Wreford ls. Named for Fourmile Creek, in SW. part of Richardson Co., Nebr. Type loc. head of a branch of Fourmile Creek, near Kans.-Nebr. line, about 10½ mi. S. and ½ mi. E. of Humboldt, Nebr. Thickness in Nebr. about 7½ ft.; increasing southward to 20 or more ft. at Strong, Cambridge, and Dexter, Kans. With exception of about 1 ft. of gray sh. above a thin basal cherty ls., the Fourmile memb. is massive gray to bluish-gray chert-bearing ls., but its chert content decreases somewhat from southern Kans. into Okla. Underlies Havensville sh. memb. of Wreford ls.

R. C. Moore, 1936 (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 12), replaced Fourmile ls. of Condra and Upp with new name *Threemile ls.*, probably because of prior use of *Fourmile* for a ss. in Okla.

E. C. Reed (Asst. State Geol. Nebr.), 1936 (letter dated Oct. 16). Nebr. State Surv. continues to use *Fourmile* for the ls. for which Kans. Surv. has substituted *Threemile.*

Fournier group.

Ordovician to Devonian: New Brunswick.

G. A. Young, 1911 (Canada Geol. Surv. Mem. 18, p. 47).

Fowkes formation. (In Wasatch group.)

Eocene: Southwestern Wyoming.

A. C. Veatch, 1907 (U. S. G. S. P. P. 56). *Fowkes fm.*—"White beds;" light-colored rhyolitic ash beds with interbedded lss. containing fresh-water shells, fish, and plants. Thickness 0 to 2,500+ ft. Middle fm. of Wasatch group in

SW. Wyo. Uncon. underlies Knight fm. and overlies Almy fm. (basal fm. of Wasatch group). Named for Fowkes ranch, about 9 mi. from Evanston, around which the fm. is well exposed.

Fowler limestone.

Upper Ordovician: Southern Kentucky.

A. F. Foerste, 1901 (Geol. Soc. Am. Bull., vol. 12, p. 434). *Fowler ls.*—Dense ls., 1 to 1½ ft. thick, at top; in middle shaly bluish ls., 1 to 2 ft. thick, carrying Richmond fossils; at bottom ls. layer with branching bryozoans. Included in Richmond group. Overlain by Rennix lss. and underlain by 15 ft. of thin-bedded ls. and other unnamed strata of Richmond group.

Named for Fowlers Landing, Cumberland County (?).

Fowler moraine.

Pleistocene (Wisconsin stage): Southeastern Michigan. Shown on moraine map (pl. 32) in U. S. G. S. Mon. 53. Named for Fowler, Clinton Co.

Fox sandstone.

An abbreviated form of *Fox Hills ss.* employed by C. [R.] Keyes.

†Fox rocks.

A name applied locally in W. Va. to Gilmore ss. memb. of Greene fm.

Fox Bush sand.

A subsurface sand in southern Kans. that is said to lie at about horizon of Bartlesville or Burbank sand.

Foxen formation.

Pliocene (middle): Southern California (Santa Maria district).

W. W. Porter, II, 1932 (A. A. P. G. Bull., vol. 16, No. 2, p. 136). *Foxen fm.* (*middle Plio.*).—This fm. was described by C. F. Tolman at joint meeting of Le Conte Club and Cordilleran section of Geol. Soc. Am. at Stanford Univ., Jan. 29, 1926. Abstract in Geol. Soc. Am. Bull. 38 (1927), and use of term *Foxen* by writer is essentially same as Tolman's. The fm. is younger than lower Plio. Sisquoc fm., on which it lies, and is tentatively referred to middle Plio. Above it, in some localities conformably and in others uncon., lie the fossiliferous yellow sss. generally known as "Fernando." The Foxen is a clay sh. varying locally to diatomite. Characterized by distinctive micro-fauna which has been found in many well cores and in pit samples from surface outcrops on Harris Grade road. An easily accessible outcrop is on N. side of Purisima Hills near foot of Harris Grade road which connects Lompoc with Coast Highway at Harris Station. It is exposed in cuts on W. side of creek just S. of small bridge about 1 mi. S. of Harris Station. Foxen diatomite can be seen in Solomon Hills near summit of Howard Canyon road, and above Sisquoc fm. S. and E. of Sisquoc Ranch House. Thickness 40 ft. in surface sections in Solomon Hills to several hundred ft. in wells in Santa Maria Valley; is approx. 600 ft. on Harris Grade road.

W. W. Porter, II, 1933 (letter dated Nov. 9). *Foxen fm.* was discussed and described in reference to Tolman given above, but in condensing material for G. S. A. abstract the column with means (including Foxen) was omitted. I know of no actual publication of name *Foxen* except in my paper, and more recently in R. D. Reed's book "Geol. of Calif."

R. D. Reed, 1933 (Geol. of Calif., p. 233), divided Plio. of Santa Maria dist. into (descending): *Dendraster* cgl., 0–200 ft.; *Upper Foxen sand* (well-sorted fine yellow sand), 0–1,000 ft.; *Middle Foxen* (foraminiferal and diatomaceous claystone), 800± ft.; and *Lower Foxen* (sand near margins, diatomaceous sh. and claystone in middle of basin), 1,800± ft.

H. W. Hoots and S. C. Herold, 1935 (Geol. of nat. gas, A. A. P. G., p. 156). Etchegoin of Santa Maria dist. underlies (with local uncon.) Schumann fm., overlies (with local uncon.) Santa Margarita fm., and is divided into (descending): Upper Foxen sand, 1,000 ft.; local uncon.; Foxen foraminite, 700 ft.; Foxen diatomite and Lower Foxen sand (contemporaneous), 1,800 ft.

Fox Ford bed. (In Strawn formation.)

Pennsylvanian: Central Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 374, 378). *Fox Ford bed.*—Ss., about 500 ft. thick. Memb. of Strawn div. Overlies bed No. 8 (250 to 300 ft. of clay interstratified with ss. at base) and underlies Horse Creek clays and shales.

Named for Fox ford on Colorado River in central Tex. mineral region.

Fox Hills sandstone. (In Montana group.)

Upper Cretaceous: South Dakota, North Dakota, eastern Montana, Wyoming, and eastern Colorado.

F. B. Meek and F. V. Hayden, 1862 (Phila. Acad. Nat. Sci. Proc., vol. 13, pp. 419, 427). *Fox Hills beds (Formation No. 5 of Cret.).*—Gray, ferruginous and yellowish ss. and aren. clays. Occurs at Fox Hills, near Moreau River, along base of Bighorn Mtns, and on North and South Platte Rivers. Thickness 500 ft. Top fm. of Upper Cret. in Nebr. [which at that time included Wyo., Mont., and Dak.]. Underlies the Tert. Fort Union or Great Lignite group and overlies Fort Pierre group [Pierre sh. of present nomenclature]. [The Fox Hills ss. is not present in Nebr. as now delimited.]

In 1876 the name *Laramie* was introduced for deposits formerly called "Lignitic group," and the Laramie was defined as resting on the Fox Hills.

C. A. White, 1878 (U. S. Geol. and Geog. Surv. Terr. 10th Ann. Rept., pp. 21, 22, 30), transferred "Fort Pierre group" (Pierre sh.) from Colorado group, in which it had for many years been included, to overlying Fox Hills "group." (See 1878 entry under *Colorado group.*) The term "group" as used in early repts was applied in a formational sense, e. g., Fort Pierre "group," Fox Hills "group," Fort Union "group," etc.

C. A. White, 1879 (U. S. Geol. and Geog. Surv. Terr., 11th Ann. Rept., pp. 186–187). *Fox Hills group,* a consolidation of Fort Pierre group (Cret. No. 4) and Fox Hills group (Cret. No. 5) for Colo. and adjacent territories, but not for Upper Missouri River region, where it will continue to be used in restricted sense applied to it by its authors. In Colo. and adjacent territories neither the lithological nor paleontological characteristics of the equivalents of Fort Pierre and Fox Hills groups, respectively, are such as to afford any satisfactory ground for a separation, such as has been made in Upper Missouri River region, and even in that region a blending of the fossils of each has frequently been found.

In 1888 (Colo. Sci. Soc. Proc., vol. 3, pt. 1, p. 93, footnote) G. H. Eldridge, "with the approval of Dr. C. A. White," introduced *Montana group* to replace Fox Hills in broad sense of White—i. e., to include Fox Hills ss. and Pierre sh. of present nomenclature, which were mapped by Hayden Survey as *Fox Hills group* and *Fort Pierre group.* The original restricted definition of Fox Hills is the one that has been in use for many years.

Rocky Mtn Assoc. Pet. Geol., by its committee, composed of T. S. Lovering, H. A. Aurand, C. S. Lavington, and J. H. Wilson, 1932 (A. A. P. G. Bull., vol. 16, No. 7, pp. 702–703). After field conference [in eastern Colo.] with J. B. Reeside, Jr., of U. S. G. S., *the Rocky Mtn Ass. Pet. Geol. has agreed to restrict term Fox Hills as follows:* The base of Fox Hills fm. shall be considered as horizon below which the section is predominantly gray marine clay shales and sandy shales of Pierre age, and above which the section changes rapidly to a buff to brown ss. containing numerous large gray to brown hard sandy concretions. This lower concretionary memb. is commonly overlain by a series of light-gray to brown sss. and sandy shales. The top of Fox Hills fm. shall be considered as horizon above which the section is composed predominantly of fresh- and brackish-water deposits accompanied by coals and lignitic shales, and below which it is predominantly marine.

Named for exposures in Fox Ridge, NW. Armstrong and SW. Dewey Co., S. Dak. (shown on pl. 1 of U. S. G. S. Bull. 575).

†Fox Hills group (broad sense).

Upper Cretaceous: Rocky Mountain States.

See 1878, 1879, and 1888 entries under *Fox Hills ss.*

Foxian series.

A term applied by C. R. Keyes to Fox Hills ss. and its supposed equivalents.

Foy's limestone. (Allegheny formation.)

Pennsylvanian: Western Pennsylvania (Lawrence County).

J. P. Lesley, 1879 (2d Pa. Geol. Surv. Rept. Q_2, pp. xxii, 320). *Foy's ls.*, 2 ft., Foy's Knob, Wayne Twp, Lawrence Co. May be Freeport Upper ls. "The name *Foy's ls.*, given to the bed in the Third Index [at back of volume], is merely a convenience for avoiding the difficulty in making the Index, and is not intended to advocate the insertion of a third coal bed in the Freeport group." Lies 35 ft. under Brush Creek coal.

Fraction breccia.

Miocene (upper): Central Nevada (Tonopah and neighboring districts).

J. E. Spurr, 1905 (U. S. G. S. P. P. 42, pp. 39+, map, etc.). *Fraction dacite breccia.*—Soft brownish or greenish rock of volcanic origin, sometimes solid, occasionally dimly horizontally layered or packed, at times definitely stratified, and even contains well-bedded tuffs. Is dacitic, essentially like Heller and Brougher dacites. In places is nonfragmental and a flow. Thickness varies, but in New York Tonopah shaft it is 745 ft. thick. Overlies Heller dacite and underlies Tonopah rhyolite dacite. [The fm. is mapped at and around Fraction No. 1 and Fraction No. 2 mines, which appear to be the geographic feature for which the fm. was named.]

A. Knopf, 1921 (U. S. G. S. Bull. 715, pp. 150–154). *Fraction rhyolite breccia of Siebert fm.*—Rhyolite breccia predominates in the Fraction throughout Divide dist., and the rock is therefore renamed *Fraction rhyolite breccia.* Thickness 600+ ft. The intercalated beds of soft fine-grained white tuff range in thickness from a few inches to 200 ft. Some thin beds of gritty tuff occur with the fine-grained tuffs. The intercalated white tuffs correspond in composition to Spurr's Siebert tuff of Tonopah dist.

T. B. Nolan, 1930 (Univ. Nev. Bull., vol. 24, No. 4, p. 21). For the fm. which was first described by Spurr as *Fraction dacite breccia,* and whose southern continuation in Divide dist. was renamed by Knopf the *Fraction rhyolite breccia,* the writer proposes the simplified name *Fraction breccia,* because at Tonopah the basal portion of the fm. contains locally very large amounts of andesitic-appearing debris, with result that there has at times been considerable confusion as to proper correlation of the beds, which have, for example, been considered to represent the "Midway andesite." All examples of "Midway andesite" cappings of veins that were seen by writer proved to be basal part of Fraction breccia. The Fraction breccia is considered by H. G. Ferguson (U. S. G. S. Bull. 723, pp. 42–43, 1924) to be basal memb. of Esmeralda ("Siebert") fm. and is therefore of upper Mio. age.

Fraction dacite breccia.

Fraction rhyolite breccia.

See *Fraction breccia.*

Frame shale member. (In Hamilton group.)

Middle Devonian: Central Pennsylvania (Bedford County).

B. Willard, 1935 (Geol. Soc. Am. Proc. 1934, June 1935, p. 361). [See this citation under *Mahantango fm.* Not defined.]

B. Willard, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 8, Aug. 31, pp. 1279, 1283). Near Chaneysville, Bedford Co., Pa., Mahantango fm. is divided into 3 intergrading members (descending): *Frame sh. memb.,* 343 ft.; Chaneysville ss. memb., 182 ft.; and Gander Run sh. memb., 850 ft. The Frame memb. is gray to olive sandy sh. with local sss. and an occasional thin ls. lens. Fossils. Named for Frame School, about 6 mi. N. of Chaneysville. Tentatively recognized in Blair Co.

Francis formation.

Pennsylvanian: Central southern and central Oklahoma (Pontotoc, Seminole, and Okfuskee Counties).

G. D. Morgan, 1924 (Bur. Geol. [Okla.] Bull. 2, pp. 113–119, pls. 3, 27, and map). [Name was also used by Morgan, but not defined, in Okla. Geol. Survey Circ. 12, pl. and p. 15, 1923.] *Francis fm.*—Consists of (ascending): (1) DeNay ls. memb.; (2) dark-blue and black shales 30± ft.; (3) nearly 20 ft. of sss.; (4) 250± ft. of dark and sometimes calc. shales; (5) 100± ft. of coarse brown sss. and chert cgls.; and (6) 100± ft. of sh. with few thin sss. and one rather persistent conglomeratic ls., often very fossiliferous. Underlies Belle City ls. and overlies Seminole fm. Large fauna.

Named for town of Francis, Pontotoc Co., which is situated on E. edge of outcrop.

Franciscan formation (group, where subdivided).

Jurassic (?): Western California.

A. C. Lawson, 1895 (Am. Geol., vol. 15, p. 347, and U. S. G. S. 15th Ann. Rept., p. 415). *Franciscan series.*—Several thousand ft. of sed. and volcanic rocks with which are associated various basic intrusives, notably peridotite serpentines. Is of either Cret. or Jurassic age. Includes foraminiferal lss., great fms. of peculiarly bedded radiolarian cherts, and certain highly crystalline schists. The San Francisco ss. is dominant sed. fm. of series. In vicinity of San Pedro Point a basal fm. of cgls., coarse grits, sss., shaly sss., shales, and argill. lss. is exposed.

The Franciscan rocks, which attain thickness of several thousand ft., are usually treated as a fm., but in San Francisco folio (No. 193) of U. S. Geol. Survey they were divided into five named and mapped fms. (descending)—Bonita ss., Ingleside chert, Marin ss., Sausalito chert, and Cahil ss., the latter including Calera ls. memb. The broader term *San Francisco ss.* is no longer used. The intrusive serpentine is not a part of the fm. The Franciscan rests uncon. on granite, and is uncon. overlain by Knoxville fm.

Named for extensive exposures at San Francisco.

Francis Creek shale and limestone. (In Carbondale formation.)

Pennsylvanian: Central western Illinois (Mercer and Fulton Counties).

T. E. Savage, 1927 (Am. Jour. Sci., 5th, vol. 14, p. 309). *Francis Creek sh. and ls.*, 0 to 65 ft. thick in Fulton Co. Rests on Colchester (No. 2) coal and uncon. underlies Vergennes ss. in Fulton Co.

H. R. Wanless, 1929 (Ill. Geol. Surv. Bull. 57, pp. 49, 89). *Francis Creek sh.* [*restricted*].—In Alexis quad. [chiefly in Mercer Co.] consists of 0 to 9 ft. of soft gray sh. resting on Colchester (No. 2) coal, and lying 21± ft. below Pleasantview ss., all included in Carbondale fm. The name *Francis Creek* has been applied (Savage, 1927) to all strata of suite IV above Colchester (No. 2) coal, because they are well exposed along Francis Creek, Fulton Co., but the cited type exposure does not well exhibit the upper members of the suite, and so it is proposed that name be applied only to the soft gray sh. btw. the coal and the black laminated concretionary sh. (1 ft. thick) in lower part of Carbondale fm.

Francoisian series.

A term introduced by C. [R.] Keyes (Iowa Acad. Sci. Proc., vol. 22, p. 253, 1915) to include Skrainka diabase, Iron Mtn porphyry, and Knob Lick granite of SE. Mo., which are now commonly considered to be pre-Camb. Derivation of name not stated.

Franconia breccia.

Late Devonian or late Carboniferous: Northwestern New Hampshire (Ammonoosuc River region).

N. H. Geol. Surv. 4th Ann. Rept., 1872, as interpreted by J. D. Whitney and M. E. Wadsworth in Harvard Coll. Mus. Comp. Zool. Bull., vol. 7 (geol. ser. I), opp. p. 396. *Franconia breccia* included in Laurentian. Younger than White Mtn gneiss and Bethlehem gneiss.

C. H. Hitchcock, 1873 (Boston Soc. Nat. Hist. Proc., vol. 15, pp. 304–309). *Franconia breccia* (Laurentian?) is younger than White Mtn and Bethlehem gneisses, of which it contains fragments.

C. H. Hitchcock, 1874 (Geol. N. H., pt. 1, btw. pp. 508 and 545). *Franconia breccia group* covers a few sq. mi. in Franconia. Younger than White Mtn series.

C. H. Hitchcock, 1877 (Geol. N. H., pt. 2, pp. 137–141, by J. H. Huntington, and btw. pp. 251 and 270). *Franconia breccia* occurs in Franconia and Lincoln. Younger than Montalban gneisses and schists. [On a later page, btw. 658 and 675, he seems to include it in his Montalban.]

C. R. Williams, 1934 (Appalachia, vol. 20, No. 4). *Franconia breccia* is composed of angular fragments of Kinsman granodiorite in a matrix of fine-grained granite very similar to Bickford granite. Well exposed in Franconia Notch and on Eagle Cliffs. Carbf. (?).

M. P. Billings and C. R. Williams, 1935 (Geology of Franconia quad., N. H., p. 20). *Franconia breccia* is result of shattering of Kinsman quartz monzonite by some unknown process, and the filling of the fractures with a granite very similar to Bickford granite. [The map states, beneath block labeled *Intrusive breccia: "The 'Franconia breccia' of Hitchcock.* Consists of angular fragments of Kinsman quartz monzonite and older schists in a matrix of fine-grained gray granite." The rock is assigned to New Hampshire magma series, late Dev. or late Carbf.

†Franconia gravel.

Pleistocene: Eastern Virginia.

L. F. Ward, 1895 (U. S. G. S. 15th Ann. Rept., pp. 326–330, 339). *Franconia gravel* is applied to disturbed sands, gravels, and cobbles that occupy a wide belt on landward margin of Potomac fm. throughout greater part of its length. If of Potomac age they were deposited toward close of Aquia Creek period. Most complete exposure at gravel pits of Alexandria & Fredericksburg R. R. at Franconia Station, 6 mi. SW. of Alexandria. *May possibly belong to the Lafayette.* Overlain by Columbia (Pleist.) fm.

In U. S. G. S. Washington folio, No. 70, 1901, the deposits at the gravel pits at Franconia Station are mapped as Columbia fm.

Franconia sandstone.

Upper Cambrian: Southeastern Minnesota, southwestern Wisconsin, and eastern Iowa.

C. P. Berkey, 1897 (Am. Geol., vol. 20, btw. pp. 345–383). *Franconia ss.*—Compact and thick-bedded layers overlain by fine incoherent sand; contains thin seams of green sh. Thickness 100 ft. Underlies St. Lawrence dolomites and shales and overlies *Dresbach shales* at St. Croix Dalles. Named for exposures in vicinity of Franconia, Chisago Co., Minn.

C. W. Hall, 1901 (Int. Min. Cong., 4th sess., pp. 165–171). *Franconia* (sss. and shales) underlies St. Lawrence and overlies *Dresbach ss.* in SE. Minn.

C. P. Berkey, 1906 (Geol. Soc. Am. Bull., vol. 17, pp. 229–250). *Franconia ss.*, 75 to 100 ft. thick, underlies St. Lawrence dolomites and shales and overlies *Dresbach shales* in St. Croix Dalles region.

F. F. Grout and E. K. Soper, 1914 (Minn. Geol. Surv. Bull. 11). *Franconia ss.*, 100 ft. thick, underlies St. Lawrence fm. and overlies *Dresbach ss.*

F. W. Sardeson, 1916 (U. S. G. S. Minneapolis-St. Paul folio, No. 201). *Franconia ss.*—Coarse white water-bearing ss. above, and beds of greensand and calc. sh. below. Thickness 85 to 100 ft. Underlies St. Lawrence fm. and overlies *Dresbach ss.*

F. T. Thwaites, 1923 (Jour. Geol., vol. 31, p. 549). *Franconia ss.* of Wis. underlies Mazomanie fm., overlies Dresbach fm., and includes, at base, Ironton memb. The fm. is fine-grained, gray to green, and for most part somewhat calc., but varies considerably in different parts of State. Greater part is highly glauconitic, especially near bottom and top. Above Ironton memb. is about 15 ft. of micaceous sandy sh.

E. O. Ulrich, 1924 (Wis. Acad. Sci. Trans., vol. 21, pp. 71–93). *Franconia* underlies Mazomanie ss. in Wis. and overlies Dresbach ss.

Mazomanie ss. of Ulrich is now considered by many geologists to be a part of Franconia ss. (See under *Mazomanie ss.*) The fm. overlying Franconia ss. is called *St. Lawrence fm.* by U. S. Geol. Survey and *Trempealeau fm.* by Ulrich and some others. The basal memb. of the Franconia is Ironton ss. memb.

See Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 199, 467 for details of beds at Franconia type loc. In this rept several names are introduced for the members of the Franconia above the basal Ironton ss. memb.

C. R. Stauffer, 1925 (Jour. Geol., vol. 33, p. 709). At Dresbach, Minn., the *Franconia ss.* consists of 102 ft. of massive yellowish to white medium- to fine-grained ss., with occasional shaly partings. It underlies St. Lawrence fm. and overlies Dresbach fm. (ss. with some shaly beds).

E. Peterson, 1929. (See 1929 entry under *Dresbach ss.*)

In some early repts Franconia ss. appears to have been included in St. Lawrence fm.

A. C. Trowbridge and G. I. Atwater, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 45–50). *Franconia beds* are of formational rank. The fm. should include the greensands, sss., shales and lss., many of which are glauconitic, that lie btw. the nonglauconitic Dresbach sss. below and the St. Lawrence sh. or dol. above. It includes Ironton memb. at base. We can not agree with Ulrich that Mazomanie ss. is younger than Franconia. The Mazomanie fauna, according to Raasch (personal communication), has been found in upper part of the Franconia of western Wis. and the Franconia fauna has been found below the Mazomanie fauna in the Mazomanie areas of eastern Wis.

J. M. Wanenmacher, W. H. Twenhofel, and G. O. Raasch, 1934 (Am. Jour. Sci., 5th, vol. 28, p. 13). [See digest under *Mazomanie ss.*]

W. H. Twenhofel, G. O. Raasch, and F. T. Thwaites, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 11, pp. 1687–1744). *Franconia fm.* divided into (descending): Bad Axe memb. (*Dikelocephalus postrectus* zone); Hudson memb. (*Ptychaspis-Pensaukia* zone); Goodenough memb. (*Conaspis* zone); and Ironton memb. (*Camaraspis* zone). The fm. was named for Franconia, Minn., where cliffs along Lawrence Creek expose 100± ft. of strata assigned thereto. Upper members of fm. are not exposed at type loc. Most conspicuous characteristic of fm. is presence of glauconite, which is present throughout. Overlies Galesville memb. of Dresbach fm. and underlies Basal greensand and cgl. memb. of Trempealeau fm.

Franconia moraine.

Pleistocene (Wisconsin stage): Northeastern Minnesota.

R. T. Chamberlin, 1905 (Jour. Geol., vol. 13, pp. 247–250). Runs almost N. and S. westward from St. Croix River. Occurs on uplands back of Franconia, Chisago Co.

Franey granite.

Age (?): Cape Breton Island.

W. J. Wright, 1914 (Canada Geol. Surv. Summ. Rept. 1913, p. 276).

Frankenfield.

Cretaceous: Jamaica.

R. T. Hill, 1899 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 34, p. 42).

Frankford gneiss.

Pre-Cambrian: Southeastern Pennsylvania (Philadelphia County).

T. D. Rand, 1900 (Phila. Acad. Nat. Sci. Proc. 1900, pt. 1, p. 279). *Frankford gneiss.*—Highly feldspathic gneiss containing little mica and hornblende, very hard. Valuable building stone. Exposed at Frankford, Philadelphia Co. Is a part of Philadelphia mica schists and gneiss group.

Is a part of Wissahickon fm.

Frankfort shale.

Upper Ordovician: Central and east-central New York.

L. Vanuxem, 1840 (N. Y. Geol. Surv. 4th Rept., pp. 372–373). *Frankfort sl.*—Underlies Pulaski shales and grades imperceptibly into underlying black sl. or sh. [Utica] that rests on Trenton ls. Is lighter colored than underlying rocks. In many places upper part alternates with layers of fine-grained ss. Seen to greatest advantage on Frankfort [Moyer] Creek, back of the village, from whence it takes its name.

In 1911 (N. Y. State Mus. Bull. 149, p. 12) J. M. Clarke introduced *Indian Ladder beds* for upper several hundred ft. of *Frankfort sh.* as formerly identified in Mohawk Valley, which he stated carry a different fauna from lower beds of the Frankfort as then known. In 1912 (N. Y. State Mus. Bull. 162) R. Ruedemann restricted *Frankfort sh.* to fm. as exposed in Utica region, which is absent in Mohawk Valley, where sh. formerly called Frankfort has been found to be much older, and here named by him *Schenectady fm.* As thus restricted, basal limit of true Frankfort is defined as top of true Utica sh.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 42). In final rept by Vanuxem the Frankfort sh. is described as lower memb. of Hudson River group. Typical exposure is along Moyer Creek, SW. from Frankfort, Herkimer Co., where it is overlain by Oneida cgl., the Pulaski being absent. From Mohawk Valley it extends N. and W. into Lewis and Jefferson Counties, where it forms basal part of Lorraine of Emmons. Indian Ladder beds is a local fm.=in age to Frankfort sh.

R. Ruedemann, 1925 (N. Y. State Mus. Bull. 258), restricted Frankfort sh. to Utica Basin and to 500+ ft. of rocks older than Indian Ladder beds. He showed Frankfort as thus restricted is=his Atwater Creek and Deer Creek shales and some younger beds of the unit in Black River region to which he applied the name "Whetstone Gulf fm." His subdivisions of Lorraine group are Upper Lorraine or Pulaski fm. and Lower Lorraine or Whetstone Gulf fm. [new name], the latter=Indian Ladder beds and Frankfort sh. "The Frankfort is a local shore facies of the lower Whetstone Gulf horizons."

†Franklin type.

Pre-Cambrian: Northern New Jersey.

F. L. Nason, 1889 (N. J. Geol. Surv. Ann. Rept. 1889, p. 31). *Franklin type.*—Occurs at Franklin Furnace in ledges btw. hotel and Mine Hill. Not correlated with fms. of Smock and Britton. Is probably mentioned as a biotite gneiss. At Franklin Furnace is intimately associated with Montville type.

Is a facies of Pickering gneiss, formerly considered to be of Archean age, but now classified simply as *pre-Camb.*, "Archean system" having been abandoned.

Franklin limestone.

Pre-Cambrian: Western New Jersey, eastern Pennsylvania, and Delaware.

J. E. Wolff and A. H. Brooks, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, pp. 431–456). *Franklin white ls.*—Coarsely crystalline rock, frequently containing graphite in disseminated scales. Is typically white, but often has a bluish tinge. Is pre-Camb., and older than Hardistonville [Hardyston] qtzite. [Named for occurrence at Franklin Furnace, N. J.]

A. C. Spencer, 1908 (U. S. G. S. Franklin Furnace folio, No. 161). *Franklin ls.*—White, highly crystalline ls. or marble, varying greatly from place to place in texture and composition, and to less degree in color. As a rule coarsely granular, but some of rock is finely granular or even nearly amorphous. Color usually milky white, but locally it has a pink or yellow tinge and elsewhere it is grayish. Some of it is rather siliceous, and in a few places thin beds of ss. have been noted. Uncon. underlies Hardyston qtzite and Kittatinny ls. Although Pochuck gneiss and Franklin ls. are regarded as older than Byram and Losee gneisses, which appear to cut them, the original relations btw. them are not determinable. In Franklin Furnace area the Pochuck gneiss passes beneath Franklin ls.

The name *Franklin ls.* is now restricted to the white ls. to which it was originally applied. The associated siliceous rocks (formerly in large part included in Pochuck gneiss) are now regarded as older than Franklin ls. and are by definition included in Pickering gneiss, although in places some siliceous rocks are so intimately associated with the ls. that they are not readily separable from it and for convenience are mapped with the ls. The Franklin ls. was formerly classified by U. S. Geol. Survey as Archean, but, that term having been discarded, the fm. is now classified as pre-Camb.

Franklin limestone. (In Washington formation.)

Permian: Southwestern Pennsylvania (Greene County).

J. J. Stevenson, 1907 (Geol. Soc. Am. Bull., vol. 18, pp. 97, 102). *Franklin ls.*—Coarsely brecciated and very hard. Rarely more than 6 ft. thick and often much less. Lies 20 to 35 ft. below Upper Washington ls. and 25 to 40 ft. higher than Jollytown coal. Its characteristic fragments were found in Franklin and Amwell Twps very close to its proper position.

Franklin sandstone.

Eocene: Western Washington (Puget Sound region).

See under *Franklin series.*

Franklin series. (In Puget group.)

Eocene: Western Washington (Puget Sound region).

G. W. Evans, 1912 (Wash. Geol. Surv. Bull. 3, pp. 42–49). *Franklin series.*—Middle div. of Puget fm. in King Co. Chiefly sss. and shales, with 27 coal and bony beds. Basal 210 ft. (massive close-grained ss.) is called *Franklin ss.* It forms div. line btw. Franklin series and underlying Bayne series. Thickness of Franklin series 3,620 ft. Underlies Kummer series. [Apparently named for town in King Co.]

Franklin group.

Carboniferous: British Columbia.

C. W. Drysdale, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 135), and 1915 (Canada Geol. Surv. Mem. 56, p. 48).

Franklin granodiorite.

Jurassic: British Columbia.

C. W. Drysdale, 1915 (Canada Geol. Surv. Mem. 56, p. 61).

Franklin monzonite.

Oligocene: British Columbia.

C. W. Drysdale, 1915 (Canada Geol. Surv. Mem. 56, p. 77).

Franklindale limestone lentil (of Chemung formation).

Upper Devonian: Central northern Pennsylvania (Bradford County).

H. S. Williams and E. M. Kindle, 1905 (U. S. G. S. Bull. 244). *Franklindale ls. memb. of Chemung fm.*—A belt of ls. bands associated with purple shales and sss. in upper part of section, comprising zones 58 to 75. Is a constant feature over most of W. half of Bradford Co. Replaces Burlington ls. of Sherwood (2d Pa. Geol. Surv. Rept. G, p. 37), which is preoccupied. Exposed in Gulf Brook section, W. of Franklindale, Bradford Co.

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 571–592). Franklindale ls. of Williams and Kindle is older than "Burlington ls." of Sherwood, and is lithologically different. Writer therefore replaces "Burlington ls." of Sherwood with *Luthers Mills coquinite.* [See also under *Luthers Mills coquinite.*]

Franklin Furnace band.

Name applied by A. C. Spencer, 1908 (U. S. G. S. Franklin Furnace folio, No. 161), to a part of Pochuck gneiss, which is well exposed in zinc mines at Franklin Furnace and at other places in the vicinity.

Franklin Mountain formation.

Silurian: Mackenzie.

M. Y. Williams, 1923 (Canada Geol. Surv. Summ. Rept. 1922, pt. B, p. 78).

†Franks conglomerate.

Pennsylvanian: Central southern Oklahoma.

J. A. Taff, 1903 (U. S. G. S. Tishomingo folio, No. 98). *Franks cgl.*—Coarse ls. and chert cgls., gritty ss., ls., and sh., 200 to 500 ft. thick. Probably represents upper portion of Glenn fm. Lies uncon. on all older Paleozoic rocks. Is youngest Carbf. fm. present in quad. A broad belt of this cgl. extends across NW. part of Arbuckle region from W. end of Arbuckle Mtns to vicinity of Franks. From NW. corner of Tishomingo quad. northeastward it crosses eroded edges of Ord., Upper Sil., and Dev. fms. From a nearly flat position on Hunton ls. near Franks it extends SE. uncon. across Woodford chert and Caney sh. Occupies approx. strat. position of Wapanucka ls.

B. F. Wallis, 1915 (Okla. Geol. Surv. Bull. 23, pp. 23–31). *Franks cgl.*—A coarse ls. cgl., 0 to 500 ft. thick. Covers broad area to N. of Arbuckle Mtns. To SE. of Franks it thins rapidly and changes from heavy cgl. to thin ls., ss., and sh. Two mi. S. of Jesse it can not be distinguished from underlying Caney sh., on which it rests uncon., or from overlying Atoka fm. A short distance E. of Jesse the Wapanucka ls. occupies approx. same position as Franks cgl.

K. F. Mather, 1917 (Am. Jour. Sci., 4th, vol. 43, pp. 134–139). *Franks cgl.* is probably near-shore equiv. of Wapanucka, Atoka, and possibly even higher strata. It overlaps Caney sh. and rests on early Paleozoic strata to SW.

R. C. Moore, 1921 (Geol. Soc. Am. Bull., vol. 32, p. 48). *Franks cgl.* contains an upper Penn. fauna in interbedded lss. It has been traced northward and found= Seminole cgl.

G. E. Burton, 1921 (A. A. P. G. Bull., vol. 5, p. 176). During summer of 1919 E. H. Bauman traced *Franks cgl.* at Sulphur northward into Seminole cgl. at Ada.

G. D. Morgan, 1923 (Okla. Geol. Surv. Circ. 12). *Franks cgl.* is=Boggy, Savanna, and McAlester fms. Suggest name be abandoned. But in view of long use of term it will probably be more satisfactory to retain it, with restrictions that have not heretofore been applied to it. It is writer's opinion the Franks should be restricted to (1) the Penn. strata occurring near town of Franks and (2) to those exposures of ls. cgls. and their immediately associated strata which occur in Arbuckle area and which, in common with the strata at Franks, have the 3 characteristics of being (a) fossiliferous, (b) highly folded or faulted, or both highly folded and faulted, and (c) nonarkosic. The Franks represents shoreward phase of McAlester, Savanna, Boggy, and possibly younger fms. In no way is it=Wapanucka ls.

S. Weidman, 1923 (Jour. Geol., vol. 31, No. 6, pp. 466+). Prefer *Franks series* (instead of *Franks cgl.*), since at least as many as 5 distinct cgl. beds can be distinguished at Franks and at other places on N. side of Arbuckle Mtns. The beds of cgl. are each 100 to 350 ft. thick, interstratified with ls., sh., and ss. There are places where thicknesses may reach 1,000 ft. or more. Such great thicknesses of cgl., it is believed, are rarely if ever formed upon shores of ancient or present seas under ordinary conditions. [Discusses probability they are of glacial origin.] The lowest cgl. bed is 150± ft. thick, and overlies eroded edges of pre-Penn. rocks at Franks and vicinity.

G. D. Morgan, 1924 (Okla. Bur. Geol. Bull. 2, pp. 119–123). *Franks cgl.*—In vicinity of town of Franks (type loc.) conglomeratic strata are exposed through a section of approx. 1,500 ft. Many beds are fossiliferous and all are nonarkosic and highly folded and locally faulted. They were followed eastward and traced into McAlester, Savanna, and Boggy fms. The Wapanucka ls. was found to emerge from beneath the cgls. at a point 2± mi. SE. of town of Franks. The lower part of typical Franks cgl. is=parts of McAlester, Savanna, and Boggy fms., and upper part correlates with parts of Wewoka, Holdenville, Seminole, and Francis fms. It is advisable to abandon Franks cgl. and refer to the conglomeratic strata of Franks area by the names of the several fms. which the section there is known to include. If Franks is retained it should be restricted to the strata in type area, around Franks, and to those Penn. ls. cgls. of Arbuckle region that are (a) fossiliferous, (b) highly folded or faulted, and (c) nonarkosic. The cgls. near Sulphur, which have in some previous repts been mistaken for Franks cgl., are traceable into outcrops of the arkosic Vanoss fm., a much younger fm.

C. N. Gould, 1927 (Obsolete Okla. names: Univ. Okla. Bull., Proc. Okla. Acad. Sci., vol. 6, pt. 2, p. 235). *Franks cgl.* has been shown by Morgan to consist not of a single geologic horizon, but to represent the shoreward phase of McAlester, Savanna, Boggy, and possibly younger fms. However, the term "Franks" will probably continue to be used, to apply in a general way to the various cgls. of Arbuckle Mtn region.

Named for exposures in vicinity of Franks, Pontotoc Co.

Fraser River formation.

Cretaceous: British Columbia.

L. Reinecke, 1920 (Canada Geol. Surv. Mem. 118, p. 13).

Freda sandstone. (In Oronto group.)

Pre-Cambrian (upper Keweenawan): Northern Michigan and northern Wisconsin.

A. C. Lane and A. E. Seaman, 1907 (Jour. Geol., vol. 15, pp. 680, 692). *Freda ss.*—Red ss. with some felsitic and basic debris and salt water. Thickness 900+(?) ft. Composes lower part of Lake Superior ss. of earlier repts, or the part of that ss. W. of the Copper Range. Overlies Outer cgl. [Is shown in section as underlying Jacobsville ss. See quotation under Jacobsville ss. In his 1911 rept.

(Mich. Geol. and Biol. Surv. Pub. 6, geol. ser. 4, p. 41) Lane expressed opinion that Freda and Jacobsville sss. are same fm.]

See under *Oronto group.*

Named for exposures at new stamp mills at Freda, Houghton Co., and along adjacent shore.

Frederick limestone.

Upper Cambrian: Central northern Maryland.

C. R. Keyes, 1890 (Johns Hopkins Univ. Circ. 84, vol. 10, p. 32). *Frederick ls.*—Has geographic extent of nearly 100 sq. mi. Greatest length perhaps 30 mi.; max. breadth, near Frederick City, 6 mi. Along W. border Frederick Valley lss. are covered by Mesozoic red sss. ("Newark fm." of Russell). To E. the lss. pass gradually into shales and slates, the whole forming apparently a conformable series. The lss. are in great part bluish, compact, and heavily bedded, but on approaching the shales they become more and more thinly bedded and very dark blue or nearly black, owing to bituminous matter present. In places the rock is highly siliceous. From the thin-bedded belt the ls. passes into a more earthy facies and grades into dark-colored calc. shales and these into slates or sandy shales. The shales and lss. form a continuous series and probably represent a fm.=Chazy, Trenton, and Hudson River groups of N. Y. section, according to Chazy-Trenton fossils recently obtained in Frederick Valley lss.

G. H. Williams, 1891 (Geol. Soc. Am. Bull., vol. 2, pl. 12, pp. 303, 311, 317). *Frederick ls.* [mapped]. Overlain by Triassic ss. and trap. We now know *Frederick Valley ls.* to be of same age (Trenton-Chazy) as the valley ls. of Va., from Chazy-Trenton fossils obtained from it by C. R. Keyes. It is oldest fm. of Piedmont plateau of Md. To E. the Frederick ls. is succeeded and apparently overlain by carbonaceous and hardly altered shales, which may represent Hudson River horizon.

R. S. Bassler, 1919 (Md. Geol. Surv. Camb. and Ord. vol., pp. 115–117 and map). *Frederick ls.* is new name proposed for the strata in Frederick Valley uncon. overlying Beekmantown ls. and containing a fauna probably of Chazyan age. The rocks are shown to advantage in numerous quarries and natural outcrops around Frederick. Fossils rare, but suggest a Chazyan or early Mohawkian age, with possibility more in favor of the former. The Frederick ls. consists of thin-bedded dark-blue argill. strata separating into layers usually less than 2 in. thick. Thickness seems to be not less than 200 ft. On W. side of valley it is covered by Newark series; on E. side it is faulted against pre-Camb. shales and slates.

A. I. Jonas, 1927 (Geol. Soc. Am. Bull. vol. 38, p. 119), stated Frederick ls. is of upper Chazyan age.

G. W. Stose and A. I. Jonas, 1935 (Wash. Acad. Sci. Jour., vol. 25, No. 12, p. 565). On E. and W. sides of Frederick Valley the *Frederick ls.* lies uncon. on Antietam qtzite. East of Le Gore quarry [Frederick Co.] it lies on Le Gore ls. [Upper Camb.].

G. W. Stose and A. I. Jonas obtained additional fossil collections which were pronounced Upper Camb. by several paleontologists, and age was changed to Upper Camb. Jan. 1936. They found †Le Gore ls. to be same as Grove ls. (Lower Ord., lower Beekmantown).

Fredericksburg group.

Lower Cretaceous (Comanche series): Texas and southern Oklahoma.

R. T. Hill, 1887 (Am. Jour. Sci., 3d, vol. 33, pp. 296–299). *Lower or Fredericksburg div. (Comanche Peak) of Comanche series or Lower Cret.*—Lss., with some flints and chalk. Overlies Dinosaur sand [Trinity group] and underlies Washita div. Includes: *Ammonites acutocarinatus* horizon; *Hippurites* ls. (="Caprina ls."); Comanche Peak fauna (="Fredericksburg" of Roemer); *Gryphaea pitcheri* (="Comanche Peak group"); and *Requienia texana* (="Caprotina ls.").

R. T. Hill, Oct. 1887 (Am. Jour. Sci., 3d, vol. 34, p. 303), placed provisional bdy line btw. Washita and Fredericksburg groups at top of "Caprina" [Edwards] ls.

R. T. Hill, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. 105–136), divided Fredericksburg into (descending) Caprina chalky lss., Comanche Peak chalk beds, and Basal or Alternating beds, the latter including 1st *Caprotina* horizon.

R. T. Hill, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 503–528). *Fredericksburg or Comanche Peak div.* includes Caprina ls. [Edwards ls.]; Comanche Peak chalk;

Gryphaea rock and Walnut clays or *Exogyra texana* beds; and, tentatively, Paluxy sands. Overlies Trinity div. (which includes Glen Rose or Alternating beds, above, and Trinity or Basal sands) and underlies Kiamitia clays.

J. A. Taff, 1892 (Tex. Geol. Surv., 3d Ann. Rept., pp. 269–279, 327, etc.) included Kiamichi clay in Fredericksburg, at top, and Walnut clay at base, and excluded Paluxy sand. Taff in 1893 (Tex. Geol. Surv., 4th Ann Rept.) included Kiamichi in Fredericksburg and excluded Paluxy.

R. T. Hill, 1894 (Geol. Soc. Am. Bull., vol. 5, pl. 13, pp. 317–319), divided *Fredericksburg group* into Caprina ls., Comanche Peak chalk, and Walnut clays, and included Kiamichi clay in Washita group and Paluxy sand in Trinity group. Hill also followed this classification in 1901 (U. S. G. S. 21st Ann. Rept., pt. 7), as did Udden, Baker, and Böse in 1916 (Univ. Tex. Bull. 44, pp. 59–77); Adkins, 1920 (Univ. Tex. Bull. 1856, p. 10); and Dumble, 1920 (Univ. Tex. Bull. 1869).

W. M. Winton, 1925 (Univ. Tex. Bull. 2544), included Kiamichi in Fredericksburg and treated it as "final phase of the Goodland." G. Scott, 1926 (Am. Jour. Sci., 5th, vol. 12, pp. 157–161) excluded Kiamichi from Washita group.

H. P. Bybee and F. M. Bullard, 1927 (Univ. Tex. Bull. 2710, p. 21), excluded Kiamichi from Fredericksburg, as did Bullard, 1928 (Okla. Geol. Surv. Bull. 47, pp. 13–15).

C. I. Alexander, 1929 (Univ. Tex. Bull. 2907) included Kiamichi in Fredericksburg but excluded it from Goodland.

J. S. Redfield, 1929 (Univ. Okla. Bull., vol. 9, pp. 76–77), included Kiamichi in Washita group, as did Bullard and Redfield, 1930 (Okla. Geol. Surv. Bull. 40–OO).

R. H. Cuyler, 1929 (A. A. P. G. Bull., vol. 13, pp. 1292–1299). Kiamichi fm., heretofore considered to belong to Washita group, is now considered, because of its characteristic Fredericksburg fauna, as a transitional fm. btw. the two groups.

J. M. Armstrong and G. Scott, 1930 (geol. map of Wise Co., Tex. dated March 1930), included Kiamichi in Washita group; but on June 1930 geol. map of Parker Co., Tex., they included Kiamichi in Fredericksburg group.

W. S. Adkins, 1933 (Univ. Tex. Bull. 3232), included Kiamichi in Fredericksburg group. *He stated (p. 323): There is some evidence of an uncon. at top of* Kiamichi over parts of Okla. and Kans. Also (p. 339): From Fort Worth to S. of Waco the Edwards is overlain, apparently uncon., by Kiamichi clay. South of Waco the Kiamichi is absent. Also (p. 344): The Kiamichi is very close in age to upper Edwards, differing largely in presence of *Gryphaea navia* and a few other zone fossils. [On pp. 325–326 he discussed fossils.]

S. A. Thompson, 1935 (A. A. P. G. Bull. vol. 19, No. 10, p. 1536), included Kiamichi in Fredericksburg group; proposed the new name *Gatesville fm.* to include Edwards and Comanche Peak lss. and Walnut clay, which he proposed be reduced to rank of members; and recommended abandonment of Goodland ls. He stated the Edwards, Comanche Peak, and Walnut are in part contemp. with one another, and that they contain essentially same fauna. Also that there is uncon. at top of Kiamichi. [This is a disputed point.]

W. C. Mendenhall, 1935 (p. 1537 of book last cited above), questioned advisability of new name *Gatesville fm.* and of abandoning Goodland ls., and stated that assignment of Kiamichi to Fredericksburg group is still considered a debatable question by some geologists.

The U. S. Geol. Survey at present divides Fredericksburg group into Edwards ls., Comanche Peak ls., and Walnut clay.

Named for Fredericksburg, Gillespie Co., Tex.

Fredericksburg gneiss.

Pre-Cambrian: Northeastern Virginia.

J. T. Lonsdale, 1927 (Va. Geol. Surv. Bull. 30). ***Fredericksburg gneiss.***—Largely a granite gneiss, foliated, banded, coarse grained; in general the light bands are wider than the dark. Embraced in area extending as far as 8 mi. SW. and 8 mi. NW. of Fredericksburg. Best exposed in quarries NW. of Fredericksburg.

A. I. Jonas, 1928 (Va. Geol. Surv prel. ed. of geol. map of Va.), mapped the gneiss around Fredericksburg as ***Baltimore (?) gneiss.***

Fredericksburg granite.

Pre-Cambrian: Northeastern Virginia.

J. T. Lonsdale, 1927 (Va. Geol. Surv. Bull. 30). ***Fredericksburg granite (quartz monzonite).***—Has been quarried to considerable extent near Fredericksburg. Best exposed along Rappahannock River in both Stafford and Spotsylvania Counties. It intruded the Fredericksburg granite gneiss [Baltimore (?) gneiss of 1928 Va. map], from which it cannot be separated.

†Fredericksburg sandstone.

A name loosely applied in some early repts (see W. B. Rogers, Phila. Acad. Nat. Sci. Proc., vol. 1, p. 142, 1842) to the ss. around Fredericksburg, Va., which is in part the Patuxent fm. (Lower Cret.). (See U. S. G. S. Patuxent folio, No. 204, 1917, p. 5.)

Fredericksburg freestone.

Trade term for ss. quarried from Potomac group in vicinity of Fredericksburg, Va. See under †*Rappahannock series.*

†Fredericktown dolomite.

Upper Cambrian: Southeastern Missouri.

C. R. Keyes, 1895 (Mo. Geol. Surv. Sheet Rept. No. 4 (vol. 9), pp. 18, 19, 48). *Fredericktown dol.*—Non-cherty mag. ls. 275 ft. thick; lower 75 ft. chiefly hard grayish ls. with some sandy material and shaly layers; upper 200 ft. buff dol. tolerably free from siliceous matter. Underlies Le Sueur dol. and overlies La Motte ss. in Mine La Motte and neighboring districts, Mo.

H. F. Bain and E. O. Ulrich, 1905 (U. S. G. S. Bull. 260, p. 234, and Bull. 267, p. 12). *Fredericktown ls.*=Bonne Terre ls. [Same statement by G. H. Scherer, 1905 (Bradley Geol. Field Sta. Drury Coll. Bull., vol. 1, pt. 2, p. 67).]

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, p. 254). *Fredericktown ls.,* 200 ft. thick, underlies Le Sueur dol. and overlies La Motte ss.

These rocks are now divided into Elvins group and Bonneterre dol.

Named for exposures at Fredericktown, Madison Co.

†Frederick Valley limestone.

See under *Frederick ls.*

Fredonia oolite member (of Ste. Genevieve limestone).

Mississippian: Western Kentucky and Tennessee, southeastern Missouri, and southern Illinois and Indiana.

E. O. Ulrich and W. S. T. Smith, 1905 (U. S. G. S. P. P. 36, pp. 24, 40). *Fredonia ls.*—White oolitic ls. interbedded with blue oolite, thin bands of subcrystalline and crinoidal lss., and seams of green clay sh. and fine-grained argill. ls. Thickness probably 150 ft. Basal memb. of Ste. Genevieve ls. Underlies Rosiclare ss. memb. of Ste. Genevieve and overlies, probably uncon., St. Louis ls.

The beds consisting chiefly of oolite and oolitic ls. the name has been changed to *Fredonia oolite memb.*

Named for Fredonia, Caldwell Co., Ky.

Freedom dolomite.

Pre-Cambrian (middle? Huronian): Central southern Wisconsin (Sauk County).

S. Weidman, 1904 (Wis. Geol. Nat. Hist. Surv. Bull. 13, p. 51). *Freedom fm.*—Upper part, dol. 500 ft. thick; lower part, iron ore, ferruginous slates, ferruginous dol., and ferruginous chert, 450 to 500 ft. thick. Appears to grade into underlying Seeley sl. and to lie uncon. below [so-called] Potsdam ss. Does not outcrop. Found only by exploration SW. of North Freedom. Is known to cover 5 or 6 sq. mi. in secs. 2, 3, 9, 10, 11, 15, 16, 17, and 20 of town of Freedom. Assigned to pre-Camb.

C. R. Van Hise and C. K. Leith, 1909 (U. S. G. S. Bull. 360, p. 720), indicated Freedom dol. may be middle Huronian.

Freeman.

See *Lower Freeman sand.* (Archer Co., Tex.)

Freeport coal group. (In Allegheny formation.)

Pennsylvanian: Western Pennsylvania and Maryland, northern West Virginia, and eastern Ohio.

H. D. Rogers, 1858 (Geol. Pa., vol. 2, pt. 1, pp. 474–492). *Freeport group,* 100 to 250 ft. thick, underlies *Mahoning massive bed of ss.* and overlies *Freeport or contorted ss.* Includes Upper Freeport coal, Freeport ls., and Lower Freeport coal.

J. P. Lesley, 1877 (2d Pa. Geol. Surv. Rept. H_3, p. xxiii). Lower Productive Coal Measures [Allegheny fm.] divided into (descending) *Freeport coal group*, Kittanning coal group, and Clarion coal group.

I. C. White, also J. P. Lesley, 1878 (2d Pa. Geol. Surv. Rept. Q). *Freeport group* extends from top of Upper Freeport coal to top of Upper Kittanning coal.

G. H. Ashley, 1926 (Pa. Topog. and Geol. Atlas No. 65, Punxsutawney quad., pl. 4, p. 28). *Freeport fm.* extends from top of Upper Freeport coal to top of Upper Kittanning coal.

Freeport coal group is treated by U. S. Geol. Survey as an economic memb. in upper part of Allegheny fm., extending from top of Upper Freeport coal down to top of Upper Kittanning coal.

†Freeport limestone member (of Allegheny formation).

Pennsylvanian: Western Pennsylvania and Maryland, northern West Virginia, and eastern Ohio.

H. D. Rogers, 1858 (Geol. Pa., vol. 2, pt. 1, p. 492). *Freeport ls.*, 4 to 7 ft. thick, in midst of Freeport group, being separated from overlying Upper Freeport coal by 1 to 10 ft. of fire clay and sh. and from underlying Lower Freeport coal by 30 to 40 ft. of sl. and slaty ss. [As thus defined the name appears to have been applied to *Upper Freeport ls.* of current nomenclature.]

F. Platt, 1875 (2d Pa. Geol. Surv. Rept. H, pp. 1–9). *Freeport ls.* lies btw. Middle Freeport coal and Lower Freeport coal.

I. C. White, 1876 (Lyc. Nat. Hist. Annals, vol. 11, pp. 14–18, also 2d Pa. Geol. Surv. Rept. K), applied *Freeport ls.* to 2 to 4 ft. of ls. separated from overlying Upper Freeport coal by 3 to 15 ft. of fire clay and sh. and from underlying Lower Freeport coal by 45 to 82 ft. of beds, including one unnamed coal.

J. J. Stevenson, 1876 (2d Pa. Geol. Surv. Rept. K), applied *Freeport ls.* to 0 to 4 ft. of ls. lying 5 to 15 ft. below Upper Freeport coal and 55 to 65 ft. above Lower Freeport coal.

F. Platt, 1877 (2d Pa. Geol. Surv. Rept. H_2, p. xxviii), applied *Freeport ls.* to a ls. btw. Upper and Middle Freeport coals, and applied *Middle Freeport ls.* to a ls. btw. Lower and Middle Freeport coals in Cambria Co., Pa., but with statement that so-called Middle Freeport coal would probably in future be called *Lower Freeport*, that so-called *Middle Freeport ls.* would be called *Lower Freeport ls.*, and that so-called Lower Freeport coal would be called *Kittanning coal.*

F. and W. G. Platt, 1877 (2d Pa. Geol. Surv. Rept. H_3, p. 316), changed *Freeport ls.* of previous repts to *Upper Freeport ls.*; *Middle Freeport ls.* to *Lower Freeport ls.*; *Middle Freeport coal* to *Lower Freeport coal*; and *Lower Freeport coal* to *Upper Kittanning coal.* These are names that have been in common use for many years.

Same as *Upper Freeport ls. memb.* of current nomenclature.

Freeport sandstone member (of Allegheny formation).

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

H. D. Rogers, 1858 (Geol. Pa., vol. 2, pt. 1, pp. 474–477). *Freeport or contorted ss.*—Massive ss., 15 to 60 ft. thick, underlying Lower Freeport coal and separated from Kittanning coal by 75 ft. of sh. and ss. [As thus defined the name applies to †Lower Freeport ss. of later repts.]

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q). *Freeport ss.* is same as *Lower Freeport ss.*

I. C. White, 1879 (2d Pa. Geol. Surv. Rept. Q_2). *Lower Freeport ss.* is same as *Freeport ss.* of earlier repts. It is present at Freeport [Armstrong Co.], Pa.

Freeport clay.

See *Upper Freeport clay* and *Lower Freeport clay.*

Freeport gravel.

Pleistocene: Northwestern Illinois.

O. H. Hershey, 1897 (Am. Geol., vol. 19, pp. 207–209). *Freeport gravel.*—Ancient river gravel occurring locally in Kansan drift 2 mi. E. of Freeport, Stephenson Co.

F. W. Sardeson also discussed this fm. in Am. Geol., vol. 20, 1897, pp. 400–401.

Freeport formation.

See under *Freeport coal group*, G. H. Ashley, 1926.

†Freezeout limestone.

Triassic (?): Central Wyoming (Freezeout Mountains).

F. B. Peck, 1904 (Wyo. Hist. and Geol. Soc. Proc. and Coll., vol. 8, pp. 28–41). The uppermost memb. of Triassic in Freezeout Mtns, Wyo., is bed of ls. 10± ft. thick, which for convenience we can term *Freezeout ls.* Overlies Triassic "Red Beds."

Same as Alcova ls. memb. of Chugwater fm., according to J. B. Reeside, Jr. This name appears to have been overlooked, as it is not listed in U. S. G. S. alphabetic list of geol. names in literature, and was only recently (1936) discovered by compiler of this lexicon.

Freezeout tongue (of Chugwater formation).

Permian: Southeastern Wyoming (Laramie Basin to Freezeout Hills).

H. D. Thomas, 1934 (A. A. P. G. Bull., vol. 18, No. 12, pp. 1664, 1670). *Freezeout tongue of Chugwater fm.*—Red sh. lying btw. Forelle ls. below and Little Medicine tongue of Dinwoody fm. above, and extending from Laramie Basin to Freezeout Hills. Upper part of this tongue of Chugwater extends laterally into lower part of Dinwoody fm., and rest of this tongue extends laterally into upper part of Phosphoria fm. This tongue contains a few beds of ls., breccia, and gyp., which may be tongues of the Phosphoria, but most of which are probably local lenticular beds. Thickness 110± ft. The Freezeout tongue by definition is limited to localities where the Forelle can be definitely recognized. At present Forelle has not been certainly identified except in Laramie Basin and N. into Freezeout Hills.

Fremont limestone.

Upper and Middle Ordovician: Eastern and central Colorado.

C. D. Walcott, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 154–167). *Fremont ls.*—At Canyon City consists of (descending): (1) Impure variegated banded ls. with interbedded sss. and argill. beds, 15 to 30 ft.; (2) compact, hard light-gray ls. breaking into angular fragments and with a band of purple and gray calcareo-aren. sh. at base, 45 ft.; (3) dark reddish-brown ss. parting, 10 ft.; (4) hard, compact, light-colored ls., 45 ft.; (5) gray siliceous mag. ls., somewhat ferruginous in lower part, 170 ft. Total thickness at Canyon City 285–300± ft. Rests on Harding ss. and is overlain by Carbf. ls.

According to E. Kirk, the Fremont ls. contains a Richmond (Upper Ord.) fauna in all but lower 10 ft.

Named for exposures in Fremont Co.

Fremont erosion cycle.

Pliocene: Central western Wyoming.

E. Blackwelder, 1915 (Jour. Geol., vol. 23, pp. 310–340). The oldest erosion cycle recognized in central western Wyo. Assigned to Plio. Named for fact that the principal remnants of Wind River Plateau can be overlooked from Fremont Peak.

French slate.

Pre-Cambrian: Southeastern Wyoming (Medicine Bow Mountains).

E. Blackwelder, 1926 (Geol. Soc. Am. Bull., vol. 37, pp. 620, 622, 645, 649). *French sl.*—Largely dark brown to blackish gray phyllites, with thin beds of qtzitic rocks and some laminae rich in magnetite and hematite. Thickness 2,000 ft. Overlies Towner greenstone, with probable conformity. Named for French Creek, the south fork of which runs along outcrop of the fm. for several mi. Considered of early Algonkian age.

French Bar formation.

Oligocene (?): British Columbia.

J. D. MacKenzie, 1921 (Canada Geol. Surv. Summ. Rept. 1920, pt. A, p. 76).

French Creek limestone member.

Mississippian: Northwestern Pennsylvania.

K. E. Caster, June 9, 1934 (Bulls. Am. Pal., vol. 21, No. 71, pp. 135–136). It is here proposed that *upper Meadville ls.* be known as *French Creek ls.*, from outcrops in ravines eroded by tributaries to French Creek, Crawford Co. Type section is ravine at "Glendale" Cemetery, in Meadville city. Thickness 1 to 2 ft. In early part of this rept this ls. was called *Conneaut ls.*, but Conneaut is withdrawn as name for the ls., at request of G. H. Chadwick, who desires to apply "Conneaut" to a different unit in same region. [Table opp. p. 61 shows this ls. as overlain by Custards sh. memb. (=upper Meadville sh. of early repts) and underlain by Harvest Home sh. memb., all included in his Meadville stage (Meadville monothem).]

French Creek shale. (In Wabaunsee group.)

Pennsylvanian: Northeastern Kansas and southeastern Nebraska.

R. C. Moore, May 1, 1935 (Kans. Geol. Surv. Bull. 20, table opp. p. 14). *French Creek sh.* underlies Caneyville ls. and overlies Jim Creek ls.

G. E. Condra, late in 1935 (Nebr. Geol. Surv. Paper No. 8, pp. 9–10). *French Creek sh.*, about 7 mi. S. of Humboldt [SE. Nebr.?], 16 ft. Divided into (descending): Gray sandy sh., 2 ft.; Lorton coal, 2 to 4 inches; dull-gray argill. laminated sh., 6+ ft.; dull-gray irregular impure ls., grading laterally into ss., 10 inches; ss. or sh., gray green, bedded locally with plant remains, 6 ft. Underlies Nebraska City ls. and overlies Jim Creek ls.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 49, 240). *French Creek sh.* overlies Jim Creek and underlies Caneyville ls. It is bluish gray or yellowish brown, clayey to sandy; some light-brownish or tan ss. in upper part; Lorton coal near top. Av. thickness 30± ft. Is recognized across all of Kans. Type loc., French Creek, NE. part of Pottawatomie Co., Kans.

French Lick stone. (In Chester group.)

Mississippian: Southwestern Indiana (Orange County).

E. T. Cox, 1871 (Ind. Geol. Surv. 2d Ann. Rept., p. 81). Fine-grained reddish brown gritstone extensively quarried into grindstones and whetstones. Known on market as *French Lick stone.* Supposed to be same as Hindostan stone. [E. M. Kindle, 1896, has shown that French Lick stone is upper ss. of Chester group, while Hindostan stone is Penn. and a part of Mansfield ss.]

Named for French Lick Springs, Orange Co.

French Pond granite.

Late Devonian or late Carboniferous: Northwestern New Hampshire (Moosilauke quadrangle).

M. P. Billings, 1935 (Geology of Littleton and Moosilauke quads., N. H., Moosilauke map, pp. 28, 36). *French Pond granite.*—Heterogeneous body of granite with 3 phases. Is late Dev. or late Carbf. Assigned to New Hampshire magma series. Occurs just W. of French Pond.

Frenchtown diorite.

Age (?): Northeastern Maryland.

G. P. Grimsley, 1894 (Cincinnati Soc. Nat. Hist., Jour., vol. 17). Gabbro diorite near Frenchtown, Cecil Co. Described under heading *Frenchtown diorite.*

Frenck shale.

Pennsylvanian: Northeastern Kansas and southeastern Nebraska.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3, pp. 94, 96). [See under *Dover ls.*, Moore 1932 entry. On p. 58 thickness is given as 21 ft.]

R. C. Moore and G. E. Condra, 1932 (Oct. 1932 revised chart), transposed *Frenck sh.* and *Table Creek sh.* [restricted] by applying *Frenck* to sh. *overlying* Dover ls. and *Table Creek* to sh. underlying Dover ls. [Derivation of name not stated.]

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 10), called the sh. overlying Dover ls. the *Friedrich-Dry sh.* and the sh. underlying Dover ls. the *Table Creek sh.* and did not use *Frenck sh.* See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 238, 240). *Frenck sh.* (derived from erroneous spelling of French Creek on maps) was applied to beds btw. Dover ls. below and Jim Creek (Nebraska City) ls. above, and is abandoned. French Creek sh. comprises upper part of what was termed "Frenck sh." in 1932 Guide Book.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Fresh Pond moraine.

Name applied by J. B. Woodworth to the glacial ridge forming the highest land in Cambridge, Mass.

Friar's Hill series.

Age (?): West Indies.

J. W. W. Spencer, 1901 (London Geol. Soc. Quart. Jour., vol. 57, p. 498).

Friar's Hill gravels and marls.

Pleistocene: Antigua.

A. P. Brown, 1914 (Phila. Acad. Nat. Sci. Proc., vol. 65, p. 605).

†Frickham bed.

U. S. G. S. Bull. 191, p. 167. (Error for *Trickham bed.*)

Friedrich shale. (In Wabaunsee group.)

Pennsylvanian: Eastern Kansas and southeastern Nebraska.

R. C. Moore, May 1, 1935 (Kans. Geol. Surv. Bull. 20, table opp. p. 14). *Friedrich sh.* underlies Jim Creek ls. and overlies Grandhaven ls.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 49, 238). *Friedrich sh.* is here proposed to include clayey and sandy beds that overlie Grandhaven ls. and underlie Jim Creek ls. The unweathered sh. is chiefly bluish gray, but it commonly weathers yellowish or brownish. Locally there is ss. in upper part, and in S. part of Greenwood Co. a thin coal bed near top. Av. thickness 15± ft. Type loc., Friedrich Creek, sec. 6, T. 22 S., R. 11 E., Greenwood Co., Kans.

Friendsville black shale. (In Conemaugh formation.)

Pennsylvanian: Western Maryland (Allegany and Garrett Counties).

C. K. Swartz, W. A. Price, and H. Bassler, 1919 (Geol. Soc. Am. Bull., vol. 30, p. 574). *Friendsville black sh.*—Marine fauna (Cambridge?). Underlies Albright ls. and overlies Thomas coal; all included in Conemaugh fm.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, p. 60, pl. 7). Thomas ss. is found above Thomas coal at places in Upper Potomac Basin, replacing Friendsville sh. [On pp. 95, 98, 100 he says Friendsville sh. is same as Cambridge black sh.]

Probably named for occurrence at Friendsville, Garrett Co.

Friendsville formation.

Pennsylvanian: Indiana.

See 1935 entry under *St. Wendell ss.*

†Frijole limestone member (of Delaware Mountain formation).

Permian: Western Texas (Guadalupe and Delaware Mountains).

W. G. Blanchard, Jr., and M. J. Davis, 1929 (A. A. P. G. Bull., vol. 13, pp. 973, 987). Delaware Mtn fm. in Guadalupe Mtns is capped by a dark shaly ls. that will be designated in this paper as *Frijole ls.* This memb. is extremely persistent and is recognizable in well cuttings as far E. as western Winkler Co. Below Frijole ls., deep in underlying Delaware Mtn ss., other ls. members are present that lithologically are practically indistinguishable from Frijole ls. [Authors showed (p. 988) that typical Delaware Mtn fm. of Delaware Mtns included in its upper part the equiv. of Capitan ls., and that Frijole ls. was its top bed. This interpretation of position of Frijole ls. is also that of R. E. King, 1931 (Univ. Tex. Bull. 3042, pp. 11-13) and E. H. Sellards, 1933 (Tex. Univ. Bull. 3232, pp. 159-160, 181).]

Although the 1929 publication cited is first known appearance of *Frijole ls.* in print, the name had for 2 or 3 yrs previously been in common use among geologists working in the region.

Named for exposures at Frijole P. O., Culberson Co.

This name is now replaced by *Lamar ls. memb.*, it having been found that the ls. at Frijole P. O. is not top memb. of Delaware Mtn fm., but an older ls. See W. B. Lang, 1937 (A. A. P. G. Bull., vol. 21, No. 7).

Frijole shale.

Permian: Western Texas (Loving County).

J. E. Adams, 1936 (A. A. P. G. Bull., vol. 20, No. 6, p. 785). *"Frijole" sh.* is locally misapplied to the black sh. encountered in wells at top of Delaware Mtn section. Because of lack of suitable name *Frijole* is used in this incorrect sense throughout present paper. This sh. is upper thin dark clastic memb. of Delaware Mtn group. Cores show the fm. consists of 3 members: (1) The upper 23 ft. is hard, dense black silt or silty sh.; (2) the next 7 ft. is hard, fine-grained, thinly laminated ss.; (3) a 1-ft. bed of dense, hard black sh. The fm. is extensively shattered in some local areas and many cracks are filled with veins of coarsely crystalline white calcite.

Frio clay.

Tertiary (Oligocene?): Eastern Texas.

E. T. Dumble, 1894 (Jour. Geol., vol. 2, p. 554). *Frio clays.*—Dark-colored (greenish gray, red, and blue), usually massive, gypseous clays, with laminated and bedded sandy clays, sand, and sand rock. Overlies Fayette sands (which rest on Yegua clays), and underlies Oakville (Mio.). Included in Eocene. Typically exposed btw. Weedy Creek and Oakville, on Atascosa and Frio Rivers, and on the Nueces S. of Tilden.

E. T. Dumble, 1903 (Am. Inst. Mg. Engrs. Trans., vol. 33, pp. 913–987). *Frio clays* overlie Fayette sands and underlie Oakville beds (Mio.). Top fm. of Lower Claiborne stage of Eocene.

E. T. Dumble, 1911 (Tex. Acad. Sci., vol. 11, pp. 50–51). *Frio* overlies Fayette and underlies Corrigan beds. Is top subdivision of Claiborne stage. [The †Corrigan beds are now called *Catahoula tuff*.]

E. T. Dumble, 1915 (Jour. Geol., vol. 23, pp. 481–498). *Frio clays* overlie Fayette and uncon. underlie Jackson [so called]. Not recognized E. of Colorado River in Tex. All fossils are characteristic of Lower Claiborne.

J. A. Udden, C. L. Baker, and E. Böse, 1916 (Univ. Tex. Bull. 44, pp. 81, 86–87). The *Frio* is a fm. of yellow and dark clays which weather white and are accompanied by gyp. Contains few marine fossils. Total thickness 660± ft. Thins to NE. and is not found E. of the Colorado and perhaps not E. of San Antonio River. In LaSalle and McMullen Counties it consists of greenish and pinkish red, compact, jointed clay that has small lime nodules and concretions of siliceous ls. Lower part consists of fossiliferous brown marl. Along Rio Grande it consists of gray and green gypseous clays, with sands. The clays often weather white and contain leaf impressions and ferruginous and calc. concretions. Outcrops in Karnes, Live Oak, McMullen, Duval, Webb, Zapata, and Starr Counties. Belongs to lower Claiborne, but some geologists consider Fayette and Frio as Jackson. Frio overlies Fayette and underlies Corrigan or Catahoula and also underlies Oakville Miocene.

E. T. Dumble, 1920 (Univ. Tex. Bull. 1869). Of the few marine fossils found by us in *Frio clays* there were none characteristic of beds later than Lower Claiborne, and it was accordingly referred to that group. There is a possibility, however, that further collections may show that it belongs to Upper rather than Middle Eocene.

A. C. Trowbridge, 1923 (U. S. G. S. P. P. 131D). *Frio clay,* 100 to 400 ft. thick, overlies Fayette ss. and underlies Oakville ss. The Frio and Fayette are both of Jackson age.

T. L. Bailey, 1923 (Univ. Tex. Bull. 2333). *Frio fm.* (*Jackson*) in Colorado Co. consists, in wells, of black noncalc. gray, green, and pink, often bentonitic clay, with some beds of tuff and lignite. Dark-colored beds contain marine fossils. Shows an apparent alternation btw. fresh and salt water conditions, and may be partly if not largely of river-delta origin. Thickness 648 ft. Overlies Fayette (Jackson) and uncon. underlies Corrigan fm. (=Catahoula ss.).

A. Deussen, 1924 (U. S. G. S. P. P. 126). *Frio clay,* 235 to 705 ft. thick, underlies Catahoula ss. and overlies Fayette ss. Assigned to post-Claiborne Eocene.

T. L. Bailey, March, 1924 (Sci., n. s., vol. 59, pp. 299–300), introduced *Gueydan fm.* for beds (of volcanic origin) uncon. overlying Frio fm. and uncon. underlying Oakville ss.

E. T. Dumble, 1924 (A. A. P. G. Bull., vol. 8, No. 4, July-Aug., pp. 424–436). *Frio group.*—Gypseous clays, chiefly with sands and sandrock, which weather white, but when wet may be green, blue, red, or yellow; contain concretions of ls. with manganese dendrites. Thickness 600± ft. No fossils except a leaf impression, but Jackson age is indicated by fact that we have traced what we consider to be its continuation S. to Conchos River in Mexico, where it forms a good part of Pomeranes Mtns, and on eastward-facing slopes of these mtns it is overlain by Lower Olig. beds. Rests uncon. on Whitsett beds, also of Jackson age, and is overlain by Oakville ss.

T. L. Bailey, 1926 (Univ. Tex. Bull. 2645). The name *Frio fm.* is here used with a different significance from its usage by any previous writer, so far as known. It here designates those predominantly argill. strata which lie conformably or discon. beneath Gueydan fm. [Catahoula tuff] and conformably on Fayette fm. Thickness 0 to 250 ft. Type loc. of Frio described by Dumble in 1894 occurs in upper part of Gueydan fm. of present writer. The Frio of Dumble's 1903 map of Live Oak Co., includes most of Gueydan and practically none of Frio of present rept, while in McMullen Co. it includes the Frio and most of lower Gueydan but excludes the beds of his type loc. in Live Oak Co. The Frio as defined by Dumble in 1924 is practically same as Gueydan fm. The Frio of Trowbridge [as mapped] (U. S. G. S. P. P. 131D, pp. 97–98, 1923) includes Frio, Oakville, and Lagarto fms. along N. side of Rio Grande. The Frio clay of Deussen includes Gueydan and Frio of this rept. The Frio and Fayette compose Jackson group in this area.

The †Gueydan fm. has been proved to be same as the Catahoula, and is now called *Catahoula tuff*, since in Tex. it consists chiefly of tuff.

In 1931 the name "Yeager clay" was introduced by Julia Gardner and A. C. Trowbridge (A. A. P. G. Bull., vol. 15, No. 4, p. 470) for the nonvolcanic clays underlying Catahoula tuff and overlying Fayette ss. because of the many conflicting uses of *Frio clay*. Later, however, it was agreed btw. Tex. Geol. Survey and U. S. Geol. Survey to drop the name "Yeager" and to adopt in its stead the definition of Frio clay that restricts that name to the beds beneath Catahoula tuff (= †Corrigan fm. and including Fant tuff memb.) and above Fayette ss. or Jackson fm. This is definition of Frio clay at present approved by U. S. Geol. Survey and by Tex. Geol. Surv. according to Univ. Tex. Bull. 3232, 1933. But A. C. Ellisor (A. A. P. G. Bull., vol. 17, No. 11) includes Fant tuff in Frio clay.

Named for exposures at and near mouth of Frio River, Live Oak Co.

Frisbie limestone.

Pennsylvanian: Eastern Kansas, southeastern Nebraska, and northwestern Missouri.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 92, 97). [See under *Wyandotte ls.* Derivation of name not stated.]

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pp. 18, 59). *Frisbie ls.*—Basal memb. of Wyandotte ls. Consists of 1 to 3 ft. of gray, even, blocky ls., in one layer. Named for Frisbie, Johnson Co., Kans.; exposed at middle of N. side of sec. 17, T. 12 S., R. 23 E. Is recognized farther into NW. Mo. and farther S. into Miami Co., Kans., than any other memb. of Wyandotte ls.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), stated that Newell is author of this name.

Frisco limestone.

Lower Devonian: Central southern Oklahoma (Arbuckle Mountains).

C. A. Reeds, 1926 (Am. Mus. Nat. Hist. Jour., vol. 26, pp. 470–473). Massive bedded coquina-like gray ls., 0 to 20 ft. thick, which rests on Bois d'Arc fm. Best exposed in bed and bank of Bois d'Arc Creek and in vicinity of Coal Creek 7 mi. S. of Frisco [Pontotoc Co.]. Is top fm. of Hunton group. Carries Oriskany fauna. Stratigraphically lower than Woodford chert.

In 1911 Reeds named top fm. of Hunton ls. of Taff the *Bois d'Arc ls.*

Frog Mountain sandstone.

Middle Devonian (Onondaga): Northern and central Alabama and northwestern Georgia.

C. W. Hayes, 1894 (Geol. Soc. Am. Bull., vol. 5, p. 470). *Frog Mtn ss.*—May be Oriskany. Underlies Chattanooga black sh. and overlies Rockwood ss. in NE. Ala. and NW. Ga. Assigned to Dev.

C. W. Hayes, 1895 (U. S. G. S. 16th Ann. Rept., pt. 3, pls. 20 and 21 and p. 555). *Frog Mtn ss.*—Coarse friable ss. and sandy sh. containing Lower Dev. fossils. Uncon. underlies Chattanooga sh. and uncon. overlies Rockwood ss. in NE. Ala. and NW. Ga.

C. W. Hayes, 1902. (See under *Armuchee chert.*)

C. Butts, 1927 (Am. Jour. Sci., 5th, vol. 14, pp. 365–380). All Dev. sss. of Ala. have heretofore been called Frog Mtn ss., but the 300 ft. of Dev. ss. at Frog Mtn, the type loc., is all of Onondaga age. The name *Frog Mtn ss.* is therefore here restricted to the sss. in Ala. that are of Onondaga age, the new name *Clear Branch ss.* is introduced for the sss. in Ala. that are of Oriskany age, and the new name *Ragland ss.* is introduced for the sss. in Ala. that are of Hamilton age. The restricted Frog Mtn ss. is present in Frog Mtn and elsewhere in Cherokee Co. and N. part of Calhoun Co., and also at Leeds, Shelby Co., and probably farther S. to Shelby, Calera, and Centerville regions.

C. Butts, 1927 (U. S. G. S. Bessemer-Vandiver folio, No. 221, p. 10). Writer has not visited Frog Mtn [Cherokee Co.], the type loc., but E. O. Ulrich found that *Frog Mtn ss.* at that locality consists of 150± ft. of coarse red ss., with *Spirifer macrothyris* and *Amphigenia curta* (?) at top, underlain by 200 ft. of sandy, calc., mag.?, and cherty beds with rounded quartz grains scattered through mag. ls. and quartz grains increasing toward bottom; fossiliferous cherty-looking rock at bottom contains *Chonetes mucronatus*. These beds are all of Onondaga age, so far as evidence goes. The fm. is overlain by Floyd sh. and underlain by ls. of Beekmantown age, probably Newala ls. The Frog Mtn ss. extends NE. into Ga., and is present in upper part of Armuchee chert. (See under *Armuchee chert.*)

Frondosa limestone.

Ordovician: Southern New Mexico.

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257–259; Conspectus of geol. fms. of N. Mex., pp. 4, 7). *Frondosa lss.*—Main body of Mid Ordovicic series in Franklin Mtns, which carries a Galena-Trenton fauna. Thickness 100 ft. [Derivation of name not stated.]

Frontenac.

Name applied to a glacial lake, of Pleist. age, in Ontario Basin.

Frontenac formation.

Paleozoic (pre-Ordovician?): Southeastern Quebec (Mount Megantic area).

H. W. McGerrigle, 1935 (Quebec Bur. Mines, Rept. Minister Mines 1934–35, pt. D, pp. 71, 74–78). Pillow lavas, tuffs, tuffaceous sediments. Underlie large part of Mount Megantic area of Frontenac Co.

Frontier formation. (In Colorado group.)

Upper Cretaceous: Western Wyoming and southern Montana.

W. C. Knight, 1902 (Eng. and Min. Jour., vol. 73, p. 721, in a paper on Uinta Co., SW. Wyo.). *Frontier fm.*—A coal-bearing ss. fm., 2,000± ft. thick, in which there is a thick stratum of evenly bedded light-brown ss., above and below which are beds of clay and sh. Extends N. from Kemmerer an unknown distance and S. to Diamondville, Cumberland, Spring Valley, and old R. R. cut just E. of Hilliard. Well developed at town of Frontier. Underlies Hilliard fm. and overlies Cret. beds of Benton age.

W. C. Knight, 1903 (Geol. Soc. Am. Bull., vol. 13, pp. 542–544). *Frontier fm.* has in past been called *Fox Hills*, but I could not find in it a Fox Hills fauna such as is common to Fox Hills of eastern Wyo.; therefore have named the beds *Frontier fm.* Is characterized by *Ostrea soleniscus*. Underlies Hilliard fm.

A. C. Veatch, 1907 (U. S. G. S. P. P. 56, on SW. Wyo). *Frontier fm.*—Alternating beds of yellow and gray ss. and yellow, gray, and black carbonaceous clays with numerous coal beds. Distinctive Benton fossils. Thickness 2,200 to 2,600 ft. In upper part of fm. is Oyster Ridge ss. memb. Underlies Hilliard fm. and overlies Aspen fm.

In Rock Springs uplift is overlain by Baxter sh. and underlain by Aspen sh. In Hanna Basin and elsewhere in Wyo. it underlies Carlile sh. and overlies Mowry sh.

Front Range granite group.

Pre-Cambrian: Colorado.

T. S. Lovering and others, 1935 (Geol. map of Colo.). *Front Range granite group.*—Comprises all granites and related rocks in Colo. that are older than Uinta Mtn group and younger than Needle Mtns group. Includes Curecanti, Vernal Mesa, Powderhorn, Twilight, Eolus, Tenmile, Whitehead, and Trimble granites of SW. Colo.; also Pikes Peak, Sherman, Silver Plume, Cripple Creek, and Mount Rosa granites of eastern Colo., and unnamed granites and related rocks in different parts of State. Named for development in Front Range.

†Frostburg formation.

Permian: Western Maryland.

P. T. Tyson, 1837 (Md. Acad. Sci. Trans., vol. 1, pp. 92–98). *Frostburg coal fm.*—Shales, slates, lss., sss., and coals, 1300± ft. thick. Rests uncon. on old red ss. Georges Creek, in its passage from Frostburg, cuts through beds of the series. Fossils; but no marine remains found.

W. B. Clark, 1897 (Md. Geol. Surv. vol. 1, pl. 13, p. 188). *Frostburg fm.*—Lss., sss., and shales, the lss. in several bands and at different horizons; most important ls. bed forms base of fm. Thickness of fm. 0 to 250 ft. Present in patches. Mapped. Overlies, apparently conformably, Elkgarden fm. and underlies Newark fm. Probably Perm. Named for Frostburg, Allegany Co.

Same as Dunkard group.

Frozenhead grit. (In Anderson sandstone.)

Pennsylvanian: Northern Tennessee (Morgan County).

L. C. Glenn, 1925 (Tenn. Geol. Surv. Bull. 33B, pp. 324, 328). *Frozenhead grit* (p. 324); *Frozenhead ss.* (p. 328). [Shown in section of Anderson fm., as lying about 25 ft. above Pilot Knob ss. (basal memb. of Anderson).] Top lies about 300 ft. below top of Frozenhead Mtn.

Fruitland formation.

Upper Cretaceous: Southwestern Colorado and northwestern New Mexico.

C. M. Bauer, 1916 (U. S. G. S. P. P. 98P). *Fruitland fm.*—Brackish and fresh-water beds conformably overlying Pictured Cliffs ss. Consists of ss., sh., and coal, ranging from sandy sh. and shaly or clayey ss. in all conceivable proportions, to rocks that can definitely be called ss. or sh. Lateral and vertical variation of beds very rapid. Large concretions of iron carbonate occur at several horizons. The fm. is more sandy than overlying Kirtland sh., into which it grades through ss. lenses that are apparently of fluviatile origin. Thickness 194 to 292 ft. Comprises basal part of so-called Laramie of Holmes' 1877 rept. Named for small settlement on San Juan River, in San Juan Co., N. Mex., which is an outcrop of the fm.

J. B. Reeside, Jr., 1924 (U. S. G. S. P. P. 134). Fruitland fm. is 438 ft. thick on Florida River; 430 ft. thick in Red Mesa quad., SW. of Durango, Colo.; on La Plata River near Colo.-N. Mex. line it is 530 ft. thick. It seems most logical, in light of present knowledge, to consider both Fruitland and overlying Kirtland sh. as of late Montana age, possibly=latest part of Pierre sh. and part of Fox Hills ss. of region E. of Rocky Mtns.

Fry sand.

A subsurface sand, of Penn. age, in Fry, Byler, George, Smith-Ellis, and Thrifty fields, Brown Co., north-central Tex. Lies at 1,350± ft. depth.

†Fucoides caudagalli beds.

Lower Devonian: Southeastern New York.

L. Vanuxem, 1840 (N. Y. Geol. Surv. 4th Rept., p. 377). *Fucoides caudagalli beds.*—An argill. mass, in places somewhat sandy, of a black or dark-green color, which becomes lighter and by long weathering blanches. Is extraordinary for the peculiar fossil which it contains. Underlies Schoharie layers [Schoharie grit] and overlies Oriskany ss.

A paleontologic name. Replaced by *Esopus grit.*

Fulda sandstone.

Permian: Central northern Texas.

E. C. Case, 1907 (Am. Mus. Nat. Hist. Bull. 23, pp. 660–662). *Fulda ss.*—Ss., few inches to 20 ft. thick, varying from bright blue to all shades of brown, yellow, buff, and brilliant red; in places very massive. Included in Clear Fork div. Is older than Wichita cgl. and younger than Wichita div.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 169). *Fulda ss.* belongs in Clyde fm., of Wichita group.

Named for prominent development near little station of Fulda, Baylor Co.

Fullerton formation.

Pleistocene (Aftonian): Southern, central, and northern Nebraska.

A. L. Lugn and G. E. Condra, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, p. 190). *Fullerton fm.* (Aftonian), of silt and clay, 8 to 60 ft. thick, rests conformably on Holdrege fm.

A. L. Lugn, 1934 (Nebr. State Mus. vol. 1, Bull. 41, pp. 326, 343–345). *Fullerton fm.*—Largely fluvial inwash-outwash deposits of dark calc. silt and clay with some sand. Of Aftonian age. Thickness 0 to 65 ft. Covers 15,000± sq. mi. Extends continuously under Platte River Valley and plains to N. and S., but exposed only in N. part of State and at Fullerton, Nance Co. Occurs also in southern central Nebr. Rests conformably on Holdrege fm. and is overlain uncon. by Grand Island fm.

Fullington shale.

Lower Cretaceous (Comanche series): Central southern Kansas.

F. W. Cragin, 1895 (Am. Geol., vol. 16, pp. 361, 379). *Fullington shales.*—Zone of *Gryphaea roemeri,* constituting lower and major part of Kiowa shales. Divided into Blue Cut shales, or zone of typical and abundant *G. roemeri,* above, and Black Hill sh. or Wafer sh. below. Underlies Tucumcari shales and overlies Champion shell bed.

Named for Fullington ranch, at Belvidere, Kiowa Co.

Fulmer Valley sand.

Name applied to a subsurface sand, of probable Dev. age, in SW. N. Y. See N. Y. State Mus. Bull. 239, 240, map opp. p. 16, 1922.

Fulton shale. (In Eden group.)

Upper Ordovician: Southwestern Ohio, southeastern Indiana, and north-central Kentucky.

A. F. Foerste, 1905 (Sci., n. s., vol. 22, p. 150). *Fulton layer.*—Geographic name for *Triarthrus becki* horizon, consisting of 4 or 5 ft. of clay at base of the Eden at Cincinnati.

Basal fm. of Eden group. Regarded by E. O. Ulrich as of latest Utica age and by R. Ruedemann as of earliest Lorraine age. Is overlain by Latonia sh.

Named for Fulton, formerly a suburb of Cincinnati, but now forming part of First Ward.

Fulton shale member (of Monongahela formation).

Pennsylvanian: West Virginia, western Pennsylvania, and eastern Ohio.

G. P. Grimsley, 1907 (W. Va. Geol. Surv. Rept. Ohio, Brooke, and Hancock Counties, p. 92). *Fulton green sh.*—On fresh exposures is bright-green, finely laminated sh., but weathers bluish green. Thickness 0 to 5 ft. Underlies Uniontown ls. and overlies Benwood ls. Exposed at Fulton, Ohio Co., W. Va.

The Ohio and W. Va. Geol. Surveys in 1931 applied *Arnoldsburg ls.* to lower part of Uniontown ls. of previous usage, and restricted *Uniontown* to younger beds.

Fulton loam.

Pleistocene: Western Kentucky.

F. J. Fohs, 1907 (Ky. Geol. Surv. Bull. 9, p. 67). *Fulton loam.*—Brown loam, 0 to 15 ft. thick, composing upper part of Columbia fm. Overlies Port Hudson clays (lower part of Columbia fm.) and underlies Recent alluvium.

Probably named for Fulton or for Fulton Co.

Funeral conglomerate.

Tertiary: Southwestern Nevada and southeastern California.

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 52, 78). *Funeral cgls.*—Term suggested for main gravel beds superposing the borate sediments in Death Valley region, where the deposits are finely developed on flanks of Funeral Range, [NE. of Death Valley in SE. Calif.]. Compose lower fm. of Virgen [Virgin] series in Nev. Plio. perhaps.

Funston limestone. (In Council Grove group.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., p. 23). *Funston ls.* is new name for middle part of Speiser sh. as defined by Condra in 1927. In Nebr. it consists of (descending): (1) Gray ls., 1 ft. or more; (2) greenish argill. sh., 2 ft. or more; (3) gray ls., 1 ft. or more; (4) massive aren. ls. that weathers yellowish, 1⅓ to 2 ft. In southern Kans. the basal zone is 2 or more ft. thick and becomes dominant part of the memb. at type loc., in bluffs of Kansas River Valley S. of Funston, Kans. Named for Camp Funston, Riley Co., Kans. Underlies Speiser sh. restricted and overlies Blue Rapids sh.

G. E. Condra, 1935. (See under *Bigelow ls.*)

Furnace limestone.

Upper Cambrian (?), Ordovician (?), and Mississippian (?): Southern California (San Bernardino Mountains).

F. E. Vaughan, 1922 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 13, No. 9, pp. 344, 352–365, and map). *Furnace ls.*—White to nearly black coarsely crystalline ls., 4,500 ft. or more thick. Grades downward into Arrastre qtzite and grades upward into Saragossa qtzite. Is intruded by granites. No fossils found. Probably Upper Camb. and Ord.

A. O. Woodford and T. F. Harriss, 1928 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 17, p. 270). Fossils collected close to top of Furnace ls. are pronounced by G. H. Girty to be probably Carbf., and more probably Miss. than Penn. or Perm. Thus a Miss. (?) age is suggested for at least a part of Furnace fm.

Named for Furnace Canyon, San Bernardino Co., which is cut in the fm.

Furnacean series.

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 52, 78). *Furnacean series* is locally used to designate the chief borate-bearing beds of Death Valley dist., fully outcropping in Furnace Canyon, E. of Death Valley, Inyo Co., SE. Calif. In Nev. divided into Millett clays above and Redhill ss. below. Older than Piutean series and younger than Amargosan series. Of Miocene age.

Furnaceville iron ore.

Silurian: Central and western New York.

J. M. Clarke, 1906 (N. Y. State Mus. 2d Rept. Dir. Sci. Div., 1905, p. 12). [See under *Irondequoit ls.*]

C. A. Hartnagel, 1907 (N. Y. State Mus. Bull. 114, p. 20). *Furnaceville ore.*—Included in Clinton fm. of Rochester and Ontario Beach quads. Underlies Wolcott ls. and overlies Sodus sh.

G. H. Chadwick, 1908 (Sci., n. s., vol. 28, pp. 346–348). The *Furnaceville ore bed* lies *in* and not *below* Wolcott ls. [J. M. Clarke, 1910 (N. Y. State Mus. Bull. 140) treated Furnaceville as distinct fm., but E. O. Ulrich (Geol. Soc. Am. Bull., vol. 22, pl. 28, 1911) apparently included it in Wolcott ls., since he showed Wolcott resting on Sodus sh.]

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 48). *Furnaceville iron ore* occurs at Rochester and extends E. into Wayne Co., where it is typically developed in vicinity of Furnaceville, and where it directly overlies Sodus sh., but at Rochester a thin band of ls. intervenes btw. Sodus sh. and the ore.

G. H. Chadwick 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 327–368). Sodus sh. restricted to upper part of Sodus sh. as previously defined and used, the underlying beds down to top of Thorold ss. being named (descending): Sterling Station ore, Reynales ls., *Furnaceville ore,* Bear Creek sh., and Maplewood sh. The iron ore underlying true Wolcott ls. is here named *Verona iron ore.* The true *Furnaceville ore* is a much older bed. Hartnagel miscorrelated Wolcott ls. with the much older Reynales ls. The iron ore overlying Wolcott ls. is here named *Wolcott Furnace ore.*

E. O. Ulrich, 1923 (Md. Geol. Surv. Sil. vol., p. 191), included *Furnaceville sh.* in Reynales ls. On p. 347 he included *Furnaceville ore* in Reynales ls.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 317, 324, 325), included *Furnaceville ore* in Reynales ls., of which it is said to be basal 4 ft.

Furnaceville shale.

Silurian: Central and western New York and western Ontario.

M. Y. Williams, 1919 (Canada Geol. Surv. Mem. 111, p. 47), used *Furnaceville (Sodus) sh. memb.* for part of Clinton fm. in Ontario; and G. S. Hume, 1932 (Canada Geol. Surv. Econ. Geol. ser., No. 9, p. 24), used *Furnaceville sh.* in Ontario.

See also 1923 entry under *Furnaceville iron ore.*

Fuson shale. (In Inyan Kara group.)

Lower Cretaceous: Western South Dakota, southeastern Montana (in wells), eastern Wyoming, and northwestern Nebraska.

N. H. Darton, 1901 (U. S. G. S. 21st Ann. Rept., pt. 4, p. 530). *Fuson fm.*—Very fine-grained sss. and massive shales and clay; of white, gray, buff, purple, and maroon colors. Thickness 30–100 ft. Underlies Dakota ss. as here restricted and overlies Minnewaste ls. Included in Dakota ss. of previous repts. Striking exposures in Fuson Canyon [on E. side of Black Hills, S. Dak.], for which it is named.

W. W. Rubey (1930) made this top fm. of *Inyan Kara group,* q. v.

Fusselman limestone.

Silurian (Niagaran): Western Texas and southern New Mexico.

G. B. Richardson, 1908 (Am. Jour. Sci., 4th, vol. 25, pp. 476, 479–480). *Fusselman ls.*—Massive, whitish, mag. ls. approx. 1,000 ft. thick. Overlies Montoya ls., apparently conformably. Underlies Hueco ls., also apparently conformably. Contains fossils of upper Niagaran age. Outcrops in El Paso quad., in Franklin and Hueco Mtns.

Named for exposures in Fusselman Canyon, Franklin Mtns, N. of El Paso, Tex.

Gabbs formation.

Upper Triassic: Southwestern Nevada (Tonopah and Hawthorne quadrangles).

S. W. Muller and H. G. Ferguson, 1936 (Geol. Soc. Am. Bull., vol. 47, pp. 241–252). *Gabbs fm.*—Purple to black sh. and dark-brown to black ls., 420 ft. thick. Conformably underlies Sunrise fm. (Lower Jurassic) and conformably overlies Luning fm. (Upper Triassic). Fossils from middle, base, and top. Assigned to Upper Triassic. Named for Gabbs Valley Range, where, in New York Canyon area, it is best exposed.

Gabilan limestone.

Pre-Jurassic (?): Western California (San Francisco Bay region).

G. F. Becker, 1888 (U. S. G. S. Mon. 13, pp. 128, 181). *Gavilan ls.*—In Gavilan Range [spelled *Gabilan* by U. S. Geographic Board], some 60 mi. S. of Bay of San Francisco, the lowest sed. fm. encountered is in part ls., which at points is very crystalline. Associated with it are rocks of Archean gneiss type. It is possible it is a memb. of Knoxville series much more metamorphosed than usual, but it appears more probable it is a remnant of some older fm. which has perhaps undergone repeated metamorphism.

Is now known to be of pre-Franciscan age, and in San Francisco region occurs as inclusions in quartz diorite that has been called "Montara granite," of late Jurassic (?) age. (See also under *Sur series.*)

†Gabouri limestone.

Mississippian: Central eastern Missouri.

I. N. Nicollet, 1843 (Rept intended to illustrate a map of the Hydrog. Basin of Upper Mississippi River; 26th Cong., 2d sess., S. Ex. Doc. 237, p. 33), used once, casually, "Gabouri ls." for what he a few sentences farther along called "oolitic ls. of the Gabouri" exposed at Ste. Genevieve, Mo. According to C. [R.] Keyes (Pan-Am. Geol., vol. 44, pp. 149–150, 1925) the Gabouri ls. of Nicollet is Spergen ls., and he would revive Nicollet's name. The only known uses of "Gabouri" in literature are Nicollet's casual use and Keyes' proposed revival of the term.

Gabriola formation.

Upper Cretaceous: British Columbia.

C. H. Clapp, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 100).

Gaffney marble.

Cambrian (probably Lower): Southern North Carolina and northwestern South Carolina.

A. Keith and D. B. Sterrett, 1921 (Limestones and marls of N. C., by G. F. Loughlin et al.: N. C. Geol. and Econ. Surv. Bull. 28, pp. 28, 72–75). *Gaffney marble.*—A rather variable fm. ranging from very fine to medium fine-grained marble, and from bluish gray to white in color. Most of it has a schistose or banded structure, made more evident by presence of impurities, such as mica and hornblende. In some places the marble is highly magnesian. Thickness 30 to 300 ft. Overlies Blacksburg schist. Is of Camb. age, probably Lower Camb.

Named for exposures at Gaffney, Cherokee Co., S. C.

Gage shale. (In Chase group.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., p. 45). *Gage sh.*—Top memb. of Doyle fm. Consists of shales, of alternating gray, greenish gray, and chocolate red colors. Thickness increases from 28 ft. in Nebr. to 50 ft. in southern Kans. Overlies Towanda ls. memb. and underlies Stovall ls. memb. of Winfield fm. Named for Gage Co., Nebr. Type loc. btw. 1 and 2 mi. S. of W. side of Wymore, Nebr.

Gagné Brook series.

Ordovician (?): Quebec.

F. R. Burton, 1931 (Quebec Bur. Mines Ann. Rept. 1930, pt. D, p. 109).

†Gainesville.

Lower Cretaceous (Comanche series): Northeastern Texas and southwestern Arkansas.

F. W. Cragin, 1895 (Am. Geol., vol. 16, pp. 384–385). If it be needful to sometimes use a collective name for the Washita and Denison divisions of Comanche series, the name *Gainesville,* from the north Tex. town of that name, which practically marks bdy btw. Washita and Denison, is appropriate. [His Washita div. included Denton, Fort Worth, and Duck Creek. His Denison div. included Grayson, Choctaw, Pawpaw, and North Denison.]

Practically synonymous with Washita group.

Gainesville sand.

A subsurface sand, of Middle Dev. age, in western Ky.

Gakona formation.

Eocene (upper): Southeastern Alaska (central Copper River region).

W. C. Mendenhall, 1905 (U. S. G. S. P. P. 41, p. 52, map). *Gakona fm.*—Fresh-water deposits. Upper part soft, fissile or massive gray or buff shales, with interbedded gravel, sand, and lignite beds. Lower part coarse, thoroughly indurated cgl., at least 500 ft. thick; appears to be basal memb. Thickness of fm. 2,000+ ft. Contains Eo. plants. Occurs E. of Gakona Glacier.

Galatia sandstone. (In McLeansboro formation.)

Pennsylvanian: Southeastern Illinois (Saline County).

G. H. Cady, 1926 (Ill. State Acad. Sci. Trans., vol. 19, pp. 256–258). *Galatia ss.*—A cuesta-forming ss., about 75 ft. thick, lying about 500 ft. above base of McLeansboro fm. Lies strat. higher than Brushy Creek ss. and also about 100 ft. higher than an unexposed ls. that is correlated with Shoal Creek ls. Crops out about ½ mi. N. of Galatia, Saline Co.

Gale sand.

Pleistocene (Wisconsin): Western Washington (Puget Sound region).

B. Willis and G. O. Smith, 1899 (U. S. G. S. Tacoma folio, No. 54). *Gale sands.*—Stiff and clayey sands derived from Osceola till; partly stratified and partly washed and redistributed. Steilacoom gravels differ from Gale sands in their prevailing coarseness. Named for creek in Tacoma quad., which flows across part of area covered by Gale sands.

Galena dolomite.

Middle Ordovician (Trenton): Northern Illinois, Iowa, and southern Minnesota and Wisconsin.

J. Hall, 1851 (Rept. on geol. of Lake Superior land district, by J. W. Foster and J. D. Whitney, pt. 2, pp. 146–148). In going westward [from Escanaba River] I had not an opportunity of observing the overlying deposits of Trenton ls. until I arrived in Wis. Here, in numerous localities, as well as in Ill. and Iowa, the deposit above that which is marked by an abundance of fossils characteristic of the Trenton, is a grey, or drab-colored ls., very friable, forming part of "cliff ls." of Ohio and Ind. repts, and is called by Dr. Owen, in his rept on Lead region, the "upper mag. ls." From its position and lithologieal characters it appears that this ls., which is principal lead-bearing rock in these States, is a continuation of that noticed on the Escanaba, lying above the fossiliferous beds of Trenton ls.; but that it has increased in thickness, as traced westwardly, and becomes an important memb. of the series; and hence we have designated it in the classification of the rocks as *"Galena ls."* In neighborhood of Galena, Dubuque, Mineral Point, and other places there are numerous localities where a direct succession in the beds may be traced. It is very evident that this ls. diminishes in thickness eastwardly from these points, and becomes a very subordinate memb. of the series, losing, at same time, its metalliferous character. This lead-bearing rock, as before observed, rests upon fossiliferous strata of Trenton age. The galena sometimes penetrates the Trenton series, in films or sheets, but does not form veins, as in the gray heavy-bedded ls. above. From all the evidence, therefore, the lead-bearing or Galena ls. must be regarded as a distinct memb. of lower Sil. system, which is not recognized to E. Believed to underlie Hudson River group, but relations not positively determined. [In strat. columns on pp. 2 and 5, by J. W. Foster and J. D. Whitney, *Galena ls.* is placed beneath so-called Hudson River group and above Trenton ls.]

J. Hall, 1858 (Iowa Geol. Surv. Rept. 1855–57, vol. 1, pt. 1, pp. 42, 56, 57, 58, 60). *Galena ls.*—This rock, which succeeds Trenton ls. proper, or, as shown in preceding sections, alternates with that rock at junction of the two, is a most important and interesting fm. in Iowa. It is a gray or drab-colored, often yellowish, porous, and subcrystalline rock, usually friable but sometimes compact and possessing a considerable degree of tenacity. It varies in different parts of its extent; the porous and friable character being that prevailing in central part of its greatest development, while other characters supervene toward its northern and northwestern margin. This rock has been designated by Dr. Owen "Upper Mag. ls;" but this term, as originally applied, included also Niagara ls., causing the two to be confounded for a long time; and in order to avoid the difficulty arising therefrom the name *Galena ls.* has been proposed. The great interest of this rock arises from its being the chief depository of the lead ore found in Iowa, Ill., and Wis. [On p. 290, by J. D. Whitney, is statement that city of Galena [Ill.] is surrounded by bluffs of Galena ls. On p. 350, also by Whitney, is statement that Galena ls. is most fully and characteristically developed on Miss. River in neighborhood of Galena and Dubuque.] Thickness [pp. 42, 56, 57, 58] 30 to 250 ft. [The so-called Trenton ls. of Hall is Platteville ls. of modern nomenclature, and is of Black River age.]

The Galena dol. continued for many years to be classified as post-Trenton, although J. Hall in 1862 (Wis. Geol. Surv. Rept. 1, pp. 32–33) assigned it to Trenton group. In 1873 (Minn. Geol. Nat. Hist. Surv. 1st Ann Rept.) N. H. Winchell stated that lower beds of Galena are interstratified with underlying Trenton ls., but he and others continued to treat Galena as post-Trenton. In 1879 (Geol. and Nat. Hist. Surv. Minn., vol. 3, pt. 2, Final Rept., p. lxxxix) N. H. Winchell and E O. Ulrich assigned the

Galena to the Trenton and the underlying so-called Trenton shales and lss. to the Black River. In 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 332–368) C. W. Hall and F. W. Sardeson also definitely assigned the Galena to the Trenton, and divided it and the underlying beds (also called Trenton) into several faunal zones. In 1895 (Am. Geol., vol. 15, pp. 33–39) N. H. Winchell stated: "It may therefore be considered that Galena ls. is only a phase of the Trenton intensified in its type region and fading out in all directions." In 1905 H. F. Bain (U. S. G. S. Bull. 246, pp. 18–19) introduced *Platteville ls.* for the beds underlying the massive-bedded Galena dol. in NW. Ill. and SW. Wis., which he stated are pre-Trenton. In 1906 the upper beds of Platteville ls. of Bain were removed from the Platteville by S. Calvin, who named them *Decorah sh.* and included them in his *Platteville stage.*

Since 1906 *Galena dol.* has been generally accepted as of Trenton age, as overlying Decorah sh., and as underlying Maquoketa sh. in upper Miss. Valley region. However, A. C. Trowbridge et al., 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., fig. 1, p. 61, etc.), use *Trenton (Galena) group* to include (descending) Dubuque, Stewartville, Prosser, and Decorah exclusive of Spechts Ferry memb. of Kay, which they include in underlying Platteville ls. On p. 286 Kay also used this classification, but on p. 288 he stated that in northern Iowa and Minn. "it is *more convenient* [italics are Kay's] to consider the Spechts Ferry as a lowest memb. of Decorah fm."

Named for excellent exposures in bluffs of Mississippi River in neighborhood of Galena, Joe Daviess Co., Ill.

See also under *Decorah sh.* and *Platteville ls.*

†Galena series.

Middle Ordovician: Upper Mississippi Valley region.

F. W. Sardeson, 1896 (Am. Geol., vol. 18, pp. 356–368). ***Galena series*** is here used to designate the fms. that have been called *Trenton group* in Iowa, Ill., Wis., and Minn. [Included (descending) Galena dol., Decorah sh., and Platteville ls. of current nomenclature. The Galena and upper part of the Decorah are of Trenton age, but the Platteville is now generally considered to be of Black River age.]

A. C. Trowbridge et al., 1935 (Conf. Rept. Kans. Geol. Soc.), employed *Trenton (Galena) group* to include Galena ls. and Decorah sh. of previous repts, but this was not adopted by Iowa, Ill., Minn., and Wis. State Surveys, which adhered to Galena dol. for the beds overlying Decorah sh.

Galena King limestone.

Miners' local name for the principal ore-bearing ls. in Galena mine, Stockton dist., central northern Utah. Occurs in lower part of Oquirrh fm. (Penn.). Lies 550± ft. below Paisley ls. and about 113 ft. above Rambler fm., both local miners' terms. (See U. S. G. S. P. P 173, 1932.)

Galesburg shale. (In Kansas City group.)

Pennsylvanian: Eastern Kansas, northwestern Missouri, southeastern Nebraska, and southwestern Iowa.

G. I. Adams, 1903 (U. S. G. S. Bull. 211, p. 36). ***Galesburg shales.***—Fossiliferous, sandy shales, 75 to 100 ft. thick, underlying Dennis ls. and overlying Hertha ls. [Later work proved this lower ls. not to be the Hertha but the younger Bethany Falls ls.]

H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines vol. 13). ***Galesburg sh. memb. of Kansas City fm.*** (5 to 10 ft. thick in NW. Mo.) underlies Winterset ("Dennis") ls. memb. (25 to 40 ft. thick) and overlies Bethany Falls ls. memb. [This definition of Galesburg sh. was followed for many years. In Kans. the Kansas City deposits are treated as a *group* by U. S. Geol. Survey and Galesburg sh. as a fm. In SE. Kans. the Galesburg is treated as a memb. of Coffeyville fm.]

In 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 91, 97) R. C. Moore (1) revived *Dennis ls.;* (2) divided it into (descending) Winterset ls. memb. ("same as Winterset as previously recognized in Kansas and Mo."), Stark sh. memb., and Canville ls. memb.; and (3) stated: So-called Galesburg sh. of Kansas City is mainly Stark sh. Moore also assembled Bethany Falls ls. and underlying beds into a fm. which he named *Swope ls.* (q. v.), and assembled Dennis, Galesburg, and his Swope ls. into his Bronson group.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21), stated that Stark sh. and Canville ls. are present at both Dennis and at Galesburg, and that they are included in Galesburg sh. of Kansas City area, but he includes them in the Dennis, as explained under *Dennis ls.*

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 92+). In Linn Co., where Canville ls. disappears, Stark sh. rests on Galesburg sh., and lower 1 to 3 ft. of Stark sh. being there black fissile sh., it is easy to separate Stark and Galesburg shales. (Upper part of Stark is 2 to 5 ft. thick.) Where Canville ls. is missing in southern Kans. the absence of black sh. at horizon of Stark memb. makes it impossible to recognize Stark sh., and upper bdy of Galesburg sh. is here extended up to base of Winterset ls.

These changed definitions have not been considered by U. S. Geol. Survey for use in its publications. (See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.)

Named for Galesburg, Neosho Co., Kans., which, according to R. C. Moore (1936), is built largely on Winterset ls.

Galesville member.

Upper Cambrian: Southern Minnesota and Wisconsin, Iowa.

A. C. Trowbridge and G. I. Atwater, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 45, 79). It is proposed that *Dresbach fm.* be defined to include the sss. and shales that lie btw. the Red Clastic series and the Franconia in southern Minn. and northern Iowa, btw. the pre-Camb. and the Franconia in southern and central Wis., and btw. the Keweenawan and the Franconia along the Saint Croix, and that this fm. be subdivided into 3 members, the lower 2 of which are called Mount Simon and Eau Claire respectively, and that the new name *Galesville memb.* be applied to the uppermost memb. [now known as *Dresbach ss.*], which is exposed from top to bottom on the bluff of Beaver Creek at the mill dam at Galesville, Wis., where it is 86 ft. thick.

The foregoing classification was also used by Trowbridge et al in Rept. 9th Ann. Field Conf. Kans. Geol. Soc., 1935, passim; also by Twenhofel, Raasch, and Thwaites in Geol. Soc. Am. Bull., vol. 46, 1935, No. 11, pp. 1687–1744.

The U. S. Geol. Survey at present uses ***Dresbach ss.*** for the rocks underlying Franconia ss. and overlying Eau Claire ss.

Galice formation.

Upper Jurassic: Southwestern Oregon.

J. S. Diller, 1907 (Am. Jour. Sci., 4th, vol. 23, pp. 401–421). *Galice fm.*—Mainly dark to black slates, some ss. and cgl. Jurassic fauna. Well exposed at Galice, Oreg., on Rogue River, also on Galice Creek. [Table placed Galice fm. below Dothan fm., but p. 421 stated Galice overlies Dothan.]

J. S. Diller, 1914 (U. S. G. S. Bull. 546, pp. 17–18). Jurassic sed. rocks of Galice-Kerby-Waldo region consist of 2 fms.—Galice fm. on SE. and Dothan fm. on NW., separated by an irregular belt of igneous rocks, mainly greenstone and serpentine. Relative position indicates Dothan fm. is younger than Galice. The Cret. is markedly uncon. on Jurassic.

J. S. Diller and G. F. Kay, 1924 (U. S. G. S. Riddle folio, No. 218). Thickness of *Galice fm.* in this quad. 100 to 2,000 ft. Part of these rocks connect with type Galice. May include some unfossiliferous rocks older than Galice. Is thought =Mariposa fm. of Calif. Relations of Dothan fm. to Galice fm. not established, but believed to be uncon. Relations of Galice fm. to May Creek fm. (Dev.?) are a thrust fault.

Galisteo sandstone.

Tertiary (?): Central northern New Mexico.

F. V. Hayden, 1869 (U. S. Geol. and Geog. Surv. Terr. 3d Ann. Rept., pp. 40, 67, 90). *Gallisteo sand group.*—Variegated sands and sss., of varied texture, from a fine aggregate of quartz particles to a rather coarse puddingstone. In some beds are irregular layers of dull dusty brown concretionary aren. ls. Colors vary from light reddish to deep brick red, dull purplish, very deep yellow, white, brown, drab, etc. Only fossils enormous silicified trunks of trees. Named for fact that they are, so far as known, confined to valley of Gallisteo Creek, although they pass under the Santa Fe marls, and northern limit is concealed from view. Overlies Placer Mtn group. Are doubtless middle Tert.

Galisteo is commonly accepted spelling of this name.

Galiuro rhyolite.

Tertiary: Southeastern Arizona (Galiuro Mountains).

W. P. Blake, 1902 (Eng. and Min. Jour., vol. 73, p. 546). The Galiuro Range consists of ancient rhyolites which I name the "Galiuro rhyolite."

N. H. Darton, 1924 (geol. map of Ariz.), mapped the rocks of Galiuro Mtns as of Tert. age.

Galiuro limestone.

Pennsylvanian: Southeastern Arizona (Gila Basin).

A. A. Stoyanow, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 508, 517–521). *Galiuro ls.*—Name here applied to Penn. part of Ransome's Tornado ls., which is discarded, the Miss. rocks included under that name being Escabrosa ls. In certain ways the Galiuro ls. is different from Naco ls., the Penn. of extreme SE. Ariz. The beds composing it are individualized lithologically, as compared with the monotonous lead-gray ls. beds of the Naco. At type section (in Galiuro Mtns, at junction of Gila and San Pedro Rivers, 45± mi. NE. of Tuscon and 6 mi. E. of Winkelman, S. of Deer Creek coal field and Ash Creek, and at foot of Saddle Mtn) the Penn. beds are light-gray, white, and light-brown ls. beds rich in nodules and bands of chert, all very fossiliferous. In this part of mtns the fm. is 950 ft. thick. Uncon. overlain by Cret. cgls. and qtzites. Basal 40 ft. of Galiuro fm. consists of alternating aren. and argill. shales with layers of ls. at top, which may be conveniently called "Fusulinella beds." Next above are lss. that might be called "Marginifera beds." The overlying strata are white, yellow, brown, and pink ls., often silicified, and with frequent inclusions of cherty nodules. Upper part of Galiuro ls. consists of thinner-bedded pink and brown hard, compact lss., often more or less silicified and containing well-preserved bryozoan reefs, and may be called "Orthotichia beds." [Discusses fossils, and gives many details.]

Gallatin limestone.

Upper Cambrian: Southern Montana and northwestern Wyoming.

A. C. Peale, 1893 (U. S. G. S. Bull. 110), and 1896 (U. S. G. S. Three Forks folio, No. 24). *Gallatin fm.*—Mainly calc., 835 ft. thick. In vicinity of Three Forks, Mont., divided into (descending): (1) Pebbly lss. (light colored, laminated, yellowish brown at base, dove-colored at top with dark-blue layers), 145 ft.; (2) *Dry Creek shales* (brownish yellow, red, and pink, with shaly calc. sss.), 30 ft.; (3) *Mottled lss.*, 260 ft. (massive-bedded, the lower 20 to 25 ft. being laminated, light-gray or brownish); (4) *Obolella shales*, 280 ft. (more calc. than aren.; soft shaly beds with few thin ls. bands, dark greenish in lower part, lighter in upper part); (5) *Trilobite lss.*, 120+ ft. (thin-bedded dark-gray central part massive). Conformably overlain by Jefferson ls. and rests on Flathead shales. [In Bull. 110 mapped on both sides of Gallatin River near Gallatin, Mont. In Three Forks and Livingston folios is mapped in parts of Gallatin Range, SE. part of Three Forks quad. and W. part of Livingston quad. The Gallatin Range extends into NW. corner of Yel. Park.]

W. H. Weed, 1896 (U. S. G. S. Yellowstone Park folio, No. 30). *Gallatin ls.*—Named for typical occurrence in Gallatin Range [the S. extension of which is in NW. corner of Yel. Park], where it forms upper part of Camb. series and is 110 ft. thick. It is essentially a series of lss., more massively bedded than those of underlying Flathead fm., and forms first prominent ls. bluff that rises above the Archean areas. Lowest bed is massive mottled black and gray ls. 50+ to 100 ft. thick. Above this mottled ls. the rocks are more thinly bedded and carry Upper Camb. fossils. Is overlain by Jefferson ls. [Since base of Gallatin ls. is here drawn at base of †Mottled ls., this definition of Gallatin is a restriction of Peale's

1893 definition. In 1918 the beds btw. base of †Mottled ls. and top of Flathead qtzite were named *Gros Ventre fm.* The Gallatin ls. as now generally accepted is overlain by Jefferson ls. and underlain by Gros Ventre fm. and is considered to be wholly of Upper Camb. age.]

Gallatinian series.

A term applied by C. [R.] Keyes (Pan-Am. Geol., vol. 46, 1926) to part of Belt series of Mont.

Gallego sandstone member (of Miguel formation).

Upper Cretaceous: Southwestern New Mexico (Alamosa Creek Valley, Socorro County).

D. E. Winchester, 1920 (U. S. G. S. Bull. 716A). Massive yellow ss. containing *Halymenites*. Thickness 93 ft. Occurs near middle of Miguel fm., about 983 ft. below Bell Mtn ss. memb. Named for Gallego Creek, Socorro Co.

Gallegos sandstone.

Pennsylvanian (?): Central northern New Mexico (Sandia Mountains).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257–259; Conspectus of geol. fms. of N. Mex., pp. 3, 7). *Gallegos sss.*—Thick ss. beds in middle of Maderan lss. in Sandia Range. Thickness 100 ft. [Derivation of name not stated.]

Gallinas shale.

Name introduced by C. [R.] Keyes (Conspectus of geol. fms. of N. Mex., 1915, pp. 2, 7) for 200 ft. of shales forming "basal memb. of Coloradan series, well developed on Gallinas Creek, near Las Vegas."

Gallitzin limestone. (In Conemaugh formation.)

Pennsylvanian: Western Pennsylvania (Armstrong County).

J. P. Lesley, 1880 (2d Pa. Geol. Surv. Rept. H_5, p. 312), applied *Gallitzin ls.* to a concretionary ls. described by W. G. Platt in body of this rept as separated from overlying Gallitzin coal by 2 ft. of shales and from *underlying* Johnstown iron ore (which rests on Lower Mahoning ss.) by 10 ft. of shales.

J. D. Sisler, 1925 (Pa. Geol. Surv., 4th ser., Bull. M_7, p. 268), gives following downward succession of beds in lower part of Conemaugh fm. of Somerset Co., Pa.: Elk Lick ls., Berlin coal, Berlin ls., Platt coal, Price coal, Coleman coal, Coleman ls., Philson (Rose) coal, Philson ls., *Johnstown iron ore,* Brush Creek (Gallitzin) coal, Mahoning ss.

Gallup sandstone member (of Mesaverde formation).

Upper Cretaceous: Northwestern New Mexico (Gallup-Zuñi Basin).

J. D. Sears, 1925 (U. S. G. S. Bull. 767). *Gallup ss. memb.*—Three thick persistent cliff and ridge-forming sss. traceable throughout Gallup-Zuñi Basin. Upper and in places lower sss. are pink on E. side of basin; all 3 are generally light-gray on W. side of basin, but in places the upper ss. is pink or red. The upper ss. contains lenses of very coarse grains, in many places an arkose. Between the sss. are sh. The lower sh. contains several thin coal beds. The upper sh. contains at most places from 1 to 3 commercial coal beds. Thickness of memb. 180 to 250 ft. Underlies Dilco coal memb. Is basal memb. of Mesaverde fm. in this basin. Overlies (conformably) Mancos sh. Named for town of Gallup, part of which is built on uppermost ss. bed.

†Galt limestone.

See under *Guelph dol.*

Galt moraine.

Pleistocene (Wisconsin stage): Southern Ontario. Shown on moraine map (fig. 8) in U. S. G. S. Niagara folio (No. 190), p. 17.

Galt sand.

A subsurface sand, 25± ft. thick, in upper (Trinity) part of Comanche Cret. of Talco field, Titus and Franklin Counties, Tex., lying lower than Carr sand. Named for Galt well No. 1 of Humble Oil & Refining Co.

Galton series.

Name applied by R. A. Daly (Canada Dept. Int., Rept. Chief Ast. 1910, vol. 2, p. 97, pl. opp. p. 178, 1913) to rocks in Gallatin Range (Montana-British Columbia) which he correlated with pre-Camb. rocks classified by U. S. Geol. Survey as Belt series, but which he classified as Lower, Middle, and Upper Camb. Includes Roosville fm. at top and Altyn ls. at base.

Galum limestone member (of McLeansboro formation).

Pennsylvanian: Southwestern Illinois (Perry County).

A. H. Bell, C. Ball, and L. McCabe, 1931 (Ill. Geol. Surv. Press Bull. No. 19). *Galum ls. memb.*—Earthy yellow nodular ls.; fossils rare or absent. Thickness 3 ft. Top lies 6 to 19± ft. below Cutler ls. memb. and base lies 35± ft. above Herrin (No. 6) coal in vicinity of Pinckneyville and Jamestown, Perry Co. Well exposed along Galum Creek, near Pinckneyville.

Galway formation.

Upper Cambrian: Eastern New York.

J. M. Clarke, 1910 (N. Y. State Mus. Bull. 140, pp. 11–12 and map). *Galway fm.*—A series of distinctly transitional beds underlying Little Falls dol. and overlying Potsdam ss. in Broadalbin quad., Fulton and Saratoga Counties. Best developed at Galway, Saratoga Co.

W. J. Miller, 1911 (N. Y. State Mus. Bull. 153, pp. 8–38 and map), described and mapped the rocks btw. Little Falls dol. and Potsdam ss. in Broadalbin quad. as *Theresa fm.*, a name that has priority over Galway fm.

Only record of Galway fm. is Clarke's 1910 publication.

Gamache series.

An abbreviated form of *Gamachian series.*

Gamachian series.

C. Schuchert and W. H. Twenhofel, 1910 (Geol. Soc. Am. Bull., vol. 21, p. 700). *Gamachian series*, of Cincinnatic system, follows Richmondian series and has no known representative elsewhere in North America [than Mingan and Anticosti Islands, Gulf of St. Lawrence]. These strata are seen to best advantage at Gamache (or Ellis) Bay, where the characteristic fossils of the series occur in abundance. On Anticosti it embraces all of Ellis Bay stage, but eventually it may possibly be shown that upper portion of Charleton stage should be included in this series. In other words, this Gamachian series is intended to include all American deposits later in age than the youngest Richmondian of Ind. and Ohio and older than Anticosti series, which in United States is thought to have its basal equiv. in typical Medina and Edgewood stages. [Schuchert's *typical Medina* is upper Medina or Albion ss.]

E. O. Ulrich, 1913 (12th Int. Geol. Cong., Canada, p. 15). The Gamachian series of Schuchert "corresponds to lower part of upper Medina [Sil.] and name is superfluous."

W. H. Twenhofel, 1914 (Canada Geol. Surv. Mus. Bull. 3, p. 8). *Gamachian series* (*Ellis Bay fm.*) assigned to Ord.; is younger than any div. assigned to Richmond, and older than any North American fm. referred to Sil. [Its large fauna listed.]

The 1915 edition of Pirsson and Schuchert's Textbook of geol., pt. 2, p. 629 (table), showed *Gamache* as overlying Richmond and underlying Oswegan, and as forming topmost Ord. In index *Gamache series* was used. The 1924 edition of this Textbook also included *Gamache* in Ord. and placed it above the Richmond.

A. F. Foerste, 1924 (Canada Geol. Surv. Mem. 138, p. 27). The Upper or Gamachian div. of the Richmond has little in common with Richmond faunas elsewhere, except in the case of those species which were already present during Vaurial time and which continued their existence into the overlying Gamachian or Ellis Bay div.

The foregoing are only records of this name.

Gammon ferruginous member (of Pierre shale).

Upper Cretaceous: Northeastern Wyoming and southeastern Montana.

W. W. Rubey, 1930 (U. S. G. S. P. P. 165A). *Gammon ferruginous memb.*—Basal memb. of Pierre sh. in NE. Wyo. and SE. Mont. Consists of 800 to 1,000 ft. of light-gray mudstone and sh. with abundant concretions and thin beds of siderite. Fossils scarce, but consist of marine species. Commonly forms bare buttes. Includes Groat ss. bed, 150 ft. thick, near top and Pedro bentonite bed at base. Rests on Beaver Creek chalky memb. of Niobrara fm. There is a possible uncon. at or near base of Gammon memb. Named for exposures along Gammon Creek, in T. 57 N., Rs. 67 and 68 W., Cook Co., Wyo.

Ganado series.

Tertiary or Pleistocene: Northeastern Arizona. See 1932 entry under *Bidahochi fm.*

Gander Run shale member. (In Hamilton group.)

Middle Devonian: Central Pennsylvania (Bedford County).

B. Willard, 1935 (Geol. Soc. Am. Proc. 1934, June 1935, p. 361). [See this citation under *Mahantango fm.* Not defined.]

B. Willard, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 8, Aug. 31, pp. 1279, 1282). Near Chaneysville, Bedford Co., Pa., Mahantango fm. is divided into 3 intergrading members (descending): Frame sh. memb., 343 ft.; Chaneysville ss. memb., 182 ft.; and *Gander Run sh. memb.*, 850 ft. The Gander Run memb. consists of brown-weathering, dark-gray sandy sh. with some shaly ss. Rarely well exposed and nearly barren. Named for stream occupying the valley underlain by these strata 6 to 8 mi. N. of Chaneysville. Not recognized in Blair Co.

Ganges formation.

Cretaceous: British Columbia.

C. H. Clapp, 1917 (Canada Geol. Surv. Mem. 96, p. 229).

Gannett group.

Cretaceous(?): Southeastern Idaho and southwestern Wyoming.

G. R. Mansfield and P. V. Roundy, 1916 (U. S. G. S. P. P. 98G, pp. 76, 82, 83). *Gannett group.*—Includes 5 distinct subdivisions (descending): Tygee ss., 100 ft.; Draney ls., 200 ft.; Bechler cgl., 1,775 ft.; Peterson ls., 205 ft.; and Ephraim cgl., 1,025 ft. Total thickness over 3,300 ft. Rests with apparent conformity on Stump ss. (Jurassic) and is uncon. overlain by Wayan fm. Fossils not distinctive but probably Cret. Named for Gannett Hills, in Bannock Co., Idaho, and Lincoln Co., Wyo., in E. part of Wayan quad., where all of its fms. are well exposed.

Gannett erosion cycle.

Name applied by G. R. Mansfield (Jour. Geol., vol. 32, 1924, p. 485) to a Pleist. erosion cycle in SE. Idaho.

Gansevoort.

Middle Ordovician: Eastern New York (Mohawk Valley).

R. Ruedemann and G. H. Chadwick, 1935 (Sci., n. s., vol. 81, No. 2104, p. 400). *Gansevoort* introduced for middle Canajoharie or zone of *Glossograptus quadrimucronatus cornutus* in Mohawk Valley.

†Gant bed.

Silurian (Niagaran): West-central Tennessee.

A. F. Foerste, 1903 (Jour. Geol., vol. 11, pp. 576, 582–583). *Gant bed.*—Fossiliferous lss. underlying Hardin ss. and forming upper part of Brownsport bed in vicinity of Martin's mill, on Indian Creek, Wayne Co. Includes at base the 5 to 10 ft. of coarse sandy fossiliferous ls. here named *Gant ls.* This is overlain by 9 ft. of bluish better-bedded ls., partly fine-grained and partly crinoidal, succeeded by 14 ft. of much weathered and poorly exposed lss.

Nongeographic name. Replaced by Bob crystalline ls. memb. of Brownsport fm., of which it composes middle and upper parts.

Named for A. B. Gant homestead, about 1 mi. NE. of Martin's mill, Wayne Co. (Mr. Gant no longer lives here.)

†Gant limestone.

Silurian (Niagaran): West-central Tennessee.

A. F. Foerste, 1903 (Jour. Geol., vol. 11, pp. 576, 582-583). [See explanation under †*Gant bed.*]

Gantz sand.

A subsurface sand, of late Dev. or Miss. age, 15 to 60 ft. thick, lying 1,916 ft. below Pittsburgh coal in eastern Greene Co., Pa. Named for Gantz farm, Franklin Twp., Washington Co., Pa. Considered to be part of 100-foot sand.

†Gap latite.

Miocene: Southwestern Colorado (Platoro-Summitville region).

Field name used by E. S. Larsen for rocks he named *Fisher quartz latite.* This field name crept into print in Colo. Geol. Surv. Bull. 13, 1917, simultaneously with the adopted name.

Gap sandstone member (of Nelagoney formation).

Pennsylvanian: Central northern Oklahoma (Osage and Washington Counties).

M. I. Goldman, 1920 (U. S. G. S. Bull. 686W, pp. 330, 333). *Gap ss.*—Named for occurrence at top of Gap Ridge, in SW. cor. of T. 29 N., R. 13 E., in NW. cor. of Washington Co. The gap, locally known as "Osage Gap," through which pass a high road and the branch of Atchison, Topeka & Santa Fe Ry btw. Pawhuska, Okla., and Caney, Kans., cuts through this ridge. In its exposure at the gap the ss. is 10 ft. or less thick, but thickens to N., where it forms surface of most of Ramsey anticline. It is=part of Revard ss. of neighboring Twps. Is very lenticular. Not recognized to W. across valley of Coon Creek, in sec. 32, T. 29 N., R. 12 E., and can be seen to pinch out within ½ mi. to S. of the gap. Lies short distance [15± ft. in later repts] below Possum ss.

Gaptank formation.

Pennsylvanian: Western Texas (southeast of Glass Mountains).

J. A. Udden, C. L. Baker, and E. Böse, 1916 (Univ. Tex., Bur. Econ. Geol. and Tech. Bull. 44, p. 47). *Gaptank fm.*—Named by Udden. Consists of (descending): (1) Mainly several masses of ls. separated by shaly and sandy material; (2) shales interbedded with lss.; (3) cgls. alternating with lss., sss., and shales. Thickness 1,500± ft. Is of upper Penn. age, and probably=Cisco fm. Occurs at Gaptank, 24 mi. NE. of Marathon, and extends short distance to SE. and 15 mi. to SW. [This definition included beds named *Wolfcamp fm.* in 1917.]

J. A. Udden, 1917 (Univ. Tex. Bull. 1753, pp. 38-41, pl. 3). *Gaptank fm.* [restricted] underlies Wolfcamp fm., where latter is present, and uncon. underlies Hess fm. where Wolfcamp is absent. Böse and C. L. Baker rept uncon. at base. Overlies Haymond fm. *Uddenites* zone included in Wolfcamp fm.

E. Böse, 1917 (Univ. Tex. Bull. 1762, pp. 15-16, 21-22). *Gaptank fm.* as originally defined included Wolfcamp fm. As now restricted consists of mostly shales, lss., and ss. of uppermost Penn. age. Underlies Wolfcamp fm. and overlies Haymond fm. *Uddenites* zone included in Wolfcamp fm.

I. A. Keyte, W. G. Blanchard, Jr., and H. L. Baldwin, Jr., 1927 (Jour. Pal., vol. 1, pp. 175-178, pl. 31), placed *Uddenites* zone in Gaptank fm., 400 ft. below base of Wolfcamp fm.

C. Schuchert, 1927 (Am. Jour. Sci., 5th, vol. 14, pp. 383-400). Writer believes *Uddenites* zone belongs to Wolfcamp fm., but Keyte, Blanchard, and Baldwin believe it belongs to Gaptank fm. It is here included in Wolfcamp. There is an uncon. at its base.

P. B. and R. E. King, 1928 (Univ. Tex. Bull. 2801). *Uddenites* zone is basal part of Wolfcamp, and there is uncon. at its base.

I. A. Keyte, 1929 (A. A. P. G. Bull., vol. 13, pp. 903-906). *Uddenites* zone belongs in Gaptank fm., and there is an erosinal uncon. btw. it and overlying Wolfcamp fm., and the faunas are different.

P. B. and R. E. King, 1929 (A. A. P. G. Bull., vol. 13, p. 925). *Uddenites memb.* of Wolfcamp fm. is uncon. on underlying rocks.

P. B. King, 1931 (Univ. Tex. Bull. 3038, pp. 43-57). *Uddenites memb.* included in base of Wolfcamp fm. (basal Perm.). R. E. King and writer are convinced of Perm. age of this memb., which is uncon. on older beds. Present investigation has shown that Wolfcamp fm. is present along almost the whole of Glass Mtns escarpment. Near type loc. it consists in large part of green or blue clay shales, with rather abundant thin fossiliferous ls. beds; but to SW., where the fm. encroaches upon the strongly folded rocks, it becomes coarsely clastic, with several hundred ft. of basal cgl. followed by sandy shales with sparse fossils. Thickness at type loc. 700 ft. For convenience of reference and mapping Wolfcamp fm. is here divided into 3 members (descending): (1) Upper memb., comprising about three-fourths of total thickness, is largely blue and green clay shales with thin layers of ls., and contains unmistakable Perm. fossils, including *Schwagerina,* which first appears at base of this memb.; (2) the Gray ls. memb., a rather thick-bedded, scarp-forming ls. about 50 ft. thick, containing few fossils; (3) *Uddenites memb.,* consisting of sh. with a few thin ls. beds, and varying in thickness up to 300 ft. The *Uddenites memb.* is exposed ¾ mi. NE. of summit of Leonard Mtn, but is absent W. of Leonard Mtn, where basal beds of Wolfcamp fm. are cgls., ranging from 10 ft. thick W. of Iron Mtn to 450 ft. near Lenox. The Gaptank fm. is 1,800 ft. thick in vicinity of Gap Tank. Its basal bed is the *Chaetetes* ls., 50 ft. thick, characterized by large masses of *Chaetetes milleporaceous.* [Gives detailed sections and fossil lists of Gaptank and Wolfcamp fms.] Cgls. first appear in Gaptank fm. several hundred ft. above its base. They are 15 to 50 ft. thick and 5 in number in one area. In upper 788 ft. of Gaptank fm. are 5 lss., 40 to 75 ft. thick, separated by sss. and shales. The 5th ls. is top bed of fm.

P. B. King, 1934 (Geol. Soc. Am. Bull., vol. 45, pl. 103), treated *Uddenites-bearing sh. memb.* as top bed of Gaptank fm., and assigned it to Penn. This is present definition of U. S. Geol. Survey. (See also *Wolfcamp fm.*)

Named for a tank, sometimes locally called "Gap Tank," located in a gap locally called Stockton Gap and Marathon Gap.

Garber sandstone.

Permian: Central northern Oklahoma.

F. L. Aurin, H. G. Officer, and C. N. Gould, 1926 (A. A. P. G. Bull., vol. 10, pp. 786–799). *Garber ss.*—A series of red clay shales, and red sandy shales, and red sss. overlying Wellington fm. and underlying Hennessey sh. in north-central Okla. Divided into Lucien sh. memb. below and Hayward ss. memb. above. Included in Enid group. Thickness 600 ft. Named for exposures at Garber, Garfield Co.

J. M. Patterson, 1933 (A. A. P. G. Bull., vol. 17, No. 3, pp. 252–256). *Garber fm. redefined.*—Aurin, Officer, and Gould give 600 ft. as thickness of Garber. They indicate considerable more thickness and greater breadth of outcrop for Garber of this area (Logan and Lincoln Counties, Okla.) than writer has found, but their thicknesses and contacts were only approximates. Writer finds thickness 260 to 300± ft., instead of 600 ft. as given by them. The base is not far from where writer has mapped it, but top in northern Logan Co. is about 6 mi. W. of where writer shows contact. Since most geologists familiar with area are agreed on top of Garber at Oklahoma City, and since no one can find a horizon for top of Garber as shown by Aurin, Officer, and Gould W. of Guthrie, Hayward, and Garber, it is proposed top of Garber be taken as that recognized at Oklahoma City, which is shown correctly by A. Travis on his map of Oklahoma Co. (Okla. Geol. Surv. Bull. 40, vol. 2, map 37). This is best break from predominant sand deposition to predominant sh. deposition, and a much more mappable top contact than that indefinitely defined by Aurin, Officer, and Gould. The Garber of S. part of Logan Co. is probably 90 percent ss., but at N. line of Co. it is about half ss. and half sh.

J. C. Ross, 1933 (A. A. P. G. Bull., vol. 17, No. 3, p. 255). Referring to Patterson's paper, serious objection can be made to what amounts to redefinition of fms. established by Aurin, Officer, and Gould in 1926, which is foundation on which later work must be based, or at least until their divisions are superseded. Their paper was defective in that type areas of the new fms. were not definitely set out, and no means were provided for identifying the contacts and working them both ways, but it was published before the present mass of detail was accumulated. In Logan Co. area their divisions are readily made out, at least in a thin zone, and it is not certain they should be changed. Patterson's divisions are more prominent beds, and for Logan Co. area more convenient. Agreement, however, would have to be reached concerning a much greater area, from Garvin to Noble, to upset the boundaries established by the nomenclators.

Garber sand.

A subsurface sand in SW. Okla., correlated with a part of Garber ss. (Perm.). The name has also been applied to a subsurface sand in central northern Okla. correlated with basal part of Pawhuska fm. (Penn.). In Garber pool, Garfield Co., the latter sand lies at 2,000 ft. depth, the Crews sand at 1,800 ft., and the Hoover at 2,400 ft.

†Garber limestone.

Miners' local name for an ore-bearing ls. in Deseret ls. (upper Mississippian), Ophir dist., central northern Utah. Is worked in Garber tunnel. (See U. S. G. S. P. P. 173, 1932.)

Gardeau shale member (of Portage formation).

Upper Devonian: Western and west-central New York.

J. Hall, 1840 (N. Y. Geol. Surv. 4th Rept., pp. 390–392, 452–455). *Gardeau flagstones or Lower Fucoidal group.*—Thick mass (100 to 250 ft.) of sh. and flagstones, or thin strata of fine-grained ss. at intervals of a few ft. and often a few inches. Throughout greater part of group the lower surfaces of the sss. are covered with fucoides and one side is covered with a glazing of sh. Along Genesee River this group commences a short distance above Mount Morris and continues to lower falls at Portage. Most extensively exposed along Gardeau Reservation [Livingston and Wyoming Counties], hence name. Underlies Portage or Upper Fucoidal group [Nunda ss.] and overlies Cashaqua sh., the intervening Ithaca group being absent in these counties (Steuben, Allegany, Cattaraugus, Livingston, and Genesee) and in Genesee Valley.

D. D. Luther, 1902 (N. Y. State Mus. Bull. 52). Hall's Gardeau divided into (descending): (1) *Gardeau flags,* 428 ft.; (2) ss. correlated with Grimes ss., 25 ft.; (3) flags and shales [later named Hatch sh.], 209 ft.; (4) second black band [later named Rhinestreet sh.], 52 ft.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 78), included Dunkirk sh. of Erie Co. in the Gardeau as restricted by Luther (see 1912 quotation under *Portland sh.*), stating that it occurs next above horizon of Grimes ss., and apparently within basal Gardeau.

F. Houghton, 1914 (Buffalo Soc. Nat. Sci. Bull., vol. 11). The Dunkirk sh. is distinct enough to warrant our excluding it from the Gardeau. [He excluded it in his classification, but stated that it merged with the Gardeau.]

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69), applied *Gardeau sh.* to beds btw. Nunda and Grimes sss. in Cattaraugus and Allegany Counties, but placed Dunkirk sh. at a much higher strat. horizon, where it is still placed.

In 1930 the U. S. Geol. Survey adopted, for use in its publications, *Gardeau sh. memb. of Portage fm.* for the beds underlying Nunda ss. (†Portage ss. of some authors) and overlying Grimes ss. This is definition of N. Y. State Survey, 1931. (See W. Goldring, N. Y. State Mus. Hdb. 10, p. 369.)

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60, No. 2, pp. 96, 98, 193), proposed to restrict Gardeau to lower part of the Gardeau of previous repts and named the upper part *Letchworth sh.*

G. H. Chadwick, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, p. 352), included Gardeau and underlying Grimes in Chemung group.

†Garden limestone.

An abbreviated form of *Garden City ls.* (Lower Ord. of Utah) employed by C. [R.] Keyes.

Garden City limestone.

Lower Ordovician (Beekmantown): Northeastern Utah and southeastern Idaho.

G. B. Richardson, 1913 (Am. Jour. Sci., 4th, vol. 36, pp. 407, 408). *Garden City ls.*—Thick- and thin-bedded gray ls., 1,000 ft. thick. Conformably underlies Swan Peak qtzite and overlies St. Charles ls. with evidence of erosional uncon. Contains Beekmantown fauna.

Named for exposures in Garden City Canyon, Rich Co., NE. Utah.

Garden Creek phyllite.

Cambrian (?): Southern central Idaho (Bayhorse quadrangle).

C. P. Ross, 1932 (Idaho correlation chart compiled by M. G. Wilmarth). *Garden Creek phyllite.*—Intensely sheared and metamorphosed argill. rocks at least several hundred ft. thick. Base not exposed. Underlies Bayhorse dol. with uncon. (?). Named for creek on which Challis is located.

C. P. Ross, Oct. 31, 1934 (Geol. Soc. Am. Bull., vol. 45, p. 941, etc.). *Garden Creek phyllite.*—Exclusively soft, easily weathered dark-gray, nearly black phyllite, locally slightly calc., with abundant sericite on cleavage surfaces. Bedding is represented by thin crenulated bands, visible only on close inspection. Several hundred ft. thick. Base nowhere exposed. Recognized only along inner gorges of Garden and Bayhorse Creeks, in N. part of Bayhorse quad. Provisionally referred to Camb. No fossils.

Garden Gulch member (of Green River formation).

Eocene: Northeastern Utah (Uinta Basin) and northwestern Colorado (Garfield and Rio Blanco Counties).

W. H. Bradley, 1931 (U. S. G. S. P. P. 168). *Garden Gulch memb. of Green River fm.*—Light-gray beds. Characteristic feature paper sh. with discrete laminae less than 1 mm. thick, which constitutes 20 to 40 percent of memb. and occurs in unbroken units 20 to 70 ft. thick, intercalated with thicker units of flaky sh. and thickly laminated marlstone, some of which is shaly. Contains only a few beds of fine-grained ss. and siltstone. Total thickness 200± ft. in Hells Hole Canyon, near Watson, Utah, and 700± ft. in Parachute Creek Canyon, N. of Grand Valley, Garfield Co., Colo. Overlies Douglas Creek memb. and underlies Parachute Creek memb. Named for thick exposures in bluffs near mouth of Garden Gulch, a short tributary of Parachute Creek, in secs. 7, 8, T. 6 S., R. 96 W., Garfield Co., Colo.

†Gardiner interval.

Pleistocene: Southeastern Massachusetts (Marthas Vineyard, Gardiners Island, etc.).

A. C. Veatch, 1906 (U. S. G. S. P. P. 44). [See 1906 item under †*Gayhead interval.*]

Gardiner clay.

See *Gardiners clay.*

Gardiners clay.

Pleistocene: Southeastern New York (Long, Gardiners, and Fishers Islands) and islands of southern New England (Block, Nantucket, Marthas Vineyard, No Mans Land, and probably Cape Cod).

M. L. Fuller, 1905 (Geol. Soc. Am. Bull., vol. 16, pp. 367–390). *Gardiner clay* (interglacial), 30 to 150 ft. thick. Conformably overlies Jameco gravel (glacial) and conformably underlies Jacob sand (interglacial) on Fishers Island. Correlated with early part of Yarmouth stage of Mississippi Valley.

M. L. Fuller, 1906 (Sci., n. s., vol. 24, pp. 467–469). *Gardiner clay.*—In some places occurs as a single bed; in other places is split into a series of clays interbedded with sands. Color varies from red through gray and brown to black. Small shell fauna. Present on Long Island, Fishers Island, Block Island, Marthas Vineyard, Cape Cod, and Mass. coast to Boston.

M. L. Fuller, 1914 (U. S. G. S. P. P. 82). *Gardiners clay,* named for Gardiners Island, at E. end of Long Island, on which several clay beds with included sands are well exposed at a number of places. Time of deposition is called *Gardiners stage.* Outcrops at many places on Long Island, and is found on Robins, Plum, Fishers and Gardiners islands.

J. B. Woodworth and E. Wigglesworth, 1934 (Harvard Coll. Mus. Comp. Zool. Mem., vol. 52). *Gardiners clay* occurs on Block and Nantucket Islands, Marthas Vineyard, No Mans Land, and is doubtfully identified on Cape Cod.

Gardiners stage.

The time covered by deposition of *Gardiners clay.*

Gardner dolomite.

Mississippian (lower): Central northern Utah (Tintic district).

G. F. Loughlin, 1919 (U. S. G. S. P. P. 107). *Gardner dol.*—Is recognized as a distinct fm. because it contains a great variety of recognizable fossils, most of which were found on spur W. of Gardner Canyon. Fm. consists chiefly of fine-grained gray to dark bluish-gray dol.; small chert nodules in some beds; a few beds of black dense carbonaceous ls. interstratified. Top is mapped at base of lowest exposed black cherty beds of Pine Canyon ls. At or near top is 100 ft. of black highly carbonaceous and pyritic shaly ls. Thickness 435 to 700 ft. Overlies Victoria qtzite. Fossils are of Madison age, G. H. Girty says.

Garfield sandstone. (Of Chester group.)

Mississippian: Western central Kentucky.

A. F. Foerste, 1910 (Ky. Geol. Surv. Rept. Prog. 1908 and 1909, pp. 79, 84). *Garfield ss.*—Chiefly ss., but locally replaced to considerable extent by clay. Thickness 127 ft. Underlies Stephensport bed and overlies Clover Creek ls. in Meade and Breckinridge Counties.

According to C. Butts, 1917 (Ky. Geol. Surv., Miss. series in west Ky., p. 87), this is Cypress ss.

Named for Garfield, Breckinridge Co.

Garfield formation.

Pennsylvanian: Central Colorado (Monarch-Tomichi region).

R. D. Crawford, 1913 (Colo. Geol. Surv. Bull. 4, p. 66). *Garfield fm.*—In descending order: (1) Dominantly qtzite with subordinate sh. beds; (2) dominantly sh. with some qtzite; (3) chiefly ls. with interstratified black sh., 200 ft.; (4) black sh. with thin strata of qtzite and impure ls., 700 ft.; (5) qtzite and cgl. 30 ft. Total thickness 2,600 to 2,800 ft. Overlies Ouray ls. (Miss.-Dev.), with apparent conformity. Uncon. underlies Kangaroo fm. Named for Garfield, Chaffee Co. Fossils [listed].

Garfield formation.

Pre-Cambrian: Southwestern South Dakota (Lawrence County).

J. O. Hosted and L. B. Wright, 1923 (Eng. and Min. Jour.-Press, vol. 115, pp. 793–799, 836–843, and maps). *Garfield fm.*—Banded (black and red) fine-grained hard, cherty ferruginous qtzite, in many places highly pyritiferous. Graphitic schists usually overlie the qtzite, and are also pyritiferous. The fm. is locally known as "Iron Dike," because of iron content and long dikelike outcrops. Thickness 60 ft. Believed to be of Keewatin age. Older than Pluma fm. and younger than Northwestern fm.

Derivation of name not stated, but occurs in Lead dist., Lawrence Co.

Garfield sand.

Drillers' term; western Pa.; see under *Cherry Grove sand.*

Garibaldi volcanic formation.

Pleistocene: British Columbia.

E. M. J. Burwash, 1918 (The geol. of Vancouver and vicinity, p. 77).

†Garland conglomerate. (In Pottsville formation.)

Pennsylvanian: Northwestern Pennsylvania.

J. F. Carll, 1875 (2d Pa. Geol. Surv. Rept. I, pp. 38, 45–46). *Garland cgl.*—The cgl. capping the hills at Garland, Warren Co. [On p. 38 is called *Olean cgl. (Garland).*]

J. F. Carll, 1880 (2d Pa. Geol. Surv. Rept. I_3, pp. 12–57). *Garland cgl.* is used in these pages as a convenient local geographical name for lowest memb. of Carbf. Cgl. series in NW. part of State. It is apparently identical with Olean cgl. of McKean Co. At Garland quarries, about 1 mi. NW. of Garland, it is 40 ft. thick, massive, coarse grained, obliquely bedded, yellow and white in some parts, iron stained in others, with pebbly horizontal layers and pockets, especially in lower portion. Basal deposit of Pottsville cgl.

Replaced by Olean cgl. memb. of Pottsville fm., better-established name.

Garland sand.

Drillers' term for a sand of Upper Dev. (Chemung) age in NW. Pa.

Garley Canyon sandstone member (of Mancos shale).

Upper Cretaceous: Central eastern Utah (Book Cliffs and Wasatch Plateau).

E. M. Spieker and J. B. Reeside, Jr., 1925 (Geol. Soc. Am. Bull., vol. 36, p. 438). *Garley Canyon ss. memb. of Mancos sh.,* 0 to 140 ft. thick, lies considerable distance below Emery ss. memb. of Mancos and considerable distance above Ferron ss. memb. in Wasatch Plateau. [Named for prominent exposures in walls of Garley Canyon, Carbon Co. Later repts give distance below Emery ss. as 400 to 500 ft., and distance above Ferron ss. as 2,300 to 2,400 ft.]

Garner formation. (In Strawn group.)

Pennsylvanian (Allegheny): North-central Texas (Brazos River region).

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 106, 108). *Garner fm.* has been proposed by G. Scott and J. M. Armstrong (ms. of geol. rept. on Parker Co.) to include lower part of Mineral Wells fm. of Plummer and Moore. Consists of a coal seam, shales, ss., and cgls.; some thin lss. are present, one near middle of Mingus memb. Thickness of fm. 400 to 500 ft. The Thurber coal with some associated thin lss. and shales marks the beginning of the fm. Next overlying this memb. is Mingus memb., consisting of 250 or 300 ft. of sandy sh. The overlying Brazos ss. and cgl. (top memb. of Garner fm.) is 25 or 30 ft. thick. [On p. 106 Sellards listed, beneath the Thurber coal, the following members in Garner fm. (descending): Goen ls., Plummer, 1929; Santo ls., Plummer, 1929; and Barton Creek ls., Plummer, 1929, preoccupied and discarded.] Type loc., Garner, Parker Co.

F. B. Plummer and J. H. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, pp. 15–30). *Garner fm.* was named by Scott and Armstrong (unpublished ms.) to include all strata in Brazos River section from base of Thurber coal up to top of Brazos River ss. (25 to 75 ft. thick). The beds (145 to 210 ft. thick) btw. Thurber coal and Brazos River ss. comprise the Mingus sh. memb. The fm. is a shallow-water partly marine, partly fluviatile, and partly lacustrine deposit. It is uncon. on Millsap Lake fm.

Garnet Range formation.

Pre-Cambrian (Belt series): Central western Montana (Missoula to Helena region).

C. H. Clapp and C. F. Deiss, 1921 (Geol. Soc. Am. Bull., vol. 42, p. 681, figs. 2, 3). *Garnet Range fm.*—Chiefly qtzites of different colors and types, but including some argillite and ss. Thickness 7,600 ft. Conformably underlies Sheep Mtn. fm. and overlies McNamara fm., all included in Missoula group. [Detailed section given.] Type loc. on N. side of Blackfoot Canyon from Johnson Gulch 2 mi. E. of Bonner eastward to 1 mi. from mouth of West Twin Creek. Blackfoot Canyon forms NW. bdy of Garnet Range, the W. part of which is composed largely of rocks of Garnet Range fm.

†Garnett limestone.

Pennsylvanian: Eastern Kansas.

E. Haworth and M. Z. Kirk, 1894 (Kans. Univ. Quart., vol. 2, pp. 110, 120–121). Hard compact lss., separated into two parts by 8 to 10 ft. of sh. Here called *Burlington or Garnett ls.,* ultimate choice of name being left to future. Overlies Le Roy shales. Separated from higher Strawn ls. by 75 to 100 ft. of sh.

H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. Mines, vol. 13). "Garnett ls." of Kans. includes (descending) Stanton ls., Vilas sh., and Plattsburg ls.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, p. 70). Moore's restricted *Lansing group,* to include only Stanton ls., Vilas sh., and Plattsburg ls., corresponds to Garnett ls. of early Kans. Surv. The revival of *Garnett* might not be desirable, however, inasmuch as the term has been used for several different units and has never had wide acceptance.

Named for Garnett, Anderson Co.

Garnuan series.

A term introduced by C. [R.] Keyes for a part of the pre-Camb. rocks of N. Mex. (See his Conspectus of geol. fms. of N. Mex., 1915, pp. 4, 7. Derivation of name not stated.)

Garrard sandstone. (In Eden group.)

Upper Ordovician: Central Kentucky.

M. R. Campbell, 1898 (U. S. G. S. Richmond folio, No. 46, p. 2). *Garrard ss.*—Calc. ss. and sh. or mudstone. 70 to 130 ft. thick, grading imperceptibly into Richmond fm. above and into Winchester ls. below.

A. M. Miller, 1905 (Ky. Geol. Surv. Bull. 2, pp. 8–23). *Garrard substage* (top div. of Eden stage of central Ky.) consists of 65 ft. of fine-grained ss. with concretionary layers in middle. To N. ss. is wanting at this horizon. Lower part of Eden stage consists of 200 ft. of blue sh. and thin lss., overlying Winchester substage [restricted to lower 40 ft. of Campbell's Winchester]. The lower beds of Eden age were named *Million sh.* by J. M. Nickles in 1905. This sh. underlies Garrard ss.

A. F. Foerste, 1906 (Ky. Geol. Surv. Bull. 7). *Garrard ss.* of Richmond folio [as mapped?] includes Mount Hope bed and Paint Lick bed.

G. C. Matson, 1909 (U. S. G. S. W. S. P. 233). *Garrard ss. memb. of Eden sh.*—Upper part of Eden sh. in S. part of Blue Grass region, Ky. Consists of shaly sss., in some places concretionary, having max. thickness of 150± ft. Thins gradually to N. Lower part of Eden consists of blue sh. with sandy layers and locally beds of ls.

Named for Garrard Co.

Garrett conglomerate.

Lower Cretaceous (Comanche series): Northeastern New Mexico.

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257–259; Conspectus of geol. fms. of N. Mex., pp. 2, 7). *Garrett cgl.*, 50 ft. thick, basal memb. of Early Cretacic section in NE. N. Mex. and SW. Kans. [Derivation of name not stated. Keyes has also applieu the name in Colo. He describes it as older than Kiowa sh.]

Garrett Mill sandstone member (of Warsaw formation).

Mississippian: Southeastern Kentucky and northern central Tennessee (Overton County).

C. Butts, 1922 (Ky. Geol. Surv., ser. 6, vol. 7, pp. 89, 107, 122). *Garrett Mill ss. memb.*—Generally flaggy ss., 5 to 10 ft. thick. Is persistent throughout northern Overton Co. and thence as far N. as Pulaski Co., where it is represented by a few inches of sandy ls. at top of the Warsaw in bluff of Cumberland River just N. of Burnside. It is the only ss. in a considerable thickness of ls., and extends over several counties (Overton Co., Tenn., to Pulaski Co., Ky.). Is top memb. of Warsaw fm. Lies stratigraphically higher than Somerset sh. memb. of Warsaw. [Page 122 shows a few ft. of sh. btw. St. Louis ls. and Garrett Mill ss.] Named for exposures at Garrett Mill, on Eagle Creek, 3 mi. N.-NE. of Livingston, Overton Co., Tenn. The mill stands on the ss.

Garrison shale. (In Council Grove group.)

Permian: Eastern Kansas, northern Oklahoma, and southeastern Nebraska.

C. S. Prosser, 1902 (Jour. Geol., vol. 10, p. 712). Florena shales below (2 to 13 ft. thick) and Neosho memb. above (130 ft. thick), with aggregate thickness of 140 to 145 ft., are now united to form *Garrison fm.*, so named on account of good exposures from Garrison S. in Big Blue Valley.

This name was continued in use for many years. In 1936 (Kans. Geol. Surv. Bull. 22, pp. 50, 251) R. C. Moore discarded the name, treating the numerous named subdivisions into which it had in recent years been differentiated as fms. within Council Grove group. The U. S. Geol. Surv. has not yet had occasion to reconsider retaining the name for its publications.

Named for exposures at Garrison, Pottawatomie Co., Kans.

Gartland oil sand.

Drillers' term; western Pa.; see under *Cherry Grove sand.*

Garvin beds.

Permian: Central southern Oklahoma (Garvin County).

A. R. Denison, 1923 (A. A. P. G. Bull., vol. 7, No. 6, pp. 627–644). *Garvin beds.*—Upper part of subsurface Perm. in Robberson field, Garvin Co. Consists of 1,200 ft. of "red beds," gumbo, and gravel with one or two ls. beds, one of which, occurring from 950 to 1,000 ft. depth, is recorded as present in most of early wells drilled for which accurate logs were made. Carries a few water sands near surface. Overlies Mauldin beds and underlies Perm. shales and sss.

Gary moraine (also **morainic system**).

Pleistocene (Wisconsin stage): South Dakota, North Dakota, Minnesota, Iowa.

T. C. Chamberlin, 1883 (U. S. G. S. 3d Ann. Rept., p. 393). Next later than Altamont moraine. Named for development in vicinity of Gary, Deuel Co., S. Dak.

See also F. Leverett's moraine map in U. S. G. S. P. P. 161, 1932. Is of late Wisconsin age.

Gasconade dolomite.

Lower Ordovician (Beekmantown): Eastern and central Missouri.

F. L. Nason, 1892 (Mo. Geol. Surv. vol. 2, pp. vii, 12, 93, 114–115, pl. III). *Gasconade ls.*—Great series of ls. beds interstratified with thin beds of ss. that underlie Roubidoux ss. in Ozark uplift and compose lower fm. of Ozark series. Includes 3d and 4th Mag. lss. and separating sss. of earlier repts.

A. Winslow, 1894 (Mo. Geol. Surv. vols. 6 and 7), and 1895 (Am. Geol., vol. 15, pp. 81–89), stated that Gasconade ls. underlies Roubidoux or Saccharoidal [?] ss. and includes Jefferson City ls., Moreau ss., Osage ls., Cole Camp ss., and Proctor ls.

S. H. Ball and A. F. Smith, 1903 (Mo. Bur. Geol. and Mines vol. 1, 2d ser.). *Gasconade ls.*—Whitish or grayish cherty and noncherty dol. with beds of chert and occasional sss. Thickness 250 ft. Is=Third Mag. ls. of Swallow. Underlies St. Elizabeth fm. [Roubidoux] and overlies Gunter ss. [This definition was followed by S. H. Ball, 1904; C. F. Marbut, 1904; E. R. Buckley and H. A. Buehler, 1904; E. M. Shepard, 1904; E. R. Buckley, 1905; H. A. Buehler, 1907; and C. [R.] Keyes, 1914.]

H. F. Bain and E. O. Ulrich, 1905 (U. S. G. S. Bulls. 260, 267). *Gasconade ls.*—Chert-bearing dolomitic lss. and sss., 450 to 650 ft. thick. Underlies Roubidoux fm. and overlies Elvins fm. Is=3d and 4th Mag. lss. and 3d ss., also=Lesueur ls. Includes Osage ls., Gasconade ls., Cole Camp ss., Gunter ss. and Proctor ls. [This definition was followed by G. H. Scherer, 1905.]

E. R. Buckley, 1908 (Am. Min. Cong. Rept. Proc. 10th Ann. sess., p. 286). *Gasconade* of Mo. underlies Roubidoux and uncon. overlies Proctor. [This definition of Gasconade (which includes Gunter ss. memb. at base) was followed by C. F. Marbut, 1908; E. R. Buckley, 1909; R. S. Bassler, 1911; E. O. Ulrich, 1911; G. W. Crane, 1912; H. A. Buehler, 1917; C. L. Dake, 1918; E. B. Branson, 1918; M. E. Wilson, 1922; H. A. Buehler, 1922; and E. B. Branson, 1923; and it was for many years the accepted definition of U. S. Geol. Survey.]

H. S. McQueen, 1930 (Insoluble residues as a guide in stratigraphic studies, Mo. Bur. Geol. and Mines, separate). *Gasconade fm. restricted.*—Dol., light colored, finely crystalline with characteristic hard blue chert. Thickness 140 to 200 ft. Chert is dominant constituent; much of it is vitreous and quartzose, but lacks the even glassy texture of the Eminence and to some extent the chert of the Van Buren, and it is also darker than any similar material in Van Buren or Eminence. Uncon. underlies Roubidoux fm. and uncon. overlies Van Buren fm. [See further explanation under *Van Buren fm.* This is definition of Gasconade dol. that has been adopted by Mo. Geol. Survey and is now followed by U. S. Geol. Survey.]

Named for exposures on Gasconade River, central Mo.

Gascons formation. (In Chaleur series.)

Silurian (Niagaran): Quebec (Gaspé Peninsula).

C. Schuchert and J. D. Dart, 1926 (Canada Geol. Surv. Bull. 44 p. 48).

S. A. Northrop, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, p. 271). Fauna of Gascons fm., of middle Sil. Chaleur series, is transitional btw. Clinton and Lockport.

Gaspe series.

Devonian and Mississippian: Quebec.

W. E. Logan, 1863 (Canada Geol. Surv. Repts 1843–63, pp. 406–453, 880–886). *Gaspe series.*—Is Middle and Upper Sil., Dev., and Lower Carbf. Includes Gaspe ls., Gaspe ss., and Bonaventure fm.

Subsequent writers assigned Gaspe ls. and Gaspe ss. to Dev. and Bonaventure fm. to late Miss.

Gaspe sandstone.

Devonian: Quebec.

W. E. Logan, 1863 (Canada Geol. Surv. Repts. 1843–63, pp. 394–404). *Gaspe sss.,* Dev., Canada. Included in Gaspe series.

C. Schuchert, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 174–175). *Gaspe sss.* are late Dev.

C. H. Kindle (1936) stated fossils of lower memb. of Gaspe ss. are probably Middle Dev. (See under *Malbaic cgl.*)

Gaspe limestone.

Devonian: Quebec.

W. E. Logan, 1863 (Canada Geol. Surv. Repts 1843–63, pp. 390–394). *Gaspe lss.*—Middle and Upper Sil., Canada.

J. M. Clarke, 1908 (N. Y. State Mus. Mem. 9, p. 26). *Gaspe lss.* of Quebec are Dev.

F. J. Alcock, 1922 (Canada Geol. Surv. Summ. Rept. 1921, pt. D, p. 81), and 1926 (Canada Geol. Surv. Summ. Rept. 1924, pt. C, p. 139). *Gaspe ls.* of Quebec is Dev.

W. A. Parks, 1931 (Geol. Soc. Am. Bull., vol. 42, p. 787). *Gaspe ls. series* embraces Grand Greve, Cape Bon Ami, and St. Alban.

Gasper formation.
Gasper oolite. } (Of Chester group.)

Mississippian: Kentucky, southwestern Virginia, Tennessee, and northern Alabama.

C. Butts, 1917 (Ky. Geol. Surv. Mississippian fms. of western Ky., pt. 1, pp. 64–84). *Gasper oolite.*—Thick-bedded ls. and oolite, and in parts of Breckinridge Co. (also in Meade, Hardin, Grayson and perhaps Hart Co.) it includes, near middle, the Sample ss. memb., which has a max. thickness of 40 ft. Total thickness of fm. 100+ ft. Replaces Ulrich's "Tribune ls." Is not known W. of E. part of Crittenden Co., Ky. Rests uncon. on Fredonia oolite memb. of Ste. Genevieve ls., the intervening Rosiclare and Ohara members of the Ste. Genevieve and the Bethel ss. being absent. Is older than Cypress ss. The Ridenhower sh. is = in part at least Gasper oolite and possibly is represented in only upper part of Gasper fm. Named for exposures in bluffs along Gasper River in Warren Co., Ky.

C. Butts, 1926 (Geol. Surv. Ala., Spec. Rept. No. 14), defined *Gasper fm.* of that region as underlying Cypress ss. and overlying Bethel ss.

A. H. Sutton and J. M. Weller, 1932 (Jour. Geol., vol. 40, No. 5, pp. 430, 439–441). Uncertainty regarding the beds which Butts himself intends to include within typical Gasper has made it impossible for writers to recognize "Gasper" as a valid fm. name. Therefore *Girkin* is proposed as a designation for beds of Renault and Paint Creek age in that part of West. Ky. where the Bethel (Sample) ss. is not developed. [See under *Girkin fm.*]

Gaspereau formation.

Carboniferous: Nova Scotia.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 210).

Gasport limestone member (of Lockport dolomite).

Silurian: Western New York and Ontario.

E. M. Kindle, 1913 (U. S. G. S. Niagara Falls folio, No. 190). *Gasport ls. memb.*—Light-gray to white coarse-grained semicrystalline crinoidal ls., generally nonmagnesian. Thickness 6 to 20 ft. In literature has been called Lower Niagara ls., Lockport Encrinal marble, and Crinoidal ls. Overlain by dark-gray to chocolate-colored saccharoidal dol.; underlain by drab mag. ls. [later named De Cew ls.]. Named for exposures at Gasport, Niagara Co., N. Y.

Gasport shaly channel.

Silurian: Western New York.

R. Ruedemann, 1925 (N. Y. State Mus. Bull. 265, pp. 5–14). *Gasport shaly channel.*—Is intercalated in Lockport ls., but faunule differs entirely from that of surrounding Lockport ls. The channel rock itself, for most part, consists of calc. and argill. sh., sandy near top, and containing six thin layers of shaly ls. By its dark-brown color it contrasts strikingly with the light-buff Lockport ls. Passes laterally, with a jagged margin of interlocking layers, into coralline and crinoidal beds of Lockport ls. and therefore represents an original depression btw. the reefs. Probably represents the filling of a depression or lagoon.

Gassetts schist.

Upper Cambrian(?): Southeastern Vermont (Windsor County).

C. H. Richardson, 1929 (16th Rept. Vt. State Geol., pp. 210, 225). *Gassetts schist.*—Silvery white, highly garnetiferous, muscovite schist; scaly texture, or muscovite is arranged in parallel plates and is by far the most abundant constituent. Is a highly metamorphosed sediment, which in certain outcrops has been affected by intrusives bearing boron and fluorine. Is a new and the oldest memb. of Upper Camb. Missisquoi group. Underlies the typical sericite schists and qtzites of that group, of which it is the lower memb. Overlies Bethel and Cavendish schists. Outcrops at Gassetts [Ludlow quad.] in N. part of Chester [Twp], and at other places [mentioned] in Reading, Cavendish, Baltimore, and Chester Twps. Assigned to Upper Camb.

See also C. H. Richardson, 1931 (17th Rept. Vt. State Geol., pp. 198, 223). Also 18th Rept. Vt. State Geol., where Richardson and J. E. Maynard state type loc. is just N. of Gassetts railroad station.

Gastineau volcanic group.

Triassic (Upper): Southeastern Alaska (Juneau region).

G. C. Martin, 1926 (U. S. G. S. Bull. 776, pp. 92, 247, chart opp. p. 120). *Gastineau volcanic group.*—In descending order, sl., andesitic tuff, calc. sl. with Upper Triassic fossils, and andesitic lava with local lenses of sl. Thickness possibly 5,000 ft. Assigned to Upper Triassic. Overlies Perseverance sl. and underlies Thane volcanic group.

Named for Gastineau Peak, which is in midst of the group. Whether the whole group is Upper Triassic is now considered questionable.

Gates limestone.

Silurian: Western New York.

G. H. Chadwick, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 335, 356, 358, 359, 360, 361, 364). *Gates ls.*—About 20 ft. of beds at Rochester, heretofore included in Rochester sh., which apparently are absent at Niagara, and which are really a ls., being quarried and sold as such. Are uncon. overlain by Decew (basal) memb. of Lockport dol., and are separated from Rochester sh. [restricted] below by a perfectly clean-cut line or clay seam. Carry few fossils except *Lingula lamellata.* Named for town [in Monroe Co.], in which the beds appear in the canal prism. Probably continues to thicken E. of Rochester under the drift and is very likely the rock forming the falls at Wolcott village. Present at Ontario, N. Y., and at Wallington and probably at Red Creek [both in Wayne Co.]; also doubtfully identified at South Granby and Brewerton, N. Y., and at Hamilton, Ont. Absent in Lakeport well [Madison Co.].

Gates formation.

Cretaceous: British Columbia.

F. H. McLearn, 1923 (Canada Geol. Surv. Summ. Rept. 1922, pt. B, p. 6).

Gatesburg formation.

Upper Cambrian: Central Pennsylvania (Blair to Center Counties).

C. Butts, 1918 (Am. Jour. Sci., 4th, vol. 46, pp. 527, 534, 537; name proposed by E. S. Moore). *Gatesburg fm.*—Thick-bedded steely-blue, coarsely crystalline dol., with many interbedded qtzite layers up to 10 ft. thick; contains considerable silicified oolite, also, near middle, Ore Hill ls. memb., and at base Stacy dol. memb. Underlies Mines dol. and overlies Warrior ls. Named for Gatesburg Ridge, Center Co.

Gatesville formation. (In Fredericksburg group.)

Lower Cretaceous (Comanche): North-central Texas.

S. A. Thompson, 1935 (A. A. P. G. Bull., vol. 19, No. 10, pp. 1508, 1530, 1531–1533, 1536). Edwards ls., Comanche Peak ls., and Walnut clay of Fredericksburg group are in part contemp. with one another and contain essentially same fauna. They are here treated as members of *Gatesville fm.*, new name for lower part of Fredericksburg group, the Kiamichi clay being upper fm. of that group. [It is still a debated question whether Kiamichi should be included in Fredericksburg group.] Type loc. *is near State Training School for Boys N. of Gatesville,* Coryell Co.

W. C. Mendenhall, 1935 (p. 1537 of book cited above) questioned usefulness of this name.

Gateway formation.

Pre-Cambrian: Southern British Columbia and northwestern Montana (Galton Range).

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines, Mem. 38, maps 2, 3, 4). *Gateway fm.*—Chiefly thin-bedded siliceous metargillite; some dol. at base. [Younger than Purcell lava and Siyeh fm.]

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, pp. 107, 136, 178). *Gateway fm.*—Chiefly metargillite and qtzite. Upper memb. (1,850 ft.) consists of thin-bedded highly siliceous metargillite interstratified with subordinate more or less sericitic metasandstone; carries abundant salt crystal casts, and is almost certainly contemp. with lower part of Kintla fm. Lower memb. (125 ft.) consists of dol., ss., ls., qtzite, metargillite, and at once suggests possible identity or origin with Sheppard fm. The fm. is well exposed on heights E. of Gateway, Mont., and overlooking Tobacco Plains. Rests conformably on Purcell lava, and grades into overlying Phillips fm.

Gato formation.

Pliocene: Dominican Republic.

C. J. Maury, 1931 (Sci., n. s., vol. 73, p. 42).

Gatun formation.

Miocene (middle): Panama.

E. Howe, 1907 (Isthmian Canal Comm. Rept., pp. 108–138).

Gautreau formation.

Mississippian: New Brunswick (Stony Creek oil and gas field).

G. W. H. Norman, 1932 (Canada Geol. Surv. Econ. Geol. ser., No. 9, p. 170).

Gauvin andesite.

Age (?): New Brunswick.

F. J. Alcock, 1935 (Canada Dept. Mines Geol. Surv. Bur. Econ. Geol. Mem. 183, p. 72).

Gavilan.

See *Gabilan ls.*

Gaviota formation.

Eocene and Oligocene (?): Southern California (Santa Barbara County).

W. L. Effinger, 1935 (Pan-Am. Geol., vol. 64, No. 1, p. 75). *Gaviota fm.* is proposed for that assemblage of marine strata falling within "*Turritella variata* zone" of Woodring in Santa Ynez Range, Santa Barbara Co. Type area is W. of Gaviota Pass, and type loc. is designated as Cañada de Santa Anita, where the fm. consists of 1585 ft. of sss. and siltstones overlying Tejon fm. (Eo.) and underlying Sespe fm. Lower part of fm. is believed to be Eo.; upper part may include some Olig.

H. G. Schenck and R. M. Kleinpell, 1935 (p. 76 of book cited above). Microfossils and strat. relations suggest *Gaviota fm.* is late Eo.

See also under *Refugian stage.*

†Gay Head clays.

Trade name applied to part of Cret. deposits of Marthas Vineyard, Mass.

†Gayhead interval.

Pleistocene: Southeastern Massachusetts (Gay Head, Marthas Vineyard, etc.).

J. B. Woodworth, 1896 (U. S. G. S. 17th Ann. Rept., pt. 1, pp. 975–988). *Gay Head interval of erosion and folding* separates Sankaty beds (interglacial) from succeeding Tisbury [Manhasset] beds (glacial).

A. C. Veatch, 1903 (Jour. Geol., vol. 11, pp. 766–776). There is nothing on Long Island which can clearly be referred to *Gayhead interval* except by inference.

A. C. Veatch, 1906 (U. S. G. S. P. P. 44). As the name Gay Head belongs more properly to the folding than to the erosion interval which followed, the name *Gardiner interval* is suggested for the latter, from Gardiner Island, where the truncated folds can be well observed.

Gaysport member. (In Conemaugh formation.)

Pennsylvanian: Southeastern Ohio (Muskingum County).

W. Stout, 1918 (Ohio Geol. Surv., 4th ser., Bull. 21, p. 258). *Gaysport memb.*—Siliceous ls. or calc. ss. Marine fossils. Thickness 0 to 2½ ft. Lies 20 ft. 4 in. below horizon of Duquesne coal and 16 ft. 3 in. above Ames ls. Occurs locally in Muskingum Co. Best developed in vicinity of Gaysport, Bluerock Twp., Muskingum Co.

Gazley Creek sands and clays.

Eocene: Southern central Texas (Bastrop County).

W. A. Price and K. V. W. Palmer, 1928 (Jour. Pal., vol. 2, p. 22), loosely applied this name to gray ss. containing a Cook Mtn fauna and to overlying sands and clays on S. bank of Colorado River at mouth of Gazley Creek, in W. edge of Smithville, Bastrop Co.

†Gebo formation.

Upper Cretaceous: Northwestern Wyoming (Park County).

D. F. Hewett, 1914 (U. S. G. S. Bull. 541, pp. 91, 100). *Gebo fm.*—Massive ss., buff near base and white near top, separated by thin beds of sh.; near base 1 or more coal beds. A few plants and invertebrates of Montana types. Thickness 1,120 ft. along Shoshone River and to S. Underlies Meeteetse fm. and overlies Colorado sh. Named for Gebo, near Thermopolis, near which extensive mining operations have been conducted on a coal bed near base of fm.

Later work proved this fm. is same as Mesaverde fm. of Colo., and it was therefore discarded and mapped as Mesaverde on 1924 geol. map of Wyo.

Gemini limestone.

Ordovician: Central northern Utah (Tintic district).

G. W. Crane, 1915 (Am. Inst. Min. Engrs. Bull. 106, pp. 2149–2151). *Gemini ls.*—Forty-five or more relatively thin alternating horizons of blue, gray, light-gray, and white ls., of varying texture and hardness, but all generally distinctly bedded. Thickness 902 ft. Underlies Chief Consolidated ls. and overlies 920 ft. of white lime sh. [later named Opohonga ls. The fm. was evidently named for Gemini mine.]

The Chief Consolidated and Gemini lss. of Crane compose Bluebell dol.

Genesee group.

Upper Devonian: New York, Pennsylvania, Maryland, northern West Virginia, and across western Virginia.

L. Vanuxem, 1842 (Geol. N. Y., pt. 3, pp. 168–169). *Genesee sl.*—A black argill., fissile mass., appropriately a mudrock. Is the *Black sh. and sl.* and *Upper Black sl.* of repts. Thickness 100 ft. Underlies Portage or Nunda group (which includes Cashaqua sh., Gardeau and Portage groups, and Sherburne flagstone and sh.), and overlies Tully ls.

In succeeding years the names *Genesee beds*, *Genesee sh.*, and *Genesee group* were applied to the beds btw. Portage group and Tully ls., but bdy btw.

the Portage and Genesee was by some placed at top of a so-called "Lower Black Band" and by others at base of or 10 to 15 ft. below base of this "Band." In 1903 (N. Y. State Mus. Hdb. 19, p. 23) J. M. Clarke introduced *Middlesex black shales* for the "Lower Black Band" and *Rhinestreet black sh.* for the "Upper Black Band," both of which, "for paleontologic reasons," he included in Portage group. In 1904 (N. Y. State Mus. Bull. 63) J. M. Clarke and D. D. Luther applied *Genesee beds* to strata btw. Middlesex sh. and Tully ls., which they divided into Standish flags and shales (top), 15 ft.; West River sh.; Genundewa or Styliola ls.; and *Genesee sh.*, the latter defined as densely black bituminous sh. 95 ft. thick, resting on Tully ls. They stated: It was clearly this excessively black mass of sh. that it was intended [by Hall] to distinguish by the name *Genesee*, and it is here proposed to restrict *Genesee* to this lower memb. only. [In several places in text (pp. 23 and 25) they casually alluded to restricted Genesee sh. as *Gorham shales*, probably from their occurrence at or near town of Gorham. These casual references to *Gorham* were evidently not intended as a geol. name, and they constitute the only known record of *Gorham*.]

The broad use of Genesee was applied in many repts during succeeding years, but the repts of Clarke and Luther continued to restrict the name to the beds btw. Genundewa and Tully lss., although they subsequently stated (N. Y. State Mus. Bull. 81, 1905, and N. Y. State Mus. Bull. 128, 1909) that Genesee sl. as originally defined and as used by Hall included their restricted Genesee sh., the Genundewa ls., and the West River sh., but that [1905 citation] it has seemed best to retain that name [*Genesee sl.*] in application to lower part of the series as exhibited on Genesee River, for the lower beds are highly bituminous and regularly slaty, and it was to indicate this bituminous character that the rock series was specially and separately designated. C. A. Hartnagel's Hdb. 19 (1912) applied *Genesee* in both the broad and the restricted sense. In 1920 (Geol. Soc. Am. Bull., vol. 31, p. 118) G. H. Chadwick proposed to replace the restricted Genesee sh. with *Geneseo black sh.* The Middlesex sh. appears to have been consistently included in Portage group until K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, pt. 1, pp. 201–202), included it in the Genesee, in which he also included Tully ls.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369), adopted the restricted definition of Genesee (i. e. the basal memb., or Geneseo sh. of Chadwick) and included the overlying Genundewa ls., West River sh., and Standish sh. in Portage group; but Cooper (1935) used *Geneseo*, as defined by Chadwick, i. e., for the sh. above Tully ls. and below Genundewa ls.

G. H. Chadwick, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, p. 352), included all of above beds in *Genesee group*, and discussed fauna on pp. 310+.

The U. S. Geol. Survey in March 1936, at request of W. H. Bradley (who had in preparation a rept (Bull. 899–A) on structure and gas possibilities in Steuben and adjacent counties in south-central N. Y.), adopted *Genesee group* to include the following *fms.* (descending): Standish ss., West River sh., and Geneseo sh. (redefined to include Genundewa ls. lentil at top).

Named for abundant exposures along Genesee River and Valley, N. Y., especially in gorge of Genesee River below Portage.

Genesee Valley limestone and shales.

Triassic: Northern California (Sierra Nevada).

J. P. Smith, 1910 (Jour. Geol., vol. 18, chart opp. p. 220). *Genessee Valley limestone and shales.*—Triassic. Older than Sailor Canyon shales [restriction ? of Sailor Canyon fm.], and overlies Paleozoic.

J. S. Diller (U. S. G. S. Bull. 353, 1908) mapped the Triassic rocks of Genesee Valley region as *Swearinger sl.* and *Hosselkus ls.* Name probably derived from occurrence in Genesee Valley, E. of Genesee, Plumas Co.

Geneseo shale. (In Genesee group.)

Upper Devonian: New York.

G. H. Chadwick, 1920 (Geol. Soc. Am. Bull., vol. 31, p. 118). *Geneseo black sh.*—The name "Genesee" is in duplicate use for the group (including the West River) and for the part beneath Genundewa ls., which is under water at Hall's type loc. To avoid confusion the variant *Geneseo* may be given to the latter, which is 84 ft. thick in the fall on Fall Brook, Geneseo, N. Y.

See also *Gorham sh.*

G. H. Chadwick, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, p. 310). *Geneseo black sh.* goes out of section just before plunging under Lake Erie.

G. A. Cooper and J. S. Williams, 1935 (Geol. Soc. Am. Bull., vol. 46, p. 824). Chadwick's name *Geneseo* is adopted for the black sh. overlying Tully ls. and underlying Genundewa ls., because use of *Genesee* in two senses is confusing. The Geneseo is 75 ft. thick in vicinity of type section of the Tully, 100 ft. at Cayuga Lake, 85 ft. in Genesee Valley, 2 ft. on Cazenovia Creek, Erie Co., and on shore of Lake Erie consists of remnants a few inches thick. In Unadilla Valley writers could not find it.

The U. S. Geol. Survey in March 1936, at request of W. H. Bradley (who has in preparation a rept on structure and gas possibilities in Steuben and adjacent counties in south-central N. Y.), adopted *Geneseo sh.* for basal fm. of *Genesee group*, and redefined *Geneseo* by including in it, at top, *Genundewa ls. lentil.* The Genundewa was included in Geneseo sh. "because of its small thickness and the similarity of its fauna to that of the Geneseo, and because at some places it consists of several layers of ls. separated by black sh."

Geneva limestone.

Middle Devonian: Central and southeastern Indiana (Shelby to Jennings Counties).

J. Collett, 1882 (Ind. Dept. Geol. and Nat. Hist. 11th Ann. Rept., pp. 63, 81, 82). *Geneva ls.*—Buff mag. ls. (Corniferous), 38 ft. thick, at top of Dev. in Shelby Co. Overlain by glacial drift and underlain by 0 to 14 ft. of stratified Dev. rubble ls. (Corniferous?) or by Sil. strata.

E. M. Kindle, 1901 (Ind. Dept. Geol. and Nat. Res. 25th Ann. Rept.). *Geneva ls.*—Soft dark-buff to brownish fine-grained mag. ls., 3 to 30 ft. thick. Lies btw. Niagara and Jeffersonville lss. Is=Shelby bed of Foerste, which should be abandoned. Believe Geneva ls. replaces Sellersburg and Jeffersonville to N.

J. F. Newsom, 1903 (Ind. Dept. Geol. and Nat. Res. 26th Ann. Rept.). *Geneva ls.*, 2 to 30 ft. thick, to N. apparently replaces Jeffersonville and Sellersburg beds.

T. C. Hopkins, 1904 (Ind. Dept. Geol. and Nat. Res. 28th Ann. Rept.). Jeffersonville ls. includes *Geneva ls.*, Shelby beds, and Hartsville beds.

E. M. Kindle, 1913 (Jour. Geol., vol. 21, p. 313). Fauna of Geneva ls. indicates it is of either Schoharie or Onondaga age, probably Schoharie.

W. N. Logan, 1920 (Ind. Dept. Cons., Div. Geol. Pub. 8, btw. pp. 50 and 57), called the ls. beneath Silver Creek ls. *Geneva (Jeffersonville) ls.*

E. R. Cumings, 1922 (Hdb. Ind. Geol., pt. 4, Sep. Pub. 21, p. 466). *Geneva ls.* of Collett may represent a facies of some part of the Jeffersonville. What actual relationships of Geneva and Jeffersonville-Sellersburg fms. are has not been satisfactorily determined. The Geneva may be a lithologic facies of one or both of these fms., or, more likely, a distinct fm. older than the Jeffersonville. Ulrich apparently correlates it with Schoharie, though his reasons are not stated. It occurs in Jennings, Decatur, Bartholomew, and Shelby Counties.

Named for Geneva, Shelby Co.

†Geneva quartzite.

Lower Ordovician: Northeastern Utah (northern Wasatch Mountains).

E. Blackwelder, 1910 (Geol. Soc. Am. Bull., vol. 21, pp. 519, 526–527, 542). The Ogden qtzite as originally defined has no existence. In Ogden Canyon 2 thick beds of qtzite appear to be separated by several hundred ft. of sh. and ls. Geologists of 40th Par. Surv. considered the lower of these to be Camb. The upper fm. was named "Ogden qtzite," and its age was thought to be approx. Dev. This classification stood unchallenged for more than a generation. A few years ago F. B. Weeks (unpublished rept, 1908), found Ord. fossils in a qtzite and sh. fm, N. of Brigham. This qtzite was separated from the Camb. qtzite by a thick series of sh. and ls., and on this account Weeks considered it to be="Ogden qtzite." But the "Ogden qtzite" in Ogden Canyon is now believed to be merely a slab of Camb. qtzite repeated by an overthrust. An early Paleozoic qtzite formerly correlated with "Ogden qtzite" is widely distributed in Wasatch Mtns, and is now bereft of its name, since the typical "Ogden qtzite" must be ruled out. As it is clearly exposed and well marked by fossils E. and N. of Geneva, it will be called the *"qtzite at Geneva."* Seems to be best exposed in N. part of Wasatch Range. It is a cream-colored calc. qtzite interbedded with green sh. near top and bottom and altogether not over 400 ft. thick. It is doubtless in this qtzite Weeks found Ord. fossils. The same fauna was found by writer at 2 points near Geneva in 1909. [In footnote on p. 519 he calls this fm. *Geneva fm.*]

The name *Geneva* being preoccupied, G. B. Richardson in 1913 named the Ord. qtzite *Swan Peak qtzite*, the name by which it is now known.

†Geneva sands.

Pleistocene: Southeastern Alabama and Georgia.

See description under †*Ozark sands.*

Probably named for Geneva or Geneva Co., SE. Ala.

†Genevieve group.

Mississippian: Missouri.

H. S. Williams, 1891 (U. S. G. S. Bull. 80, p. 169). *Genevieve group.*—Geographic name proposed for Archimedes group of B. F. Shumard. Includes Chester, St. Louis [broad and abandoned usage], and most of Warsaw, the faunas of which are more closely allied than they are to faunas of the Keokuk and Burlington.

Includes Chester and Meramec groups of present terminology.

Named for exposures in Ste. Genevieve Co.

Genevieve limestone.

An abbreviated form of *Ste. Genevieve ls.*, employed by C. [R.] Keyes.

Gennet Creek formation. (In Chester group.)

Mississippian: Southwestern Indiana.

M. A. Harrell, 1935 (Ind. Dept. Cons. Pub. No. 133, p. 78), listed (but did not define) *Gennet Creek fm.*, 10 to 35 ft. thick, as underlying Mount Pleasant ss. and overlying Bristow ss. In previous repts the Mount Pleasant had been defined as resting on Bristow ss.

Genoa moraine.

Pleistocene (Wisconsin stage): Southern Wisconsin and northeastern Illinois. Shown on moraine map (pl. 23) of U. S. G. S. P. P. 106. Named for Genoa Junction, Walworth Co., Wis.

Genshaw formation.

Middle Devonian: Northeastern Michigan (Thunder Bay region).

A. S. Warthin, Jr., and G. A. Cooper, 1935 (Wash. Acad. Sci. Jour., vol. 25, No. 12, pp. 524–526). *Genshaw fm.*—Four persistent thin gray ls. beds, alternating with gray calc. shales, all containing a large sp. of *Atrypa* and *Gypidula romingeri.* Measured thickness, 51 ft. Underlies Killians ls. and rests on clay shales of Ferron Point fm. Type loc., region around Genshaw School, sec. 13, T. 32 N., R. 8 E., Alpena Co.

Gent facies.

Name applied by P. B. Stockdale (Ind. Dept. Cons., Div. Geol. Pub. 98, pp. 77, 178, etc., 1931) to a lithologic facies of his Carwood fm. in a part of southern Ind.

Gentile Valley group.

Pleistocene or late Tertiary: Southwestern Idaho (Gentile Valley).

A. C. Peale, 1879 (U. S. Geol. and Geog. Surv. Terr. 11th Ann. Rept., pp. 612, 642, and map). Near one of our substations in Gentile Valley a coarse cgl. outcrops, which was horizontal and seemed to be older than the soft deposits in center of valley. In Portneuf Canyon a similar cgl. was noted, also on E. side of Cache Valley. These beds I have provisionally designated *Gentile Valley group.*

According to G. R. Mansfield (personal communication) these beds may be Pleist. or may belong to Salt Lake fm. (Tert.).

Genundewa limestone lentil (of Geneseo shale).

Upper Devonian: Western and west-central New York.

J. M. Clarke, 1897 (N. Y. State Geol. 15th Ann. Rept.). [The ls. in midst of Genesee sh. had for many years been called *Styliola ls.* (from its characteristic fossil), and described as somewhat concretionary, sometimes inclined to be shaly, composed almost wholly of *Styliola fissurella,* having a thickness of 0 to 4 [8] ft. (thinning out to E.), and lying from 20 to 86 ft. above base of the Genesee. In 1897 rept cited above Clarke referred to it as *Genundewah or Styliola ls.* In 1903 (N. Y. State Mus. Hdb. 19, chart) Clarke used the following title: *Genesee sh. incl. Genundewa ls.,* while D. D. Luther (N. Y. State Mus. Bull. 69, p. 1001) referred to it as *Styliola or Genundewa ls.*]

J. M. Clarke, 1904 (N. Y. State Mus. Mem. 6, pp. 199–214). The *Genundewa or Styliola ls.* of Genesee shales is a thin sheet sometimes interrupted, sometimes nodular, but virtually continuous from Lake Erie to Seneca Lake.

J. M. Clarke and D. D. Luther, 1904 (N. Y. State Mus. Bull. 63, p. 26). *Genundewa ls. or Styliola ls.*—Dark-gray soft shaly ls. in layers 2 to 10 inches thick, separated by dark or black sh. Where purest is composed almost wholly of shells of *Styliola (Styliolina) fissurella.* Divides the mass of Genesee deposits into nearly equal parts in Canandaigua and Naples quads. Typical outcrop on shore of Canandaigua Lake, at foot of Bare Hill or, as it should be termed, *Genundewa.* [On map accompanying this rept the hill is called "Bare Hill." It is in Yates Co.] Included in Genesee group, which is divided into (descending): Standish flags and shales, West River sh., Genundewa or Styliola ls., and Genesee sh. restricted [which Chadwick proposed (1920) be replaced by *Geneseo shale*].

J. M. Clarke and D. D. Luther, 1905 (N. Y. State Mus. Bull. 81, p. 5). *Genundewa ls.* named for Genundewa Point on Canandaigua Lake.

See further explanation under *Genesee sh.*

The U. S. Geol. Survey in March 1936, at request of W. H. Bradley (who has in preparation a rept on structure and gas possibilities in Steuben and adjacent counties in south-central N. Y.), adopted *Geneseo sh.* for basal fm. of *Genesee group,* and redefined Geneseo by including in it, at top, *Genundewa ls. lentil.* The Genundewa was included in Geneseo sh. "because of its small thickness and the similarity of its fauna to that of the Geneseo, and because at some places it consists of several layers of ls. separated by black sh."

George River limestone.

Age(?): Nova Scotia.

H. Fletcher, 1878 (Canada Geol. Surv. Rept. Prog. 1876–77, p. 426).

George River limestone series.

Age(?): Nova Scotia.

H. Fletcher, 1900 (Canada Geol. Surv., Descriptive note on Sydney coal field, p. 5).

George River series.

Pre-Cambrian: Nova Scotia.

G. A. Young, 1913 (12th Int. Geol. Cong. Guidebook 1, p. 268).

Later repts, by other geologists, assigned these rocks to pre-Camb.

Georges Fork sandstone member (of Atoka formation).

Pennsylvanian: Eastern Oklahoma (Muskogee and McIntosh Counties).

C. W. Wilson, Jr., 1935 (A. A. P. G. Bull., vol. 19, No. 4, pp. 503-520). *Georges Fork ss. memb. of Atoka fm.*—Thin to massive-bedded ss.; medium-grained; commonly greenish brown on fresh surface, weathering to brown; surfaces of bedding planes often covered with fucoidal markings. Fossils. Thickness 35 ft. Base lies 80 to 120 ft. above Pope Chapel ss. memb. and top lies 60 ft. below Dirty Creek ss. memb., the intervals being occupied by sh. Named for exposure E. of Georges Fork, in secs. 24 and 25, T. 12 N., R. 19 E.

Georgetown limestone. (In Washita group.)

Lower Cretaceous (Comanche series): Central and southern Texas.

T. W. Vaughan, 1900 (U. S. G. S. Uvalde folio, No. 64). *Georgetown ls.*—Name proposed by R. T. Hill for impure, yellowish, argill. ls., 40 or more ft. thick, characterized by *Kingena wacoensis*. Underlies Del Rio clay and overlies Edwards ls. Is equal in part to ls. formerly called Fort Worth ls. Exposures very small.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7). Upper 10 ft. of *Georgetown ls.* correlates with Main Street ls. The rest of Georgetown has lithologic aspect of Fort Worth ls. but is paleontologic equiv. of Kiamitia clay, Duck Creek fm., Fort Worth ls., and lower Denison beds. Thickness of Georgetown at Austin 49.9 ft. Underlies Del Rio clay and overlies Edwards ls.

J. A. Udden and C. L. Baker, 1916 (Univ. Tex. Bull. 44). Del Rio clay=Grayson marls and Main Street ls.

L. W. Stephenson, 1918 (U. S. G. S. P. P. 120, pl. 18). Del Rio clay=Grayson marl and probably Main Street ls.

W. S. Adkins, 1920 (Univ. Tex. Bull. 1856). *Georgetown ls.* includes equivalents of lower part of Main Street ls., Pawpaw fm., Weno fm., Denton fm., Fort Worth fm., and Duck Creek marl, but not of Kiamitia fm., which disappears at Brazos-Colorado uplift.

W. M. Winton and G. Scott, 1922 (Univ. Tex. Bull. 2229, pp. 12–15). Kiamitia is not represented in central Tex. despite statements of earlier writers.

W. S. Adkins, 1923 (Univ. Tex. Bull. 2340). *Georgetown fm.* of McLennan Co. is composed of 7 well differentiated and partially mappable members, which are strat. and paleontologic equivalents of the fms. of same names in north-central Tex. and southern Okla., and their relations with these fms. have been accurately traced, viz., Mainstreet, Pawpaw, Weno, Denton, Fort Worth (30± ft.), Duck Creek (30± ft.), and Kiamitia (5 to 9 ft.). Underlies Del Rio fm. and overlies Edwards ls.

H. P. Bybee and F. M. Bullard, 1927 (Univ. Tex. Bull. 2710, p. 21), correlated *Georgetown ls.* with Pawpaw, Weno, Denton, Fort Worth, Duck Creek, and Kiamichi.

R. H. Cuyler, 1929 (A. A. P. G. Bull., vol. 13, pp. 1292–1299), correlated uppermost part of Georgetown ls. with Main Street ls.

Basal fm. of Washita group in Tex. W. of Brazos River.

Named for Georgetown, Williamson Co.

Georgia slate.

Lower Ordovician (Beekmantown): Northwestern Vermont (Franklin County).

E. Hitchcock, 1861 (Rept. Geol. Vt., vol. 1, pp. 357–386). *Georgia group or Georgia sl.*—Consists of clay sl.; roofing sl.; clay sl. approximating to micaceous ss.; various kinds of ls.; brecciated ls.; and cgl. composed of pebbles of ls. Includes what Prof. [E.] Emmons has called black sl., in part, Taconic sl., and roofing sl. Age in doubt. Thickness 2,000 ft. Overlain by Talcose cgl.; is younger than the Quartz Rock, which has been mistaken for Potsdam ss., and the Red Sandrock series. The Georgia sl. is fully exposed in town of Georgia [Milton quad.], Franklin Co., where its most interesting fossils have been found.

A. Keith, 1923 (Am. Jour. Sci., 5th, vol. 5, pp. 122–126). *Georgia sl.*—Almost entirely sl., soft, and as a rule dark gray or bluish gray; much of it is banded. At base are several specialized and very important beds, chief of which is Swanton cgl. [later renamed *Corliss cgl.*], which has been separated as a distinct fm.; being separated from Georgia sl. by a great uncon., and, with Georgia sl., overlapping onto Highgate sl., Milton dol., Colchester fm., and Mallett dol. Possibly there are other and higher cgls., but all now known are explainable as basal beds. The sl.

lies in synclines and its upper part has been removed by faulting or erosion; original thickness therefore unknown, but is likely to be over 2,000 ft. in Georgia. Lies in a belt 34 mi. long, whose S. end is in Colchester and N. end in Highgate. North of main belt several narrow strips of fm. extend to Canada, and several prongs of the sl. project from main fm. in vicinity of St. Albans. In town of Ga., for which the fm. is named, the belt is widest—about 3 mi. Narrows to N. and S. In earlier repts Georgia has been used in both narrower and broader senses. In 1861 Hitchcock, in his original use of *Georgia sl.*, included only the slates of Georgia and their supposed equivalents elsewhere. This usage was followed in the main by other geologists. The underlying lss. and sss. were treated as another fm.—the "Red Sandrock." In present paper the Georgia sl. is somewhat restricted from Hitchcock's original limits by cutting off about 300 ft. of beds (Highgate sl.) from base of fm., because they are Upper Camb., while bulk of Georgia sl. is post-"Saratogan," and because there are 2 great unconformities btw. the 2 parts. The Swanton cgl. was also included in original definition of Georgia sl.

A. Keith. 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 379), assigned Georgia sl. to Lower Ord., based on Beekmantown fossils found in it, and applied new name *Corliss cgl.* to the cgl. previously called *Swanton cgl.* C. Schuchert, 1933 (Am. Jour. Sci., 5th, vol. 25, pp. 359, 379–380) also assigned the Georgia to Lower Ord., based on fossils identified as Beekmantown by G. A. Cooper.

†Georgia beds.

Original form of †Georgian series.

†Georgia group.

See under *Georgia sl.*

†Georgian epoch (or series).

Discarded name for Lower Cambrian (Waucoban epoch or series). See U. S. G. S. Bull. 769, pp. 94–96, 100.

Gering formation.

Miocene: Western Nebraska.

N. H. Darton, 1898 (U. S. G. S. 19th Ann. Rept., pt. 4, pp. 735, 747–755). *Gering fm.*—Coarse sands, soft sss., and cgl.; the sands laminated, massive, cross-bedded, and of light-gray color. Often comprises two or more members, more or less distinctly separated by unconformities. Greatest development is SW. of Gering, Nebr., where it is 200 ft. thick. It is possible upper memb. of Gering fm. is basal portion of overlying Arikaree fm. Rests uncon. on White River group.

These deposits are now considered to be local sediments in stream channels, and are covered by the broader term *Arikaree fm.*, of which they form basal part.

Gerlane formation.

Quaternary: South-central Kansas.

G. L. Knight, 1934 (Geol. Soc. Am. Proc. 1933, p. 91). *Gerlane fm.*—A Quat. continental deposit of south-central Kans., with type loc. near Gerlane, Barber Co. Is of alluvial origin; derived from Perm. and Tert. fms. in the area. Occurs both as valley filling and as surface wash, the former type best developed in larger valleys, giving them smooth broad floors. Where partly removed by erosion the Gerlane forms terraces along valley sides. The surface-wash phase covers much of intervalley areas of lower slopes. Thickness 100+ ft. in drills near Sharon, in what is believed to have been valley of Medicine Lodge River before it changed its course.

Germantown sands.

Subsurface sands (First Germantown and Second Germantown) in Pottsville fm. (Penn.) of SE. Ohio.

Germer tuffaceous member (of Challis volcanics).

Tertiary (late Oligocene or early Miocene): Southern central Idaho (Custer County).

C. P. Ross, 1932 (Idaho correlation chart compiled by M. G. Wilmarth). *Germer tuffaceous memb. of Challis volcanics.*—Tuff, tuffaceous ss., cgl., and rhyolite flows. Thickness 0 to 2,000+ ft. Type, Germer Basin, Bayhorse quad. Overlain by Yankee Fork rhyolite memb. of Challis volcanics and underlain by basal andesitic beds (0 to 2,000+ ft. thick) of Challis volcanics.

More fully described by C. P. Ross in rept on Casto quad., U. S. G. S. Bull. 854, 1934.

Named for Germer Basin, on S. side of Salmon River, nearly opposite mouth of Bayhorse Creek.

Gerome andesite.

Tertiary: Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 98, map). *Gerome andesite.*—Lava flows, tuffs, breccias, and intercalated beds of sh. and ss. containing impure carbonaceous seams of varying thickness. Lava flows predominate, but tuffs, breccias, and sediments compose possibly 20 percent of whole. Thickness at least 700 ft. Uncon. overlies Stevens series and granite intrusives. Lies in N.-S. depression carved in older fms. Confined to SW. corner of Co. Appears to be a northern extension of larger areas farther S. in Columbia lava plateaus. Large exposures near town of Gerome. Included in Tert.

Gerona marble.

Late Jurassic (?): Cuba.

C. W. Hayes, 1901 (Rept. geol. reconn. Cuba, p. 114). [Age not given, but J. W. Lewis, 1932 (A. A. P. G. Bull., vol. 16, p. 536), assigned it to pre-Jurassic. C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 524), assigned Gerona marble of Isle of Pines to late Jurassic.]

†Geronimo series.

Pennsylvanian (?): Southwestern Oklahoma (Wichita Mountains).

H. F. Bain, 1900 (Geol. Soc. Am. Bull., vol. 11, pp. 135, 140–141). *Geronimo series.*—Consists of ss., cgl., shales, and lss. underlying Perm. red beds in Wichita Mtns, Okla. Later than Trenton. Named for famous Apache chief, who lives as a prisoner of war at Fort Sill.

Gerster formation.

Permian: Western Utah (Gold Hill district).

T. B. Nolan, 1930 (Wash. Acad. Sci. Jour., vol. 20, No. 17, Oct. 19, pp. 421–432). *Gerster fm.*—Largely thin-bedded sandy and shaly lss., brownish gray on fresh surfaces but weathering yellowish brown or pink. Beds usually 2 in. to 1 ft. thick. Locally thin beds of ss. occur, and in most exposures moderately thick beds of cherty ls. are present. Overlies Oquirrh fm. with sharp contact. Thickness 600 ft. Contains Perm. fossils. Named for exposures in Gerster Gulch, in NW. corner of Gold Hill quad.

See also U. S. G. S. P. P. 177, 1934.

Gerty sand.

Quaternary? (Pleistocene?): Central and central southern Oklahoma.

J. A. Taff, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, p. 439). *Guertie sand.*—Gravel, sand, and silt. 30 or more ft. thick, resembling recent river or lake sand plains, probably deposited in a deserted river channel, and extending over part of McAlester coal field. [Mapped (pl. 64) as *Peaceable sand* (probably from Peaceable Creek, Hughes Co.), but Guertie adopted in text as more appropriate name. Assigned to Quat. (?).]

C. N. Gould, 1925 (Okla. Geol. Surv. Bull. 35, p. 109), gave thickness as 0 to 50 ft.

Named for Guertie, Hughes Co. The spelling of name of this town was in December 1924 changed by U. S. Geographic Board to *Gerty*.

Gething member.

Cretaceous: British Columbia.

F. H. McLearn, 1923 (Canada Geol. Surv. Summ. Rept. 1922, pt. B, p. 4).

Gettysburg shale. (In Newark group.)

Upper Triassic: Southeastern Pennsylvania.

A. I. Jonas, 1926 (Topog. and Geol. Atlas of Pa. No. 178, New Holland sheet, p. 17). *Gettysburg sh.* is second and middle memb. of the Triassic. Is composed of soft, red, shaly sss. with hard gray pebbly ss. beds, and contains beds of thick red ss. with scattered pebbles of different sizes. It is here made up of less sh. and more ss. than in type area, and is overlain by an undet. thickness of coarse cgl. interbedded with red ss., which forms upper memb. of Triassic. Thickness of Gettysburg sh. is about 1,000 ft. [On accompanying map it is mapped as "soft red sh. and ss."] It rests on "basal memb. of Triassic" (called *lower arkosic ss. and cgl. memb.*), which consists of 1,000 ft. of quartz cgl. underlain by about 500 ft. of arkosic red ss.

G. W. Stose, 1929 (U. S. G. S. Fairfield-Gettysburg folio, No. 225). *Gettysburg sh.* is *redefined* so as to include all Triassic sediments of this part of SE. Pa. that overlie New Oxford fm. (lower fm. of Newark group). These Gettysburg sediments, which compose upper fm. of Newark group in this region, aggregate approx. 16,000 ft., and consist in general of red shales and soft red sss., with minor amounts of white ss., green and yellow sh., black carbonaceous sh., and dark impure ls. Much of fm. has been metamorphosed, by intrusive diabase, to dark purple or black argillite or to white porcelanite. Near middle is Heidlersburg memb. and at top the Arendtsville fangl. memb. (consisting of quartzose cgl.) and a contemp. ls. cgl.

Named for exposures at Gettysburg.

Gettysburg granite.

A local trade term for Upper Triassic diabase quarried extensively in vicinity of Gettysburg, Pa.

†Geuda salt measures. (In Sumner group.)

Permian: Eastern Kansas.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, pp. 1–48). *Geuda salt measures.*—Chiefly clay shales, of many colors and kinds, and beds of ls., gyp., and salt. Thickness 300 to 400 ft. Divided into (descending): (1) Sh. and shaly ls.; (2) *Greeley gyp.;* (3) shales, 100 ft.; (4) Hope gyp. Basal fm. of Sumner div. Underlies Wellington shales and overlies Marion concretionary ls. (top bed of Chase lss.). Prosser's term *Marion fm.* included Geuda salt measures and lower part of Wellington, and is preoccupied. Named for town of Geuda Springs, [Sumner Co.], Kans.

Cragin later abandoned this name for *Marion fm.* The latter name has been used to include the salt beds and also to exclude them. In 1927 Kans. Geol. Survey and U. S. Geol.. Survey abandoned Marion fm. and redefined Wellington fm. so as to extend down to top of Herington ls. The salt beds are therefore now included in the Wellington.

Ghost River formation.

Devonian (?): Alberta (Front Range).

C. D. Walcott, 1921 (Smithsonian Misc. Coll. vol. 72, No. 6, p. 5). *Ghost River fm.,* Rocky Mtns, Canada. [Walcott gave a full description of this fm. in Smithsonian Misc. Coll., vol. 67, No. 8, pp. 463–464, 1923. No fossils found. Rests on Middle Camb. and is overlain by Dev. In 1927 (Canada Geol. Surv. Mem. 153, p. 13) P. S. Warren assigned the fm. to Dev., as did Walcott in 1928, and Warren in 1929.]

Giants Range granite.

Pre-Cambrian (pre-Huronian and post-Knife Lake): Northeastern Minnesota (Vermilion and Mesabi districts).

J. E. Spurr, 1894 (Minn. Geol. Nat. Hist. Surv. 22d Ann. Rept., pp. 119–124). *Giant's Range granite.*—Hornblende-biotite variety. Intrusive and post-Keewatin.

C. K. Leith, 1903 (U. S. G. S. Mon. 43, pp. 24, 186–188, etc.). The intrusive *Giants Range granite* forms core of Giants Range, and is lower Huronian.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, pp. 135–136). *Giants Range granite* extends for 20 mi. or more along Vermilion Range in contact with various fms. It includes a series of granites ranging in color from light gray to very dark gray, flesh, pink, and red. Varies from very dense fine-grained granites through medium-to coarse-grained ones. Is of lower or middle Huronian age.

Forms all of Giants Range except extreme E. end, which is formed by the Keweenawan Embarrass granite. Giants Range is southern extremity of Mesabi Range.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), assigned Giants Range granite to Algoman, which they correlated as pre-Huronian and post-Knife Lake series.

Gibson coal member (of Mesaverde formation).

Upper Cretaceous: Northwestern New Mexico (Gallup-Zuni Basin).

J. D. Sears, 1925 (U. S. G. S. Bull. 767). *Gibson coal memb.*—Light-gray to white lenticular ss., light-gray clay sh., and valuable coal beds throughout Gallup-Zuni Basin. Thickness 150 to 175 ft. Underlies Allison barren memb. and overlies Bartlett barren memb.; all belonging to Mesaverde fm. Named for village of Gibson, McKinley Co., for many years the center of mining operations in the coals of this memb.

Gibson sand.

A subsurface sand in Hardinsburg ss., of Chester (Miss.) age, in SW. Ind.

Gibson erosion cycle.

A name applied by G. R. Mansfield (U. S. G. S. Bull. 713, 1920, p. 16) to a Pleist. erosion cycle in SE. Idaho. Named for fact that little settlement of Gibson stands on the terrace developed during the interval. Later (Jour. Geol., vol. 32, p. 485, 1924) Mansfield called this *Blackfoot cycle*.

Gila conglomerate.

Pleistocene and Pliocene: Arizona and southwestern New Mexico.

G. K. Gilbert, 1875 (U. S. Geog. and Geol. Surv. 100th Mer., vol. 3, pp. 540-541). *Gila cgl.*—A system of valley beds, of which a cgl. is the characteristic memb., which are exhibited in section along the gorges of the upper Gila and its tributaries, the Bonita, Prieto, Gilita, and San Francisco creeks and rivers. The boulders of the cgl. are of local origin; the cement is calc.; interbedded by layers of slightly coherent sand, and of trass, and sheets of basalt, the latter in some cliffs predominating over the cgl. Thickness 1,000 to 1,500± ft.

Gilan series.

A term employed by C. R. Keyes instead of Gila cgl.

Gilbert shale.

Pennsylvanian (?): Northeastern Arkansas (White County).

D. D. Owen, 1858 (First rept. geol. reconn. northern counties of Ark., pp. 68–69). *Gilbert shales.*—Shaly strata, 60 ft. thick, dark or nearly black in lower part and reddish yellow and ferruginous toward top. Includes numerous segregations of carbonate of iron and carbonate of lime. Exposed 3 mi. NW. of Searcy, White Co., at "bald point," in vicinity of Widow Gilbert's farm. Belong to coal measures. Overlie heavy sss. supposed to be ss. which forms "Bee rock" and belongs to millstone grit fm.

According to later repts (see U. S. G. S. W. S. P. 399, 1916, by L. W. Stephenson and A. F. Crider) Carbf. rocks are encountered only in wells in White Co.

Gilbert limestone. (In McMillan formation.)

Upper Ordovician: Central Kentucky.

A. F. Foerste, 1912 (Denison Univ. Sci. Lab. Bull. 17, pp. 18, 23). *Gilbert memb.*—Chiefly dove-colored lss. [thickness not stated], in McMillan fm. in central Ky. Overlies Tate memb. of McMillan fm., and stratigraphically corresponds nearly to Corryville memb. to N.

Probably named for Gilbert, Lincoln Co.

Gilbert sandstones. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and D. B. Reger, 1914 (W. Va. Geol. Surv. Rept. Logan and Mingo Counties, pp. 217–219). *Upper Gilbert ss.*—Grayish white, massive, medium-grained, micaceous, 40 to 50 ft. thick; lies 1 to 10 ft. below Lower War Eagle coal and 30 to 50 ft. above Glenalum Tunnel coal. *Lower Gilbert ss.*—Massive, grayish white, very hard and aren., 50 to 80 ft. thick; underlies Glenalum Tunnel coal. Named for Gilbert, Mingo Co.

Gilbert shale. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, p. 168). *Gilbert sh.*—Roof sh. of Gilbert coal in western part of Wyoming Co. Generally dark gray to black. Frequently carries marine fossils. Thickness 2 to 40 ft. Underlies Gilbert A coal.

Gilbert Peak erosion surface.

Tertiary (Oligocene or Miocene): Northeastern Utah and southeastern Wyoming (Uinta Mountains).

W. H. Bradley, 1936 (U. S. G. S. P. P. 185). Gilbert Peak erosion surface is older than Bishop cgl. Named for large remnant of the surface that slopes westward and northward from W. base of Gilbert Peak, Utah.

Gilberts morainic system.

Gilberts moraine.

Pleistocene (Wisconsin stage): Northeastern Illinois. (See M. M. Leighton, 16th Int. Geol. Cong. Guidebook 26, 1932, p. 49.)

Gilboa formation.

Upper Devonian: Eastern New York (Schoharie Valley).

G. A. Cooper, 1934 (Am. Jour. Sci., 5th, vol. 27, pp. 1–12). *Gilboa beds.*—In Schoharie Valley, in hills N. of Gilboa and S. along shores of Gilboa Reservoir, *Spirifer mesastrialis* and other Ithaca fossils are common in the sss. This div. (250± ft. thick) is=Tully (Laurens) and Sherburne ss., and is Ithaca facies of Sherburne, Geneseo, and Tully. Nearly complete section is exposed in W. face of Reed Hill, which is taken as the type.

G. A. Cooper and J. S. Williams, 1935 (Geol. Soc. Am. Bull., vol. 46, pp. 803, 818–821, 829). At time Cooper defined *Gilboa beds* he believed all beds btw. top of Hamilton and *"Spirifer" mesastrialis* zone at Jefferson, Ruth, and elsewhere, 250 ft. thick, represented Tully, Geneseo, and Sherburne fms. in Schoharie Valley, where they could not be separated. But Cooper was in error in supposing *"Sp." mesastrialis* was at base of Ithaca. It seems best, therefore, to expand *Gilboa fm.* to include all rocks (325 ft. thick) in Schoharie Valley btw. top of Hamilton and base of red beds of Sherburne age. As thus defined the Gilboa includes Tully and Unadilla fms. which are not here separable because of disappearance of Tully fossil ***Hypothyridina.*** At place originally designated as type loc. the upper part of fm. is absent, but is well exposed along Highway 30, about 2½ mi. NE. of Grand Gorge. Top of Hamilton in Schoharie Valley is drawn at top of zone containing peculiar plicated terebratuloids, here named ***Rhipidothyris.*** Best section of the Gilboa is at Intake Building and along road from this bldg. which connects with road to Hardenburg Falls and Grand Gorge, where base of Gilboa exposed is 10 to 20 ft. above top of Hamilton. Although Gilboa fauna is almost wholly composed of Ithaca species, the fm. is actually of pre-Ithaca age. East of Schoharie Valley it is represented by Onteora beds of Chadwick. [On p. 820 is section along highway 30 2½ mi. NE. of Grand Gorge showing *Gilboa fm.* overlain by 183 ft. of ***Onteora*** *beds.* On p. 829 they say:] *Gilboa fm.* as redefined is certainly=Tully and may include some or all of Geneseo. [See further explanation under ***Unadilla*** *fm.*]

Gilboy sandstone member (of Monongahela formation).

Pennsylvanian: Southwestern Pennsylvania, northern West Virginia, and eastern Ohio.

I. C. White, 1891 and 1903. See under †*Browntown ss.*

Gilchrist shale. (In Pottsville formation.)

Pennsylvanian: Northwestern Illinois (Mercer County).

H. R. Wanless, 1929 (Ill. Geol. Surv. Bull. 57, pp. 49, 73, 83, 88, 122, 142). *Gilchrist sh.*—Blue-gray to greenish sh., micaceous in some beds; plant impressions irregularly distributed. Thickness 20 to 100+ ft. Complete thickness is penetrated by coal-test boring near Gilchrist, sec. 17, T. 14 N., R. 2 W., Greene Twp, whence name. Well exposed in pits of Hydraulic Press Brick Co. at Shale City and of NW. Clay Mfg. Co. at Griffin. Lies 6–13± ft. below top of Pottsville, or base of Colchester coal, in Alexis quad.

Gilcrease sand.

A subsurface unit 160 to 250 ft. thick, of limes, sands, and sandy limes, the top of which is encountered at a depth of 2,850 to 2,950 ft. in Papoose oil field, Okfuskee and Hughes Counties, central Okla. Has been correlated with Hartshorne ss., also with Atoka fm. Is productive in Gilcrease pool.

Giles *formation*.

Lower Devonian and Silurian: Southwestern Virginia and southeastern West Virginia.

M. R. Campbell, 1894 (Geol. Soc. Am. Bull., vol. 5, pp. 171, 177, pl. 4) and 1896 (U. S. G. S. Pocahontas folio, No. 26, p. 2). *Giles fm.*—In ascending order: Blue calc. sh. and blue ls., 30 to 40 ft.; very coarse ferruginous ss., 15 to 20 ft.; cherty ls., 30 to 40 ft.; yellow or green fossiliferous ss. of undet. thickness but probably less than 100 ft. Total thickness of fm. 30 to 200 ft. Of Lower Helderberg and Oriskany age. Overlies Rockwood fm. and underlies Romney sh. [As mapped this fm. has included beds of Sil. (Cayuga) age (see Va. chart II), but F. M. Swartz (U. S. G. S. P. P. 158, 1929) restricted name to beds of post-Cayuga age.

Named for Giles County, Va.

Gilford gabbro.

Devonian or Carboniferous: New Hampshire (Belknap Mountains). See 1936 entry (D. Modell) under *White Mtn magma series*. Crops out ¼ mi. E. of Gilford station.

†Gillespie formation. (In Trinity group.)

Lower Cretaceous (Comanche series): Central Texas.

R. T. Hill and T. W. Vaughan, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, p. 221). *Gillespie fm.*—Cross-bedded vermilion-red sands, 120 ft. thick. In Gillespie Co. rests on Paleozoic and grades up into upper beds of Glen Rose fm. Might possibly be correlated with basal sands of Travis Peak fm., but are more probably strat. equiv. of lower part of Glen Rose fm. where it rests on Travis Peak.

Apparently named for Gillespie Co.

Gillette moraine.

Pleistocene (Wisconsin stage): Northeastern New York (Essex County). See N. Y. State Mus. Bull. 187, 1916.

Gilliam thin-bedded member (of Capitan limestone).

Permian: Western Texas (Marathon region, Brewster County).

J. A. Udden, C. L. Baker, and E. Böse, 1916 (Univ. Tex. Bur. Econ. Geol. and Tech. Bull. 44, p. 52). *Gilliam fm.*—Gray, light-colored, reddish ls. and dol., nearly massive, or at least bedding planes are very dim. In middle the ls. shows thick lenticular beds. In lower part it is decidedly thin-bedded. At base we find thicker layers of reddish dol. alternating with thinly laminated layers of same rock and with thin strata of yellowish marly ss. Thickness 2,600 ft. in Gilliam Canyon, Glass Mtns. Is top fm. of Perm. of Marathon region.

J. A. Udden, 1917 (Univ. of Tex. Bull. 1753, pp. 52–53). *Gilliam fm.*—Yellow dolomitic ls., in places pinkish and even brownish in color; stratification planes sharply marked and straight, and especially in lower part the rock is quite thin-bedded. To SW. of White Elephant tank there is in this fm. a brown ss. 20 ft. thick. This ss. was also observed in Gilliam Canyon and seems to be persistent. Thickness 743 ft. Grades into overlying Tessey fm. (1,400 ft. thick), which is topmost Perm. fm., and typically exposed 2± mi. N. of mouth of Gilliam Canyon. [This appears to be a redefinition of Gilliam fm.]

P. B. and R. E. King, 1928 (Univ. Tex. Bull. 2801). *Gilliam fm.* was named for a canyon that was supposed to be spelled *Gilliam*, but Hess Canyon and Altuda topog. sheets spell the canyon *Gilliland*, and that is spelling adopted by U. S. Geographic Board. The com. on geologic names of U. S. Geol. Survey, however, regards it as inadvisable to change the spelling of the fm., which is well established as *Gilliam fm.*

P. B. King, 1931 (Univ. Tex. Bull. 3038, pp. 73–84). *Gilliam memb. of Capitan fm.* [See 1931 entry under *Tessey dol.*]

P. B. King, 1933 (Historical geol. of R. C. Moore, p. 325). *Gilliam thin-bedded ls. memb. of Glass Mtns fm.* [See 1933 entry under *Tessey dol.*]

The present approved name of U. S. Geol. Survey is *Gilliam thin-bedded memb. of Capitan ls.* See P. B. King, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 697–798).

Gillies intrusive.

Jurassic (?): British Columbia.

C. O. Swanson, 1925 (Canada Geol. Survey Summ. Rept. 1924, pt. A, p. 110).

Gilman quartzite.

Lower Cambrian: Quebec.

T. H. Clark, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 1, pp. 6, 10).

Gilmanton monzodiorite.

Devonian or Carboniferous: New Hampshire (Belknap Mountains). See 1936 entry (D. Modell) under *White Mtn magma series.* Named for Gilmanton Twp.

Gilmore sandstone member (of Greene formation).

Permian: Southwestern Pennsylvania (Greene and Washington Counties), northern West Virginia, and eastern Ohio.

J. J. Stevenson, 1876 (2d Pa. Geol. Surv. Rept. K, pp. 38–39). *Gilmore ss.*—Coarse massive ss., greatly cross-bedded and of uneven texture. Thickness 25 to 40 ft. Lies beneath Windy Gap coal, in upper part of Greene County group [Greene fm.]. Occurs on crests of higher hills in Springhill, *Gilmore,* Aleppo, and Jackson Twps, Greene Co., Pa.

I. C. White, 1891 (U. S. G. S. Bull 65, p. 22). *Gilmore ss.*, massive ss., 40 ft. thick. Belongs in upper part of Dunkard Creek series [Dunkard group].

Gilmore limestone. (In Greene formation.)

Permian: Northern West Virginia.

R. V. Hennen, 1909 (W. Va. Geol. Surv. Rept. Marshall, Wetzel, and Tyler Counties, p. 173). *Gilmore ls.*, 6 inches thick, underlies Gilmore coal and is separated from underlying Taylor ss. by 100 to 150 ft. of red sandy beds, sss., and sometimes a ls. [Probably named for association with Gilmore coal.]

Gilmore City limestone.

Mississippian: Central northern Iowa (Pocahontas and Humboldt Counties).

F. M. Van Tuyl, 1925 (Iowa Geol. Surv., vol. 30, pp. 113–114). [Author does not state that he is naming the beds described, but he uses *Gilmore City ls.* in three places, and it is in index to volume. As described, the beds in Gilmore Portland Cement Co.'s quarry, 1½ mi. NW. of Gilmore City, Pocahontas Co., consist of about 41 ft. of ls. of Kinderhook age, which is said to be probably older than Humboldt oolite, to resemble lithologically Alden ls., to rest on brownish dolomitic ls. assigned to Kinderhook group, and to be possibly=Iowa Falls dol., but "correlation is uncertain."]

L. R. Laudon, 1931 (Iowa Geol. Surv. vol. 35, pp. 349, 416–417). Alden ls. of Hardin Co. and *Gilmore City ls.* of Humboldt and Pocahontas Counties suggest Spergen both lithologically and faunally. The large crinoid fauna in base of Gilmore City ls. carries large number of Kinderhook genera. Alden ls., which is correlated with Gilmore City ls., lies uncon. on upper surface of Iowa Falls memb. of Hampton fm. This relation seems to suggest they should not be considered of Kinderhook age. [p. 349.] Alden ls. is correlated with oolitic ls. exposed near Humboldt and Gilmore City. Exact age of fauna of Gilmore City ls. is doubtful, but it is considered younger than the Kinderhook because of the fauna and the marked uncon. which separates it from upper beds of the Kinderhook. Fauna as a whole resembles certain parts of fauna of Madison ls. of the West. Type section of Gilmore City beds consists of (descending): (1) Thin-bedded white oolitic ls., numerous joints filled with green sh. (*Cyathophyllum* zone), 14 ft.; (2) very massive hard grayish-white crystalline cross-bedded oolitic ls., fossiliferous throughout but more so near the base (*Streptorhynchus* zone), 18 ft.; (3) massive greenish ls. interbedded with green sh. (*Rhodocrinus* zone), 8 ft.; (4) soft blue shaly ls. (*Camarotoechia* zone), 3 ft. [In his 1933 paper he called this *Rhynchopora* zone]; (5) brecciated ls., 2 ft. [pp. 416–417. In his 1933 paper cited below, No. 5 of type section of Gilmore City fm. is described as 15 ft. of ls., gray, lithographic, banded, carrying a brown ls. memb. in base and a brown shaly ls. memb. in top; no fossils.]

L. R. Laudon, 1933 (Univ. Iowa Studies, n. s., No. 256, vol. 15, No. 2). *Gilmore City fm.* consists almost entirely of gray, white, or blue cross-bedded ss. Thickness 210 ft. Is uncon. overlain by St. Louis ls. and uncon. underlain by Iowa Falls memb. of Hampton fm. Writer believes the fm. represents an eastward invasion of some portion of Madison sea of the West. [Listed fauna and described and discussed it.] At first glance one is impressed with similarity of this fauna with that of Spergen fm. A close examination, however, will reveal that it is not the Spergen fauna and that it is far older. It has its closest affinities with the molluscan fauna of the Wassonville memb. of Hampton fm. (Kinderhook). [Writer treated the Gilmore City as top fm. of Kinderhook.]

R. C. Moore, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 245). *Alden ls.* of northern central Iowa is uncon. overlain by St. Louis ls., uncon. underlain by Hampton fm., and is=Salem [Spergen] ls.

L. R. Laudon, 1935 (p. 247 of rept last cited). Moore revives old term Alden and correlates the fm. with Spergen. A careful study of Gilmore City fauna shows more of Spergen species are present. The abundant crinoid fauna is typically late Kinderhook and very closely related to fauna at LeGrand.

Gilmore Gulch formation.

Tertiary (?), probably pre-upper Miocene: Central Nevada (northern Nye County).

H. G. Ferguson, 1933 (Nev. Univ. Bull., vol. 27, No. 3, p. 21). *Gilmore Gulch fm.*—Consists of ss., dark sh., and siliceous tuff. Thickness 500+ ft.; base not exposed. Assigned to Tert. (?), probably pre-upper Mio. Named for exposures in Gilmore Gulch, Tybo dist. Overlies Lone Mtn dol. (middle Sil.).

Gimlet limestone.

A name applied by H. R. Wanless (Ill. Geol. Surv. Bull. 60, 1931, pp. 179–193) to a ls. locally lying higher in McLeansboro fm. (Penn.) of central western Ill. than Lonsdale ls. Derivation of name not stated.

Gimlet cyclical formation.

A name applied by H. R. Wanless (Ill. Geol. Surv. Bull. 60, 1931, pp. 179–193) to a middle portion of McLeansboro fm. (Penn.) of central western Ill., based upon the rhythmic-cycle theory of sedimentation. Derivation of name not stated.

Girard shale member (of Chemung formation).

Upper Devonian: Northwestern Pennsylvania (Erie and Crawford Counties).

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. Q_4, pp. 118–119, 251). *Girard sh.*—A succession of very argill. ashen-gray and bluish shales with now and then a thin sandy stratum. Thickness 225 ft. No fossils except fucoids. I regard them as a transition series from the Portage to the Chemung, since they rest on undoubted Portage rocks, and typical Chemung fossils occur in the overlying rocks. The distinction btw. Girard and Portage beds is one of mineral constitution, and is founded on relative proportion of ss. layers and sh. layers. Well exposed along Elk Creek above Girard, Erie Co.

W. A. VerWiebe, 1917 (Am. Jour. Sci., 4th, vol. 44, p. 41). It appears to writer, after careful study of its stratigraphy and lithology, that true relation of *Girard sh.* is with the Chemung of N. Y.

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69), showed *Girard sh.* as overlain by Chadakoin and as resting uncon. on Northeast sh. In 1924 (N. Y. State Mus. Bull. 251, p. 157) he seemed to include Cuba ss. in Girard. In 1925 (Geol. Soc. Am. Bull., vol. 36, p. 464) he showed *Girard sh.* as resting on Cuba ss., which, in turn, rested on Northeast sh. In 1933 (Pan-Am. Geol., vol. 60, No. 3, pp. 195–196) he showed *Girard* as underlying Chadakoin and overlying Northeast, and stated that it is wholly younger than Chemung.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61), divided his *Girard stage* into *Girard sh.* (above) and Cuba ss. (below), and showed it as underlying his Chadakoin stage.

G. H. Chadwick, 1935 (Geol. Soc. Am. Proc. 1934, p. 71), reported that it now seems likely Cuba ss. goes below, instead of above, Northeast sh. (See under *Northeast sh.*)

Girard moraine.

Pleistocene (Wisconsin stage): Northwestern Pennsylvania. Upper moraine of Lake Escarpment morainic system. Named for Girard, Pa. (See U. S. G. S. Mon. 41.)

Girard stage.

See Caster 1934 entry under *Girard sh. memb.*

Girardeau limestone.

Silurian (early): Southeastern Missouri and southwestern Illinois.

G. C. Swallow, 1855 (Mo. Geol. Surv. 2d Ann. Rept., pt. 1, p. 109). *Cape Girardeau ls.*—As described by B. F. Shumard [on a later page of this vol.] is a fossiliferous compact bluish-gray brittle ls. 40 to 50 ft. thick, with smooth fracture, in layers 2 to 6 in. thick, with thin argill. partings. Lowermost fm. of Upper Sil. Underlain by Hudson River group, the upper 40 ft. of which consists of blue-gray and brown argillo-mag. ls., the lower part more argill., with several thin beds of bluish gray crystalline ls.

In 1866 (Ill. Geol. Surv. vol. 1, p. 139) A. H. Worthen introduced *Thebes ss.* for a ss. in southern Ill. which he stated was separated from the younger *Cape Girardeau ls.* by brown sandy sh. In many subsequent early Ill. and Mo. repts this brown sandy sh. was included with the ss. under name *Thebes ss. and sh.* and, later, *Thebes fm.* In 1909, however (Am. Jour. Sci., 4th, vol. 28, p. 515), Savage named the sh. *Orchard Creek sh.* and restricted *Thebes* to the ss. The name of this ls. was many years ago shortened to *Girardeau ls.* (See C. R. Keyes, 1894, Mo. Geol. Surv., vol. 4, pp. 30, 40.) The Orchard Creek sh. is now classified as early Sil. and the Thebes ss. as Upper Ord. (Richmond).

E. O. Ulrich, 1904 (Mo. Bur. Geol. and Mines vol. 2, 2d ser., pp. 109–111). *Girardeau ls.* underlies Bainbridge ls. and overlies Thebes fm. in eastern Mo.

T. E. Savage, 1913 (Geol. Soc. Am. Bull., vol. 24, pp. 351–376). *Girardeau ls.* is not known farther N. than a few mi. above Cape Girardeau, Mo. Is post-Richmond.

Named for outcrops 1½ to 2 mi. above Cape Girardeau, Cape Girardeau Co., Mo.

Gird.

Name introduced by C. [R.] Keyes (Pan-Am. Geol., vol. 46, 1926) for 750 ft. of shales in Kootenai fm. of Mont. Derivation of name unknown.

Girkin formation. (In Chester group.)

Mississippian: Western Kentucky.

A. H. Sutton and J. M. Weller, 1932 (Jour. Geol., vol. 40, No. 5, pp. 430, 440, 441). Unfortunately Butts has never described the section exposed along Gasper River from which his name *Gasper* is derived, and although upper limit of this fm. is fixed at base of Cypress ss., the position of its lower bdy is uncertain. *Gasper* as a fm. name has never been adequately defined, nor has its type loc. been clearly indicated. Uncertainty regarding the beds which Butts himself intends to include within the typical Gasper has made it impossible for writers to recognize "Gasper" as valid fm. name. Along most of S. margin of West Ky. coal basin and along part of its E. border, the Bethel (or Sample) ss. is absent, and Renault and Paint Creek lss. come together to form a single formational unit. A name by which it might be known would be convenient. Gasper would be a suitable name for this unit, but unfortunately the confusion, uncertainty, and miscorrelation that have surrounded it for 15 years have permanently impaired its usefulness; and it seems advisable to select a new name rather than attempt to define the Gasper within these limits, at *this late date. Therefore Girkin is now proposed as a designation for beds of Renault and Paint Creek age in that part of west Ky. where the Bethel (or Sample) ss. is not developed. It will include everything from Ste. Genevieve ls. (with Platycrinus penicillus) below to Cypress ss. above. This part of the section is well developed in the hills that nearly surround village of Girkin in Warren Co., Ky., and an excellent section may be seen in bluff of Barren River at Greencastle, 8 mi. to W.*

Gizzard formation. (In Lee group.)

Pennsylvanian: Central Tennessee.

J. M. Safford, 1869 (Geol. of Tenn., pp. 369–370). *Lower Coal Measures (Gizzard Portion).—Alternating shales, sss., and coals, 228 ft. thick, overlying Mountain ls. and separated from overlying Upper Coal Measures by 70 ft. of cgl. [Sewanee cgl.].*

Basal fm. of Lee group in central Tenn. Uncon. overlies Pennington sh. (Miss.). Underlies Sewanee cgl.

Named for Little Fiery Gizzard Creek, Marion Co.

†Glacial epoch.

†Glacial period.

Terms applied in early repts (and still used in popular articles) to *Pleistocene epoch.*

Glacian.

Pre-Cambrian: General.

See under *Pelodian.*

Glacier division.

Pre-Cambrian: British Columbia.

R. A. Daly, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 170).

Glacier Peak volcanics.

A term that has been applied in a formational sense to the volcanic rocks of Glacier Peak, Snohomish Co., Wash. (See H. C. Culver, State of Wash. Dept. Cons. and Develop., Div. Geol. Bull. 32, 1936, p. 21.)

Glacier Point glacial stage.

Pleistocene: Eastern California (Yosemite region).

F. E. Matthes, 1929 (Sci., n. s., vol. 70, pp. 75–76). *Glacier Point glacial stage.*—Oldest of the 3 stages of Pleist. glaciation recognized in Yosemite region of Sierra Nevada. Appears to be recorded only by erratic boulders occurring singly or in rows or groups, but without accompanying fine material, at levels 100 to 200 ft. above highest lateral moraines of the second or El Portal stage. These erratic boulders occur at a level 700± ft. above Glacier Point, extending in a row from E. base of Sentinel Dome to N. end of Illilouette Ridge. Others are scattered on broad divide E. of Mount Starr King. This stage may correspond to Kansan or even Nebraskan stage. [See also F. E. Matthes, U. S. G. S. P. P. 160, 1930.]

†Glade limestone.

Lower Ordovician: Central and western Tennessee.

J. M. Safford, 1869 (Geol. Tenn., pp. 258–267). *Glade ls.*—Light-blue or dove-colored thin-bedded or flaggy ls.; fossiliferous. Thickness 118 to 120 ft. Preeminently the bed of the great "Cedar Glades" of Central Basin. Underlies Carter's Creek ls. and overlies Ridley ls. Included in Trenton or Lebanon [Stones River] group.

Nongeographic term. Replaced by Lebanon ls. Of Chazy age.

Named for fact areas in which it appears on surface abound in bare or nearly bare rocky places called glades.

†Glade sandstone.

Devonian or Carboniferous: Northwestern Pennsylvania.

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 202). [See 1933 entry under *Knapp fm.*]

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 61), replaced this name with *Cobham cgl. memb.*

Glade sand.

Drillers' term for a sand, of Upper Dev. (Chemung) age, 10 to 50 ft. thick, in western Pa.

Gladeville sandstone. (In Pottsville group.)

Pennsylvanian: Southwestern Virginia and southeastern Kentucky.

M. R. Campbell, 1893 (U. S. G. S. Bull. 111, pp. 28, 33). *Gladeville ss.*—Heavy, coarse, white ss., 100 ft. thick, massive in upper portion, becoming thin-bedded toward bottom, but carries no sh. Underlies Wise fm. and overlies Norton fm. in Bigstone Gap coal field of Va. and Ky.

Named for Gladeville (now called Wise), Wise Co., Va.

Gladwin moraine.

Pleistocene (Wisconsin stage): Northern Michigan. Shown on moraine map (pl. 32) of U. S. G. S. Mon. 53. Named for Gladwin, Gladwin Co.

Glady Fork sandstone. (In Bluestone formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 294, 321). *Glady Fork ss.*—Greenish-brown coarse massive ss., 25 to 40 ft. thick. Plant fossils at base. Underlies Lower Mud sh. and overlies Pipestem sh., all members of Bluestone group [fm.]. Type loc. in end of ridge btw. Brush Creek and Glady Fork, just SE. of Princeton, Mercer Co.

Glamorgan gabbro.

Pre-Cambrian: Ontario.

F. D. Adams and A. E. Barlow, 1910 (Canada Geol. Surv. Mem. 6, p. 152).

Glance conglomerate.

Lower Cretaceous (Comanche series): Southeastern Arizona (Bisbee region).

F. L. Ransome, 1904 (U. S. G. S. P. P. 21, pp. 56, 57+). *Glance cgl.*—Distinctly bedded red-brown cgl., 50 to 75 ft. thick, composing basal fm. of Bisbee group (of Comanche age) in Bisbee quad. Rests uncon. on pre-Camb. Pinal schist. Overlain conformably by Morita fm. Named for Glance, on El Paso & SW. R. R., near Glance mine, Bisbee quad.

Glassboro gravel.

Pleistocene: Southeastern Pennsylvania and adjacent parts of New Jersey.

H. C. Lewis, 1881 (Phila. Acad. Nat. Sci. Proc., vol. 32, pp. 296–309). *Glassboro gravel.*—Called "Fossiliferous gravel" in earlier papers, because many of its pebbles are fossiliferous. Occurs at lower elevations than Bryn Mawr gravel. Abundant in N. J. and SE. Pa. It is the yellow gravel which caps the watershed btw. the Atlantic and the Delaware at a height of nearly 200 ft. Is older than Philadelphia red gravel.

R. D. Salisbury and G. N. Knapp, 1917 (N. J. Geol. Surv., vol. 8, pp. 11, 62), used *Glassboro phase of Bridgeton fm.* See 1917 entry under *Bridgeton fm.*

Is a part of Bridgeton fm., according to U. S. G. S. Phila. folio (No. 162), 1909.

Probably named for occurrence at Glassboro, Gloucester Co., N. J.

Glass Buttes series.

Miocene: Central southern Oregon (Lake County, northeast corner).

A. Waters, 1927 (Jour. Geol., vol. 35, pp. 442–452). *Glass Buttes series.*—A closely related series of rocks of acidic composition that form main portion of Glass Buttes Range. Includes augite andesite, quartz andesite, hypersthene dacite, augite dacite, hypersthene augite dacite, perlite, obsidian, and vitrophyre. Most striking feature is pronounced banding of all the larger flows. Seven lava flows belonging to this series, each at least 50 ft. thick, occur on one fault scarp, while 2 other flows are exposed on downthrown block of same fault. This brings total known thickness up to over 400 ft., and it probably is not much thicker. Has been referred to Mio. Rests conformably on a series of olivine and augite basalts, which have also been referred to Mio. Overlain by very recent flows of olivine and augite basalt.

†Glass Mountain formation. (In Cimarron group.)

Permian: Northwestern Oklahoma and southern Kansas.

F. W. Cragin, 1897 (Am. Geol., vol. 19, pp. 353, 355). *Glass Mtn fm.*—Includes all beds, 160 ft. thick, above Salt Plain measures and below Cave Creek fm., the equiv. Cedar Hills sss. and Flower-pot shales of Kans. section not being satisfactorily identified in Okla. Included in Salt Fork div.

Named for Glass (also spelled Gloss) Mtns, Major Co., Okla.

†Glass Mountains formation.

Permian: Western Texas (Glass Mountains).

P. B. King, 1933 (Historical geol., by R. C. Moore, p. 325). *Glass Mtns fm.*—Underlies Bissett cgl. and overlies Word fm. Divided, in E. part of Glass Mtns, into (descending) Tessey massive ls. memb., Gilliam thin-bedded ls. memb., and Vidrio massive ls. memb. In W. part of Glass Mtns includes, in lower part, Altuda siliceous sh. memb. Is=Capitan ls. [See 1931 and 1933 entries under *Tessey dol.*]

This name being preoccupied, and the rocks being the southern extension of Captain ls. (an older and well-established name), the U. S. Geol. Survey designates these rocks in Glass Mtns the *Capitan ls.* (See P. B. King, Geol. Soc. Am. Bull., vol. 45, 1934, pp. 697–798.)

Glastonbury granite gneiss.

Late Carboniferous or post-Carboniferous: Central Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 114, 115, and map). *Glastonbury granite gneiss.*—Larger part is dark, well foliated, almost schistose gneiss, of fine grain, which on cleavage shows alternating patches of black biotite and white feldspar. A narrow eastern belt is more granitic and in places reaches the massiveness of true granite. The more schistose variety forms the hills SE. of Glastonbury and occurs in bed of Roaring Brook in South Glastonbury. Believed to be of igneous origin.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597), mapped the continuation of this fm. in Mass. as Monson granodiorite, of late Carbf. or post-Carbf. age. Monson has priority.

†Glauconitic group.

Descriptive term applied by L. Harper (Prel. rept. geol. and agric. Miss., 1857, p. 72) to Cret. rocks in Miss.

†Glauconitic division.

Descriptive term applied by R. T. Hill (Am. Jour. Sci., 3d, vol. 38, 1889, pp. 468–473) to Navarro group of Tex.

Glenarm series.

The provincial series of pre-Camb. metamorphosed sed. rocks present in northern Va., Md., SE. Pa., western N. J., and possibly SE. N. Y. Formerly assigned to "Algonkian system," but that term has now been discarded. In 1929 (Md. Geol. Surv. Baltimore Co. Rept., p. 104) and later repts E. B. Knopf and A. I. Jonas assigned this series to *late pre-Camb.* (For definition see U. S. G. S. Bull. 769, p. 112.)

B. L. Miller, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 5, pp. 715–756), discussed age and problems involved in rocks designated as *Glenarm series*, and concludes that much more work is needed on the problems, concerning which there has been and still is considerable diversity of opinion.

J. H. Mackin, 1935 (Jour. Geol., vol. 43, pp. 356–380). *Glenarm series* of SE. Pa. may be wholly or in part Paleozoic.

Glenburnie member (of Chaumont formation).

Middle Ordovician (Black River): Ontario (Frontenac County).

G. M. Kay, 1929 (Jour. Geol., vol. 37, No. 7, pp. 664–671; and A. A. P. G. Bull., vol. 13, No. 9, p. 1214). *Glenburnie memb. of Chaumont fm.*—Includes 2 ft. of very argill. and very fossiliferous ls. intercalated with thin beds of sh., lying above Leray ls. memb. of Chaumont fm. and below Watertown memb. of Chaumont fm. at type section in small quarry W. of road in lot 22, conc. V, 1 mi. SW. of hamlet of Glenburnie, Kingston Twp, Frontenac Co., Ont. Fossils listed. Not present in N. Y., where it is represented by uncon. btw. Watertown and Leray lss.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10), apparently does not mention this name, as it is not listed in index or tables.

Glencairn shale member (of Purgatoire formation).

Lower Cretaceous (Comanche): Eastern Colorado (Colorado Springs region).

G. I. Finlay, 1916 (U. S. G. S. Colorado Springs folio, No. 203). *Glencairn sh. memb. of Purgatoire fm.*—Dark sh. with a little intercalated ss. Thickness 10 to 145 ft. Top memb. of Purgatoire fm. Overlies Lytle ss. memb. T. W. Stanton says fossils are Comanche and belong to Washita horizon. Named for a tract of land a few mi. N. of Lytle.

Glen Canyon group.

Jurassic (?): Southern and eastern Utah, northern Arizona, southwestern Colorado, and northwestern New Mexico.

Name adopted at joint conference of J. Gilluly, J. B. Reeside, Jr., H. E. Gregory, and R. C. Moore, from area specially studied by Gregory and Moore, who suggested the name. The name first appeared in print in A. A. P. G. Bull., vol. 11, p. 787, 1927, in paper by Reeside, C. E. Dobbin, A. A. Baker, and E. T. McKnight. More fully defined by Gilluly and Reeside in U. S. G. S. P. P. 150, p. 68, 1928, and by Gregory and Moore in U. S. G. S. P. P. 164, p. 61, 1931. It includes (descending) Navajo ss., Kayenta fm. (so-called Todilto? fm. of original definition), and Wingate ss. Named for exposures in Glen Canyon of Colorado River, Kane Co., Utah, and adjacent areas in Ariz. (See also U. S. G. S. P. P. 183, 1936, p. 4.)

Glencoe marble.

Trade name for a marble quarried from Kimmswick ls. at Glencoe, Mo., according to J. Bridge (letter dated July 10, 1936).

Glendale granite.

Pre-Cambrian (?): Central northern Colorado (Boulder County).

R. D. Crawford, 1909 (Univ. Colo. Studies vol. 6, pp. 97–131). *Glendale granite.*—A massive porphyritic variety of biotite granite. Usually light-colored. Most striking feature is great number and character of phenocrysts. Probably intrusive into the older biotite granite. Occurs on both sides of Lefthand Canyon in vicinity of Glendale and Rowena [Boulder Co.].

Glendale shale.

Mississippian (early): Southeastern Tennessee (Chattanooga quadrangle).

J. H. Swartz, 1924 (Am. Jour. Sci., 5th, vol. 7, pp. 24–26). *Glendale sh.*—Hard gray sh. full of concretions, becoming much darker toward base. Thickness 2 ft. 4 in. at Chattanooga and 2 ft. 11 in. about 16 mi. E. of Chattanooga. *Lingula melie* abundant from 4 to 6 in. above base, and establishes correlation with lower part of Cuyahoga sh. of Ohio. Heretofore included in Fort Payne chert of this area, but in this rept excluded from Fort Payne. Overlies Chattanooga sh. Named for exposures at Glendale Station, just outside Chattanooga, on electric road to Signal Mtn.

Glendale beds.

Eocene (Jackson): Eastern Texas (Trinity County).

A. C. Ellisor, 1933 (A. A. P. G. Bull., vol. 17, No. 11, pp. 1302, 1316). *Glendale beds.*—John L. Brice traced across Trinity Co. a fossiliferous zone, about 8 ft. thick, which crops out at Glendale, Trinity, and S. of Groveton, and gave name *Glendale* to a section 515 ft. thick, including Manning beds of this paper. Burford and Olcott found the same fossiliferous ss. and attempted to trace it to Sabine River. Study of their geol. columns shows their Glendale ss. horizon ranges in interval in Whitsett fm. considerably above Dilworth sand (basal zone of Whitsett).

Glen Dean limestone. (Of Chester group.)

Mississippian: Southern Illinois and Indiana, Kentucky, Tennessee, and southwestern Virginia.

C. Butts, 1917 (Ky. Geol. Surv. Mississippian formations of western Ky., p. 97). *Glen Dean ls.*—Varying proportions of ls. and sh., including, locally at least, a little ss. In Breckinridge Co., Ky., consists of (descending): (1) 40 to 100 ft. of ls. and sh. with a little red sh.; (2) 30 to 60 ft. of thick- or thin-bedded ls., in part generally rather coarse-grained or crinoidal and of light- to bluish-gray color; (3) 0 to 10 ft. of green and red sh. resting on Hardinsburg ss. Is overlain by Tar Springs ss. Named for exposures along railroad on both sides of Glen Dean, Breckinridge Co., Ky.

Glendon limestone. (In Vicksburg group.)

Oligocene (lower): Coastal Plain of southwestern Alabama and Mississippi.

This name first appeared in print in 1917 (U. S. G. S. Bull. 661H, pp. 298, 300), when it was used by O. B. Hopkins for top memb. of Marianna ls., and credited by him to unpublished ms. by C. W. Cooke.

C. W. Cooke, 1918 (Wash. Acad. Sci. Jour., vol. 8, pp. 187, 195). *Glendon ls. memb. of Marianna ls.*—A series of ledges of hard, partly crystalline yellowish or pinkish ls. interbedded with softer strata of impure ls. composed largely of Bryozoa, Foraminifera, and shells of *Ostrea vicksburgensis* and *Pecten poulsoni*. Is distinguished from other parts of Marianna ls. mainly by its lithology, but a few species of organisms are restricted to it. At Glendon, [Clarke Co., SW. part of] Ala., it is 18 or 20 ft. thick and overlies 20 ft. of "chimney rock" [a facies of Marianna ls.]. Because of its hardness it is most conspicuous part of Vicksburg group in Miss. Is top memb. of Marianna ls. In Miss. it rests on Mint Spring calc. marl memb. of Marianna ls., but in Ala. it rests on the "chimney rock" facies of Marianna. Is overlain by Byram calc. marl.

In 1923 (U. S. G. S. P. P. 133) the Glendon was elevated by Cooke to formational rank and identified eastward into Ga., where, according to him, its lithology changes to sands, clays, and cherts and where it was called *Glendon fm.* These rocks in Ga. had heretofore been included in Chattahoochee fm., but mapped in part as Chattahoochee fm. and in part as Ocala ls. and Vicksburg fm. Later Cooke decided the beds in Ga. and Fla. which had been called *Glendon* were younger than true Glendon ls., and he renamed them *Flint River fm.* Still later he named the beds in eastern Fla. which had previously been called *Glendon* the *Suwannee ls.*, which he regards as probably contemp., at least in part, with Flint River fm. of western Fla. and Ga.

Glenerie limestone. (In Oriskany group.)

Lower Devonian: Southeastern New York.

G. H. Chadwick, 1908 (Sci., n. s., vol. 28, pp. 346–348). The Oriskany lss. at Glenerie are named *Glenerie ls.*, from town [in Ulster Co.]. Underlie Esopus grit and overlie Connelly cgl. [Thickness not stated.]

This is present definition of N. Y. State Survey, according to W. Goldring, 1931 (N. Y. State Mus. Hdb 10, pp. 370, 380).

Glen Eyrie shale member (of Fountain formation).

Pennsylvanian: Eastern Colorado (El Paso County region).

G. I. Finlay, 1907 (Jour. Geol., vol. 15, pp. 586–589). *Gleneyrie fm.*—Gray and buff, finely laminated sss., composed almost wholly of quartz grains with thin bands of black sh. near bottom. Can be traced northward from Manitou region to Glen Eyrie Creek [El Paso Co.], where it is well exposed, although overlying Fountain fm. comes down to basal granite a short distance to N. Pennsylvanian plants in sh. bands near base, which D. White says are of Pottsville age. Is uncon. overlain by Fountain fm. [restricted] and uncon. underlain by series of lss., the lower part of which are of Ord. age.

J. Henderson, 1909 (Colo. Geol. Surv. 1st Rept, 1908, pp. 149–184, fig. 27). [Shows *Gleneyrie ss.* of Manitou region as conformable with overlying Fountain cgl. of that area, and as=basal part of Fountain cgl. of Boulder region.]

G. I. Finlay, 1916 (U. S. G. S. Colorado Springs folio, No. 203). Lowermost 90 ft. of Fountain fm. is here separately mapped as *Glen Eyrie sh. memb. of Fountain fm.* It consists of gray ss. and sandy sh. with thin beds of black fossiliferous sh. containing traces of coal. This memb. is strikingly unlike great body of Fountain fm., altho *transitional beds occur at its top.* It is important not only because it is a readily separable lithologic unit, but because of its flora. The Glen Eyrie memb. is found only in Manitou embayment, where it crops out btw. Glen Eyrie and Manitou. Rests uncon. on Manitou ls.

Glenham belt.

Glenham gneiss

See under *Matteawan granite.*

Glenkirk limestone.

Silurian (Niagaran): West-central Tennessee.

A. F. Foerste, 1903 (Jour. Geol., vol. 11, pp. 566, 578–582, 692). [See explanation under *Lego ls. memb.*]

Named for Glenkirk, Wayne Co.

†Glenn formation.

Pennsylvanian: Central southern Oklahoma.

J. A. Taff, 1903 (U. S. G. S. Tishomingo folio, No. 98). *Glenn fm.*—Blue sh., with thin brown sss. and occasional thin lss. Thickness 1,000 to 3,000 ft. Overlies Caney sh. and may include highest Carbf. rocks exposed in Tishomingo quad.

W. L. Goldston, Jr., 1922 (A. A. P. G. Bull., vol. 6, No. 1). *Glenn fm.* of Ardmore Basin divided into (descending) Hoxbar memb., Deese memb., Cup Coral memb., Otterville ls., and Springer memb. Total thickness 12,000 to 19,000 ft.

G. H. Girty and P. V. Roundy, 1923 (A. A. P. G. Bull., vol. 7, No. 4, pp. 331–347). We are convinced it was not Taff's intention to include in Glenn fm. the beds called Hoxbar memb. by Goldston. Typical Glenn includes only Deese and "Cup Coral" members of Goldston. [For their views regarding Otterville and Springer members of Goldston see under *Otterville* and *Springer.*]

C. N. Gould, 1925 (Okla. Geol. Surv. Bull. 35, p. 25). According to Goldston the Glenn fm. is exposed only S. of Arbuckle Mtns, in SW. Johnston and northern Carter Counties, and extends across east-central Carter into northern Love Co.

H. D. Miser, 1925 (Okla. Geol. Surv. Bull. 35, p. 26, footnote). [See entry under *Hoxbar memb.*]

S. Powers, 1927 (A. A. P. G. Bull., vol. 11, No. 10, pp. 1067–1085), mapped Glenn fm. as underlying Hoxbar fm. and overlying Springer fm.

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z, pp. 7–21), recognized following units in Carter Co. (descending): Hoxbar fm., 4,000± ft.; Deese fm., 5,000± ft.; Dornick Hills fm., 1,500–4,000 ft. (including Otterville ls., 25± ft. thick, in lower part); and Springer fm., 3,000 or more ft. thick.

C. W. Tomlinson, 1929 (Okla. Geol. Surv. Bull. 46). Springer fm. was included in *Glenn fm.* by Taff in Tishomingo folio, but was excluded from Glenn by Girty, Roundy, and Miser. Best solution of Glenn is to drop it, as suggested by Gould (personal communication).

F. A. Melton, 1930 (Okla. Geol. Surv. Bull. 40LL). *Springer fm.* is lowest subdivision of Glenn fm. of Taff.

Named for Glenn, Carter Co.

Glenn sand.

A subsurface sand, of early Penn. (Cherokee) age, 10 to 200± ft. thick, in Okla., lying lower than Red Fork sand, higher than Tucker or Taneha sand, and correlated with lower sand of the series to which name *Bartlesville sand* has been applied. The typical Glenn, of Glenn pool, Carter Co., lies at 1,350 ft. depth and the Taneha at 1,550 ft.

Glenn Creek shale member (of Jefferson limestone).

Middle Devonian: Northwestern Montana.

C. F. Deiss, 1933 (Mont. Bur. Mines and Geol. Mem. 6, pp. 42 and passim). *Glenn Creek sh. memb.*—Underlies Coopers Lake ls. and overlies White Ridge ls.; all members of Jefferson ls. Thickest (66 ft.) at type loc. on White Ridge; thinnest

(7 ft.) in Nannie Basin region. Type loc. on S. side of SW. peak of White Ridge, where it consists of (descending): (1) 31 ft. of dull- and brighter-red calc. sh. with several beds (up to 14 inches thick) of gray argill. ls., and at top thinner bedded very argill. lavender-red ls.; (2) 20 ft. of thin-bedded red clay sh. with green-gray fissile sh. in upper 2 ft.; (3) 8 ft. of dull-red thick-bedded calc. sh. and shaly argill. red-gray ls. Named for Glenn Creek, whose middle branch heads at E. base of White Ridge. On Saypo topog. sheet the names Glenn Creek and Moose Creek have been interchanged.

Glenogle shale.

Ordovician: British Columbia and Alberta.

L. D. Burling, 1921 (Geol. Soc. Am. Bull., vol. 32, p. 128), and 1922 (Geol. Mag., vol. 59, pp. 453, 454). *Glenogle shales*, Ord., B. C.

C. D. Walcott, 1923 (Smithsonian Misc. Coll. vol. 67, No. 8, p. 463), gave complete definition and assigned the fm. to Lower Ord. All subsequent repts by Canadian geologists assign the fm. to Ord.

Named for Glenogle Creek, Lower Kicking Horse Canyon, near Glenogle Station, B. C.

Glen Park formation. (In Kinderhook group.)

Mississippian: Central eastern Missouri and southwestern Illinois (Jersey and Calhoun Counties).

E. O. Ulrich, 1904 (Mo. Bur. Geol. and Mines vol. 2, 2d ser., p. 110). *Glen Park ls. memb.*—Oolitic ls., 5 ft. thick, forming middle memb. of Sulphur Springs fm. Overlain by Bushberg ss. memb. and underlain by 0 to 15 ft. of sh. forming basal part of Sulphur Springs fm.

See under *Sulphur Springs fm.* The 5 ft. of oolitic ls. to which Ulrich applied name *Glen Park* appears to be only a minor part of the fm. later called *Glen Park ls.* by Moore and others.

R. C. Moore, 1928 (Mo. Bur. Geol. and Mines vol. 21, 2d ser., opp. p. 282), showed *Glen Park ls.* as present in only Jersey and Calhoun Counties, Ill., and in SE. Mo., and he showed it as underlying Hannibal sh. and overlying (with uncon. in places) Louisiana ls., and as absent in Pike Co., Ill. In 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 245) he showed Glen Park of western Ill. and NE. Mo. as lying btw. Hannibal above and Louisiana ls. below, and the Glen Park of SW. Ill. and SE. Mo. as uncon. underlying Fern Glen ls. (the uncon. representing Chouteau ls. and Hannibal sh.) and uncon. overlying Chattanooga sh., the Louisiana ls. being absent.

Named for exposures at Glen Park Station, Jefferson Co., Mo.

Glenray limestone. (In Bluefield formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Tazewell County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 301, 432). *Glenray ls.*—Gray, usually hard and somewhat sandy, but sometimes shaly, 44 to 125 ft. thick. Marine fossils. Underlies Webster Springs ss. and overlies Lillydale sh.; all members of Bluefield group [fm.]. Type loc. in Summers Co., on NW. side of Greenbrier River, opposite Glenray. Also observed in Mercer and Monroe Counties, W. Va., and in Tazewell Co., Va.

Glenrock limestone.

Pennsylvanian: Southeastern Nebraska and northeastern Kansas.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 84, 86, 88). *Glenrock ls.*—Dark gray, dense ls.; weathers light gray or slightly buff. Thickness 1 to 2 ft. in Nebr. and NE. Kans. Underlies Bennett sh. and overlies Johnson sh., all included in Elmdale sh. memb. Named for exposures high in valley side just NW. of Glenrock, Nemaha Co., Nebr.

G. E. Condra, 1935. (See under *Howe ls.*)

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), transferred this unit to Perm. This change in Perm.-Penn. bdy has not been considered by U. S. Geol. Survey for its publications.

Glen Rose limestone. (In Trinity group.)

Lower Cretaceous (Comanche series): Texas.

R. T. Hill, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 504, 507). *Glen Rose or alternating beds.*—Soft yellow mag. fossiliferous beds, siliceous at base, alternating with fine argill. sand with occasional dimension layers of almost pure crystalline lss., chalk, and mag. lss., often oolitic in structure Overlies Trinity or Basal sands and underlies Paluxy sands.

Middle fm. of Trinity group. Underlies Paluxy sand and overlies Travis Peak sand (†Basal sands).

Named for Glen Rose, Somervell Co.

Glens Falls limestone. (Of Trenton group.)

Middle Ordovician: Eastern New York (Mohawk and upper Hudson valleys).

R. Ruedemann, 1912 (N. Y. State Mus. Bull. 162). *Glens Falls ls.* proposed for basal Trenton ls., 17 ft. thick in Flat Creek ravine at Sprakers, 2½ mi. E. of Canajoharie ravine. Consists of thin layers of very fossiliferous ls. with sh. intercalations near top and a 2-inch cgl. layer at base, separating it from Tribes Hill ls. Contains ripple marks and other signs of shallow-water conditions. Fauna of both the ls. and shaly intercalations is basal Trenton. Traced by outcrops around SE. side of Adirondacks to Saratoga and Glens Falls. Are lower than any beds exposed at Trenton Falls, and therefore given distinct name. We have called them *Jacksonburg ls.*, but Jacksonburg of N. J. (typical) contains beds of Amsterdam and Lowville age, and therefore is not appropriate for these basal Trenton beds. At Glens Falls [Warren Co.] the fm. underlies Canajoharie sh. and overlies Amsterdam ls.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 39). *Glens Falls ls.* is well developed in Mohawk and upper Hudson valleys.

H. P. Cushing and R. Ruedemann, 1914 (N. Y. State Mus. Bull. 169). *Glens Falls ls.* at Saratoga Springs and vicinity consists of 40 ft. of alternating black sh. and thin black ls. Assigned to Basal Trenton, but fauna shows it lies below beds of Trenton Falls section. Underlies Canajoharie sh. and uncon. overlies Amsterdam ls.

R. Ruedemann, 1925 (N. Y. State Mus. Bull. 258). *Glens Falls ls.*, 24 ft. thick, underlies Canajoharie sh. in lower Mohawk Valley. Is older than any part of the Trenton exposed at Trenton Falls.

The present N. Y. State Survey assigns Glens Falls ls. to Trenton group. (See W. Goldring, N. Y. State Mus. Hdb. 10, 1931.)

Glenwood shale. (In Platteville limestone.)

Middle Ordovician (Lowville): Northeastern Iowa, western Illinois, southern Minnesota and Wisconsin.

S. Calvin, 1906 (Iowa Geol. Surv. vol. 16, pp. 60, 61, 75). *Glenwood sh.*—Sh., 3 to 15 ft. thick in Glenwood Twp [Winneshiek Co., Iowa], lying btw. St. Peter ss. below and Platteville ls. above, described as "Basal Sh." in earlier repts, and supposed to represent initial phase of Trenton series. In lower 8 to 10 ft. it shows streaks and bands of sand, indicating close relationship with St. Peter ss. This lower part is assigned to St. Peter stage of Canadian series.

The shaly beds forming basal part of Platteville ls. in some areas consist of transitional shales and lss. 7 to 110 ft. thick, and are by most writers, including E. O. Ulrich, 1924, included in Platteville ls.; but A. Bevan (Ill. Geol. Surv. Rept. of Investigations, No. 9, 1926) advocated making them a distinct fm., under the name *Glenwood beds;* and Iowa Geol. Surv. (vol. 33, 1928, vol. 34, 1929) not only treated them as a distinct fm. but included them in *Lower* Ord. In Iowa Geol. Surv. vol. 33, pp. 33–36, 1928, many well logs record a thin bed of ls. btw. Glenwood sh. and underlying St. Peter ss., and record upper part of the Glenwood as consisting of 0–15 ft. of ss., and in SW. part of State rept a thickness of 80 ft. for the Glenwood.

F. W. Sardeson, 1933 (Pan-Am. Geol., vol. 60, p. 90). *Glenwood shales* is merely a new name for what is long known as the top of Peter ss. [St. Peter ss.].

C. R. Stauffer, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 1, pp. 125–169), described, discussed, and figured conodonts from these beds, which he stated (pp. 130–131) are "filled with Middle Ord. life, and most of its fauna is of that age." Also that "the fossil-bearing Glenwood beds belong in Mohawkian series, and are not much older than Platteville ls."

G. M. Kay and G. I. Atwater, 1935 (Am. Jour. Sci., 5th, vol. 29, Feb., pp. 98–111), treated these beds as basal memb. of Platteville ls., as did Kay (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., 1935, pp. 285–286), and the "Conf. classification," fig. 1; but according to fig. 2 of this Conf. Rept. the Iowa and Ill. Surveys exclude these beds from Platteville ls. Kay stated Glenwood memb. is overlain by Pecatonica ls. On pp. 383 to 384 of this Conf. Rept. A. Bevan stated that near Oregon, Ogle Co., NW. Ill., the *Glenwood* consists of 2½ to 12 ft. of glauconitic ss., which "in this paper is considered as a separate fm., rather than as a memb. of the Platteville." C. R. Stauffer, 1935 (Jour. Pal., vol. 9, No. 7, p. 597), also treated Glenwood as distinct fm.

†Globe limestone.

Carboniferous and Devonian: Southeastern Arizona (Globe region).

F. L. Ransome, 1903 (U. S. G. S. P. P. 12). *Globe ls.*—Hard buff and gray lss., 700 ft. thick. Underlie Whitetail fm. (Eocene ?) and overlie Apache group.

Replaced by Tornado ls. (Penn. and Miss.) and Martin ls. (Upper and Middle Dev.).

Named for development at and around Globe.

Glorieta sandstone.

Permian: Central northern New Mexico (Glorieta Mesa, Santa Fe and San Miguel Counties).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257, 262; and Conspectus of geol. fms. of N. Mex., pp. 2, 7). *Glorietta sss.*—Main body of Dakotan series (Cret.) around S. end of Rocky Mtns. Thickness 300 ft.

D. Hager and A. E. Robitaille, 1919 (Geol. rept. on oil possibilities in eastern N. Mex.). *Glorietta ss. is top memb. of Yeso fm. It consists of 500 ft. of massive* ss., even-grained and white when broken open but weathering reddish brown.

C. L. Baker, 1920 (Am. Jour. Sci., 4th, vol. 49, pp. 111, 118, 119, 126). *Glorieta ss.*, basal memb. of Upper Trias, outcrops along valley of Pecos from Glorieta Mesa downstream to somewhere btw. Puerto de Luna and Fort Sumner, and at Santa Rosa. Near Anton Chico it rests on Yeso fm.

J. L. Rich, 1921 (Am. Jour. Sci., 5th, vol. 2, pp. 295, 296). Baker has confused Glorieta ss. in parts of area with the younger (Upper Triassic) Santa Rosa ss. The Glorieta ss. is coarse, gray, massive, 300 to 500 ft. thick, underlies San Andreas ls., overlies Yeso fm., and is of Perm. age.

As there is no fm. btw. San Andres ls. and Yeso fm. as defined (now called Yeso memb. of Chupadera fm.), the ss. of Glorieta Mesa is top part of Yeso memb. of that area.

Gloucester formation.

Ordovician: British Columbia, Ontario, Quebec.

C. W. Drysdale, 1912 (Canada Geol. Surv. Summ. Rept. 1911, pp. 134, 135). *Gloucester fm.*—Crystalline ls., light to dark gray, which occurs as irregular masses interfolded with Franklin group (of greenstone, altered tuff, jasperoid, and silicified argillite), of Paleozoic (Upper?) age. [On p. 138 he states that the Gloucester property is situated on Gloucester Creek slope of Franklin Mtn, B. C., and that the rocks there are *Franklin group greenstones.*]

In 1916 P. E. Raymond used this name in Ont. (Harvard Coll. Mus. Comp. Zool. Bull., vol. 56, p. 255). In 1921 R. Ruedemann (N. Y. State Mus. Bull. 227, 228, p. 71) assigned *Gloucester sh.* of Canada to late Utica and post-Utica. In 1922 (Geol. Soc. Am. Bull., vol. 33, p. 585) Raymond stated that *Gloucester* was proposed for the "Utica" black sh. of Ont., which overlies Collingwood black sh. and ls. In 1924 A. F. Foerste (Canada Geol. Surv. Mem. 138, chart opp. p. 58) placed Gloucester above

Collingwood and assigned both to Utica. In 1925 (N. Y. State Mus. Bull. 258, p. 64) Ruedemann assigned *Gloucester sh.* to upper Utica, correlated it with Atwater Creek and Deer River of N. Y., and placed it above Collingwood sh. On p. 149 he appears to assign topmost part of *Gloucester* to basal Frankfort time. In 1933 G. M. Kay (Am. Jour. Sci., 5th, vol. 26, No. 151, p. 2) applied *Gloucester fm.* in Jefferson Co., N. Y. and assigned it to Trenton group, as he did in 1935 (Geol. Soc. Am. Bull., vol. 46, pp. 227, 228).

Goathaunt member (of Siyeh limestone).

Pre-Cambrian (Belt series): Northwestern Montana (Glacier National Park).

C. L. and M. A. Fenton, 1931 (Jour. Geol., vol. 39, No. 7, pp. 670–679). *Goathaunt memb. of Siyeh fm.*—Massive impure dark-gray mag. ls., weathering buff; some interbeds of dolomitic metargillite and a few thin beds of ss. Molar teeth and shear structures common in upper part. Thickness 2,000+ ft. Can be studied throughout Glacier Nat. Park. Most accessible on trail to Swift Current Pass. Underlies *Collenia (?) frequens* zone and overlies *Collenia symmetrica* zone of Siyeh fm. [Derivation of name not stated, but probably Goathaunt Mtn.]

Goat Mountain formation.

Jurassic or Triassic: British Columbia.

S. J. Schofield, 1926 (Econ. Geol., vol. 21, p. 273).

Gober tongue of Austin chalk.

Upper Cretaceous: Northeastern Texas (Hunt, Fannin, and Lamar Counties).

L. W. Stephenson, 1927 (A. A. P. G. Bull., vol. 11, pl. 1, pp. 8–12). Above Brownstown marl as here restricted is a tongue of Austin chalk formerly incorrectly correlated with Annona chalk and in this paper designated *Gober tongue of Austin chalk.* Village of Gober, Fannin Co., is located on this chalk. Where this tongue connects with main body of Austin chalk it probably is not less than 400 ft. thick, but it gradually thins out to E. and appears to pinch out entirely in E. part of Lamar Co. Between Honey Grove, Fannin Co., and High, Lamar Co., the lower part of the Gober is composed in part of soft, more or less chalky clay or marl. The lowest layers of chalk exposed in cut 1¼ mi. W. of High are regarded as forming base of Gober tongue. From central Fannin Co. to E. part of Lamar Co. the uppermost bed of Gober tongue is a soft tough ls. facies 1 to 10 ft. thick. It is conformably overlain by Taylor marl.

†Godiva limestone.

Mississippian, Devonian, Silurian (?), and Upper to Lower Ordovician: Central northern Utah (Tintic district).

G. W. Tower, Jr., and G. O. Smith, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, p. 624). *Godiva ls.*—As distinguished from underlying Eureka ls. is essentially a pure ls., 2,216 ft. thick. For 1,200 ft. above base the prevailing colors are gray and blue and the beds are diversified by occurrence of two or three sandy beds. Upper 1,000 ft. consists mainly of blue crystalline and black carbonaceous beds containing many fossils, with occasional beds rich in chert nodules and lenses. Underlies Humbug intercalated series. [Accompanying map shows Godiva Mtn is largely composed of this fm.]

G. F. Loughlin and W. Lindgren, 1919 (U. S. G. S. P. P. 107), divided these rocks into following fms. (descending): Pine Canyon ls., Gardner dol., Victoria qtzite, Pinyon Peak ls., and Bluebell dol., which range in age from lower Miss. to Lower Ord.

Godiva limestone. (Also spelled *Goldiva.*)

Eocene: Utah.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, p. 36). *Godiva lss.* (also *Goldiva lss.*)—Lss., 800 ft. thick, uncon. below Washakie shales and uncon. above Wasatchan series. Bottom fm. of Greenian series in Utah. [Derivation of name not stated.]

Goen limestone. (In Millsap Lake formation.)

Pennsylvanian: Central northern Texas (Palo Pinto County).

F. B. Plummer, 1929 (Tex. Bur. Econ. Geol., geol. map of Palo Pinto Co.). [*Goen ls.*, *in lower part of Mineral Wells fm., is shown as separated from overlying* Thurber coal by a thin sh., and as lying 60 ft. above Santo ls., all members of Mineral Wells fm.]

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 106). *Goen ls.* is memb of Garner fm., the name *Mineral Wells fm.* being restricted to upper part of original Mineral Wells fm.

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, pp. 16–24). The ls. in upper (Grindstone Creek) memb. of Millsap Lake fm. that caps the knolls around Goen Cemetery and is well seen on N. side of Millsap-Brazos road ½ mi. by road NE. of Goen Cemetery entrance, is here named *Goen ls.* It lies in upper part of Grindstone Creek memb. of Millsap Lake fm., 50 ft. above Santo ls.

Goff coal group. (In Williams Fork formation.)

Upper Cretaceous: Northwestern Colorado (Meeker quadrangle).

E. T. Hancock and J. B. Eby, 1930 (U. S. G. S. Bull. 812, p. 206). *Goff coal group.*—The 700 ft. of coal-bearing beds that underlie Lion Canyon memb. of Williams Fork fm. and is separated from Fairfield coal group below by 1,000± ft. of rocks almost barren of coal.

†Gogebic series.

A name applied in some early repts to †Animikie group (upper and middle Huronian) of Gogebic dist., Mich. (See U. S. G. S. Bull. 360, 1909, index.)

Golconda formation. (Of Chester group.)

Mississippian: Southern Illinois and Indiana, western Kentucky and Tennessee, and northwestern Alabama.

A. D. Brokaw, 1916 (Ill. Geol. Surv. Extr. from Bull. 35) and 1917 (Ill. Geol. Surv. Bull. 35, pp. 19–29, on parts of Saline, Williamson, Pope, and Johnson Counties, SE. Ill.). *Golconda fm.*—Shales and lss., variable in color and character, with a red sh. in places. Thickness 100 to 300 ft. Underlies Hardinsburg ss. and overlies Cypress ss.

C. Butts, 1917 (Ky. Geol. Surv. Mississippian formations of western Ky., p. 91). *Golconda fm.*—Consists of (descending) solid ls., 30 to 40 ft.; sh. and ls., 80 ft.; dark, argill., coarsely crystalline or fragmental fossiliferous ls. called *Pterotocrinus capitalis* zone, 10+ ft.; and dark sh., 20 ft. Underlies Hardinsburg ss. and overlies Cypress ("Big Clifty") ss. Named for Golconda, Pope Co., SE. Ill., just N. of which the full thickness outcrops on the river bluff.

Gold Creek quartzite.

Middle (?) Cambrian: Northern Idaho (Pend Oreille district).

E. Sampson, 1928 (Idaho Bur. Mines and Geol. Pam. 31, p. 9). *Gold Creek qtzite.*—Distinguished from any rock in Belt series by coarseness of grain. Is rather *coarse-grained throughout, with many pebble beds, some of which contain pebbles* as large as 3 in. diam. Color generally pure white. Cross-bedding is characteristic feature. Is very resistant to weathering and generally forms ridges and cliffs. Probably more than 200 ft. thick and less than 600; 400 ft. is fair approx. *Named for exposures on North and South Gold Creeks near Lakeview.* Conspicuous outcrops on summit of ridge above cement rocks plant at Port Rock. Basal fm. of Camb. in this area. Believed to be uncon. on Algonkian Striped Peak fm. Overlain by Rennie sh. (Middle Camb.).

†Golden formation or group.

Name suggested by A. C. Veatch (Jour. Geol., vol. 15, p. 548, 1907) as appropriate substitute for the so-called "Lower Laramie" (=typical Laramie). From Golden, Colo.

Golden Bar andesite rocks.

Age (?): Mexico.

R. T. Hill, 1904 (Greene Consolidated Gold Co. [Prospectus], p. 16).

Golden Eagle limestone.

Pennsylvanian: Southwestern Illinois (Calhoun County).

H. E. Culver, 1925 (Ill. Geol. Surv. Coop. Min. ser., Bull. 29, p. 20). [See description under *Piasa ls.* Position within McLeansboro fm. not defined. It appears to be the 5 ft. of gray concretionary ls., containing *Fusulina*, which on p. 39 of book cited is described as one of prominent beds of Calhoun Co., and there lying near top of the Penn., being overlain by 6 ft. of brown sh. and underlain by sandy brown sh. and a concealed interval aggregating 65 ft. Presumably named for exposures at or near Golden Eagle, Calhoun Co.]

†Golden Gate series.

Jurassic (?): Western California.

H. W. Fairbanks, 1895 (Jour. Geol., vol. 3, pp. 416–426). *Golden Gate series.*—Jasper, ss., sh., sl., and large bodies of fine-grained greenish eruptives. Extends from Santa Barbara Co. NW. through Coast Ranges to Klamath Mtns. Uncon. overlain by Knoxville beds and rests uncon. on crystalline basement complex.

Is same as Franciscan fm.

Named for development on N. and S. shores of Golden Gate.

Golden Ray limestone.

Middle Cambrian: Central northern Utah (Tintic district).

G. W. Crane, 1915 (Am. Inst. Min. Engrs. Bull. 106, pp. 2149–2151). *Golden Ray ls.*—Five thick horizons of heavily bedded dark-blue to bluish-gray dolomitic ls., interspaced by 5 relatively thin horizons of fine-grained light-gray to white, thinly laminated impure ls. Thickness 1,559 ft. Underlies Centennial ls. and overlies Tintic sh. [Evidently named for Golden Ray mine.]

These rocks were later subdivided into 3 fms., named (descending) Herkimer ls., Dagmar ls., and Teutonic ls.

Goldenville formation.

Cambrian or pre-Cambrian: Nova Scotia.

J. E. Woodman, 1904 (Am. Geol., vol. 33, p. 368; vol. 34, p. 14). [No age assignment. Later repts, by several geologists, assign it to Camb. or pre-Camb.]

†Golden Wall sandstone. (In Blair formation.)

Upper Cretaceous (Montana): Southwestern Wyoming (Sweetwater County).

J. W. Powell, 1876 (Geology of eastern portion of Uinta Mtns, pp. 40, 48, 155). *Golden Wall ss.* (also *Golden Wall group*).—Thinly laminated gray and buff ss. forming basal memb. of Point of Rocks group.

A. R. Schultz, 1920 (U. S. G. S. Bull. 702, pp. 23, 32, 33, pl. 1). Massive yellowish sss. near top of Blair fm. give rise to main scarp surrounding Baxter Basin, Sweetwater Co., Wyo., which is often referred to as the "golden wall."

†Gold Hill porphyry.

Eocene: Western central Colorado (Tenmile district).

S. F. Emmons, 1898 (U. S. G. S. Tenmile Special folio, No. 48), applied *Gold Hill porphyry* to mass of Elk Mtn porphyry on Gold Hill.

Gold Hill conglomerate.

Triassic (?): Southwestern Colorado (Ouray district).

J. D. Irving, 1905 (U. S. G. S. Bull. 260, p. 56). [In section of Gold Hill the Dolores fm. [Triassic and Jurassic?] is shown as consisting of *Gold Hill cgl.* underlain by ss.]

Gold Hill formation.

Cambrian? (Upper Cambrian?): Central Nevada (Manhattan district).

H. G. Ferguson, 1924 (U. S. G. S. Bull. 723). *Gold Hill fm.*—Marine sediments, of probable Upper Camb. age, laid down in shallow water, A series of schistose sl., qtzite, and ss. No fossils except a few annelid trails, but they occur considerably lower than rocks carrying Ord. fossils and bear some lithologic resemblance to known Camb. of other Nevada ranges. Are probably Upper Camb. Exposed thickness 5,000± ft.; base not exposed. Upper 2,500± ft. consists of a series of siliceous schist, ss., and qtzite, the schist predominating. Beneath this succession is (descending): (1) White Caps ls. memb., 30± ft. thick; (2) schist with several thin beds of qtzite, nearly 200 ft.; (3) Morning Glory ls. memb., 15 ft.; (4) siliceous schists, 140 ft.; (5) Pine Nut ls. memb., 10 ft.; (6) a short distance below the Pine Nut memb. lies a thick series of quartzose schists with subordinate calcitic and lime silicate schists and, rarely, thin beds of qtzite. In fault contact with overlying Mayflower schist. Exposed W. of Gold Hill.

Goldiva limestones. (See also *Godiva.*)

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, pp. 279, 308). Over a large area of NW. Colo. the Greenian, or Green River, series of Wyo. forms the bedrock. At E. extremity of Uinta uplift the sequence consists chiefly of calc. shales and lss., attains a thickness of 800 ft., and is the Goldiva fm. of Utah and Wyo. This is followed [above] by the whitish Washakie shales, 1,200 ft. thick. The two members are separated by a well-defined erosional uncon.

Derivation of name not stated.

†Gold Ledge porphyry.

A name applied by J. E. Spurr to an altered ls. containing the gold ores of Mercur dist., central northern Utah, which occur in Great Blue ls. (upper Miss.).

Gold Road latite.

Tertiary (middle or late): Northwestern Arizona (Oatman district).

F. L. Ransome, 1923 (U. S. G. S. Bull. 743). Chiefly volcanic flows, with tuff and intrusive material. Mainly biotitic latite, but includes some glassy and lithophysal rocks that should perhaps be classed as rhyolite. Between some flows are layers of tuff. Basal flow is conspicuously biotitic. Thickness 3,000 to 4,000± ft. Overlies Oatman andesite. Named for settlement and mine, both of which are called Gold Road.

Goliad sand.

Pliocene: Southern Texas.

J. T. Lonsdale and J. R. Day, Feb. 9, 1933 (Ground water res. of Webb. Co., Tex., U. S. G. S. Press Bull. 68861). The name *Goliad fm.* has been proposed by Texas geologists and is being considered as a substitute for *Reynosa.*

A. Deussen, 1933 (A. A. P. G. Bull., vol. 17, No. 5, May, p. 485). The fm. which geologists are calling *Goliad ss.* in SW. Tex. according to my interpretation represents basal portion of what I conceive to be Reynosa fm.

W. A. Price, 1933 (A. A. P. G. Bull., vol. 17, No. 5, p. 492). The field name "*Goliad ss.*," first employed by H. A. Noble and Irving K. Howeth in a Shell Co. field rept in 1928, has come into somewhat general use in south Tex. but has no standing in nomenclature, since it has not been described in publication by its authors.

L. Bowling and A. P. Wendler, 1933 (A. A. P. G. Bull. vol. 17, No. 5, p. 529), used *Goliad* (*Reynosa*) in table.

F. B. Plummer, 1933 (Tex. Univ. Bull. 3232, pp. 530, 740, 741, 750–761, 782). [On p. 530 *Goliad fm.* is applied to all Plio. deposits of Tex. underlying Lissie fm. (Pleist.) and overlying Lagarto restricted and Oakville fms. (the latter two being assigned to Plio. and Mio.), and *Goliad* is shown as=*Citronelle group* and is divided, in central and SW. Tex., into (descending) Lababia, Lagarto Creek beds, and Lapara members. On p. 750 Plummer stated:] The need for Citronelle as a group name arises from recent differentiation and mapping in Tex. of new Plio. unit *Goliad fm.*, which outcrops in SW. Tex. btw. Lagarto clay [restricted] and Lissie sand as far NE. as Colorado River. East of Colorado River the Goliad fm. is covered by sands thought to be Plio. in age and as yet unnamed but included in Citronelle group. The Citronelle uncon. overlies Lagarto fm. [restricted] and underlies Lissie sand. The Goliad fm. outcrops along San Antonio River at Goliad, Goliad Co., Tex. It includes most of strata that were placed in Reynosa fm. by Deussen and by Trowbridge. The name has been accepted by San Antonio Geol. Soc., Houston Geol. Soc., and Bur. of Econ. Geol., but San Antonio committee decided to include Lapara sand in Goliad fm. There is important uncon. at base of the Lapara. Average thickness of Goliad est. at 250 ft. The fm. was named by I. K. Howeth and P. F. Martin in ms. presented at annual meeting of San Antonio Geol. Soc., Corpus Christi, Feb. 27, 1932.

Goliad sand is adopted name of U. S. Geol. Survey for the fm. defined in Tex. Univ. Bull. 3232, 1933, i. e., to include all beds below Lissie fm. (Pleist.) and above Lagarto clay as restricted by Plummer (to beds uncon. underlying Lapara sand memb.). (See also under *Uvalde gravel.*)

Gonic formation.

Carboniferous (Pennsylvanian?): Southwestern Maine and southeastern New Hampshire.

F. J. Katz, 1917 (Wash. Acad. Sci. Jour., vol. 7, p. 199). *Gonic fm.*—Graywacke schists, mica schists, and garnet-staurolite phyllites, occurring in belt 2 to 4 mi. wide running from Sanford, Me., to Barrington, N. H.

F. J. Katz, 1917 (U. S. G. S. P. P. 108, pp. 172, 174). *Gonic fm.*—Aren. (graywacke) and argill. materials, metamorphosed to schist and phyllite. Mostly rather thin-bedded, fine-grained, and of whitish or light-gray to dark-gray color. Includes mica schist and phyllite and interbedded fine- to medium-grained micaceous graywacke schists in beds up to 2 ft. thick; fine-grained light- and dark-gray phyllites abundantly studded with dark staurolite crystals; and a little coarse muscovite schist composed almost wholly of mica and very thin laminae of quartz. Argill. materials predominate, but the graywacke is also prominent. Thickness unknown. Believed to underlie Rindgemere fm. Assigned to Penn. (?). Named for exposures near Gonic, Strafford Co., N. H.

Gonzales limestone member (of Graham formation).

Pennsylvanian: Central northern Texas (Brazos River region).

C. S. Ross, 1921 (U. S. G. S. Bull. 726G, p. 307). *Gonzales ls. memb. of Cisco fm.*—Coarse-grained dark-gray ls. containing large numbers of *Campophyllum.* Thickness 0 to 4 ft. Lies 96 ft. above Home Creek ls. and 80± ft. below Bunger ls. Strat. position corresponds closely to that of Jacksboro ls. Plummer finds Jacksboro thins to S. and plays out 10 to 15 mi. SW. of Jacksboro, and writer finds Gonzales thins to N. and plays out near N. border of Lacasa area, leaving interval of nearly 40 mi. over which neither bed has been traced; hence local name. To W. replaced by sh. Named for Gonzales Creek, Stephens Co.

The Cisco is now treated as a group in this area, divided into several fms., and Gonzales ls. is now treated as a memb. of Graham fm.

†Gonzales shale.

Pennsylvanian: Central northern Texas (Shackelford and Stephens Counties).

F. B. Plummer, March, 1929 (Tex. Bur. Econ. Geol., geol. map of Palo Pinto Co.); showed *Gonzales sh.*, 100± ft. thick, as basal part of Cisco in Palo Pinto Co., and as underlying Gonzales ls. lentil, 0 to 5 ft. thick.

O. F. Hedrick, E. Owens, and P. A. Meyers, 1929 (Tex. Bur. Econ. Geol., geol. map of Shackelford Co.). *Gonzales sh.*, 25 ft. thick, lies in lower part of Cisco group, 15 ft. below Gonzales ls. lentil.

This name is not listed in index to Univ. Tex. Bull. 3232, 1933, nor in list of Penn. units on pp. 103–106.

Gonzales Creek shale member (of Graham formation).

Pennsylvanian: Central northern Texas (Brazos River region).

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31; Univ. Tex. Bull. 2132, pp. 127–134). In SE. Young Co. 230± ft. of sh. and ss. occur above Jacksboro ls. This portion of Graham fm. of Brazos River valley is named *Gonzales Creek memb.*, for a creek in Eastland Co. [?]. Where Jacksboro ls. is absent the Gonzales Creek memb. rests on underlying Finis sh. It underlies Bunger ls. memb. of Graham fm., and is composed of poorly bedded, lenticular dark-brown sss., sandy shales, red clays, gypsiferous black clays, 2 ls. lentils, and a coal bed. The sss. are lenticular and the shales variable. One ls. lentil occurs 30 ft. below Bunger ls. and the other 80 ft. below the Bunger.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 112), stated that Home Creek ls. of Jack Co. includes Jacksboro ls.

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, pp. 61–63), divided the lower 125 ft. of Graham fm. that is present in Palo Pinto Co., into the following members (descending): Bunger ls., 6 ft.; Gonzales Creek sh., 116 ft.; Eastland ss. (new name), 10 to 15 ft.; and Finis sh., 50 ft.

Goobic sand.

See *Gubik sand.*

Goodenough member (of Franconia sandstone).

Upper Cambrian: Southwestern Wisconsin (Juneau County).

A. C. Trowbridge et al., 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., summer of 1935, fig. 1, pp. 81, 92, 134, 140, 159, 431, 449, 454, 446, etc.). *Goodenough memb. of Franconia fm.*—At Goodenough Hill (NE¼ S. 13, T. 15 N., R. 2 E.) consists of (descending): (1) Coarse white ss., 10.2 ft; (2) covered, 4½ ft.; (3) ss., fine grained, glauconitic, with hematite layer at base, 25.1 ft. Rests on Ironton memb. of the Franconia and underlies Hudson memb. of Franconia. [On p. 309 of this book G. O. Raasch stated that Goodenough memb. is *Conaspis* zone.]

W. H. Twenhofel, G. O. Raasch, and F. T. Thwaites, Nov. 30, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 11, pp. 1700, etc.). *Goodenough memb.* is term proposed by writers for that part of Franconia fm. bearing *Conaspis* fauna. Its discrimination is based primarily on faunal criteria, but it can locally be differentiated into 3 lithologic units (*descending*)—Lower Greensand, Micaceous Sh., and Calcareous strata, which are typically exposed over Tomah-Sparta area. The Lower Greensand consists of 40 ft. of horizontally and cross-laminated glauconitic sss. alternating with thicker beds of nonlaminated glauconitic sss. irregularly mottled by areas of blue or yellow silt. It is called Lower Greensand in contrast to greensand at top of Franconia fm. Type loc. of Goodenough memb. is Goodenough Hill, in southern Juneau Co., btw. Elroy and Mauston.

†Good Hope formation.

Tertiary? (Pliocene?): Southern Maryland and District of Columbia.

W. B. Clark, 1890 (Johns Hopkins Univ. Circ., vol. 9, No. 81, pp. 69–70). The term *Good Hope fm.* has been employed by [N. H.] Darton [in unpublished field notes] for coarse gravels and sands that cap the higher bluffs and show in their topog. relief more extensive denudation than the later and lower Columbia fm.

In subsequent repts the deposits referred to were mapped as "Lafayette fm.," but that term was discarded years ago. According to F. Bascom and C. W. Cooke (personal communication) these beds are of Plio. (?) age. Whether they correspond to Bryn Mawr gravel of SE. Pa. is a debated point.

Named for Good Hope Hill, D. C.

Goodland limestone. (Of Fredericksburg group.)

Lower Cretaceous (Comanche series): Northeastern Texas, central southern and southeastern Oklahoma, and southwestern Arkansas.

R. T. Hill, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 504, 514). *Goodland ls.*—Single persistent layer, representing Fredericksburg or Comanche Peak div. Resembles Caprina [Edwards] ls. in hardness but has Comanche Peak fauna. Considered northern attenuation of Comanche Peak beds. Overlies *Exogyra texana* beds (Walnut clays and *Gryphaea* breccia) or, where they are absent, Paluxy sands.

J. A. Taff, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1). *Goodland ls.* of R. T. Hill is=Texana ls. [Walnut clay] and perhaps Comanche Peak ls.

R. T. Hill, 1894 (Geol. Soc. Am. Bull., vol. 5, pl. 13). *Goodland ls.* is northward continuation of Caprina ls. [Edwards ls.] and Comanche Peak, and overlies Walnut clay and underlies Kiamitia [Kiamichi] clays.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, pp. 114+). *Goodland ls.*= Edwards ls. and Comanche Peak ls.

J. A. Taff, 1902 (U. S. G. S. Atoka folio, No. 79) and 1903 (U. S. G. S. Tishomingo folio, No. 98, p. 6). *Goodland ls.*=Edwards ls., Comanche Peak ls., and Walnut clay of Tex.

J. A. Taff, 1905 (U. S. G. S. Bull. 243, pp. 307–312). *Goodland ls.*=Edwards ls. and Comanche Peak ls.

J. A. Udden, C. L. Baker, E. Böse, 1916 (Univ. Tex. Bull. 44, p. 62). In N. part of State it is impossible to separate Comanche Peak from Edwards ls. Both together are represented by *Goodland ls.*, which extends from Grayson to Red River and into Okla.

L. W. Stephenson, 1918 (U. S. G. S. P. P. 120H, pp. 135–137). Basal 3 to 6 ft. of Goodland ls. consists of layers of persistent, hard, thin-bedded coquina-like ls. with interbedded thin layers of dark marly sh., which in this paper [on NE

Tex. and Marshall and Bryan Counties, Okla., just W. of Choctaw Co., Okla., in which is type Goodland] are called *Walnut shaly memb.* These beds were not recognized by Hill (Geol. Soc. Am. Bull., vol. 2, pp. 502–514, 1891) in type section at Goodland, Choctaw Co., Okla. Although Taff's usage of Goodland has been adopted by U. S. G. S., writer believes future investigations will show Goodland ls. should be restricted to massive ls. above this Walnut shaly memb., in accordance with Hill's original usage. [Some geologists believe this bed is younger than any part of typical Walnut clay.]

E. T. Dumble, 1920 (Univ. Tex. Bull. 1869). *Goodland ls.* of Red River region, 10 to 40 ft. thick, is=Edwards ls. and Comanche Peak beds.

W. S. Adkins and W. M. Winton, 1920 (Univ. Tex. Bull. 1945). *Goodland fm.*= Edwards and Comanche Peak.

W. M. Winton and G. Scott, 1922 (Univ. Tex. Bull. 2229, pp. 17–33). *Goodland fm.* is 128 to 140 ft. thick in Johnson Co., Tex., where it exhibits the transition from typical Goodland of No. Tex. to Edwards and Comanche Peak fms. of central Tex. The upper (hard) 35 ft. is=Edwards and lower (soft) 140 ft. is=Comanche Peak. The correlation is proved by transition and fossils. It overlies Walnut fm. and underlies Kiamitia.

W. M. Winton, 1925 (Univ. Tex. Bull. 2544, pp. 9–40). In Denton Co., Tex., *Goodland ls.* is 40 to 75 ft. thick; in W. part of Tarrant Co. it is 116 ft. thick. Is=Edwards and Comanche Peak to S.

H. P. Bybee and F. M. Bullard, 1927 (Univ. Tex. Bull. 2710, p. 21). *Goodland ls.* of Marshall Co., Okla., is=Edwards ls. and Comanche Peak ls.

C. I. Alexander, 1929 (Univ. Tex. Bull. 2907, pp. 14–46). *Goodland fm.* is 20 ft. thick on Red River and 140 ft. on Brazos River. Upper part (white ls. alternating with seams of yellow clay or marl) is=Edwards fm. Lower part (largely laminated clays and shales with a few seams of yellowish marl and several ledges of chalky white soft ls.) is=Comanche Peak fm. It overlies Walnut fm. and underlies Kiamichi.

W. S. Adkins, 1933 (Univ. Tex. Bull. 3232, pp. 334–338). The Comanche Peak is a chalky-limy facies. To N. it is continuous with "Goodland" ls., which is of same lithology and fossils. *Goodland ls.* in Red River Valley is same as Comanche Peak, because (1) Edwards is defined as consisting of the rudistid facies and similar rock, and does not outcrop N. of Fort Worth; and (2) the Goodland contains *Oxytropidoceras acutocarinatum*, a species which marks middle and lower parts of Fredericksburg group. At Goodland is less than 20 ft. thick. [His table on p. 270 shows Goodland overlain by Kiamichi and underlain by Walnut. His table on p. 328 shows Goodland of north-central Tex. is=Comanche Peak plus a thin representative of Edwards ls.]

S. A. Thompson, 1935 (A. A. P. G. Bull., vol. 19, No. 10, pp. 1536, 1537). *Goodland ls.* is a synonym for Comanche Peak ls., which has priority by 30± years. Goodland should be abandoned. Hill, who is author of name Goodland, stated at Dallas, 1934, meeting of A. A. P. G. that Goodland is a synonym of Comanche Peak.

W. C. Mendenhall, 1935 (p. 1537 of book last cited above). It is questioned whether Goodland is actually a synonym of Comanche Peak and should be abandoned. Goodland seems to be a useful name for the northern thin ls. of the Fredericksburg where the Edwards is either very thin or not recognizable as such.

Named for Goodland, Choctaw Co., Okla.

Goodland moraine.

Pleistocene (Wisconsin stage): Southeastern Michigan. Named for Goodland Twp. Is shown on moraine map (pl. 32) of U. S. G. S. Mon. 53.

Goodnight formation.

Pliocene: Panhandle of Texas.

W. F. Cummins, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 201–203). *Goodnight div.*—Fresh-water deposits of white, yellowish, and red sandy clays, including heavy cgl. bed and some ss. and ls. Contains fossils which differ from the other Tert. fossils of Staked Plains. Thickness 225 ft. Stratigraphically and paleontologically underlies Blanco beds and overlies Loup Fork beds.

J. W. Gidley, 1903 (Am. Mus. Nat. Hist. Bull. 19, p. 632). *Goodnight beds* of Cummins are identical with Clarendon beds, and former name as a distinct horizon should be abandoned.

Mapped as *Ogallala fm.* (*Plio.*) on 1932 geol. map of Tex.

Named for Goodnight, Armstrong Co.

Goodrich quartzite.

Pre-Cambrian (upper Huronian): Northwestern Michigan (Marquette district).

C. R. Van Hise and W. S. Bayley, 1895 (U. S. G. S. 15th Ann. Rept., p. 591). *Goodrich qtzite.*—Conglomeratic qtzites and qtzites. Max. thickness 1,550 ft. Included in Ishpeming fm. Equiv. to Bijiki schist of E. part of Marquette dist. Overlies Negaunee fm. Named for exposures at Goodrich mine.

Later repts by C. R. Van Hise and others state that Goodrich qtzite underlies Bijiki schist.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184). *Goodrich qtzite* uncon. overlies Negaunee iron-fm. and underlies Greenwood iron-fm., which is overlain by Clarksburg volcanics, an older fm. than Bijiki iron-fm memb. of Michigamme sl., from which it is separated by lower sl. memb. of Michigamme. [In previous repts Greenwood iron-fm. was included in either Clarksburg volcanics or Goodrich qtzite.]

†Goodridge formation.

Permian and Pennsylvanian: Southeastern Utah (southern San Juan County).

E. G. Woodruff, 1912 (U. S. G. S. Bull. 471, p. 80, etc.). *Goodridge fm.*—Massive-bedded crystalline ls., and soft sandy sh. and ss. Thickness 1,542 ft. Underlies Moenkopi fm. Occupies strat. interval of Rico and Hermosa fms. of SW. Colo. [Named for town of Goodridge, now known as Mexican Hat.]

Later detailed work by several geologists (especially J. B. Reeside, Jr., and A. A. Baker) resulted in subdividing these rocks into Rico and Hermosa fms., and the name "Goodridge fm." has therefore been discontinued.

Goodridge sand.

A subsurface sand in upper part of Rico fm. (Perm.) in southern part of San Juan Co., SE. Utah.

Goodsir formation.

Ordovician and Cambrian: British Columbia.

C. D. Walcott, 1912 (Smithsonian Misc. Coll., vol. 57, No. 7, p. 230). *Goodsir fm.*, Ord., B. C.

L. D. Burling, 1916 (Canada Geol. Surv. Summ. Rept. 1915, p. 98). *Goodsir sh.* of B. C. is Camb. and Ord.

Several subsequent Canada Geol. Surv. repts, by different authors, assigned this fm. to Ord. and Camb.; Walcott, 1928 (Smithsonian Misc. Coll., vol. 75, p. 232), assigned it to Camb.; P. S. Warren, 1929 (Canadian Field Nat., vol. 43, p. 24), assigned it to Camb. and Ord. (?).

Goodsir series.

A term employed by C. [R.] Keyes (Pan-Am. Geol., vol. 42, 1924, p. 288) for Ord. rocks in Alberta that presumably correspond to Goodsir fm. of Walcott.

Goodsprings dolomite.

Devonian (?) to Upper Cambrian: Southeastern Nevada (Goodsprings region).

D. F. Hewett, 1931 (U. S. G. S. P. P. 162, pp. 10, 11, etc.). *Goodsprings dol.*—Thin-bedded light- and dark-gray mottled dol., with some mag. ls., and, locally, near top 50 to 75 ft. of dolomitic and sandy sh. Thickness 2,450± ft. Underlies Sultan ls. (Dev.) and (outside of Goodsprings quad.) overlies Bright Angel sh. (Middle Camb.), which is not exposed in the quad. Named for town of Goodsprings, to S., W., and NW. of which it covers broad areas. According to E. Kirk the fossils from 1,500 to 2,000 ft. below top are Upper Camb.; a few forms from higher up suggest early Ord., a few fossils from 400± ft. below top suggest Sil.; 2 species from 100± ft. below top are probably Dev. [Mr. Hewett sent an advance copy of his Goodsprings section, and of the names he proposed to apply to the fms., to W. S. Glock, who in 1929 (Am. Jour. Sci., 5th, vol. 17, pp. 326 to 339) described the *Goodsprings dol.* in east-central part of Spring Mtn Range, Goodsprings quad.]

Goodwin formation.

Lower Ordovician: Eastern Nevada (Eureka region).

C. D. Walcott, 1923 (Smithsonian Misc. Coll., vol. 67, No. 8, pp. 466–467, 475). *Goodwin fm.*, new name, proposed for lower 1,500 ft. of Pogonip fm., the name *Pogonip* to be restricted to upper part of Pogonip of previous repts. Consists of bluish-gray lss., distinctly bedded. Fossils listed. Named for Goodwin Canyon, Eureka dist. Assigned to lower Ozarkian.

Goodwinian series.

A name applied by C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 53, 78), to lower part of Pogonip ls. of Nev., or to the beds designated by Walcott as *Goodwin fm.* Also to St. Charles ls. (Upper Camb.) of Utah.

Goodwyn sandstone. (In Hinton formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 297, 358). *Goodwyn ss.*—Greenish gray and massive, or reddish brown and shaly; 25 to 40 ft. thick. Underlies Lower Tophet sh. and overlies Upper Goodwyn sh.; all members of Hinton group [fm.]. Type loc. along Princeton-Narrows road on Fivemile Creek, at Goodwyn Chapel, Mercer Co. Also observed in Summers Co. Should be present in Monroe Co.

Goodwyn shale. (In Hinton formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 297, 359–360). *Upper Goodwyn sh.*—Dark, sandy, fissile; 1½ to 10 ft. thick; underlies Goodwyn ss. and overlies Goodwyn coal or Lower Goodwyn sh. *Lower Goodwyn sh.*—Dark and calc., with marine fossils near top, and red and variegated with streaks of ss. near base; 40 to 75 ft. thick; underlies Goodwyn coal or Upper Goodwyn sh., and overlies Upper Bellepoint ss. All are members of Hinton group [fm.]. Type loc. same as Goodwyn ss.

Goose Bay argillite.

Age (?): British Columbia.

R. G. McConnell, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 42).

Goose Bay formation.

Jurassic (?): British Columbia.

V. Dolmage, 1923 (Canada Geol. Surv. Summ. Rept. 1922, pt. A, p. 13).

†Goose Creek marl.

†Goose Creek phase.

Pliocene: Southern South Carolina (Berkeley County).

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 12, 18, 19). *Goose Creek phase.*—During Mio. time the gulf waters coursing through Fla. archipelago scoured the coast of Carolina along a shore line a portion of which extended N. of present sites of Wadmalaw and Stono Rivers to Cherokee mines and thence S. of Bees Ferry (on Ashley River), by Yeaman's Hall (Goose Creek), and thence along Cooper River to the Grove, whence it proceeded easterly along Wando River above Cainhoy. Along this shore line the marl was deeply incised to a comparatively abrupt escarpment along a portion of which the thin marl pertaining to Goose Creek phase was more prominently deposited. This marl also formed along southwesterly margin of embayment of eastern Tert. division, where it was succeeded by Pee Dee phase, which extended over depressed areas as far N. as Sparrow Swamp. In eastern Tert. division the Goose Creek type of marl interruptedly appears along Pee Dee River from Bostick to Allison's Landing underlying Pee Dee marl.

According to C. W. Cooke (personal communication, 1935) the beds on Goose Creek belong to Waccamaw fm. (Plio.).

Named for exposures at Yeaman's Hall, on Goose Creek, N. of Charleston, Berkeley Co.

Goose Creek granite.

Pre-Cambrian: Central southern Montana (Stillwater, Carbon, Yellowstone, SE. Park County regions).

T. S. Lovering, 1929 (U. S. G. S. Bull. 811A, p. 16). Gneissic gray granite locally carrying schist inclusions. Oldest rock in Cooke dist., SE. corner of Park Co. Goose Creek flows over it for practically its entire length.

Goose Lake slate.

Pre-Cambrian: Northwestern Michigan.

See 1907 entry under *Wewe sl.*

Goose Neck sand.

A subsurface sand in southern San Juan Co., SE. Utah, that probably lies in Hermosa fm. (Penn.).

†Goose Pond limestone.

Name applied by B. K. Emerson (U. S. G. S. Bull. 159, pp. 51–52, 1899) to Coles Brook (†Hinsdale) ls., as exposed N. and E. of Goose Pond, eastern Berkshire Co., Mass.

Goose Run sand.

Subsurface sand, 10 to 40 ft. thick, lying at horizon of Sewickley ss. memb. of Monongahela fm. (Penn.) in SW. Pa. and Washington and Monroe Counties, eastern Ohio. Discovered in 1899–1900 on Goose Run, E. of Marietta, Washington Co., Ohio. (W. Stout et al., Geol. of nat. gas, A. A. P. G., 1935, pp. 898–900.)

Gordon sandstone. (In Strawn formation.)

Pennsylvanian: Central northern Texas.

E. T. Dumble, 1890. [See under *Richland ss.*]
F. B. Plummer, 1919. [See first entry under *Mineral Wells fm.*]

Probably named for Gordon, Palo Pinto Co.

Gordon shale.

Middle Cambrian: Central western Montana (Powell County).

C. D. Walcott, 1917 (Smithsonian Misc. Coll., vol. 67, No. 1, Pub. 2444, pp. 7–8, and No. 2, Pub. 2445, pp. 16–19). *Gordon sh.*—A name proposed for the fine argill. shales carrying *Albertella* fauna in Mont. Of greenish and purplish color. Thickness 284 ft. on ridge btw. Gordon and Youngs Creeks, Powell Co. [Detailed section given.] Underlies Meagher ls. and overlies Flathead (?) ss. Type loc. on Gordon Creek, 6 mi. from South Fork of Flathead River, Ovando quad., Powell Co. The sh. extends across the ridge btw. Gordon and Youngs Creek, about halfway btw. Gordon Mtn and Cardinal Peak.

Gordon sand.

A subsurface sand, of late Upper Dev. or early Carbf. age, 6 to 100 ft. thick, lying 2,147 ft. below Pittsburgh coal in E. part of Greene Co., Pa., and in W. Va. Named for Gordon farm, near Washington, Washington Co., Pa., where it was discovered in August 1885. A sand 5 to 100 ft. higher is called *Gordon Stray sand*. The name has also been applied to a subsurface sand, 20 ft. thick, lying 130 to 225 ft. below top of Marble Falls ls. (Penn.) in central Tex.

Gordon Mountain limestone.

Upper or Middle Cambrian: Northwestern Montana.

C. F. Deiss, 1933 (Mont. Bur. Mines and Geol. Mem. 6, pp. 39 and passim). *Gordon Mtn ls.*—Gray to chocolate-gray massive lss. underlying Switchback ls. and overlying Pentagon sh. Thickest (272 ft.) in Dearborn area; thinnest (140 ft.) in Wall Creek area. Most distinguishing characteristic is the number of green sh. zones interbedded at irregular intervals in the lss. Forms top of central and principal peak of Gordon Mtn. Type loc. is middle part of the cliffs which form lower part of E. side of a peak 8,300 ft. elev., the top of which is just 1 mi. S. 48° E. of top of Pentagon Mtn.

Gore limestone. (In Pottsville formation.)

Pennsylvanian: Southeastern Ohio.

E. Orton, 1878 (Ohio Geol. Surv., vol. 3, pp. 889, 898, 903; pls. opp. pp. 889, 900, 912, 921). *Gore ls.*—Dark-blue ls., resembling Zoar ls., but 30 to 40 ft. above the Zoar. Often replaced by flint. Traceable from Hocking Valley to Ohio River.

Later repts state it is Upper Mercer ls. memb. of Pottsville fm. (See Ohio Geol. Surv., 4th ser., Bull. 21, 1918, p. 102.)

Probably named for occurrence at Gore, Hocking Co.

Gorge formation.

Upper Cambrian: Northwestern Vermont (St. Albans quadrangle, Franklin County).

C. Schuchert, 1933 (Am. Jour. Sci., 5th, vol. 25, pp. 359, 367, 368, 375–377). *Gorge fm.*—About Highgate Falls and to N. the Upper Camb. facies is again very different, since here there is (1) a lower massive dol. 80 ft. thick; followed unbroken upward by (2), a thick series (162 ft.) of thin-bedded dark-blue lss., mag. lss., black sl., qtzites, and intraformational flat-pebble cgls. of dol. and ls. pieces, and black dolomitic sl.; in lower part thick beds of ss. The upper Gorge (or No. 3) consists of (descending) a layer of small-pebble intraformational cgl., 1 ft.; banded black sl., 6 ft.; sandy dol., 6 ft.; upper great cgl., 10 to 15 ft.; thin-bedded dolomites and lss., sh., and sandy beds, 12 to 15 ft., with an erratic block of gray dolomites 5 ft. thick and 10 ft. long; massive blue-gray dol. in 5 or 6 beds with intraformational slabby dol. pieces, 15 ft.; lower still is another great cgl. 26 ft. thick; the whole making a thickness of 80± ft. The Gorge fm. is overlain by lower Highgate, consisting of a series of alternating impure lss. and shales in thin beds of about equal thickness. The Gorge fm. rests uncon. on Parker sl. (Lower Camb.), the Middle Camb. being absent. It contains fossils [listed]. Thickness 0–300± ft. The name *Gorge fm.* is unsatisfactory, but for want of a local geographic name it is here applied to all strata in *Highgate gorge* [at Highgate, St. Albans quad.] beneath Highgate fm. There is no apparent break anywhere within Gorge fm. Keith correlates the cgl. zones with Mill River ls. cgl., but writer regards them as local intraformational cgls. and not basal cgls., as in the Mill River. The middle part of Gorge fm. is the Missisquoi of Keith, 1924. [Schuchert shows his Gorge fm. to be=Milton dol. (see under *Milton dol.*), and these beds at Highgate Falls were clearly called *Milton dol.* by Keith in his original definition of Milton.]

Gorham shales.

A term casually applied by J. M. Clarke and D. D. Luther in 1904 (N. Y. State Mus. Bull. 63, pp. 23, 25) to basal beds of Genesee sh. (beneath Genundewa ls.), which were later named *Geneseo sh.* by Chadwick. See explanation under *Genesee sh.*

Gorham sand.

Gorham sand or basal cgl. is name locally applied to lower 20 to 80 ft. of unexposed Penn. rocks of Ness and Hodgeman Counties, SW. Kans., which are correlated with upper part of Des Moines series. (See R. G. Moss, Kans. Geol. Surv. Bull. 19, p. 36, 1932.)

E. A. Koester, 1935 (A. A. P. G. Bull., vol. 19, No. 10, p. 1414). *Gorham sand* is a near-shore phase of basal Penn. Sooy cgl. Name derived from Gorham field. Some geologists believe this sand in Gorham field and elsewhere is Ord. or Camb., but writer believes it is basal Penn.

Gose sand.

A subsurface sand in Cisco group (Penn.) of Archer Co., Tex., which occurs at any place within a 50-foot zone lying from 1 to 20 ft. beneath Gunsight ls. memb. of Graham fm. Is also called *Texhoma-Gose sand, Archer County sand, Miller sand*, and *Swastika sand*.

Goshen schist.

Silurian (?): Western Massachusetts, southeastern Vermont, and southwestern New Hampshire.

B. K. Emerson, 1892 (U. S. G. S. Hawley sheet, i. e., proof sheets of geol. maps and text intended for a geol. folio, but never completed and published in that form, although cited in U. S. G. S. Bull. 191, 1902). *Goshen schist*, flaggy, dark, garnetiferous schist, with beds of qtzite and ls. Underlies Conway schist and overlies Hawley schist.

B. K. Emerson, 1898 (U. S. G. S. Holyoke folio, No. 50, also U. S. G. S. Mon. 29, pp. 177–183, pl. 34). *Goshen schist*.—Dark, graphitic, flaggy mica schist, with biotite and garnet. Thickness 2,000(?) ft. Underlies Conway schist and uncon. overlies Hawley schist. Typical region is that surrounding the oval of Hawley schist in Goshen, Mass., where Goshen schist dips away from Hawley schist in all directions. [See also B. K. Emerson, U. S. G. S. Bull. 597, pp. 45–46, 1917.]

Goshen schist.

Pre-Cambrian: Central southern Virginia and adjacent part of North Carolina (Virgilina district).

F. B. Laney, 1917 (Va. Geol. Surv. Bull. 14, pp. 19, 23; map). *Goshen schist (Ord. ?)*.—Highly schistose, clastic, acid tuff, probably of volcanic origin, in most places so altered that little or nothing of its original structure and texture is discernible. Color light gray or white. In present condition is a well-defined sericite schist. Is probably a tuffaceous phase of Hyco quartz porphyry. Named for typical occurrence in vicinity of Goshen, in SE. part of Virgilina dist.

A. I. Jonas, 1928 (Va. Geol. Surv. prel. ed. of geol. map of Va.). [Under the block of pre-Camb. extrusive rocks younger than Glenarm series and designated "aporhyolite" is statement: "In Virgilina area called Hyco quartz porphyry and tuffaceous facies is called Goshen schist."]

Gosnell shale.

A subsurface part of Repetto siltstone (lower Plio.) in Ventura field, Ventura Co., southern Calif. Formerly included in Pico fm. (middle and upper Plio.). Thickness 75 to 2,000 ft. Lies approx. 3,000 ft. below surface.

Gosport sand. (In Claiborne group.)

Eocene (middle): Southern Alabama.

E. A. Smith, 1907 (Ala. Geol. Surv. Bull. 9, pp. 5, 18). *Gosport greensand*.—Embraces the strata of Claiborne group lying btw. top of Lisbon fm. and base of St. Stephens ls. The beds are in general highly glauconitic sands about 30 ft. thick at Claiborne and Gosport bluffs, and include the fossiliferous greensands which have made the name *Claiborne* famous, and which have furnished greater part of Claiborne fossils described and figured by Conrad and Lea.

Is top fm. of Claiborne group in Ala., and of marine origin.

Named for Gosport, a landing on Alabama River a few mi. below Claiborne Bluff, in Clarke Co.

Goss Mill limestone facies.

Name applied by P. B. Stockdale (Ind. Acad. Sci. Proc., vol. 39, pp. 213–214, 1930; Ind. Dept. Cons., Div. Geol., Pub. 98, pp. 76, 197, etc., 1931) to a local southern development ("that of the type locality") of his Floyds Knob fm. of Ind. (See under *Floyds Knob fm.*)

Gothlandian.

A term that has been applied by some European geologists to Silurian system.

Goulburn quartzite.

Pre-Cambrian: Arctic Canada.

J. J. O'Neill, 1924 (Canadian Arctic Expedition 1913–18, vol. 11, pt. A, p. 23).

Gould coal group.

Name long in use for a group of four coal beds, in Pottsville fm. (Penn.) of Cahaba coal field, central Ala., the upper coal bed lying 100 to 200 ft. below Chestnut ss. memb., and the four coals (one of which is Gould coal) occurring within a vertical section of 50 ft.

Gould shale member. (In Monterey shale.)

Miocene (middle): Southern California (Kern County).

G. M. Cunningham and W. F. Barbat, 1932 (A. A. P. G. Bull., vol. 16, No. 4, p. 418). The sh. btw. *Valvulineria californica* zone of Monterey and "Button bed" of Temblor may appropriately be called *Gould sh. memb. of Temblor.* Thickness 250 ft. in Chico-Martinez Creek area, according to Goudkoff and Hughes. Is called "Monterey sh." in unpublished ms. of A. R. May and J. D. Gilboe.

W. F. Barbat, 1932 (A. A. P. G. Bull., vol. 16, No. 6, p. 611). In reproducing authors' table I, a slight omission was made, which if uncorrected may make table misleading. A horizontal line should be drawn below the marginal word *Monterey* and opposite the dotted line in 1st column separating *Valvulineria californica* zone and "Monterey sh." With table thus corrected there is no implication that the 250 ft. of beds above Button bed in Chico-Martinez Creek area are=any portion of Monterey. Despite fact these 250 ft. of beds are not included in type sections of either Monterey or Temblor fm., authors incline toward grouping them in some way with Temblor fm. because of their faunal affinities with upper Temblor. In table I authors stated this div. is "appropriately called Gould sh. memb. of Temblor." As used in this casual manner the name has no standing in geologic time classification. In view of importance of the unit it is now proposed to define the name and to designate a type section. The *Gould sh.* is described as the 220 to 230 ft. of beds overlying Button bed memb. of Temblor fm. and underlying *Valvulineria californica* zone of Monterey fm. near center of W. half of sec. 14, T. 29 S., R. 20 E., M. D. B. L. and M., and continuing to SE. side of Chico-Martinez Creek, Kern Co. The name is from Gould Hill, on U. S. G. S. McKittrick quad., near type loc.

G. C. Gester and J. Galloway, 1933 (A. A. P. G. Bull., vol. 17, No. 10, p. 1169), included Gould sh. in top of what they called *Temblor sh.*, which they placed lower than Monterey sh.

W. P. Woodring, M. N. Bramlette, and R. M. Kleinpell, 1936 (A. A. P. G. Bull., vol. 20, No. 2, pp. 127–146), included these beds in Monterey sh., under name *Gould sh. memb.*, because they properly belong to Monterey type of sedimentation, and not to Temblor ss. type.

Gourd Head Run clay. (In Conemaugh formation.)

Pennsylvanian: Southwestern Pennsylvania (Allegheny County).

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q, pp. 159–161, 308). *Gourd Head Run clay* (local), underlies Mahoning ss. and is separated from underlying Upper Freeport coal by *Gourd Head Run ls.* (local). Upper part is plastic, lower part is nonplastic.

Gourdhead Run limestone. (In Conemaugh formation.)

Pennsylvanian: Southwestern Pennsylvania (Allegheny County).

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q, pp. 159–161, 308). [See under *Gourd Head Run clay.*]

G. B. Richardson, 1932 (U. S. G. S. Bull. 829, p. 17). The *Gourdhead Run ls.* of I. C. White crops out locally in valley of Gourdhead Run in Hampton Twp. It is of very limited occurrence and has not been found outside of this locality. There Upper Freeport coal apparently is absent, but presence of Brush Creek and Upper Freeport lss. serves to determine strat. position of this lens. It lies approx. 30 ft. above Upper Freeport ls. and 50 to 60 ft. below fossiliferous Brush Creek horizon, and therefore occurs in interval [usually] occupied by Mahoning ss. memb. This ls. is a compact, fine-textured buff and dark-colored bed, in which fossils have not been found and which has a max. observed thickness of 3 ft.

Gouverneur moraine.

Pleistocene (Wisconsin stage): Northeastern New York. Named for Gouverneur, St. Lawrence Co. (See Jour. Geol., vol. 32, pp. 645, 661, 1924.)

Gouverneur granite.

Pre-Cambrian: Northern New York (Gouverneur quadrangle, St. Lawrence County).

H. P. Cushing and D. H. Newland, 1925 (N. Y. State Mus. Bull. 259, pp. 40–41). Name *Gouverneur granite* is conveniently applied, for local use, to the granite mass just N. of Gouverneur, an oval-shaped mass with NE. trend. It consists of quite fine and even-grained orthogneiss, composed chiefly of feldspars and quartz with a very small mica content. Shows frequent coarser bands and pegmatites. Inclusions are frequent but very unequally distributed and are almost without exception of amphibolite.

A. F. Buddington, 1929 (N. Y. State Mus. Bull. 281, pp. 55–61). *Gouverneur granite mass* lies just NW. of town of Gouverneur. Forms Gouverneur phacolith, which is 5½ mi. long and 1½ mi. wide. Intrudes Grenville series. [According to p. 52 the Gouverneur phacolith belongs to his Alexandria type of granite.]

Gouverneur limestone.

Pre-Cambrian (Grenville series): Northwestern New York (St. Lawrence and Jefferson Counties).

A. F. Buddington, 1934 (N. Y. State Mus. Bull. 296, pp. 136–138 and maps). *Gouverneur ls.*—Crystalline ls., underlying garnet-bearing gneiss of Grenville series in Antwerp, Hammond, and Gouverneur quads., and overlying biotitic feldspar gneiss that composes the oldest fm. of Grenville series of this area. Thickness 5,000 ft. or less.

Government Wells sand.

A subsurface sand in upper Eocene of Driscoll pool, Duval Co., Tex.

Gowanda shale.

Upper Devonian: Western New York (Lake Erie region).

G. H. Chadwick, 1919 (Geol. Soc. Am. Bull., vol. 30, p. 157). *Gowanda beds.*—Name replaces "Portland beds," preoccupied and withdrawn. Overlie Dunkirk black sh. and uncon. underlie Laona ss. Assigned to Chemung. [The †Portland sh. had been included in Portage group by Clarke, Luther, and Hartnagel.]

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69). *Gowanda sh.* in Chautauqua Co.; *Gowanda beds* in Cattaraugus, Allegany, and Steuben Counties. Of Chemung age. In Cattaraugus Co. is overlain by unnamed ss. and underlain by Dunkirk sh.; in Allegany Co. is overlain by "Rushford ss." and underlain by Canaseraga ss. (=Dunkirk sh.); in Steuben Co. is overlain by Wellsburg ss. and underlain by Prattsburg ss.

G. H. Chadwick, 1924 (N. Y. State Mus. Bull. 251, pp. 149–157). Name *Gowanda beds* replaces *Portland* (preoccupied). Thickness 500 ft. on Cattaraugus Creek around Gowanda [Cattaraugus Co.], 250 ft. on Lake Erie. Included in Chemung group. The limited fauna of Portage type which Gowanda beds carry on Lake Erie and at Forestville gradually acquires the brachiopod facies of lower Chemung (Cayuta) sh. which it has on Caneadea Creek. Underlies Laona ss. and overlies Dunkirk sh.

See 1931 and later entries under *Chemung group.*

Gowanda moraine.

Pleistocene (Wisconsin stage): Western New York. Shown on moraine map (fig. 8) in U. S. G. S. Niagara folio (No. 190), p. 17. Named for Gowanda, N. Y.

Gower dolomite.

Silurian (Niagaran): Central eastern Iowa.

W. H. Norton, 1899 (Iowa Geol. Surv. vol. 9, pp. 422, 423). *Gower stage.*—Lss. constituting upper stage of Niagara series, and all of Niagara present in Scott

Co., the lower (Delaware) stage of Niagara not being recognized. Includes lithological varieties of rocks which have been called *Anamosa substage* and *LeClaire ls.*, but which are contemp. [?]. Overlain by Dev. Wapsipinicon ls.

The Gower dol. (including LeClaire and Anamosa) has been referred to Niagara group in the following repts: S. Calvin, 1901; W. H. Norton, 1901; S. Calvin, 1902; J. A. Udden, 1905; T. E. Savage, 1906; S. Calvin (1906 and 1907); J. E. Carman, 1909; T. E. Savage, 1914; W. H. Norton, 1921; J. V. Howell, 1923; W. H. Schoewe, 1923; G. F. Kay, 1927; and A. Folger, 1928. In 1910 C. Schuchert not only referred Gower (Le Claire and Anamosa) to Niagara group, but overlying Bertram as well. Gower (including LeClaire and Anamosa) was referred to Cayuga group (post-Salina) by E. O. Ulrich in 1911 (Geol. Soc. Am. Bull., vol. 22), and by R. S. Bassler in 1915 (U. S. Nat. Mus. Bull. 92, vol. 2, pl. 1). Later repts of Iowa Geol. Surv. describe the Gower as all dol. and 120 ft. thick.

A. H. Sutton, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 276), stated: *Gower fm.* belongs to Niagaran series and includes 2 distinct lithologic phases: (1) the Leclaire and (2) the Anamosa and Bertram fms., the former being the "reef" type of sediments. But in same rept. (pp. 249–251) M. A. Stainbrook included Bertram in Otis memb. of Wapsipinicon ls. (Dev.).

Named for Gower Twp, Cedar Co.

Goweran series.

A term introduced by C. [R.] Keyes to include Bertram, Anamosa, and Leclaire dolomites of Iowa, which he refers to Cayuga group.

Gowganda formation.

Pre-Cambrian (Huronian): Western Ontario.

W. H. Collins, 1916 (Canada Geol. Surv. Mus. Bull. 22, p. 4). Included in Cobalt series.

Graford formation (redefined). (In Canyon group.)

Pennsylvanian: Central and central northern Texas.

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, pp. 133–145). *Graford fm.*—Composed largely of sh. members with some thin lss. and a little sand. Top memb. is *Graford ls.*, one of most persistent, and can be recognized by greater height of its scarp than the other ls. members of the fm. The lss. are very fossiliferous, but shells are poorly preserved. Underlies Ranger fm. and overlies Palo Pinto fm.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31, 34). *Graford fm.*—In Brazos River Valley conformably overlies Palo Pinto ls. and underlies Seaman Ranch sh. memb. of Brad fm. In Colorado River Valley it underlies Cedarton sh. memb. of Brad fm. Includes Adams Branch ls. memb. at top (replaces Graford ls.) and Rochelle cgl. at base. Thickness 170 to 450 ft. [Adams Branch ls. replaces Graford ls. memb.] Named for town of Graford, in Palo Pinto Co. [Brazos River region], where it is typically developed, and where the upper members form prominent escarpment just W. and N. of town.

G. Scott and J. M. Armstrong, 1932 (Univ. Tex. Bull. 3224, p. 33). Devils Den ls. is arbitrarily taken as top memb. of Graford fm. in Wise Co. It is an older ls. than Adams Branch ls., which lenses out completely before Wise Co. is reached.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 104, 111), extended top of Graford fm. up to top of Clear Creek ls. of Drake, because "the top of the Graford fm. as defined at type loc. apparently falls within the Merriman (Clear Creek) ls. equiv. and not at the Adams Branch ls. as given in the original description." Also (pp. 105, 109) he transferred Capps ls. from Graford fm. to top of Strawn group, and included Devils Den ls. in Graford fm. This definition of Graford fm. was adopted by U. S. Geol. Survey in 1935.

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501, pp. 197+). Graford fm. includes, in Colorado River region, all beds below top of Adams Branch ls. memb. and above base of Capps ls. lentil or, in some areas, base of Rochelle cgl. memb.

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, pp. 47–48). *Graford fm.* was named by Plummer and Moore, and was made to include all strata from top of Palo Pinto ls. up to top of the ls. that caps the escarpment W. of Graford. This escarpment-forming ls., at time the fm. was named, was thought to be=typical Adams Branch ls. to S. Later work by Cheney, Armstrong, and others has shown that true Adams Branch ls. in Palo Pinto Co. lies much lower in section than uppermost ls. of Graford fm., and that this uppermost ls. is= Merriman ls. of Reeves. The Graford fm. of Palo Pinto Co. consists of Merriman ls. at top and 400± ft. of sh. containing lentils of sand, a lentil of coal, and a few thin layers of ls., and is divided into following members (downward): (1) Merriman ls., 20 to 75 ft., formerly mapped by Plummer and Moore as Adams Branch ls.; (2) Wolf Mtn sh.; (3) Wiles ls., 3 to 8 ft.; (4) Posideon sh., 50± ft. Underlies Brad fm. and overlies Palo Pinto ls. The Brad fm. is divided into Ranger ls. (above) and Seaman Ranch memb. (below).

Wallace Lee and C. O. Nickell in their 1934 field work found it impracticable to draw line btw. Brad and Graford fms. at top of †Clear Creek ls. (preoccupied) in Brazos River region, because this ls. is one of several lss. in this part of the column. They therefore adopted the new name *Winchell memb.* for the group of lss. and separating shales occurring in upper part of Graford fm. as expanded by Sellards and in lower part of Placid sh. memb. of Plummer and Moore. The Winchell memb. includes, in its lower part, the Clear Creek bed of Drake and the lower or ls.-bearing part of Placid sh. memb. of Plummer and Moore in Colorado River region, and Merriman ls. memb. (4 ft. thick) of Reeves in Brazos River region. Their rept has been transmitted and will soon be published by Tex. Geol. Survey.

†Graford limestone member (of Graford formation).

Pennsylvanian: Central and central northern Texas.

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, pp. 133–145). Top memb. of Graford fm. [See 1919 entry under *Graford fm.*]

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31; Univ. Tex. Bull. 2132, p. 101), correlated top memb. of Graford fm. with Adams Branch ls. of Drake and discarded *Graford ls. memb.*

†Grafton quartzite.

Pre-Cambrian: Eastern Massachusetts and northern Rhode Island.

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, p. 18). [*Grafton qtzite and cgl.* of Worcester Co., Mass., is shown in table as younger than Sutton gneiss. All of definition.]

B. K. Emerson and J. H. Perry, 1907 (U. S. G. S. Bull. 311, pp. 7, 8, 10, 12–13, and map). *Grafton qtzite.*—Generally a fine-grained massive saccharoidal qtzite of great purity. Varies from white to pale flesh color. In places shows thin lamination and cross-bedding. In other places it is greatly jointed or thinly foliated by crushing or reduced to rude columnar masses by complex strains. Consists of two flanking bands of qtzite and a central band of quartz phyllite and fine-grained micaceous quartz schist, named *Albion schist memb.* Underlies Marlboro fm. and overlies Northbridge gneiss.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, p. 25). "Grafton" qtzite is same as Westboro qtzite, which has priority; "Grafton" is therefore abandoned.

Named for occurrence at Grafton, Worcester Co., Mass.

Grafton sandstone. (In Conemaugh formation.)

Pennsylvanian: West Virginia and western Maryland.

I. C. White, 1903 (W. Va. Geol. Surv. vol. 2, pp. 244, 255, 298). *Grafton ss.*—Massive pebbly ss., lying 20 to 30 ft. above Ames ls. and a short distance below Elk Lick coal. Appears to crop out at horizon of Birmingham sh. Has been much quarried around Grafton Hills, Taylor Co.

R. V. Hennen, 1911 (W. Va. Geol. Surv. Rept. Wirt, Roane, and Calhoun Counties, p. 240). *Grafton ss.*, 10 to 20 ft. thick, underlies Birmingham sh. and overlies or lies 5 to 10 ft. above Ames Crinoidal ls.

R. V. Hennen, 1912 (W. Va. Geol. Surv. Rept. Doddridge and Harrison Counties). *Grafton ss.*, 10 to 56 ft. thick, is lenticular and often replaces Birmingham sh. almost entirely. Lies 5 to 20 ft. above Ames ls.

D. B. Reger, 1923 (W. Va. Geol. Surv. Rept. Tucker Co.). *Grafton ss.*—Massive, reddish brown, sometimes pebbly ss., 4 to 60 ft. thick. Overlies Ames sh. and separated from overlying *Upper Grafton ss.* by 8 ft. of variegated sh. The *Upper Grafton ss.*, 10 to 38 ft. thick, was not observed in outcrop, but it and the underlying variegated sh. are evidently a part of Birmingham sh.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, pl. 6). *Upper Grafton ss.* underlies Barton ls. and is separated from underlying Federal Hill coal by Birmingham red bed and other strata. *Lower Grafton ss.* overlies the sh. above Ames ls. and lies a short distance below Federal Hill coal.

Grafton formation.

Pennsylvanian: Southwestern Pennsylvania (Punxsutawney quadrangle).

G. H. Ashley, 1926 (Pa. Topog. and Geol. Atlas No. 65, Punxsutawney quad., pl. 4). *Grafton fm.*—Extends from base of Ames ls. to top of Barton coal, and includes Grafton ss.

Is a part of Conemaugh fm.

Grafton member. (In Conemaugh formation.)

A term employed by Pa. Geol. Surv. (M. E. Johnson, Topog. and Geol. Atlas Pa. No. 27, Pittsburgh quad., p. 31, 1929) to include Birmingham sh., Duquesne coal, Duquesne clay, Duquesne ls., Grafton ss., Ames ls., and Harlem coal. These boundaries differ somewhat from Grafton fm. of Ashley.

Graham jasper. (In Niobrara formation.)

Upper Cretaceous: Northwestern Kansas.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, p. 51). *Graham jasper*, the horizon of jasper near upper limit of Smoky Hill chalk in Kans. Named for Graham Co.

Graham formation. (In Cisco group.)

Pennsylvanian: Central and central northern Texas.

R. C. Moore, 1921 (A. A. P. G. Bull., vol. 5, p. 324). The lower Cisco beds are included in what has been termed *Graham fm.* by F. B. Plummer and R. C. Moore.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 18–42). *Graham fm.*—Basal fm. of Cisco group. Thickness 100 ft. to S.; 500–600 ft. to N. In Brazos River region discon. underlies Avis ss. memb. of Thrifty fm. and discon. overlies Home Creek ls. memb. of Caddo Creek fm. Distinguished from underlying beds by its very clastic character and thinner lss., and from overlying beds by its prolific and characteristic fauna. Divided into following members (descending): Wayland sh., Gunsight ls., South Bend sh., Bunger ls., Gonzales Creek sh., Jacksboro ls., and Finis sh. The older or lower members are present only to N., pinching out southward and being overlapped by younger members. Named for county seat of Young Co. [Brazos River region].

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 104), redefined Graham fm. by transferring to the underlying Caddo Creek fm. the Jacksboro ls. and Finis sh. of Brazos River region.

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501, pp. 197+). Graham fm. of Colorado River area includes all beds btw. top of Speck Mtn ls. down to top of Home Creek ls. In Brazos River region it includes all beds below Avis ss. memb. and above Home Creek ls. memb. The Avis ss. of Brazos River region is same as Parks Mtn ss. of Colorado River region.

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, pp. 61–62). *Graham fm.* was named by Plummer and Moore and made to include all strata from top of Home Creek ls. up to base of Avis ss. Total thickness 400± ft., but only lower 125 ft. is exposed in Palo Pinto Co., Brazos River region, where it is divided into following members (descending): Bunger ls., 6 ft.; Gonzales Creek sh., 116 ft.; Eastland ss. (new name), 10 to 15 ft.; and Finis sh., 50 ft. Type loc. is bluff on Salt Creek W. of Graham, Young Co. [Brazos River region].

Wallace Lee and C. O. Nickell (rept completed and soon to be published by Tex. Geol. Surv.). Graham fm. of Brazos River area includes all beds below Avis ss. memb. and above Home Creek ls. memb. The Graham fm. of Colorado River region includes all beds below Bellerophon ls. of Drake and above Home Creek ls. The Speck Mtn ls. lies in Thrifty fm., considerably above its base. [This definition of Graham fm. has been adopted by U. S. Geol. Survey.]

Graham limestone. (In Bluefield formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Tazewell County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 299, 387). *Graham ls.*—Usually gray and shaly, 0 to 3 ft. thick; marine fossils. Lies 0 to 10 ft. below Graham ss. and rests on Upper Graham sh.; all members of Bluefield group [fm.]. Type loc. same as Graham ss.

Graham sandstone. (In Bluefield formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Tazewell and Giles Counties).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Marion, and Summers Counties, pp. 299, 385). *Graham ss.*—Greenish gray, usually shaly but sometimes massive; 15 to 40 ft. thick. Underlies Clayton sh. and lies 0 to 10 ft. above Graham ls.; all members of Bluefield group [fm.]. Type loc. in a cut of Norfolk & Western Ry. about ½ mi. NW. of new station at Graham (now Bluefield), Tazewell Co., Va. Occurs in Mercer, Monroe, and Summers Counties, W. Va. Probably correlates with Big Spruce Knob ss. of Webster Co., W. Va.

Graham shale. (In Bluefield formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Tazewell and Giles Counties).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 299, 387). *Upper Graham sh.*—Gray, ferruginous, and calc.; marine fossils in upper part, plants at base; 20 to 30 ft. thick; underlies Graham ls. and overlies Graham coal. *Lower Graham sh.*—Red, variegated, and sandy, with thin sss.; 50 to 75 ft. thick; underlies Graham coal and overlies Bertha ss. All members of Bluefield group [fm.]. Type loc. same as Graham ss. Also occurs in Mercer, Monroe, and Summers Counties, W. Va.

Graham oil sand.

A subsurface sand in lower part of Penn. section of Graham field, in NW. part of Carter Co., southern Okla., 110± ft. below Ricketts oil sand and 80 to 135 ft. above Bennett oil sand. Thickness 10 to 200± ft.

Grainger shale.

Mississippian: Northeastern Tennessee, western North Carolina, and southwestern Virginia.

A. Keith, 1895 (Phil. Soc. Wash. Bull. 12, pp. 74, 78, pl. 1) and 1896 (U. S. G. S. Morristown folio, No. 27, p. 3). *Grainger sh.*—Sandy shales and shaly and flaggy sss., the latter more numerous in upper layers. Two mi. NW. of Mooresburg a thin bed of quartz cgl. lies at top of series. All beds bluish gray when fresh, and weather green and greenish gray. In bottom flags are many impressions of supposed seaweed *Spirophyton cauda-galli*. Thickness varies from 1,200 ft. in Clinch Basin to 400 ft. in Powell Basin. Of Dev. age. Overlies Chattanooga sh. and underlies Newman ls. in Tenn. Valley.

Above is first definition of fm. in its type area. The name, however, first appeared in print in 1893 (M. R. Campbell, U. S. G. S. Bull. 111, p. 38), in a description of the rocks of Big Stone Gap coal field of SW. Va., Campbell accepting Keith's name and correlating the rocks of SW. Va. with those in Morristown quad. In SW. Va. the fm. was described as consisting of 410 ft. of shales, varying from red calc. sss. at top to ash-colored micaceous shales below, finally merging into underlying Chattanooga black sh. and overlain by Newman ls. "The age of this mass of sandy shales has never been determined; they have somewhat the appearance of a transition bed between the Devonian below and the Mississippian above, but in this paper they are regarded, provisionally, as of Devonian age." The name was also used by Campbell in U. S. G. S. Estillville folio, No. 12, published in 1894, and by Keith in Knoxville folio, No. 16, published in 1895, for the shales and sss. underlying Newman ls. and overlying Chattanooga sh.

A. Keith, 1901 (U. S. G. S. Maynardville folio, No. 75, p. 4). Fossils found in Grainger fm. to NE. indicate upper part is Carbf., while a Dev. age for its lower portion is indicated by its interbedding with Chattanooga sh.

According to E. O. Ulrich and C. Butts, also J. H. Swartz, 1924 (Am. Jour. Sci., 5th, vol. 7, p. 28) and 1929 (Am. Jour. Sci., 5th, vol. 17, p. 441) the typical Grainger sh. of Tenn. is all of Miss. age.

Named for Grainger Co., Tenn.

Grampian limestone.

Ordovician and Cambrian (?): Southwestern Utah (Frisco district).

B. S. Butler, 1913 (U. S. G. S. P. P. 80). *Grampian ls.*—Heavy-bedded blue and gray ls., in part dolomitic, with limy sh. at top. Thickness 4,000+ ft. Underlies (probably conformably) Morehouse qtzite. Oldest fm. exposed in Frisco region. Lower Ord. (Chazy and Beekmantown) fossils in upper part. Lower part may be Upper Camb. Type loc. Grampian Hills, Frisco dist.

Grampus gneiss.

Pre-Cambrian: Eastern New York (Long Lake quadrangle, Adirondack Mountains).

H. P. Cushing, 1907 (N. Y. State Mus. 60th Ann. Rept., pt. 2 (also called N. Y. State Mus. Bull. 115), pp. 463, 467–469). *Grampus gneiss.*—Igneous gneisses associated with frequent bands or patches of Grenville (sedimentary) rocks and frequent rocks of doubtful nature but with Grenville look. Differs materially from Long Lake gneiss in considerable diversity shown. Age relations to Long Lake gneiss and Piercefield gneiss undet.

Named for exposures around Grampus Lake, Hamilton Co.

Grampus.

A hard subsurface sand, of Penn. age and 150 ft. thick, found near sea level in Cabin Creek field, about 20 mi. SE. of Charleston, W. Va. Lies 50 to 75 ft. above Salt sand, the basal memb. of the Penn. (See A. A. P. G. Bull., vol. 11, No. 7, p. 709, 1927.)

Granby tuff. (In Newark group.)

Upper Triassic: Central southern Massachusetts and Connecticut (?).

B. K. Emerson, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 451–456). *Granby tufa*, or the diabase tufa of the Triassic of Mass.

B. K. Emerson, 1898 (U. S. G. S. Holyoke folio, No. 50, and U. S. G. S. Mon. 29). [See 1898 entry under *Longmeadow ss.*]

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 92, 95–96). *Granby tuff.*—Thick-bedded black tuff and tuffaceous ss. ranging from fine-grained volcanic ss. to coarse diabase breccias and aggls.; from rocks made up wholly of volcanic debris to such as contain abundant fragments of granitic gneissoid rocks. Exposed 1¼ mi. N. of cemetery in Granby. Immediately after outflow of Hampden diabase, and while that sheet was still liquid, an explosive eruption took place locally, and blocks and pulverized dust of diabase were spread by the waters over a broad area, forming the Granby tuff. Then followed the uppermost layer of rusty sands, in which most of the tracks have been preserved. The whole was capped down the middle of the basin by the thin Chicopee sh., in which only leaves and small tracks are found. Is a fm. near top of Newark group.

Granby conglomerate.

Pennsylvanian (?): Southwestern Missouri.

E. R. Buckley and H. A. Buehler, 1906 (Mo. Bur. Geol. and Mines vol. 4, 2d ser., pl. 14, pp. 33, 87, 88, 100, 102). *Granby cgl.*—Basal cgl. of Penn. in Granby area. Resembles a mechanical breccia.

E. R. Buckley, 1911 (Types of ore deposits, p. 118). A ss. in Joplin dist., which was deposited upon residual mantle of broken flint and which probably belongs to the Chester, formed in many places a cgl., which, as it is found today, resembles a breccia. This cgl. has been called the *Granby*.

Probably named for Granby, or Granby Junction, Newton Co., or for Granby Branch Junction, Jasper Co.

Grandad limestone.

Silurian: Southeastern Indiana (Clark County).

W. W. Borden, 1874 (Ind. Geol. Surv. 5th Ann. Rept., pp. 138, 143, 146). *Grandad ls.*—Impure ls., 4 ft. thick, near top of Niagara; used for building purposes. Overlain by 20 ft. of mag. ls. (top of Niagara) and underlain by 14 ft. of gray crystalline ls. of the Niagara.

Derivation of name not stated.

Grand Bank series.

Pre-Cambrian: Newfoundland.

N. C. Dale, 1927 (Geol. Soc. Am. Bull., vol. 38, p. 419).

Grand Canyon series.

Provincial series term for rocks of pre-Camb. age in northern Ariz. Introduced by J. W. Powell in 1876 (Geology of eastern portion of Uinta Mtns, pp. 43, 61–62, 70). See also C. D. Walcott, 1894 (U. S. G. S. 14th Ann. Rept., pt. 2, pp. 518–519). Includes Chuar group (above) and Unkar group (below). Uncon. underlies Tonto group and uncon. overlies Vishnu schist. For complete definition see U. S. G. S. Bull. 769, pp. 113–114.

†Grand Canyon schist.

Pre-Cambrian: Northern Arizona.

J. W. Powell, 1876 (Geology of eastern portion of Uinta Mtns). *Grand Cañon schists.*—Hornblendic and micaceous schists and slates, with beds and dikes of granite. Thickness unknown. Found at bottom of Grand Cañon. Uncon. underlies Grand Cañon group [Unkar group].

Replaced by ***Vishnu schist.***

†Grand Canyon group.

Pre-Cambrian: Northern Arizona.

C. D. Walcott, 1883 (Am. Jour. Sci., 3d, vol. 26, pp. 440–441), divided Grand Canyon series into two uncon. groups, the upper of which he named *Chuar group* and the lower *Grand Canyon group*. Subsequently he replaced latter term with *Unkar group*, the name by which it is now known.

Grande limestone.

Mississippian: Southwestern New Mexico (Sierra County).

C. R. Keyes, 1908 (Am. Inst. Min. Engrs. Bi-Mon. Bull. 19, pp. 7–21). *Grande ls.*—Blue ls., 25 ft. thick, containing the Lake Valley silver ores, which were first opened at Sierra Grande workings. Consists of (descending): (1) Hard, compact, heavily bedded pure soluble ls., 10 ft.; (2) black subcrystalline ls., 2 ft.; (3) massive hard grayish blue coralline rocks, 13 to 15 ft. Underlies Lake Valley ls. [restricted to beds containing lower Burlington fossils] at Lake Valley, and uncon. overlies Dev. Berenda ls.

Grande Grève limestones.

Lower Devonian: Quebec (Gaspe Peninsula).

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 208, footnote). The term *Grande Grève fm.*, suggested by writer some time ago, has recently been accepted by Prof. J. M. Clarke and Mr. Schuchert, whilst they suggest the terms *St. Alban* and *Cape Bon Ami* to include the beds numbered 1 and 2, and 3, 4, 5, 6, respectively, in Billings' Gaspé section. (Inserted on going to press). Assigned to Dev.

J. M. Clarke, 1900 (N. Y. State Mus. Mem. 3, vol. 3, pp. 80–81). For the lss. on Gaspe Peninsula having most pronounced Oriskany traits, and forming beds 7 and 8 of Sir Wm. Logan's 1844 classification, Dr. Ami has suggested the name *Grand Grève lss.*, from the little village on the peninsula where they are best exposed and most readily accessible. To Mr. Charles Schuchert and writer, who have recently spent some time in this region, this name seems happily chosen.

Grand Falls chert member (of Boone limestone).

Mississippian (Keokuk): Southwestern Missouri, southeastern Kansas, northwestern Arkansas, and northeastern Oklahoma.

A. Winslow, 1894 (Mo. Geol. Surv. vol. 7, pp. 417–419). *Grand Falls chert.*—Very dense, hard chert, 30 ft. thick in Shoal Creek section of SW. Mo. Occurs in massive layers 6 or more ft. thick; has a gnarled and knotted structure, producing uneven surface.

C. E. Siebenthal, 1907 (U. S. G. S. Joplin folio, No. 148). *Grand Falls chert memb. of Boone fm.*—Almost wholly heavy beds of solid chert, but is not persistent and in many areas its stratigraphic horizon is occupied by ls. Its distinctive characters are heavy bedding, "live" splintery fracture, fine brecciation and cementation, and spotting. Thickness 15 to 120 ft. Lies about 100 ft. below Short Creek oolite memb. of the Boone, and from 25 to 100 ft. above base of Boone. Fossils [listed] include species distinctly suggestive of Keokuk and none particularly suggestive of Burlington. Named for development around Grand Falls, Newton Co., Mo.

Grandfield conglomerate.

Pliocene or Pleistocene: Southwestern Oklahoma.

M. J. Munn, 1914 (U. S. G. S. Bull. 547, pp. 17, 28–30). *Grandfield cgl.*—Coarse indurated quartz lime cgl., 3 to 5 ft. thick, uncon. overlying Perm. Will probably be correlated with some portion of Seymour fm. of Wichita Co., Tex.

Named for Grandfield, Tillman Co.

Grand Forks schist.

Age (?): Southern British Columbia and northeastern Washington.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, maps 9, 10, 118° to 119°). *Grand Forks schists.*—Amphibolite, hornblende schists, etc. [Mapped at and around Twp of Grand Forks, B. C.]

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 378). [This seems to be regarded as Paleozoic or older.]

†Grand Gulf sandstone.

Miocene: Southern Mississippi and southern Alabama.

B. L. C. Wailes, 1854 (Agric. and Geol. Miss., pp. 216–219). *Grand Gulf ss.*—Ss. of variable color and texture, many specimens having appearance of aggregated grains of coarse, angular black and bluish sand incorporated in matrix of white porcelain or enamel-like character, and approaching fine breccia in composition—a quality which has occasioned it to be spoken of as *petrified rock.* The range of this rock is btw. Big Black River and Bayou Pierre (on both sides of latter in some localities), and extending eastwardly to vicinity of Raymond and Mississippi Springs, near which it occurs of a softer and more uniform character or texture, and from whence that employed in basement and pavements of State House at Jackson was obtained. It is still quarried for building purposes there, and at different points in its course. The rock presents itself in mass in escarpment of bold promontory on the Mississippi, about 1 mi. below mouth of Big Black River, and immediately above town of Grand Gulf, against which the current of the river sets in full force, and by which it is deflected by its effective resistance in such a manner as to create the extensive and formerly dangerous whirlpool or eddy which gave name to the place. At many points within the scope I have mentioned this rock crops out in the beds of the watercourses and upon the sides of the ridges, exhibiting, as in that in Mississippi bluff, such an identity of character as to induce me to characterize it wherever met with as the *Grand Gulf rock.*

Owing to subsequent varied and conflicting uses of *Grand Gulf*, the ss. to which the name had been applied was in 1905 and 1906 (A. C. Veatch: La. Geol. Surv. Bull. 1, pt. 2, pp. 84, 85, 90, 1905; U. S. G. S. W. S. P. 114, pp. 180, 186, 1905; U. S. G. S. P. P. 46, p. 42, 1906) replaced by *Catahoula ss.* The †Grand Gulf ss. of Wailes is upper 14 ft. of the ss. which was called "Grand Gulf ss." in later repts.

Named for exposures in bluff at Grand Gulf, Claiborne Co., Miss.

†Grand Gulf group.

Miocene and Oligocene (?): Gulf Coastal Plain.

E. W. Hilgard, 1860 (Agric. and Geol. Miss., pp. 3, 108, 147–154). *Grand Gulf group* (also *Grand Gulf stage, or Southern Lignitic*).—White or gray ss., usually soft; black, blue, green, and gray clays and sands, with small lignite beds, tree palms, exogenous trees, Arundinaceae. Thickness 150 ft. Includes, at top, *Grand Gulf ss.* proper, 14 ft. thick. Overlain by Newer Tertiary (?) clays of the coast, and underlain by Vicksburg group.

As described and used in different areas included Catahoula ss., Hattiesburg clay, and Pascagoula clay, and the use of the name has been discontinued. Named for development of its principal memb. in bluff at Grand Gulf, Claiborne Co., Miss.

Grandhaven limestone. (In Wabaunsee group.)

Pennsylvanian: Southeastern Nebraska and northeastern Kansas.

R. C. Moore, May 1, 1935 (Kans. Geol. Surv. Bull. 20, table opp. p. 14). *Grandhaven ls.* underlies Friedrich sh. and overlies Dry sh.

G. E. Condra, late in 1935 (Nebr. Geol. Surv. Paper No. 8, p. 10), applied *Grandhaven (?)* to 1 ft. of gray, nodular, aren. ls., forming a memb. in lower part of his Friedrich-Dry sh., and lying 3 ft. above his Dover ls. fm. Derivation of name not stated.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 49, 237). *Grandhaven ls.* overlies Dry sh. and underlies Friedrich sh. Commonly consists of 2 ls. members separated by a few ft. of sh. The lower ls. is ½ to 5 ft. thick, gray to bluish, and unlike the older Dover ls. Contains many fusulinids in some exposures. The upper ls. is 1 to 8 ft. thick, very light-gray, weathering almost white, and is characterized by abundant algal deposits, and closely resembles upper memb. of Dover ls. The sh. btw. the 2 lss. is mostly bluish gray, clayey to calc., and 4 to 10 ft. thick. The Grandhaven ls. is recognized from Shawnee Co. S. to Okla., but is not seen N. of Kansas River. Type loc. is in sec. 31, T. 13 S., R. 14 E., near Grandhaven, Shawnee Co.

Grandian epoch (and series).

Term proposed by G. F. Kay (Geol. Soc. Am. Bull., vol. 42, pt. 1, pp. 449–452, 1931) to include Aftonian (interglacial) and Nebraskan (glacial) stages of Pleist. epoch (and series), which Kay would elevate to Pleist. period (and system). Named for Grand River Valley, SW. Iowa, where the Aftonian and Nebraskan stages have been studied in detail.

Grand Island formation.

Pleistocene (Kansan): Southern and eastern Nebraska.

A. L. Lugn and G. E. Condra, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, p. 190). *Grand Island fm.* (Kansan), 50 to 100+ ft. thick, lies uncon. on Fullerton bed, and is conformably overlain by Upland fm. (Yarmouth).

A. L. Lugn, 1934 (Nebr. State Mus. vol. 1, Bull. 41, pp. 326, 343–346). *Grand Island fm.*—Largely fluvial inwash-outwash deposits of sand and gravel, fine and coarse, of Kansan age. Thickness 30 to 150 ft. Upper 30 to 50 ft. are usually fine sand. In a section NW. of Holdrege it is 120 ft. thick, and upper 100 ft. is clean fine to medium sand and lower 20 ft. is mixed sand and gravel. Extends continuously under Platte River Valley and plains to N. and S., covering 15,000± sq. mi.

Named for exposures at and around Grand Island, Hall Co.

Grand Lake member.

Middle Devonian: Northeastern Michigan (Presque Isle and Alpena Counties).

A. W. Grabau, unpublished ms., 1915 (as reported by E. R. Pohl in U. S. Nat. Mus. Proc., vol. 76, art. 14, 1930. pp. 4; 25+). *Grand Lake ls. memb.*—Middle memb. of Presque Isle series in Presque Isle and Alpena Counties. Thickness 39 ft. Underlies Long Lake memb. and overlies Bell shales (basal memb. of Presque Isle series and of Traverse group). [Fossils listed. Lithology not described. Derivation of name not stated, but probably is Grand Lake, in E. part of Presque Isle Co.]

Grand Lake formation.

Pre-Pennsylvanian: New Brunswick.

W. S. Dyer, 1926 (Canada Geol. Surv. Mem. 151, p. 9).

Grand Ledge moraine.

Pleistocene (Wisconsin stage): Southern Michigan. Shown on moraine map (pl. 32) of U. S. G. S. Mon. 53. Named for Grand Ledge, Eaton Co.

†Grand Portage amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. R. Marvine, 1873 (Mich. Geol. Surv., vol. 1, pt. 2, pp. 35, 69). *Grand Portage cupriferous amygdaloid.*

R. D. Irving, 1883 (U. S. G. S. Mon. 5, p. 195). *Grand Portage cupriferous amygdaloid* occurs 670 ft. above cgl. No. 8 in Portage Lake section.

Same as Isle Royale amygdaloid, of Central Mine group. The mineralized part is Grand Portage lode.

Named for occurrence in old Grand Portage mine, Houghton Co.

†Grand Portage flow.

Includes Isle Royale (†Grand Portage) amygdaloid and underlying trap.

Grand Portage graywacke.

Pre-Cambrian (upper Huronian): Northeastern Minnesota (Grand Portage Indian Reservation).

N. H. Winchell, 1899 (Minn. Geol. Nat. Hist. Surv. Final Rept., vol. 4, p. 510). *Grand Portage graywacke.*—Slaty greenish-gray rock, 200+ ft. thick. Lies at top of Animikie and above Wauswaugoning qtzite.

U. S. Grant, 1899 (same rept. as cited above). In vicinity of Puckwunge River and along Grand Portage trail there is a fine-grained graywackelike rock which Prof. N. H. Winchell has named *Grand Portage graywacke* and referred to upper part of Animikie above the clastics of Pigeon Point.

N. H. Winchell, 1900 (Minn. Geol. Surv. Final Rept., vol. 5, pt. 1). *Grand Portage graywacke.*—Greenish, gritty, rough and unevenly bedded, having a coarse conchoidal manner of disintegrating under frost and sun. Occurs in Indian reservation at Grand Portage. Is supposed to overlie the black-sl. memb. of the Animikie.

†Grand Prairie formation.

Lower Cretaceous (Comanche series): Eastern Texas.

R. T. Hill and R. A. F. Penrose, 1889 (Am. Jour. Sci., 3d, vol. 38, p. 470). [*Grand Prairie or Upper Cross Timbers fm.* used as a local or Tex. name for Lower Cret. or Comanche series.]

Named for prairie extending from 4 mi. E. of Fort Worth to 7 mi. W. of Weatherford, Tex., which was known to old travelers as the "Grand Prairie." (R. T. Hill, Am. Jour. Sci., 3d, vol. 33, p. 300.)

Grand Pré formation.

Triassic: Nova Scotia.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 214).

Grand Rapids sandstone.

Devonian (?): Northwestern Ohio.

E. Orton, 1888 (Ohio Geol. Surv. vol. 6, p. 20) and 1890 (Ohio Geol. Surv., 3d Organization, 1st Ann. Rept., p. 24). *Grand Rapids ss.* of Wood Co. probably belongs to same level as Sylvania ss.

Grand Rapids group.

Mississippian: Michigan (Lower Peninsula).

A. C. Lane, as reported by M. E. Wadsworth, 1893 (Mich. Geol. Surv. Rept. 1891 and 1892, p. 66). *Grand Rapids group,* 300+ ft. thick, top div. of Sub-Carbf. in Mich. Underlies Parma ss. and overlies Marshall ss.

A. C. Lane, 1895 (Mich. Geol. Surv. vol. 5, pt. 2, p. 10). *Grand Rapids group* consists of 305± ft. of lss. underlain or replaced by shales and dol. with gyp. Lower part called *Michigan salt group* by Winchell. Overlies Marshall ss. and underlies Parma ss.

A. C. Lane, 1900 (Mich. Geol. Surv. vol. 7, pt. 2, btw. pp. 1 and 30) divided *Grand Rapids group* into Bayport ls. above and Michigan fm. below.

Named for exposures at Grand Rapids, where Bayport ls. is quarried.

Grand Rapids sandstone.

Lower Cretaceous: Alberta.

R. G. McConnell, 1893 (Canada Geol. Surv. Ann. Rept., vol. 5, pt. 1, pp. 29D, 55D–58D).

†Grand Rapids limestone.

A term casually applied by A. C. Lane (U. S. G. S. W. S. P. 30, 1899, p. 81) to Bayport ls. of Mich.

Grand Ridge.

Pleistocene (Wisconsin stage): Northeastern Illinois.

See under *Farm Ridge moraine.*

Grand Tower limestone.

Middle Devonian (Onondaga): Eastern Missouri and southwestern Illinois.

C. R. Keyes, 1894 (Mo. Geol. Surv. vol. 4, pp. 30, 42). *Grand Tower ls.*—Ls., 100 ft. thick in SE. Mo., underlying ls. containing Western Hamilton fossils (called Callaway ls. in table) and overlying Clear Creek ls. Equiv. of Onondaga and Oriskany of previous Mo. repts.

E. O. Ulrich, 1904 (Mo. Bur. Geol. and Mines vol. 2, 2d ser., pp. 109–111). *Grand Tower ls.* (*Keyes emend*).—Overlies Clear Creek ls. or chert of Worthen and is separated from overlying Glen Park ls. memb. of Sulphur Springs fm. by 0 to 15 ft. of sh. that may be Dev. or may be earliest Kinderhook. Contains local representatives of Hamilton and Onondaga lss.

T. E. Savage, 1910 (Ill. Acad. Sci. Trans., vol. 3, pp. 116+). *Grand Tower (Onondaga) fm.*—Consists of 125 ft. of ls. of Onondaga age underlain by 25 to 30 ft. of reddish brown friable ss. Overlies Clear Creek fm. and underlies Hamilton beds. The latter were included in Grand Tower fm. of Keyes in Mo., but in this rept the name is applied to only the western representative of Onondaga ls. of N. Y.

T. E. Savage, 1920 (Am. Jour. Sci., 4th, vol. 49, pp. 170–171). *Grand Tower ls.* underlies Lingle ls. and overlies Dutch Creek ss. in Mo. and Ill.

M. E. Wilson, 1922 (Mo. Bur. Geol. and Mines vol. 16, 2d ser.). *Grand Tower ls.*—Thick lss., in part shaly and locally containing lenses of ss.; ls. varies from fine-grained hard, brittle rock of gray or blue color to white, coarsely crystalline rock of marblelike texture; small amount of chert in lower beds in SE. Mo. In Ste. Genevieve Co., Mo., *rests on Little Saline ls.* In Callaway Co. uncon. overlies Ord. *Thickness* 250 ft. in Ste. Genevieve, Perry, and Cape Girardeau Counties; in Callaway, Montgomery, Warren, Lincoln, and Pike Counties rarely exceeds 15 ft. Overlain by Beauvais ss.

S. Weller and S. St. Clair, 1928 (Mo. Bur. Geol. and Mines vol. 22, 2d ser., pp. 141–148). *Grand Tower fm.*—While major part of Grand Tower ls. of Keyes bears fauna with Onondaga relationships, the uppermost beds carry fauna having relationships with eastern Hamilton. Savage's definition, which restricts name to western representative of Onondaga ls., is adopted in this rept. In Ste. Genevieve Co., Mo., it is 200 to 250 ft. thick, underlies Beauvais ss., and overlies Little Saline ls. Fossils listed.

Named for exposures in vicinity of Grand Tower, Jackson Co., Ill.

Grand View dolomite.

Upper Devonian: Southern central Idaho (Custer County).

C. P. Ross, 1932 (Idaho correlation chart compiled by M. G. Wilmarth). *Grand View dol.*—Moderately dark well-bedded dol. in part qtzitic. Thickness 1,250± ft. Underlies Milligen fm. and overlies Jefferson dol. Probably to be correlated with Threeforks ls. Named for Grand View Canyon, 14 mi. S. of Challis, Custer Co.

C. P. Ross, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 963–966, etc.). *Grand View dol.*—Dol. and dolomitic ls., both dark and rusty yellow, in part sandy; some thin beds of qtzite, sh., and ss. Thickness at type loc. (Grand View Canyon, near center of T. 12 N., R. 20 E.) 1,170 ft. [Detailed section.] Overlies Jefferson dol. and underlies Milligen fm. (Miss.). Fossils.

Graneros shale. (Of Colorado group.)

Upper Cretaceous: Eastern Colorado and Wyoming, southeastern Montana, South Dakota, Nebraska, Kansas, northeastern New Mexico.

G. K. Gilbert, 1896 (U. S. G. S. 17th Ann. Rept., pt. 2, p. 564). *Graneros sh.*—Name suggested by R. C. Hills. Laminated argill. or clayey gray shales with very little limy or sandy material. Thickness 200 to 210 ft. Bottom fm. of Benton group in Arkansas Valley region, Colo. Underlies Greenhorn ls. and overlies Dakota group. Named for Graneros Creek, Colo. [in Walsenburg quad., Pueblo Co.].

The Niobrara and Benton are not now treated as groups, the broader term *Colorado group*, which includes them both, being considered the more useful group name. Where the Niobrara deposits and Benton deposits are not subdivided, they are called *Niobrara ls.* and *Benton sh.*, respectively.

Granite Creek granodiorite.

Probably Cretaceous or Jurassic: Northern Idaho (Pend Oreille district).

J. L. Gillson, 1927 (Jour. Geol., vol. 35, No. 1). *Granite Creek granodiorite.*—Brilliant white rock, with lustrous black euhedral plates of biotite. More feldspathic than Bayview and Packsaddle granodiorites and contains abundance of two accessory minerals (allanite and titanite) and large amount of epidote.

Named for exposures around mouth of Granite Creek, Bonner Co.

Granite Mountain porphyry.

Early Tertiary (?): Central Arizona (Ray district).

F. L. Ransome, 1919 (U. S. G. S. P. P. 115, p. 126, pl. 45). Of the two varieties of quartz monzonite porphyry in Ray dist., the *Granite Mtn porphyry* occurs almost wholly in S. half of dist., while Teapot Mtn porphyry is characteristic of N. half. Both are intrusive. The principal body of Granite Mtn porphyry is the irregular intrusive mass that makes up much of Granite Mtn.

Granite Park member (of Siyeh limestone).

Pre-Cambrian (Belt series): Northwestern Montana (Glacier National Park).

C. L. and M. A. Fenton, 1931 (Jour. Geol., vol. 39, No. 7, pp. 670–679). *Granite Park memb.*—Top memb. of Siyeh fm. Consists of 185 ft. of thin-bedded gray lss. with interbeddings of argillite and ls. cgl.; some oolites in lower part. Upper beds commonly crowded with large colonies of *Collenia* sp. Overlies *Collenia? frequens* zone. Is well exposed along the Garden Wall, near Granite Park, Flathead Co.

Grant conglomerate.

Huronian (probably middle): Northern Minnesota (Lake County).

J. W. Gruner, 1929 (Lake Superior Min. Inst. Proc., vol. 27, pp. 184–187). *Grant cgl.*—Belt of steeply dipping cgl. that begins in sec. 10 and extends nearly 4 mi. to N., to Canadian bdy. Is very coarse in many outcrops. Can be most easily studied in vicinity of Grant Lake, Lake Co. Was formerly thought to be Ogishke cgl., but it rests on the ellipsoidal granite; greenstone pebbles numerous at the contact but become inconspicuous a few ft. away. The ellipsoidal granite was formerly thought to be Archean, but it is of later age than Knife Lake slates (which should be assigned to *Lower* Huronian), and it lies on the truncated folded slates. The Grant cgl. is probably Middle Huronian.

Grant shale. (In Chase group.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., p. 50). *Grant sh.*—Middle memb. of Winfield fm. Consists of bluish gray, argill. sh. with thin seams of fossiliferous ls. near top in most sections. Thickness 15 or 16 ft. in Nebr. and in northern central Kans., but decreases southward toward Winfield and plays out btw. there and Arkansas City, Kans. In many exposures it carries a thin pebbly subzone near top. Named for Grant Twp, Marion Co., Kans. Type loc. btw. 5 and 6 mi. N. of Florence, Kans. Overlies Stovall ls. memb. and underlies Cresswell ls. memb.

Granton trap.

Upper Triassic: Northern New Jersey (northwest of Jersey City).

N. H. Darton, 1890 (U. S. G. S. Bull. 67). *Granton trap.*—Small intrusive mass, 125± ft. thick, midway btw. Jersey City and Hackensack. [In U. S. G. S. New York City folio, No. 83, 1902, the mass of "trap" N. of Granton, N. J., was mapped as Palisade diabase, which is Upper Triassic.]

Grants Mills granite.

Carboniferous or Devonian: Northeastern Rhode Island.

C. H. Warren and S. Powers, 1914 (Geol. Soc. Am. Bull., vol. 25, pp. 437 (map) and 458). *Grants Mills granite.*—A narrow N.–S. belt of coarse biotite granite, of cream, pale-green, and pink color, passing through Grants Mills, Providence Co.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597), mapped this granite as Quincy granite.

Granville beds.

Mississippian: Central Ohio.

L. E. Hicks, 1878 (Am. Jour. Sci., 3d, vol. 16, pp. 217–219). *Granville beds.*—Comprise 111 ft. of strata in central part of Licking Co., which are only a local modification of Black Hand cgl. of E. part of county. Consist of (descending): (1) 3 to 18 ft. of coarse ss. and cgl.; (2) fucoid layer 7 to 12 ft. thick; (3) 15 to 21 ft. of compact, argill. drab ss.; (4) 60 ft. of shaly drab sss. and shales. Overlain by Licking shales and underlain by Raccoon shales. All included in Waverly group.

Named for Granville, Licking Co.

Granville enstatite serpentine.

Name loosely applied by B. K. Emerson (U. S. G. S. Mon. 29, p. 90, 1898) to a bed of serpentine in Old Hampshire Co., Mass.

Granville shale facies.

Mississippian: Central Ohio.

J. E. Hyde, 1915 (Jour. Geol., vol. 23, pp. 657, 679–682). *Granville sh. facies of Cuyahoga fm.* of central part of Licking Co. Mostly shales with finer-grained fossiliferous sss. in upper part; cgls. absent or limited to few thin beds. Thickness 588 ft. Includes (descending): Berne memb., 0 to 10 ft.; Black Hand memb. 50 to 100 ft.; Raccoon memb. 20 to 200 ft.

Corresponds to Cuyahoga fm. and lower part of Black Hand fm.

Named for Granville, Licking Co.

Grape Creek shale and limestone. (In Clyde formation.)

Permian: Central Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 412, 427). *Grape Creek bed.*—Mostly light-gray or dove-colored, rather friable fossiliferous ls., with more or less clay in southern and northern parts of field. Thickness 100 to 150 ft. Memb. of Albany div. Underlies Talpa bed and overlies bed No. 12 (12 to 75 ft. of clay).

J. W. Beede and V. V. Waite, 1918 (Univ. Tex. Bull. 1816). *Grape Creek fm.*, 130 ft. thick, underlies Talpa fm. and overlies Bead Mtn fm. [in which bed No. 12 seems to be included]. Grape Creek fm. is distinguished from Bead Mtn beds by paucity of worm and *Syringopora* remains, the introduction of Mollusca and Molluscoidea, and, most noticeably, by nature of bedding of rocks.

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, pp. 197, 198). *Grape Creek sh. and ls. bed* is basal memb. of Clyde fm. (of Wichita group). Underlies Talpa ls. and overlies Bead Mtn ls., top memb. of Belle Plains fm.

Named for Grape Creek, Coleman Co.

Grapevine sandstone. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and D. B. Reger, 1914 (W. Va. Geol. Surv. Rept. Logan and Mingo Counties, p. 211). *Grapevine ss.*—Massive, grayish white, medium-grained, micaceous, 25 to 40 ft. thick. Underlies Cedar coal and overlies Eagle sl. Named for creek in Mingo Co.

Type loc. is at mouth of Grapevine Creek, Mingo Co.

Grapevine conglomerates.

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 52, 79). *Grapevine cgls.*—Cgl., 500 ft. thick, uncon. beneath Greenwater volcanics, and composing lower fm. of Amargosan series (of early Tertic age) in Nev.

Named for good exposures around base of Grapevine Range, on E. side of Death Valley, Inyo Co., Calif.

Graphic lavas.

Pre-Cambrian: Central northern New Mexico (Magdalena Mountains).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257–259; Conspectus of geol. fms. of N. Mex., pp. 4, 7). *Graphic lavas.*—Bedded volcanic sequence superposed on pre-Camb. rocks of Magdalena Mtns. [Derivation of name not given. On p. 4 they are shown as pre-Camb.]

†Graphic-Kelly limestone.

Mississippian: Central or southwestern New Mexico (Kelly district).

C. L. Herrick, 1904 (Am. Geol., vol. 13, pp. 310–312). *Graphic-Kelly fm.*—Crystalline and light-colored lime, separated by close-grained, dense lime resembling lithographic stone known locally as *"Silver-pipe" lime.* The beds above the separating "Silver-pipe" lime are called *Kelly lime,* and the beds below it are called *Graphic lime.* Overlain by Sandia fm. and underlain by qtzite. [Occurs in Kelly mining dist., Socorro Co.]

Grassmere stage.

Name applied by W. H. Sherzer (Mich. Geol. Surv. vol. 7, pt. 1, 1900, pp. 141–142) to a Pleist. beach in Bedford and adjacent Twps, SE. Mich.

Grasston moraine.

Pleistocene (Wisconsin stage): Central eastern Minnesota (Kanabec, Pine, and Mille Lacs Counties).

F. Leverett, 1932 (U. S. G. S. P. P. 161, pp. 45–47). Named for development at Grasston, Pine Co.

Grassy shale.

A shortened form of *Grassy Creek sh.,* now employed by C. [R.] Keyes.

Grassy Creek shale.

Upper Devonian or Mississippian: Northeastern Missouri, southeastern Iowa, and western Illinois.

C. R. Keyes, 1898 (Iowa Acad. Sci. Proc., vol. 5, pp. 59–63). *Grassy Creek sh.*—Black and green shales, carrying characteristically Dev. fish. Underlie Louisiana ls. in vicinity of Louisiana, Mo. Ten mi. W. of Grassy Creek [Pike Co., Mo.] they are 30 ft. thick, but thin out to S. before limits of Pike Co. are reached; are 6± ft. in vicinity of Louisiana.

In 1902 Keyes correlated Grassy Creek sh. with Snyder Creek sh. In 1912 he restricted *Grassy sh.* (his shortened name) to lower 0–50 ft. of black sh. lying uncon. higher than Lime Creek sh., introduced *Saverton sh.* for upper blue sh. underlying Louisiana ls., and assigned both to Miss. He repeated this definition in 1913, 1915, 1917, and 1922. In latter rept. thickness was given as 3 to 60 ft.; on Grassy Creek 40 ft.

E. B. Branson, 1918 (Univ. Mo. Bull., vol. 19, No. 15). *Grassy Creek sh.*, 0–100 ft. thick, underlies Louisiana ls. and lies stratigraphically and uncon. higher than Craghead Creek sh. Assigned to Kinderhook group and correlated with Sylamore ss.

R. C. Moore, 1928 (Mo. Bur. Geol. and Mines vol. 21, 2d ser., pp. 282, etc.), stated that 20 ft. of *Grassy Creek sh.* is exposed in Pike, Jersey, and Calhoun Counties, Ill., and that it disappears to S.

A. H. Bell, 1932 (Ill. Geol. Surv. Press Bull. No. 24), gave 119 to 170 ft. of *Grassy Creek sh.* in wells of Warsaw area, Hancock Co., Ill., and included it in Kinderhook group, as did R. C. Moore, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 245).

J. M. Weller, 1935 (Ill. Acad. Sci. Trans., vol. 28, No. 2, pp. 191–192). *Grassy Creek sh.* is well exposed on Grassy Creek near center of sec. 19. The so-called Grassy

Creek sh. at Louisiana, Mo., is 4± ft. thick and is not=Grassy Creek sh. on Grassy Creek, but is Maquoketa sh. The confusion that has resulted from misinterpretation of Grassy Creek section seems to necessitate a redefinition of fms. The simplest solution is to drop name *Grassy Creek* for the basal black Kinderhook sh. If desirable, this name might be redefined and applied to the dark sh. memb. in upper part of Maquoketa. At present it does not seem advisable to distinguish the basal black sh. from the overlying greenish or bluish beds, and it is therefore proposed to expand *Saverton fm.* to include the basal Kinderhook black sh. exposed in vicinity of Louisiana which has been known as *Grassy Creek.*

Some geologists have included this sh. in Dev., others have included it in Miss.

Grassy Island granite gneiss.

Pre-Cambrian (Laurentian): Western Ontario (Rainy Lake region).

A. C. Lawson, 1913 (Canada Geol. Surv. Mem. 40, p. 97).

Grassy Knob chert.

Lower Devonian: Southwestern Illinois (Jackson and Union Counties).

T. E. Savage, 1925 (Am. Jour. Sci., 5th, vol. 10, pp. 139–144). *Grassy Knob chert* (of Oriskany age) uncon. overlies Bailey ls. (of New Scotland age) and conformably underlies Little Saline ls. (of upper Oriskany age), or, where that is absent, it uncon. underlies Clear Creek chert (of Onondaga age). Thickness 150 ft. or more. On W. side of Grassy Knob, Jackson Co., the type loc., it consists of more than 125 ft. of chert in irregular rough layers 6 to 30 inches thick, with many cavities containing a few poorly preserved fossils, overlain by 12 to 15 ft. of hard, siliceous and sandy ls. in layers 3 to 8 inches thick grading downward into bands of chert containing particles of glauconite. Not previously recognized in Ill., and does not seem to be recognized at Little Saline Creek or elsewhere in Mo. Probably restricted to area of 5 or 6 sq. mi. in southern Ill.

Grassy Mountain basalt.

Miocene and Pliocene (?): Southeastern Oregon.

K. Bryan, 1929 (U. S. G. S. W. S. P. 597, p. 55) and B. C. Renick, 1930 (Jour. Geol., vol. 38, p. 506). (Named by Renick.) *Grassy Mtn basalt.*—Amygdaloidal olivine basalt overlying and in part interbedded with upper part of Payette fm. Underlies Idaho fm. Thickness at least 400 ft.

Named for fact it caps Grassy Mtn, Malheur Co.

Graters shales. (In Brunswick formation.)

Upper Triassic: Southeastern Pennsylvania (Montgomery County) and western New Jersey.

D. B. McLaughlin, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 179). *Graters shales.*—Two or three 50-foot strata of dark sh., separated by similar thicknesses of red, traced from Grater's Ford [Montgomery Co.], Pa., around end of Chalfont fault and NE. to hills E. of Frenchtown, N. J., a distance of about 40 mi. Are a part of Brunswick fm. [of Newark group].

D. B. McLaughlin, 1933 (Mich. Acad. Sci., Arts, and Lett., vol. 18, pp. 427, 433). *Graters members.*—A group of 3 strata of black sh., separated by comparable thicknesses of red sh., occurring about 2,200 ft. above base of Brunswick fm. in Silverdale section. The term black sh. as here used covers all gray, green, or black shales in Brunswick and underlying Lockatong fm. Consists of (descending): (1) Greenish-gray argillite, massive, 50 ft.; (2) red sh., 30 ft.; (3) gray-green thick-bedded sh., 70 ft.; (4) red sh., 30 ft.; (5) greenish-gray sh., 60 ft. Named for excellent exposures in Landis Brook just W. of Grater's Ford, on Perkiomen Creek.

Gratz shale.

Upper Ordovician: Northern Kentucky and southern Ohio.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pp. 416–418, 569, pl. 27). The first of the deposits succeeding Catheys fm. in Cincinnati dome is *Gratz sh.*, which is best developed on NW. margin of dome along Kentucky River, but is recognized in a thinner bed at mouth of Licking River opposite Cincinnati, and somewhat doubtfully at several localities in Ohio and Ky. from 20 to 30 mi. up the Ohio. Seems absent on southern margin. Fauna much like Hermitage. The last of the Utica

(Fulton sh.) overlapping from the N., extends a short distance over N. flank of dome and rests with slight local uncon. on the Gratz. Of early Utica age.

R. S. Bassler, 1915 (U. S. Nat. Mus. Bull. 92, vol. 2, pl. 2) and 1919 (Md. Geol. Surv. Camb. and Ord. vol., p. 51), and A. F. Foerste, 1924 (Canada Dept. Mines, Geol. Surv. Mem. 138, No. 121 geol. ser., chart opp. p. 58), divided Cynthiana fm., of late Trenton age, into (descending) Rogers Gap, *Gratz,* Bromley, and Greendale.

Named for Gratz, Owen Co., Ky.

Gravel Head formation.

Ordovician: Newfoundland.

G. Van Ingen, 1914 (Table of geol. formations of Camb. and Ord. systems about Conception and Trinity Bays, Newfoundland, based upon 1912–13 field work). [Broadside, Princeton, N. J., private pub.]

Gravel Point stage.

Middle Devonian: Northwestern Michigan (Traverse Bay region).

See under *Charlevoix stage.*

Graves sand.

Upper Cretaceous: Southwestern Arkansas (Smackover oil and gas field, Ouachita and Union Counties).

H. G. Schneider, 1925 (A. A. P. G. Bull., vol. 9, No. 7, pp. 1116–1117). *Graves sand* of Smackover field is 35 ft. thick and lies 460 ft. below top of Nacatoch sand. Is also called 2,400-foot sand, the Meakin sand being called 2,200-foot sand and 2,300-foot sand. Named for farm on which was drilled the first well that produced from it.

Graves Creek formation.

Pleistocene: Western Kentucky.

L. C. Glenn, 1912 (Ky. Geol. Surv. Rept. Prog. 1910 and 1911, p. 26). *Graves Creek fm.*—Fine or mucky clay, sand, and gravel, 100 to 175 ft. thick, in Webster Co. Underlies Recent alluvium and overlies Union fm. (Plio.). Assigned to Pleist.

L. C. Glenn, 1922 (Ky. Geol. Surv., ser. 6, vol. 5, p. 122). The larger part of *Graves Creek fm.* is believed to be older than Union fm., but it is probable the surface part may be contemp. with Union fm. On Graves Creek, Webster Co., a well penetrates 104 ft. of this clay without reaching its base. Assigned to Pleist.

†Gravina series.

Jurassic or Cretaceous and Upper Triassic: Southeastern Alaska (Gravina Island).

A. H. Brooks, 1902 (U. S. G. S. P. P. 1, pp. 40–52, map). *Gravina series.*—Black shales or slates above and massive cgls. below. Occurs at Dall Head and elsewhere on S. end of Gravina Island. Uncon. overlies Vallenar series. Is Mesozoic, probably early Cret.

T. Chapin, 1919 (U. S. G. S. P. P. 120, p. 89). "Gravina series" of Brooks is now known to include 2 sed. fms. (one of Triassic age and one of Jurassic or Cret. age) associated with volcanic rocks of intermediate strat. position.

Gravoisan glacial epoch.

Name proposed by C [R.] Keyes, 1925 (Pan-Am. Geol., vol. 44, pp. 140–141), for time covered by isolated patches of a bouldery till of Pleist. age lying beyond the limit of Kansan till in Mo., and which "appears to be older than the Nebraskan till."

Named for occurrence on Gravois Creek, near Osage River, Morgan Co., Mo.

Keyes has also called the deposits "Gravoisan series" and "Gravoisan till."

Grawunder sand.

A subsurface sand, of Jackson (upper Eocene) age and 15 to 25 ft. thick, which according to L. P. Teas and C. R. Miller (A. A. P. G. Bull., vol.

17, No. 12, pp. 1461, 1464, 1475, 1477, 1933) lies in McElroy fm. in Humble Grawunder No. C.-1, at 3,430 ft. depth in Raccoon Bend field, Austin Co., Tex.

†Gray Band. (Also spelled Grey Band.)

Descriptive term applied in early N. Y. repts to the thin gray ss. later named *Thorold ss. memb. of Albion ss.* The term was probably originally used by Amos Eaton.

Gray porphyry group.

Eocene: Leadville district, Colorado.

S. F. Emmons, 1882 (U. S. G. S. 2d Ann. Rept., pp. 215–230), 1883 (U. S. G. S. Leadville Atlas), 1886 (U. S. G. S. Mon. 12, p. 80), and 1927 (U. S. G. S. P. P. 148), used *Gray porphyry* in a titular sense. This is a color term applied to a group of intrusive porphyries of later age than the White porphyry of Leadville dist. The restricted use of the term in Leadville Mon. 12 applied to Johnson Gulch porphyry, but "the other bodies" which Emmons stated "belong without question to this [Gray] variety" included the porphyries now known as *Lincoln porphyry, Evans Gulch porphyry, Mount Zion porphyry,* and some unnamed porphyritic rocks. Petrographic description is by W. Cross, on p. 330 of Mon. 12.

Grayback wash.

Quaternary: Central southern Colorado (San Luis Valley region).

G. M. Butler, 1910 (Colo. Geol. Surv. Bull. 2, pp. 59–61, pl. 2). *Grayback wash.*—Heavy wash, consisting of monzonite porphyry, Carbf. lss., sss., and occasional iron-ore fragments. Comprises fragments of all rocks in immediate vicinity of Grayback Mtn and some material not now represented there. Shafts 50 ft. deep in Grayback mining dist., Costilla Co., fail to reach bottom.

Grayback formation.

Devonian: Northwestern California (portions of Del Norte and Siskiyou Counties).

J. H. Maxson, 1933 (Calif. Jour. Mines and Geol., vol. 29, Nos. 1 and 2, p. 128 and map). *Grayback fm.*—Argillites, cherts, ls. (in part marble), and interbedded flows of basalt. In some respects similar to Kennett fm. of Shasta Co. Dev. fossils. [Little Grayback, a peak in Siskiyou Co., is in midst of area mapped as Grayback fm.]

†Gray Bull beds.

†Gray Bull member.

Eocene (lower): Western Wyoming (Bighorn Basin).

W. Granger, 1914 (Am. Mus. Nat. Hist. Bull., vol. 33, pp. 202–205). The beds underlying Lysite fm. in Bighorn Basin were referred by Sinclair and Granger to Knight fm., but it now seems that a new name is needed to distinguish this most important Lower Eo. faunal horizon, and *Gray Bull beds* is proposed. Consists of 600 ft. of *Systemodon*-bearing gray, red, and yellowish shales; highly fossiliferous. Exposed along Gray Bull River. Overlies, apparently conformably, Sand Coulee beds, which are fossiliferous but do not contain *Systemodon.*

G. L. Jepsen, 1930 (Am. Phil. Soc. Proc., vol. 69, No. 7, pp. 474, 494). *Gray Bull memb. of "Fort Union"* redefined by including in it, at base, the 200 ft. of red-banded beds called Sand Coulee by Granger, for reason that representatives of *Homogalax* were in 1928 found in the Sand Coulee, the apparent absence of that genus being the basis for separating the Sand Coulee from the overlying Gray Bull beds of Granger, which yield *Homogalax* abundantly. Where no uncon. is detected at base of the Gray Bull as here redefined, the base is drawn at top of sediments yielding *Eohippus* (Eo.).

According to H. F. Osborn (U. S. G. S. Mon. 55, 1929) these beds are a faunal zone belonging to his *Systemodon-Coryphodon-Eohippus* zone. The U. S. Geol. Survey does not apply geographic names to faunal zones.

†Gray Cliff group.

Jurassic (?): Central southern Utah (Henry Mountains region).

G. K. Gilbert, 1877 (Geology Henry Mtns, pp. 6, 7). *Gray Cliff group* (also *Gray Cliff ss.*).—Massive cross-laminated ss., buff to red, 500 ft. thick, underlying Flaming Gorge group and overlying Vermilion Cliff group. Often difficult to distinguish by color from Flaming Gorge and Vermilion Cliff groups. [Derivation of name not stated.]

Replaced by Navajo ss., the more widely applied name. (See A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., U. S. G. S. P. P. 183, 1936.)

†Gray Cliff sandstone.

See †*Gray Cliff group.*

†Gray Cliff limestone.

Mississippian: Southeastern Arizona.

See under *Modoc ls.*

Graydon channel sandstone.

Pennsylvanian: Western and central Missouri.

A. Winslow, 1894 (Mo. Geol. Surv. vol. 7, pp. 422–425). *Graydon Springs ss. and cgl.*—Remnants of more or less friable, usually micaceous ss. of red or yellow color, 25 or more ft. thick, usually underlain by cgl. made up of pebbles and boulders of Lower Carbf. chert. The ss. and cgl. rest uncon. on Lower Carbf. lss., occupying depressions in latter. Shore deposit laid down probably in early Coal Measure times.

E. N. Babcock and J. Minor, 1904 (Bradley Geol. Field Sta. Drury Coll. Bull., vol. 1, pt. 1, pp. 22–27). State Geol. Buckley, in speaking of this river fm. [Graydon ss.] where it occurs as a cgl. filling old river channels, differentiates btw. this and *Graydon proper*. The fm. filling the channels he terms *Saline Creek cave cgl.*, and this is in places, he says, overlain by the Graydon. This Saline Creek cave cgl. would seem to be but the lower or local beds of Graydon ss. and cgl. The fm. is of river and estuary origin. The deposit at Graydon Springs would seem to be the remains of a great river.

F. B. Van Horn, 1905 (Mo. Bur. Geol. and Mines vol. 3, 2d ser.). *Graydon ss.*, 2 to 70 ft. thick in Moniteau Co., uncon. overlies Burlington and Chouteau lss. and at least in one place the Coal Measures shales.

Named for exposures at Graydon Springs, Polk Co.

Graydon shales.

Pennsylvanian: Southwestern Missouri (Green County).

E. M. Shepard, 1905 (Bradley Geol. Field Sta. Drury Coll. Bull., vol. 1, p. 56). *Graydon shales.*—Soft olive-green, sometimes carbonaceous shales or soapstone, frequently containing fossil leaves, evidently in pockets, in Graydon ss., and associated with clays.

†Graydon Springs sandstone and conglomerate.

See *Graydon channel ss.*

Grayhorse limestone member (of Sand Creek formation).

Pennsylvanian: Central northern Oklahoma (Osage County).

K. C. Heald, 1918 (U. S. G. S. Bull. 686K, p. 130). [The strat. section of rocks exposed in T. 27 N., R. 7 E., Osage Co., shows a thin ls., called *Grayhorse ls.*, lying 85 ft. below Foraker ls. and 57 ft. below a micaceous ss. This ls. was named by C. F. Bowen in Bull. 686L, but Heald's chapter in Bull. 686K was released before Bowen's rept in Bull. 686L.]

C. F. Bowen, 1918 (U. S. G. S. Bull, 686L, p. 138). *Grayhorse ls.*—Dark brownish-gray crystalline conglomeratic ls., usually 2± ft. thick but locally 4 ft. thick. Contains numerous small pebbles ranging in size from mere grains to that of a large pea, which weather dirty white and give rock a mottled appearance. In most places contains numerous large specimens of *Myalina subquadrata*, some of which are 3 or 4 in. in longest dimension. The outcrops on steep slopes break off in large slabs as much as 10 ft. across which strew the slope below.

Is older than Foraker ls. and younger than Stonebreaker ls. Named for excellent exposure on crest of Little Grayhorse anticline, in NW¼ sec. 11, T. 24 N., R. 6 E.

Basal memb. of Sand Creek fm. (See under *Sand Creek fm.* Also see 1936 entry under *Caneyville ls.*)

Grayhorse sand.

A subsurface sand, of Penn. age, in central northern Okla., reported to correlate with a part of Pawhuska fm.

Grayson marl member (of Denison formation).

Lower Cretaceous (Comanche series): Northeastern Texas and central southern Oklahoma.

F. W. Cragin, 1894 (Colo. Coll. Studies, vol. 5, pp. 43–48). *Grayson marls.*—Yellow, highly calc., sparingly aren., fossiliferous marls, 15 to 40 ft. thick. Top memb. of *Exogyra arietina* marl and of Main Street ls. in Cooke and Grayson Counties. Overlies Choctaw ls. memb. of Main Street ls.

R. T. Hill, 1901 (U. S. G. S. 21st. Ann. Rept., pt. 7, pp. 114–115, 121–124, 245, 246–249, 266–271, pls. 7, 18), restricted *Main Street ls.* to beds underlying Grayson marl, or to those called "Choctaw ls." by Cragin. He defined *Grayson marl* as grayish marls, lighter colored than Main Street ls., 15 to 60 ft. thick, and as forming top memb. of Denison fm. This is definition followed by U. S. Geol. Survey.

Named for numerous outcrops in Grayson Co., Tex.

Grayson granite gneiss.

Pre-Cambrian: Southwestern Virginia (Grayson County).

A. I. Jonas, 1928 (Va. Geol. Surv. prel. ed. of geol. map of Va.). *Grayson granite gneiss.*—Porphyritic biotite granite gneiss containing coarse pink to white feldspar phenocrysts with numerous dark schistose layers and cut by pegmatite. Probably = part of Cranberry granite. Covers most of Grayson Co.

A. I. Jonas, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 1, p. 55), changed this name to *Grayson granite.*

†Graysonton formation.

Cambrian (Middle and Lower): Southwestern Virginia.

M. R. Campbell, 1894 (Geol. Soc. Am. Bull., vol. 5, pp. 171, 175, 183, and pl. 4). *Graysonton fm.*—Complex mass of red and green shales and interbedded lss., the lss. generally siliceous, showing gradual transition from the siliceous green sh. to a solid ls., the whole highly charged with iron and giving rise to deep-red soils; occasionally a bed of pure blue ls. is seen, but they are not common. No reliable estimate of thickness. Apparently unfossiliferous, but probably of Middle or Lower Camb. age. Basal Paleozoic fm. Underlies, apparently conformably, Shenandoah ls.

Same as Watauga sh., which has been mapped over large area.

Named for Graysonton, Montgomery Co.

†Gray Sparry ls.

A name applied in early New York repts to Onondaga ls.

Grayville formation.

Pennsylvanian: Indiana.

See 1935 entry under *St. Wendell ss.*

†Great limestone. (In Monongahela formation.)

Pennsylvanian: Western Pennsylvania and northern West Virginia.

H. D. Rogers, 1839 (Pa. Geol. Surv. 3d Ann. Rept.). The *Great ls. deposits* consist of numerous beds of ls. separated by thin seams of sh., and aggregate 51 to 72 ft. in thickness. Occur in upper part of Pittsburgh series, being separated from underlying Pittsburgh coal by 75± feet of sh. and ss.

H. D. Rogers, 1858 (Geol. Pa., vol. 2, pt. 1, pp. 503–507). *Great ls. bed.*—A series of alternating calc. and argill. strata 60 to 70 ft. thick. Is older than Uniontown coal, younger than Redstone coal, and includes, about in middle, the Sewickley coal. The ls. overlying the Sewickley coal is 22+ ft. thick, and the ls. underlying it 25± ft. thick. [As thus defined "Great ls." apparently included Uniontown ls. at top, Benwood ls., and Fishpot ls.]

J. J. Stevenson, 1876 (2d Pa. Geol. Surv. Rept. K). *Great ls.*—I propose to limit this term to the double mass occurring btw. Uniontown and Sewickley coals. It is usually in 2 divisions but in one place it is in 3 divisions.

F. Platt, 1877 (2d Pa. Geol. Surv. Rept. H_8), applied the names *Great Pittsburg ls.* and *Pittsburg ls. group* (pp. 88, 100) to lss. extending from top of Uniontown ls. to base of Redstone ls.

The descriptive term "Great ls." as used in Pa. repts for many years included the Benwood and Uniontown ls. members of Monongahela fm.

†Great conglomerate.

Pennsylvanian: Appalachian region.

J. P. Lesley, 1856 (Manual of coal, pp. 91–105). The *Great Cgl.*, No. XII (Millstone Grit of Europe). Underlies the Lower [coal] series and consists of an upper cgl. 15 ft. thick, a middle sh. 50 ft. thick, and a basal cgl. 30 ft. thick. [Corresponds to Pottsville fm. of present terminology.]

Great conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan and Wisconsin.

R. D. Irving, 1883 (U. S. G. S. Mon. 5, pp. 186, etc., pls. 17 and 18). *The Great cgl.*—Red ss. and cgl. underlying Lake Shore trap and overlying Marvine's Group C [Eagle River group] of Eagle River section. Thickness 2,200 ft.

Is basal fm. of Copper Harbor group.

Named for fact it was supposed to be very much thicker than Outer cgl. Is well established in the literature.

†Great gabbro.

A name applied in some early repts to Duluth gabbro.

†Great Bend conglomerate.

Name applied in some early repts to Olean cgl. of Warren Co., NW. Pa. (See first entry under *Olean cgl.*) According to F. A. Randall (2d Pa. Geol. Surv. Rept. I, pp. 51–54, 1875) the cgl. at Great Bend, Warren Co., is 40 ft. thick.

Great Bend limestone. (In Chemung formation.)

Upper Devonian: Northeastern Pennsylvania (Susquehanna County).

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. G_5, p. 91). *Gread Bend ls.*—Passing down to Susquehanna River we find a thin calc. layer, filled with Chemung shells, at 400 ft. below base of "Fort" 76 cliff or New Milford lower ss. The layer varies from ½ ft. to 2 ft. in thickness and sometimes disappears entirely. It occurs on land of Mr. Lusk, about 20 ft. above level of the Susquehanna. Rests on finely laminated shales, apparently with uncon. in some places. Is present at Great Bend, Susquehanna Co.

Great Bend coal group.

A term applied to a group of strata in lower part of Tongue River memb. of Fort Union fm. in SW. N. Dak., and including coals G, H, and I. (See A. G. Leonard, 1908, N. Dak. Geol. Surv. 5th Bien. Rept.)

Great Blue limestone.

Mississippian (upper): Central northern Utah (Oquirrh Mountains region).

J. E. Spurr, 1895 (U. S. G. S. 16th Ann. Rept., pt. 2, pp. 374–376). *Great Blue ls.*—In Mercur mining dist. consists of (descending): (1) Massive dark-blue ls. interbedded with sss., 1,000 ft.; (2) black sh., 100 ft.; (3) massive dark-blue ls., 2,500 ft.; (4) black sh. 25 ft.; (5) massive dark-blue ls., 1,000 ft. Underlies Upper Intercalated series (alternating sss. and lss.) and overlies Lower Intercalated series (alternating thin lss. and calc. sss.). Occupies most of Mercur Basin. Max. thickness 5,000± ft.

J. Gilluly, 1932 (U. S. G. S. P. P. 173, pp. 7, 29–31, 32). *"Great Blue" ls.* [redefined].—Consists of a lower and an upper ls. separated by shaly beds, 85 ft. thick, herein named *Long Trail sh. memb.* The lower ls. is 500± ft. thick, according to 4 measurements by writer, instead of 1,000 ft. as reported by Spurr. The upper ls. is blue-gray ls. like the lower ls. and contains sporadic chert layers, some sandy ls., and a very subordinate quantity of black sh. In places the upper 200 to 300 ft. of upper ls. memb. consists of interbedded ls. and sh. Estimated thickness of upper ls. 3,000± ft. The upper black sh. of Spurr and the overlying limy shales and interbedded lss., aggregating 1,140 ft., are here separated from the "Great Blue" ls. and named *Manning Canyon sh.* The "Great Blue" ls. rests on Humbug fm. ("Lower Intercalated series" of Spurr).

The term "Great Blue ls.," although nongeographic, is so well known to mining public that no attempt has been made to replace it with a geographic name.

†Great Carolinian bed.

See †*Carolinian bed.*

†Great Copper Harbor conglomerate.

A name that has been applied to Great cgl., of Copper Harbor group.

†Great Falls coal series.

†Great Falls group.

Lower Cretaceous: Central northern Montana (Great Falls region).

J. S. Newberry, 1887 (School Mines Quart., vol. 8, p. 328). *Great Falls coal series* is Lower Cret. and exact synonym of Kootenie of Canada. [In 1891 (Am. Jour. Sci., 3d, vol. 41, p. 193) Newberry called the beds *Great Falls group,* and repeated statement that they are same as Kootenie of Canada.]

Replaced by Kootenai fm., the older name.

Great Slave group.

Pre-Cambrian (upper Huronian?): Canada.

C. H. Stockwell (Canada Geol. Surv. Summ. Rept. for 1932, part C). Occurs on Great Slave Lake, Canada.

Great Smoky conglomerate.

Lower Cambrian: Western North Carolina, eastern Tennessee, and central northern Georgia.

A. Keith, 1907 (U. S. G. S. Nantahala folio, No. 143, p. 3). *Great Smoky cgl.*—Cgl., ss., qtzite, graywacke, mica-schist, garnet schist, and sl. Original character of beds is plainest in the cgls., whose layers are 1 to 50 ft. thick. All of rocks except the sl. have a decided gray color, becoming whitish on exposure and weathering of contained feldspar. The cgl. pebbles are not often coarse and seldom exceed half an inch in length. From this they grade into coarse and fine sss., qtzites, and graywackes. Traced southward less and less cgl. is found. There is always a heavy bed at top, however, and usually several near base. Interbedded with the coarse rocks are numerous seams and beds of light- and dark-gray schist and darker sl., usually less than a foot thick, but in places 25 or 30 ft. thick. Thickness of fm. 5,500 to 6,000 ft. Underlies Nantahala sl. and overlies Hiwassee sl.

Named for extensive development in Great Smoky Mtns, in S. part of Knoxville quad., which adjoins Nantahala quad. on N.

Greece Ranch horizon.

Oligocene: Southwestern Washington (southwestern Lewis County).

B. L. Clark, 1924 (Pan-Pacific Sci. Cong., Australia, 1923, Proc., vol. 1, p. 877). At present writer recognizes at least 5 distinct Eocene faunas in western No. Am., with suggestion of a sixth. Four of these have been proved not only to represent distinct faunal units, but strat. units as well—that is, the fms. containing the different faunas are separated one from the other by unconformities in certain areas at least. The *Greece Ranch horizon* is the sixth and questionable Eo. horizon. The fauna may possibly be Eo. It was collected from Greece ranch locality near Vader, on Cowlitz River, and from beds which rest uncon. on Cowlitz fm. and are stratigraphically below beds of Lincoln horizon. It is very possible the fauna represents uppermost Eo. The determination of what is upper Eo. and Olig. in western No. Am. is indirect.

L. G. Hertlein and C. H. Crickmay, 1925 (Am. Phil. Soc. Proc., vol. 64, No. 2, pp. 242–246). The oldest of the 4 Olig. faunas of Wash. is known only at Greece's ranch, on left bank of Cowlitz River ½ mi. below village of Toledo. The fauna was discovered by Anderson and Martin and was described by Dickerson in 1917 (Calif. Acad. Sci. Proc., 4th ser., vol. 7, pp. 157–182). A few more species were added in 1918 by K. E. Van Winkle (Univ. Wash. Pub. Geol., vol. 1, No. 2, pp. 81–92). Presumably the next younger fauna than Greece Ranch is the *Barbatia merriami* fauna, which occurs in Lower Porter beds of Porter and Oakville and definitely underlies Upper Porter beds. [Their 4 Olig. subdivisions are (descending) Blakeley, Porter, Lincoln, and Greece Ranch.]

T. J. Etherington, 1931 (Univ. Calif. Pub., Bull. Dept. Geol. Sci., vol. 20, No. 5, pp. 33–56), assigned *Greece Ranch horizon* to oldest Olig., and stated that it rested with marked uncon. on Eocene.

See also *Gries Ranch horizon.*

Greeley gypsum. (In Sumner group.)

Permian: Central Kansas.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, p. 10). *Greeley gyp.*—A gyp. bed in Geuda salt measures, about 100 ft. higher stratigraphically than Hope gyp.

G. P. Grimsley, 1899 (Univ. Geol. Surv. Kans., vol. 5, pp. 58–61), gives further description of this gyp. bed.

Named for Greeley Twp, Saline Co.

Green sand.

A subsurface sand, lying at 1,850 to 1,900 ft. depth, in Lawrence Co., Ill.

Greenberry formation.

Mississippian: British Columbia.

W. A. Johnston and W. L. Uglow, 1926 (Canada Geol. Surv. Mem. 149, p. 20).

†Greenbrier series.

Mississippian: Pennsylvania and northern West Virginia.

J. J. Stevenson, 1878 (2d Pa. Geol. Surv. Rept. K_3). If it is thought best to replace *Umbral* by a geographical term, the series might be called *Greenbrier series*, from Greenbrier River, in W. Va. *Mauch Chunk* is objectionable, because at that locality only shales occur, a condition characterizing the series only in central and eastern Pa., while in all the rest of the enormous area in which this series is exposed there is a large proportion of ls. In Pocahontas Co., W. Va., along Greenbrier River, the conditions are a mean btw. the extremes of ls. and sh., so that the locality would be a fitting one from which to name the series. Underlies Pottsville cgl. and overlies Pocono ss. Includes (descending) Upper Mauch Chunk shales (including Sharon group of coal beds) 82+ ft.; Mountain ls. (exposed in Loyalhanna Gap); Lower Mauch Chunk shales 90 ft., and Siliceous [Loyalhanna] ls. 50± ft.

Includes Mauch Chunk sh. and Loyalhanna ls.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 142). [See this entry under *Cameron red sh. memb.*]

Greenbrier limestone.

Mississippian: Southern Pennsylvania, western Maryland, northern West Virginia and Virginia.

W. B. Rogers, 1879 (Macfarlane's Geol. Ry. Guide, p. 179). *Greenbriar ls.* underlies Greenbriar shales [Mauch Chunk sh.] and overlies Montgomery grits and coal measures [Pocono ss.]. Is=Umbral shales of Pa.

I. C. White, 1882 (The Virginias, vol. 3, pp. 102–103). *Mountain or Greenbrier ls.*—Underlies Greenbrier or Mauch Chunk sh. and overlies Vespertine or Pocono of Pa. At base the "Siliceous ls.," 105 ft. thick, is tentatively included, although in writer's opinion it really belongs to Vespertine.

In some subsequent repts the †Siliceous (Loyalhanna) ls. was treated as a distinct fm., and in other repts it was included in either Greenbrier ls. or Pocono ss. It is now treated by U. S. Geol. Survey as a distinct fm. in Pa. and as a memb. of Greenbrier ls. in western Md. and northern Va. and W. Va., where the Greenbrier replaces lower part of Mauch Chunk sh. It is considered to be of post-Ste. Genevieve age.

Named for exposures on Greenbrier River, Pocahontas Co., W. Va.

†Greenbrier shales.

Mississippian: West Virginia.

W. B. Rogers, 1879 (Macfarlane's Geol. Ry. Guide, p. 179). *Greenbriar shales* of Va. and W. Va. underlie Great cgl. and cgl. coal group (XII of Pa.) and overlie Greenbriar ls. Are = Rogers' Umbral shales of Pa.

Same as Mauch Chunk sh., the name now in common use.

Greenbush cyclical formation.

A name applied by H. R. Wanless (Ill. Geol. Surv. Bull. 60, 1931, pp. 179–193) to a portion of upper part of Pottsville fm. (Penn.) of central western Ill., based upon the rhythmic-cycle theory of sedimentation. Derivation of name not stated.

Greencastle bed.

Middle Ordovician: Central southern Pennsylvania (Franklin County).

R. S. Bassler, 1919 (Md. Geol. Surv. Camb. and Ord. vol., pp. 49, 133, 120, 140–147, 152, 153, 154). *Greencastle bed.*—Heavy impure ls., 0 to 200 ft. thick, forming top memb. of Chambersburg ls. Not developed in Md. Deposited in trough extending from near Mason-Dixon line through Greencastle, Pa. Not known elsewhere in No. Am. Occurs btw. Black River and Trenton time of N. Y. [On p. 154 he says it is late Black River or early Trenton.] Lies uncon. on *Christiana* bed.

Green Cove beds.

Eocene: Western Wyoming (Wind River Basin).

H. E. Wood, 2d, 1934 (Am. Mus. Nat. Hist. Bull., vol. 67, art. 5, pp. 245–249). *Green Cove beds.*—Name suggested provisionally for "so-called Bridger" of Wind River Basin, from the section at Green Cove, E. of Hailey, "so-called Bridger" being an unwieldy term. Sinclair and Granger (1911) described this Bridger (?) as consisting of 375 ft. of ss., sh., and tuff lying btw. the red banded clays of the Wind River [below] and the Uinta [?] shales [above], and as conformable, so far as known, with the Wind River and as possibly uncon. (erosional) with Uinta [?]. Writer found distinct uncon. at base of the beds, where they rest on red-banded Lost Cabin beds. Berry (1925 and 1930) has reported the flora from the beds as approx. = Green River. The beds are probably = some part of the Bridger or Lower Uinta. [The so-called "Lower Uinta" of Uinta Basin, Utah, is = upper part of Bridger fm. of Bridger Basin, Wyo., and is included in Bridger fm. by U. S. Geol. Survey.]

†Green Crinoidal limestone.

A descriptive term applied in early Pa., W. Va., Ohio, and Md. repts to Ames ls. member of Conemaugh fm.

Greendale limestone. (In Cynthiana formation.)

Middle Ordovician (Trenton): Central northern Kentucky.

A. F. Foerste, 1906 (Ky. Geol. Surv. Bull. 7, pp. 10, 19, 211). *Greendale bed.*—Name suggested by J. M. Nickles for argill. lss. interbedded with calc. clays and clay shales, constituting lower part of Cynthiana fm. Overlies Perryville (top div. of Lexington fm.) and underlies Point Pleasant div. (named by Orton) of Cynthiana fm., which is characterized by distinctly less argill. material and by presence in some localities of 80 percent of calcium carbonate and 12 percent of mag. carbonate, with very little silica or alumina, but along Ohio River the siliceous material in lss. at top of Cynthiana fm. is increased to 10 to 20 percent. Thickness of Cynthiana fm. 40 to 90 ft. [Thickness of subdivisions not stated. See also under *Nicholas ls.*]

A. F. Foerste, 1909 (Denison Univ. Sci. Lab. Bull. vol. 14, pp. 289–324), divided Cynthiana fm. into (descending) Nicholas ls., *Greendale,* and Perryville, and repeated this classification in 1910 (Denison, vol. 16). In 1914 (Cincinnati Soc. Nat. Hist. Jour., vol. 21, pp. 109–145) Foerste introduced *Millersburg ls. memb. or Orthorhynchula phase of Cynthiana fm.* and stated that it had been included in *Greendale div.* of Cynthiana fm. in former papers; also that "the Greendale memb. as developed near Lexington is regarded as approx. equiv. of the much more richly fossiliferous Millersburg ls. further eastward."

A. M. Miller, 1915 (Am. Jour. Sci., 4th, vol. 40, pp. 651–657) and 1919 (Dept. Geol. and Forestry of Ky., ser. 5, Bull. 2), divided Cynthiana fm. into Point Pleasant ls. above and Greendale ls. below (the Perryville being excluded from Cynthiana).

R. S. Bassler, 1915 (U. S. Nat. Mus. Bull. 92, vol. 2, pl. 1) and 1919 (Md. Geol. Surv. Camb. and Ord. vol., p. 51), and A. F. Foerste, 1924 (Canada Dept. Mines Geol. Surv. Mem. 138, No. 121 geol. ser., chart opp. p. 58), divided Cynthiana fm. into (descending) Rogers Gap, Gratz, Bromley, and Greendale.

Probably named for Greendale, Fayette Co.

Greene formation. (Of Dunkard group.)

Permian: Southwestern Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

J. J. Stevenson, 1876 (2d Pa. Geol. Surv. Rept. K, pp. 35–44). *Greene County group.*—Includes all the rocks of the Upper Barren Series above Upper Washington ls. Thickness 800± ft. Satisfactorily exposed only in Greene Co., although it has a considerable thickness in Washington Co. Typical section is in Centre Twp, Greene Co., Pa. [The foregoing definition conforms to present usage.]

Top fm. of Dunkard group. The present Pa. Geol. Survey classifies the Dunkard as a *series* and the Greene as a *group*. The U. S. Geol. Survey classifies the Dunkard as a *group* and the Greene and Washington as *fms.*

Named for exposures on high lands of central and SW. parts of Greene Co., Pa.

†Greene County group.

Permian and Pennsylvanian: Western Pennsylvania.

H. D. Rogers, 1858 (Geol. Pa., vol. 2, pt. 1, pp. 503–507). *Upper or Greene County group.*—Includes Pittsburg coal at base and a considerable thickness of strata above Waynesburg coal. Thickness 800 to 900 ft. [As thus used the name covers all of Monongahela fm. and part at least of overlying Dunkard group. The term "Greene County group" has also been used in a restricted sense, or for the beds now known as *Greene fm.*]

Greenfield dolomite.

Silurian (Cayugan): Western Ohio and Vanceburg, Kentucky.

E. Orton, 1871 (Ohio Geol. Surv. Rept. Prog. 1870, p. 307 and fig. 1, opp. p. 310). *Greenfield stone.*—The Helderberg ls. of Highland Co. [SW. Ohio]. Thickness 15–100 ft. Overlain by Dev. black sl. and underlain by Hillsboro ss., top fm. of Niagara group.

E. Orton, 1874 (Ohio Geol. Surv. vol. 2, pt. 1). *Greenfield stone.*—In all SW. Ohio the Helderberg ls. or Waterlime group can be perfectly distinguished by local name *Greenfield stone,* derived from its most extensive and valuable exposures, which occur at Greenfield, Highland Co. Consists chiefly of even, thin-bedded light-brown mag. ls. scarcely to be distinguished in chemical composition from the heavy beds of Niagara ls. beneath, but it has peculiarities of color and bedding that serve to distinguish it from all other lss. associated with it. It disappears at Latham, Pike Co., and is not seen again till a few mi. below Buffalo, N. Y.

A. W. Grabau, 1898 (Sci., n. s., vol. 8, p. 800). I propose to call the so-called "bullhead" ls. of vicinity of Buffalo, N. Y., the *Greenfield ls.* from town in [SW.] Ohio near which this bed both attains strong development and afforded the first fossils described from it.

C. S. Prosser, 1903 (Jour. Geol., vol. 11, btw. pp. 519 and 546). Grabau's name *Greenfield ls.* (1898) is certainly appropriate for "Lower Helderberg or Waterlime fm." in central and southern Ohio in case further study shows that Monroe fm. is not suitable for the Waterlime in this part of State.

A. W. Grabau, 1906 (N. Y. State Mus. Bull. 92, pp. 120–124), used *Cobleskill (Bullhead) ls.* for western N. Y. and stated: The name *Greenfield ls.* has been used by the author for this western type of the Cobleskill, from Greenfield, Ohio, where it is well developed.

According to A. C. Lane, C. S. Prosser, W. H. Sherzer, and A. W. Grabau (Sci., n. s., vol. 27, p. 409, 1908) the *Greenfield fm.* extends into western N. Y. and is represented by Cobleskill ls. of eastern N. Y. They also call it (Geol. Soc. Am. Bull., vol. 19, 1909) the zone of *Schuchertella hydraulica*, give its thickness as 100+ ft., and treat it as basal fm. of "Lower Monroe or Bass Islands series" of Mich. and northern Ohio.

W. H. Sherzer and A. W. Grabau, 1909 (Geol. Soc. Am. Bull., vol. 19, pp. 540–553). *Greenfield dol.* so far known only from O., where it is exposed at Greenfield [Highland Co.] and Ballville [Sandusky Co.].

A. W. Grabau, 1909 (Mich. Geol. and Biol. Surv. Pub. 2, geol. ser. 1, pp. 215–223). *Greenfield fauna* was formerly identified by writer with Bullhead or Akron fauna of western N. Y., but critical comparison shows agreement in few points only. May be called *Schuchertella hydraulica* fauna.

W. H. Sherzer and A. W. Grabau, 1910 (Mich. Geol. Surv. Pub. 2, geol. ser. 1, p. 31). At Greenfield, O., the *Greenfield dol.* discon. underlies upper Devonic Ohio sh. and discon. overlies Hillsboro ss.

J. E. Carman, 1927 (Jour. Geol., vol. 35, btw. pp. 481 and 506). *Greenfield dol.*, 75 to 100 ft. thick. Is known near Carey, Findley, and Tiffin, also in western Allen, SW. Putnam, and Van Wert Counties. No outcrop is known showing relations to Tymochtee shaly dol., but Tymochtee lies stratigraphically above Greenfield. Is basal memb. of Bass Island fm. (Lower Monroe).

A. F. Foerste, 1931 (Ky. Geol. Surv., ser. 6, vol. 36, p. 192). The only exposure of Greenfield dol. known in Ky. is along bank of Ohio River at Vanceburg [Lewis Co.].

R. J. B. Newcombe, 1933 (Mich. Dept. Cons., Geol. Surv. Div., Pub. 38, geol. ser. 32, p. 39), and W. Stout, 1933 (Shore and Beach, vol. 1, No. 3, p. 76) included this dol. in their Bass Island group.

Greenfield bed.

Upper Triassic: Central Massachusetts (Franklin County).

B. K. Emerson, 1897 (Geol. Soc. Am. Bull., vol. 8, pp. 65–72). *Greenfield bed.*—For a thickness of 30 to 70 ft. and for a distance of several mi. in vicinity of Greenfield [Franklin Co., Mass.] the basal portion of the trap sheet is a mixture of sand, fragments of various sss. and of various kinds of diabase, some with glass base, some with hyalopilitic base, and some resembling andesites, all unlike the monotonous Triassic diabase, and abundant fragments of glass, all cemented by glass, and variously shattered and recemented, and the interstices filled by a water-deposited mixture of albite, diopside, calcite, aegirine-augite, and hematite. The main mass of the trap sheet is normal and continuous above this confused mass, and in many places the basal portion of the sheet can be seen to be a continuous mass of trap beneath the breccia, so that the latter must have been formed in the midst of the sheet itself.

†Greenfield limestone.

Upper Cambrian: Eastern New York (Saratoga County).

Replaced by *Hoyt ls.*, as explained under *Little Falls dol.* The name was introduced, but not fully defined, by J. M. Clarke in 1903 (N. Y. State Mus. Hdb. 19, pp. 9, 12, and table 2). In tables he showed *Greenfield ls.* as underlying Little Falls dol. and overlying Potsdam ss. in east central N. Y. On p. 12 he stated that in Saratoga Co. the shore deposits of Potsdam ss. are overlain by heavy beds of ls. (*Greenfield ls.*). He probably named the fm. for Greenfield, Saratoga Co.

†Greenfield dolomite. (In Whitehorse sandstone.)

Permian: Southwestern Oklahoma (Blaine and Custer Counties).

C. D. Stephenson, 1925 (A. A. P. G. Bull., vol. 9, No. 3, pp. 626–631). *Greenfield ls.*—For many years the ls. capping the hills immediately W. of Greenfield in Ts. 14–15 N., Rs. 11–12 W., has been called "Day Creek dol.," but this correlation is incorrect, since Day Creek dol. lies directly above Whitehorse ss., and the ls. at Greenfield lies below Whitehorse ss. as defined by Reeves. It is writer's belief Greenfield ls. is strat. equiv. of Verden ss.

N. Evans, 1928 (A. A. P. G. Bull., vol. 12, No. 7, pp. 705–712). *Greenfield dol.* lies in upper part of Lower Whitehorse ss., 12 to 15 ft. below top of that ss. in Weatherford dist., Custer Co.

R. W. Sawyer, 1929 (Okla. Geol. Surv. Bull. 40HH). Greenfield dol. of Stephenson (1925) lies near bdy btw. Marlow and Rush Springs members of Whitehorse ss. This dol. has also been called "Day Creek dol." [See under *Day Creek dol.*]

G. G. Suffel, 1930 (Okla. Geol. Surv. Bull. 49, pp. 85, 101–111, 126, 128). *Greenfield dol.* lies in lower part of Whitehorse ss., 110 to 130 ft. above its base. Caps a rather pronounced escarpment facing North Canadian River. In some places consists of 2 ledges separated by 22 to 25 ft. of ss. The upper ledge, 6 in. thick, consists of light-pink to white, rather fine grained banded dol., very pure except for an appreciable amount of quartz sand. The lower ledge, 16 in. to 3 ft. thick, is even purer than upper ledge, as it contains very little quartz, is fine-grained, very hard, banded in various shades of pink to white. Named for exposures just W. of Greenfield, Blaine Co.

N. Evans, 1931 (A. A. P. G. Bull., vol. 15, No. 4). *"Greenfield" dol.* (preoccupied) is here replaced by *Relay Creek dolomites* (including Upper Relay Creek dol. and Lower Relay Creek dol., separated by 25 ft. of red ss. and sh.).

Greenhorn limestone. (*Of Colorado group.*)

Upper Cretaceous: Eastern Colorado and Wyoming, southeastern Montana, Nebraska, South Dakota, Kansas, northeastern New Mexico.

G. K. Gilbert, 1896 (U. S. G. S. 17th Ann. Rept., pt. 2, p. 564). *Greenhorn ls.*—Ls. beds, 3 to 12 in. thick, separated by somewhat thicker sh. beds. Thickness of fm. 25 to 40 ft. Middle fm. of Benton group in Arkansas Valley region, Colo. Underlies Carlile sh. and overlies Graneros sh. Named for Greenhorn Station, 14 mi. S. of Pueblo, Colo., and for Greenhorn Creek [Pueblo and Walsenburg quads.].

The Niobrara and Benton are not now treated as groups, the broader term *Colorado group*, which includes them both, being considered the more useful group name. Where the Niobrara deposits and Benton deposits are not subdivided, they are called Niobrara ls. and Benton sh., respectively.

Greenian series.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, pp. 36, 66, 279, 308). *Greenian series.*—The Green River shales of early writers. Divided. in Utah and Colo., into Washakie shales. 1,200 ft. thick, uncon. on Godiva [also Goldiva] lss.

Green Lake limestone.

Pre-Cambrian: Ontario.

Name applied by W. E. Logan, 1865 (Canada Geol. Surv. 16th Rept. Prog., p. 20, map), to one of the lss. in Grenville series of Ontario.

Green Lake moraine.

Pleistocene (Wisconsin stage): Southeastern Wisconsin. Shown on moraine map (pl. 23) of U. S. G. S. P. P. 106. Forms the drift dam enclosing Green Lake Basin, Green Lake Co., on W.

†Greenleaf sandstone.

Lower Cretaceous (Comanche series): Central southern Kansas.

C. N. Gould, 1898 (Am. Jour. Sci., 4th, vol. 5, pp. 170–174). *Greenleaf ss.*—Yellowish-brown ss., usually distinctly stratified but occasionally massive or cross-bedded, 40 to 110 ft. thick. Underlies Kirby clays and overlies Spring Creek clays. Included in Medicine beds.

Named for Greenleaf ranch, on upper Medicine River, 10 or 12 mi. W. of Belvidere, Kiowa Co.

This name was discarded by U. S. Geol. Survey in 1921. The ss. is a bed in Kiowa sh. and was regarded as so local as to have no strat. value. The name, however, was revived by W. H. Twenhofel in 1924 (Kans. Geol. Surv. Bull. 9), as explained in 1924 entry under *Belvidere sh.*

Green Lodge formation.

Upper Cambrian: Eastern Massachusetts (Dedham quadrangle).

E. J. Rhodes and W. H. Graves, Jr., 1931 (Am. Jour. Sci., 5th, vol. 22, pp. 364-372). *Green Lodge fm.*—An area of gray crystalline medium-grained qtzites interbedded with dark-gray fine-grained thin-bedded phyllite, occurring at and near Green Lodge, in an area previously mapped as Dedham granodiorite (which we would place in Dev.). Highly metamorphosed, due to shearing and igneous intrusion. Name suggested by Dr. L. LaForge. We found several impressions that we consider to be brachiopods; one resembles an *Obolella* and another an Upper Camb. *Lingula* of indeterminate sp. [Discuss other evidence bearing on age, and conclude by assigning *Green Lodge fm.* to Upper Camb.] Deeper portions of Green Lodge fm. were probably stoped out by igneous intrusion of Dedham granodiorite, leaving present rocks as a roof pendant in the granodiorite. Subsequent erosion reduced fm. to mere remnant, so total thickness as deposited will remain unknown, and even the remnant is largely obscured by drift.

Green Mountain gneiss.

Pre-Cambrian (?): Southwestern and northwestern Vermont (Green Mountains, which cross the State).

C. B. Adams, 1845 (1st Ann. Rept. Vt. State Geol., pp. 60–61). [*Green Mtn gneiss* is listed as next to oldest fm. in Vt., lying below talcose sl. and above "gneiss proper."]

C. B. Adams, 1846 (2d Ann. Rept. Vt. State Geol.), mentioned "the gneissoid mica sl. or *Green Mtn gneiss.*"

A. D. Hager, 1861 (Rept. Geol. Vt., vol. 2, pl. 18, geol. map of Plymouth, SW. Vt.), mapped *Green Mtn gneiss.*

J. D. Dana, 1872 (Am. Jour. Sci., 3d, vol. 4, p. 370). The so-called *"Green Mtn series"* has been pronounced on lithological evidence to be pre-Sil. and Huronian.

A. Wing, 1877 (Am. Jour. Sci., 3d, vol. 13, pp. 334–347, 404–419), showed oldest fm. of western Vt. as "gneiss, often called Green Mtn. gneiss."

C. H. Hitchcock, 1877 (Geol. N. H., pt. 2, p. 464). The *Green Mtn gneiss* underlies the green schists in Green Mtns. The Green Mtns are not Huronian but are flanked by it on both sides in N. half of Vt. They belong to Montalban series and are nearer the Laurentian than the Huronian. The use by Dr. Hunt in 1871 of *Green Mtn gneiss* for the Huronian is improper and inappropriate.

G. H. Perkins, 1910 (7th Rept. Vt. State Geol., pp. 249–256). *Green Mtn series* (of gneisses, schists, etc.) covers E. part of Burlington quad., Vt. I believe they are made of Camb. and Ord. strata.

G. H. Perkins, 1912 (8th Rept. Vt. State Geol., pp. 21–56). The foundation of Green Mtns is of Algonkian age. Archean may be represented in axis of Green Mtns.

C. H. Richardson et al., 1914 (9th Rept. Vt. State Geol., pp. 305–313), assigned *Green Mtn gneiss* to Algonkian; also in 11th Rept. Vt. State Geol.

E. J. Foyles, 1929 (16th Rept. Vt. State Geol., pp. 281-288), assigned *Green Mtn gneiss* to Lower Camb., Upper Camb., and Beekmantown (Lower Ord.).

On 1932 geol. map of U. S. the rocks of Green Mtns, Vt. are mapped as Archean gneiss and Algonkian(?) sedimentary schists.

†Green Mountain beds.

Eocene: Denver Basin region, Colorado.

G. L. Cannon, Jr., 1893 (Colo. Sci. Soc. Proc., vol. 4, p. 253). In earlier descriptions the Arapahoe group was called "Willow Creek beds" and Denver group was called "Green Mtn beds," but to prevent confusion with fms. of similar names in other parts of the country it seemed desirable to use *Arapahoe* and *Denver*. Total thickness of Denver beds is exposed only on SW. slopes of Green Mtn, the upper 900 ft. being nowhere else preserved. [The compiler has been unable to find any previous use of *Green Mtn beds.*]

Green Point series.

Ordovician (lowest): Newfoundland.

C. Schuchert and C. O. Dunbar, 1934 (Geol. Soc. Am. Mem. 1, p. 38).

Green Pond conglomerate.

Silurian: Northern New Jersey and southeastern New York.

H. D. Rogers, 1836 (N. J. Geol. Surv., p. 127). *Green-pond-mountain cgl.*—Usually a bright-red ss., rather fine grained, imbedding large water-worn pebbles, most commonly white quartz; sometimes the paste is more argill. Constitutes Long Pond, Raffenberg, and Green Pond Mtns. [In some subsequent repts the cgl. of Green Pond Mtn was wrongly designated as Potsdam ss.]

F. J. H. Merrill, 1887 (N. J. Geol. Surv. Rept. 1886). *Green Pond cgl.* (*Oneida*).—Red cgl., thickly bedded, 600 ft. thick. Lies uncon. on Lower Sil. lss. Occurs at Green Pond, Copperas, Kanouse, and Bearfoot Mtns. Lithologically resembles Oneida cgl. Overlain by 200 ft. of red sh. of Medina age.

N. H. Darton, 1894 (Geol. Soc. Am. Bull., vol. 5, pp. 367, 369, 383). *Green Pond cgl.*—Buff reddish qtzites underlain by coarse red cgls. Pebbles almost all quartz and of white or pinkish color, in which respect differs from Dev. Skunnemunk cgl. Thickness 60 to 250 ft. Grades into overlying Longwood red shales and overlies Hudson shales [Martinsburg sh.]. Age is approx. same as Shawangunk grit and Oneida cgl. and probably also represents all or a portion of the Medina. [In text he refers to the qtzites as *Green Pond qtzite*. Later repts give thickness of Green Pond cgl. as 1,500 ft.]

In 1902 (N. Y. State Mus. 54th Ann. Rept., pt. 1, pp. r144 to r150) E. C. Eckel introduced *Pine Hill qtzite* for the "series of qtzite beds overlying the Green Pond cgl. [restricted] and underlying the Longwood shales." The separation of the qtzite beds from Green Pond cgl. seems not to have found favor, for there is no other record of *Pine Hill qtzite*.

This fm. does not contain fossils, but it occupies strat. position of Shawangunk cgl. to NW., and it is correlated with that fm., which has yielded fossils of Salina age, according to some geologists, but other geologists consider the Shawangunk to be of Clinton and Medina age. The present N. Y. State Survey (W. Goldring, N. Y. State Mus. Hdb. 10, 1931, p. 333) assigns Shawangunk cgl. of N. Y. all to Clinton time, and regards it "as a continuation of" Green Pond cgl. of N. J.

†Green Pond quartzite.

Name used by N. H. Darton in 1894 and by H. B. Kümmel and S. Weller in 1902 (N. J. Geol. Surv. Ann. Rept. State Geol.) to designate the qtzites forming upper part of Green Pond cgl. In 1902 (N. Y. State Mus. 54th Ann. Rept., pt. 1) E. C. Eckel named these qtzites *Pine Hill qtzite*, and separated them from Green Pond cgl. Other geologists, however, continue to include them in Green Pond cgl., and there is no other record of *Pine Hill*. The U. S. Geol. Survey does not apply the same name to a geologic unit and to a part thereof, and it therefore does not use the term "Green Pond qtzite."

†Green Pond Mountain group.

F. J. H. Merrill, 1887 (N. Y. Acad. Sci. Trans., vol. 6, p. 59). *Green Pond Mtn group.*—Extends from northern N. J. through Orange Co., N. Y., to Hudson River and for some distance beyond. Includes (descending) slates of Upper Dev. age in valley SW. of Greenwood Lake; blue slates and grits containing fossils of probably Hamilton age; coarse white ss. and cgl. containing Oriskany and Corniferous fossils; ls. containing Lower Helderberg fossils; red cgl. and ss. of Oneida age. Rests uncon. on Magnesian ls. [Kittatinny ls.].

†Green Pond Mountain formation.

D. S. Martin, 1888 (geol. map of New York City and vicinity). *Green Pond Mtn fm.* (Oneida and Medina) assigned to Sil. Underlies Dev. and overlies Ord. mag. ls.

Green River formation.

Eocene (middle): Southwestern Wyoming, northwestern and central western Colorado, and eastern Utah.

F. V. Hayden, 1869 (U. S. Geol. Surv. Terr. 3d Ann. Rept., pp. 89–92). A little E. of Rock Spring station [Wyo.] a new group commences, composed of thinly laminated chalky shales, which I have called the *Green River shales* because they are best displayed along Green River. They are evidently of purely fresh-water origin and of middle tert. age. The layers are nearly horizontal, and, as shown in valley of Green River [SW. Wyo., NW. Colo., and eastern Utah], present a peculiarly banded appearance. Contains a fauna and very extensive flora. One of marked features of the group is great amount of combustible or petroleum slates. Is overlain by Bridger group, of upper tert. age. [Did not explain relations to his Wasatch group, introduced in same vol., but assigned both to middle Tert. and appeared to consider them as in part at least equiv.]

E. D. Cope, 1874 (U. S. Geol. and Geog. Surv. Terr. 7th Ann. Rept., btw. pp. 435 and 444). Hayden named deposits of western area *Wasatch group* and regarded it as synchronous with Green River group of eastern area. Writer has attained same opinion on paleontological grounds and hence has applied name *Green River* in both areas.

A. C. Peale, 1876 (U. S. Geol. and Geog. Surv. Terr. 8th Ann. Rept., p. 148). Wasatch group and Green River group occupy two distinct basins but are considered synchronous by Dr. Hayden and Prof. Cope.

C. King, 1876 (U. S. Geol. Expl. 40th Par. Atlas), divided the Tert. deposits of NE. Utah and adjacent areas into (descending): Wyoming cgl. (Plio.), Uinta (Eo.), Bridger (Eo.), Green River (Eo.), and Vermilion Creek (Eo.). Advance copies of this map were distributed in 1875.

F. V. Hayden, 1877 (U. S. Geol. and Geog. Surv. Terr. Bull. 3, No. 1, pp. 181–185). *Wasatch group* of Hayden is same as Vermilion Creek group of King, and *Wasatch group* has priority. [On p. 608 of this Bull. C. A. White showed Green River group as overlying Wasatch group and underlying Bridger group.]

C. King, 1878 (U. S. Geol. Expl. 40th Par. vol. 1). *Green River group* consists of calc. shales and sss., of fresh-water origin, characterized by abundant lime. Underlies Bridger group, with slight uncon., and uncon. overlies Vermilion Creek group (=Wahsatch group of Hayden). Reaches thickness of 4,000 ft. Perhaps most characteristic development is in neighborhood of Green River City, where Union Pacific R. R. crosses river [SW. Wyo.].

Later studies in SW. Wyo. and NW. Colo. resulted in showing that Green River and Wasatch fms. are in part contemp., red beds of typical Wasatch lithology being interstratified with beds of typical Green River lithology. In U. S. G. S. Bulls. 341 and 381 two of the 4 members into which the fms. were divided were included in Wasatch fm. and two in Green River fm. Later, A. R. Schultz (U. S. G. S. Bull. 702, 1920) included the 4 members in Green River fm., because his studies showed they were all time equivalents of the Green River. His subdivisions of Green River fm. consisted of (descending): (1) Plant beds and Tower ss. of Powell, 0 to 500 ft.; (2) Laney sh. memb., 0 to 950 ft.; (3) Cathedral Bluffs red beds memb., 0 to 1,500 ft.; and (4) Tipton sh. memb., 100 to 325 ft., the latter resting on unquestioned Wasatch fm. Still later the studies of J. D. Sears and W. H. Bradley proved that the Cathedral Bluffs beds are in fact a tongue of typical Wasatch fm. laterally penetrating beds of typical Green River lithology and overlain by Laney sh. memb., and that the Tipton is in reality a tongue of typical Green River deposits laterally penetrating typical Wasatch red beds, and resting on main body of Wasatch fm. (See U. S. G. S. P. P. 132, 1925.) This is present classification of U. S. Geol. Survey.

Named for exposures in valley of Green River, SW. Wyo., NW. Colo., and eastern Utah. They are especially well developed in neighborhood of Green River City, SW. Wyo., where Union Pacific R. R. crosses river.

Greensburg or Flat Rock stone.

Silurian: Southeastern Indiana (Decatur County).

E. T. Cox, 1879 (Ind. Geol. Surv. 8th, 9th, and 10th Ann. Repts., pp. 57, 88–89). *Greensburg or Flat Rock stone.*—Light grayish-buff close-grained, compact mag. ls., 20 to 130 ft. thick, near top of Niagara. At North Vernon is in contact with Hamilton fm.

Extensively quarried on Flat Rock Creek, near St. Paul, Decatur Co., and by Greensburg Stone Co. near Greensburg, Decatur Co.

Greenstone flow.

Pre-Cambrian (Keweenawan): Northern Michigan.

R. D. Irving, 1883 (U. S. G. S. Mon. 5, pp. (see index), pls. 17 and 18). *Greenstone group.*—Lustre-mottled melaphyres and coarse-grained gabbros and diabase, 1,200 ft. thick, underlying Ashbed group and overlying a group of diabases, diabase amygdaloids, and lustre-mottled melaphyres, including a number of cgl. beds. Includes Marvine's beds 91 to 108, inclusive, which we may appropriately call the *Greenstone group,* since its great basal bed forms the well known Greenstone Ridge, Keweenaw Co.

Throughout the repts on copper dist. of Mich. this fm. has been called *the Greenstone.* According to A. C. Lane (Mich. Geol. and Biol. Surv. Pub. 6, geol. ser. 4, 1911) it is 1,130 ft. thick, underlies †St. Marys epidote, overlies Allouez cgl., and is top fm. of Central Mine group.

Greenville dolomite.

Upper Cambrian: Northeastern Tennessee.

E. O. Ulrich, 1924 (Tenn. Dept. Ed., Div. Geol. Bull. 28, p. 34, and Bull 31, p. 16). [*Greenville dol.* applied in table to 400 ft. of rocks underlying Copper Ridge dol. in Athens trough of Tenn., and assigned to "Lower Ozarkian." It is understood name applies to rocks that are equiv., in whole or in part, to Bibb, Ketona, and Brierfield dolomites of Ala. Type loc. not stated, but understood to be *Greenville,* Greene Co.]

Greenville shale. (In Greenbrier limestone.)

Mississippian: Southeastern West Virginia (Monroe County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 449, 466). *Greenville sh.*—Black fissile carbonaceous sh. 0 to 100 ft. thick, with marine fossils. Underlies Alderson ls. and overlies Union ls.; all members of Greenbrier series [ls.]. Type loc. in Monroe Co., in road on N. side of Indian Creek 0.1 mi. NW. of Hunter Spring School and 1.6 mi. SE. of Greenville. Observed in only part of Monroe Co.

Greenwater volcanics.

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 52, 79). *Greenwater volcanics.*—Term restricted to the tuffs and basalt flows associated with the borate deposits of Death Valley, and presumably of Early Tertic age. Thickness 4,000 ft. Composes upper fm. of Amargosan series in Nev. Uncon. below Redhill sss. and uncon. above Grapevine cgls.

Derivation of name not stated, but probably derived from exposures at or near Greenwater, E. of Death Valley, in Inyo Co., Calif.

†Greenwich formation.

Pre-Cambrian(?): Southwestern Connecticut (Fairfield County).

J. G. Percival, 1842 (Conn. Geol. Surv. Rept., pp. 46, 49, 58, 63, 72 and map). *Greenwich fm.* (*No. 1 of Western Primary system*).—A dark micaceous subporphyritic and porphyritic fm., generally with more or less hornblende disseminated, occupying considerable part of towns of Stamford and Greenwich [Fairfield Co.] and extending along the Sound from E. side of Stamford Harbour into N. Y. State. Most characteristic rock is a very dark micaceous subhornblendic rock, generally very decomposable. Included in Western Primary system.

Mapped as Danbury granodiorite gneiss by H. E. Gregory and H. H. Robinson, 1907 (Conn. Geol. and Nat. Hist. Surv. Bull. 7).

Greenwich shale.

Cretaceous(?): Southeastern Colorado (Purgatoire Canyon).

W. T. Lee, 1901 (Jour. Geol., vol. 9, pp. 343–352). [In detailed section of Morrison fm. near mouth of Plum Canyon, Lee designated topmost 11 ft. of the Morrison as *Greenwich clay sh., soft and fine-grained.*]

Greenwich formation.

Lower Cambrian: Eastern New York (Washington and Rensselaer Counties).

T. N. Dale, 1904 (U. S. G. S. Bull. 242, pp. 43, 50, and map forming pl. 1), mapped and described the rocks of Hudson Valley btw. Hoosic River and Kinderhook Creek. The Lower Camb. is said to include part of Stockbridge ls., the *Greenwich sl.* of Washington Co., N. Y., and Rutland Co., Vt., the Vermont fm. of Mass. and Vt., and probably some areas of Beekmantown. The Greenwich sl. is not defined.

C. D. Walcott, 1910 (Smithsonian Misc. Coll., vol. 53, No. 6, p. 268). *Greenwich fm.* (*Lower Camb*).—Shales and interbedded lss. and sss. of unknown thickness, but so far as known not over 300 ft. Present in Washington and Rensselaer Counties.

Named for exposures at Greenwich, Washington Co., N. Y.

Greenwood sandstone.

Pennsylvanian: Western Arkansas coal field and central-eastern Oklahoma.

A. Winslow, 1896 (N. Y. Acad. Sci. Trans., vol. 15, p. 51). *Greenwood ss.*—Ss., 100 ft. thick, composing top memb. of Sebastian stage. Overlies Tomlinson sh. and underlies Poteau stage.

Represents lower part of Savanna ss.

Probably named for Greenwood, Sebastian Co., Ark.

Greenwood iron-formation.

Pre-Cambrian (upper Huronian): Northern Michigan (Marquette district).

J. Zinn, 1933 (Mich. Acad. Sci., Arts, and Lett., vol. 18, pp. 442, 443, 451–454). *Greenwood fm.*—This sediment is not a pure iron fm., and not of economic importance; but was deposited as an interlayered accumulation of clastic material and chemically deposited chert and siderite. The parts exposed in outcrops now consist of grunerite schist, with interlayered chloritic material or quartz sand. The unmetamorphosed parts are probably a sideritic sl. Thickness varies somewhat; minimum perhaps 50 ft. Where metamorphosed it is magnetic and creates a magnetic line that marks top of Goodrich fm. Where overlain by Clarksburg volcanics the interlayered clastic zones seem to be mostly chloritic material, but where Clarksburg is absent, as at Michigamme, the interlayered material is mostly clastic quartz.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184). *Greenwood iron-fm.* underlies Clarksburg volcanics and overlies Goodrich qtzite, all of upper Huronian age.

†Greer formation.

Permian: Southwestern Oklahoma, Panhandle of Texas, and central northern Texas.

C. N. Gould, 1902 (Okla. Geol. Surv. 2d Bien. Rept., pp. 42, 52). *Greer div.*—Red clays, shales, and sss., including dol. memb. (at top) and several named gyp. members. Thickness 150 to 300 ft. Underlies Quartermaster div. and overlies Woodward div.

C. N. Gould, 1924 (A. A. P. G. Bull., vol. 8, No. 3, pp. 324–341). Cloud Chief gyp. is eastern area of "Greer." The western area of "Greer" includes Cloud Chief gyp., Whitehorse ss., Dog Creek sh., and Blaine gyp.

C. N. Gould, 1927 (Obsolete Okla. geologic names: Univ. Okla. Bull., Proc. Okla. Acad. Sci., vol. 6, pt. 2, pp. 235–238). *Greer gyp.* was named by Gould from Greer Co., and divided into an eastern and a western area. The western area is now known to be the Blaine; the eastern area was named *Cloud Chief* in 1924, from a town in Washita Co., Okla.

Named for Greer Co., Okla. The type loc. is said by Gould to be the butte known as Cedar Top, in NW. corner of Kiowa Co., Okla. R. C. Moore and W. P. Haynes, 1917 (Kans. Geol. Surv. Bull. 3), and R. C. Moore, 1920 (Kans. Geol. Surv. Bull. 6, pt. 2), used this name in Kans. to replace Taloga fm. of Cragin (1897), which Cragin divided into Big Basin ss. and Hackberry sh. But the name is not now being used.

Greggs breccia.

Tertiary (late): Western Arizona.

W. T. Lee, 1908 (U. S. G. S. Bull. 352, p. 17). *Greggs breccia.*—Detrital fm. filling Grand Wash Trough and having exposed thickness of 1,400± ft. Composed of coarse unassorted and poorly stratified material, largely blocks of crystalline rock similar to the granite and gneiss of Virgin Mtns to W. Toward top is cemented with lime carbonate, and in places upper 200 ft. consists of travertine containing few rock fragments. This travertine is best exposed S. of Colorado River and E. of Greggs Ferry [NW. corner of Mohave Co.], where it caps conspicuous cliffs which rise 1,400 ft. or more above river. No fossils. Reference to Tert. based largely on physiographic evidence.

Greggs Landing marl member (of Tuscahoma sand).

Eocene (lower): Southwestern Alabama.

E. A. Smith, 1886 (Ala. Geol. Surv. Bull. 1, p. 12). *Gregg's Landing marl.*—Fossiliferous marine marl, 5 to 6 ft. thick, separated from overlying Bell's Landing marl by 20 to 25 ft. of dark-gray sandy clays. Included in Bell's Landing section.

E. A. Smith and L. C. Johnson, 1887 (U. S. G. S. Bull. 43, pp. 46–51). *Gregg's Landing marl.*—Dark-gray or bluish sandy clay marl or clayey sand, 4 or 5 ft. thick, with an indurated bed of variable thickness at its base. Has a peculiar group of fossils. Separated from overlying Bell's Landing marl by 20 to 25 ft. of gray sandy clays. Included in Bell's Landing series, about 60 ft. above base.

Is memb. in lower part of Tuscahoma sand.

Named for exposures at Greggs Landing, on Alabama River, in NW. part of Monroe Co.

†Greggs Landing series.

Eocene (lower): Alabama.

W. H. Dall, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, p. 346), applied this name to deposits that have for years been called *Tuscahoma fm.* or *Tuscahoma sand.*

Gregorian series.

A term applied by C. [R.] Keyes to latest Pleist. deposit (his Ashawa terrane) in Iowa. (See Pan-Am. Geol., vol. 63, No. 4, 1935, p. 281). Derivation of name not stated.

Gregory sand.

A subsurface sand, of Upper Cret. age, in Rainbow City field, Union Co., Ark.

Grenada formation. (In Wilcox group.)

Eocene (lower): Mississippi and western Tennessee and Kentucky.

E. N. Lowe, 1913 (Miss. Geol. Surv. Bull. 10, pp. 23–25). The uppermost div. [of Wilcox fm.] is chocolate-colored clays 200 to 250 ft. thick. Become pink on drying. Are associated with lignite outcrops near Grenada, Oxford, and Hernando. Since the correlation of these beds with upper Wilcox beds of Ala. is by no means certain they might be called *Grenada beds,* from place where whole thickness of the series is typically exposed. Overlie Holly Springs sand and underlie Tallahatta fm., of Claiborne group.

In present usage of names the Wilcox is treated as a group and Grenada fm. as top fm. of that group.

Named for exposures at Grenada, Grenada Co., Miss., especially on Yalobusha River, near Grenada.

Grenola formation.

Pennsylvanian: Southeastern Nebraska, across east-central Kansas, and into Oklahoma.

G. E. Condra and C. E. Busby, 1933 (Nebr. Geol. Surv. Paper No. 1). *Grenola fm.*—The Neva ls. and certain beds below it are here described as a fm., to which the name *Grenola* is applied, from Grenola, Elk Co., Kans. Dr. R. C. Moore, Director of Kans. Geol. Surv., concurs in erection of this new fm., but has not advised regarding its name. It represents a calc. marine cycle, lying btw. aren. sh. fms. It is erected on basis of its faunal and lithologic zones, which are widely persistent. It has 3 lines of outcrop in SE. Nebr. and for most of distance across east-central Kans., beyond which it is exposed in a single line of outcrops to beyond Arkansas Valley in Okla. Deep-well records show it is deeply buried and widespread in western Kans. and eastern Colo. It is underlain by Roca sh. and overlain by Eskridge sh. It contains more ls. than sh., and therefore contrasts with underlying Roca and overlying Eskridge. It has distinct persistent faunal zones, which is unlike the Eskridge and Roca fms. It is the same as the Dunlap of Kirk (Univ. Kans. Geol. Surv., vol. 1, p. 81, 1896). It is here divided into following members (descending): Neva ls., Salem Point sh., Burr ls., Legion sh., and Sallyards ls., all of which are present in type section, which is the ravines and creeks N. and S. of Highway 160, 4 to 5 mi. W. from Grenola. Combined thickness of the 5 members is 40 ft. or more.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8). *Grenola fm.* divided into (descending) Neva ls., Salem Point sh., Burr ls., Legion sh., and Sallyards ls. Overlies Roca sh. fm. and underlies Eskridge sh. fm. The Kans. Geol. Surv. correlates Legion sh. and Sallyards ls. with Roca sh. fm.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 50). *Grenola fm.* underlies Eskridge sh., overlies Roca sh. (top part of Elmdale sh. of old classification), and corresponds to Neva ls. of old classification. In revised classification it is divided into (descending) Neva ls. [restricted], Salem Point sh., and Burr ls. [Moore also transferred these rocks to Perm. This change in Perm.-Penn. bdy has not been considered by U. S. Geol. Survey for its publications.]

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Grenville series.

The provincial series of pre-Camb. metamorphosed sed. rocks present in northern N. Y. and Ont., and formerly classified as "Algonkian" by U. S. Geol. Survey, but classified as "early pre-Camb. (pre-Laurentian)" by some writers. For definition see U. S. G. S. Bull. 769, pp. 114–119. Also see under †*Oswegatchie series*, a local name applied to the Grenville rocks of Adirondack region of northern N. Y. (Franklin, St. Lawrence, and Jefferson Counties). The relations of the Grenville rocks of Adirondack region to the rocks of Westchester Co., SE. N. Y., which have been called Grenville are still in question. "Algonkian" and "Archean" having been discarded as time terms, the Grenville series is now classified simply as *pre-Camb.*

†Grenville limestone.

Pre-Cambrian: Quebec and northern New York.

W. E. Logan, 1859 (Canada Geol. Surv. Rept. Prog. 1858, pp. 35–40), 1863 (Canada Geol. Surv. 15th Rept. Prog., pp. 43–45), and 1865 (Canada Geol. Surv. 16th Rept. Prog., p. 20, map), applied *Grenville ls.* to one of the lss. of Grenville series. (See U. S. G. S. Bull. 769, 1925, pp. 114–119.)

The U. S. Geol. Survey does not apply the same name to a major unit and to one of its subdivisions.

Grenville quartzite.

Grenville amphibolite.

Pre-Cambrian: Northern New York.

R. Balk, 1932 (N. Y. State Mus. Bull. 290, p. 14). Names applied to parts of Grenville series.

Grenvillian.

A name that has been applied to part of the pre-Camb. rocks of southern New Brunswick. (See U. S. G. S. Bull. 360, 1909, pp. 502–503.)

Greta sand.

A subsurface sand in Greta field, Refugio Co., Tex., which is said to be of middle Olig. age and to overlie Frio fm. Is also called "4,400-foot sand" and "Heterostegina sand," the latter a paleontologic name. Thickness 150 ft. (See A. A. P. G. Bull., vol. 19, No. 4, 1935, pp. 544–557.)

Grey sandstone of Oswego.

A term applied in some early N. Y. repts to *Oswego ss.*

†Grey Band.

See †*Gray Band.*

Greybull sandstone member (of Cloverly formation).

Lower (?) Cretaceous: Central northern Wyoming (Bighorn and Elk Basins) and central southern Montana (Stillwater-Yellowstone-Counties region).

F. F. Hintze, Jr., 1915 (Wyo. Geologist's Office Bull. 10). Upper ss. of Cloverly fm. is locally called *Dakota or Greybull sand.* It closely resembles Dakota ss. Is discon. overlain by "Rusty Beds," 75 to 125 ft. thick, which form basal part of Lower Benton sh. [This may not be first appearance in print of drillers' term *Greybull sand,* but it seems to be the first appearance of the term in a strat. rept.]

C. T. Lupton, 1916 (U. S. G. S. Bull. 621, table opp. p. 166, pp. 167, 168). At type loc. of Cloverly fm., near Cloverly, Wyo., about 15 mi. NE. of Basin, Bighorn Co., Wyo., the Cloverly fm., according to N. H. Darton (U. S. G. S. P. P. 51, p. 52, 1906), consists of 113 ft. of strata, a detailed section of which is here given. Upper 20 ft. (light-buff or tan-colored ss.) constitutes *Greybull sand,* which carries oil and gas in Greybull field and water in Lamb anticline and Torchlight dome. The Greybull sand is overlain by Thermopolis sh.

D. F. Hewett and C. T. Lupton, 1917 (U. S. G. S. Bull. 656, p. 19), defined base of Thermopolis sh. and top of Cloverly fm. as top of Greybull ss. memb. and stated that Thermopolis sh. [of Colorado age] included the "rusty beds" [20 to 100 ft. thick] described by Washburne in U. S. G. S. Bull. 340, p. 350, 1908] as basal memb. of Colorado fm. in Bighorn Basin, Wyo.

In U. S. G. S. P. P. 149, p. 64, 1927, W. T. Lee included in his Greybull ss. memb. of Cloverly fm. the "rusty beds" assigned to Thermopolis sh. by D. F. Hewett and C. T. Lupton in 1917.

Subsequent work in Elk Basin field led committee on geologic names of U. S. Geol. Survey to sanction the transfer of the "rusty beds" to Cloverly fm., as indicated on Wyo. correlation chart compiled by the secretary and dated April 1925. Geologists working in other fields, however, continued to identify Greybull ss. as top memb. of Cloverly fm. and did not discriminate the so-called "rusty beds," but their equivalents, if present, appear to have been included in Thermopolis sh., as the thicknesses of Greybull ss. given range from 0 to 40 ft. In correlation chart (pl. 2) of U. S. G. S. P. P. 149, a thickness of 100± ft. is assigned to Greybull ss. memb. at Greybull, Wyo., and a thickness of 53 to 60 ft. at Thermopolis, Wyo., and Greybull ss. memb. of Greybull section is described (p. 64) as consisting of "many layers of rusty brown ss. and sh. which grade upward into Thermopolis sh." It is quite apparent that the 100± ft. mentioned includes at least a part of the "rusty beds" in Greybull ss. In a previous rept by A. J. Collier (U. S. G. S. Bull. 711D, 1920), the Greybull ss. of Thermopolis region is described as a massive ss. 25 ft. thick, and the "rusty beds" are not mentioned. The present practice of U. S. Geol. Survey is to include the "rusty beds" in Thermopolis sh. and treat Greybull ss. as top memb. of Cloverly fm., in Bighorn Basin, Elk Basin, and other areas in southern Mont. where it has been recognized. (See U. S. G. S. Bull. 822, 1931, pp. 23–28.) Whether this ss. is=Dakota ss. (Upper Cret.) or is an older ss. of Lower Cret. age has not been determined.

Greybull sand.

A subsurface sand believed to be at strat. horizon of *Greybull ss. memb. of Cloverly fm.*

Greyhorse limestone. (In Wabaunsee group.)

Pennsylvanian: Southeastern Nebraska and northwestern Missouri.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 9). *Greyhorse ls.*—Dark-gray impure ls., 1 ft. thick. Memb. of Pony Creek sh. fm. Overlain by 5 to 6 ft. of gray sandy sh. forming top memb. of Pony Creek fm. Underlain by Caneyville sh. memb. of Pony Creek fm. [Derivation of name not stated.]

E. C. Reed (Asst. State Geol. Nebr.), 1936 (letter dated Oct. 16). Type loc. of *Grayhorse ls.* in NW¼ sec. 11, T. 24 N., R. 6 E., Osage Res., Okla. Due to typographical error it is spelled *Greyhorse* in Paper 8. It should read *Grayhorse.*

Greylock schist.

Ordovician: Northwestern Massachusetts.

T. N. Dale, 1891 (Am. Geol., vol. 8, pp. 1–7). *Greylock schists.*—Muscovite (sericite), chlorite, and quartz schist, 1,200 to 2,000 ft. thick on Mount Greylock, Mass., where it overlies Bellows Pipe ls.

†Greylock series.

A term used by W. H. Hobbs, 1892 (Geol. Soc. Am. Bull., vol. 3, p. 460) and 1893 (Jour. Geol., vol. 1, pp. 717–736) to include Greylock schist, Bellowspipe ls., Berkshire schist, and Stockbridge ls. of Mount Greylock region, NW. Mass.

†Greylock limestone.

A name applied in some early repts (R. Pumpelly, U. S. G. S. Mon. 23, 1894) to Stockbridge ls. of Greylock Mtn region, Mass.

Greyson shale.

Pre-Cambrian (Belt series): Western central Montana (Belt Mountains).

C. D. Walcott, 1899 (Geol. Soc. Am. Bull., vol. 10, pp. 199–215). *Greyson shales.*—Consist of (descending): (1) Dark-gray siliceous and aren. shales, with interbedded bands of buff sandy shales and occasional layers of hard compact greenish-gray and drab siliceous rock; (2) bluish-gray, almost fissile shales; (3) dark coarse siliceous and aren. shales; (4) qtzites interbedded with shales in Deep Creek Canyon, 90 ft.; (5) intraformational cgls., 10 ft. in Deep Creek Canyon. Total thickness 3,000 ft. Underlies Spokane shales and overlies Newland ls. Type loc. on side of ridge btw. Deep and Greyson Creeks, SE. of Townsend.

Gries Ranch horizon.

Tertiary: Western Washington.

W. L. Effinger, 1936 (Geol. Soc. Am. Proc. 1935, p. 411). Recent investigation of "Olig." faunas of western Wash. reveals that fauna commonly referred to as "Gries Ranch fauna," and the deposits with which it is associated, have a widespread distribution throughout western Wash. and represent a distinct strat. and faunal unit in Tert. succession of Northwest. The deposits of this horizon consist of cgls., sss., and shales, with local volcanic tuffs and aggls. and are generally thin, but may reach a thickness exceeding 1,000 ft. Well-preserved Gries Ranch faunas have been recognized in Port Townsend region near town of Woodman and Port Hadlock and on shore of Puget Sound, S. of Oak Bay, and other places [mentioned]. The strat. and faunal relationships of Gries Ranch horizon show it clearly to be older than Lincoln fm. (lower Olig.) and younger than Cowlitz fm. (Eo.).

See also *Greece Ranch horizon.*

Griffin bed.

Miocene (lower): Western Florida and southwestern Georgia.

A. F. Foerste, 1894 (Am. Jour. Sci., 3d, vol. 48, pp. 52–54). *Griffin bed.*—Hard calc. clay, often deep red or clayey brown, owing to decomposition, full of

Orbitolites and a few other shells. Believe its location to be at top of Chattahoochee bed proper and about 130 ft. above base of Chattahoochee series. Thickness 6 to 8 ft.

Is a bed in Tampa ls. (†Chattahoochee fm.), according to studies of C. W. Cooke.

Named for exposures on Griffin's Creek, 4½ mi. S. of Bainbridge, Decatur Co., Ga., and about ½ mi. W. of Griffin's house.

Grimes sandstone.

Upper Devonian: Western and west-central New York.

D. D. Luther, 1902 (N. Y. State Mus. Bull. 52, pp. 616–629). *Grimes ss.*—Thin sss., 50 ft. thick, that produce the third falls in Grimes Gully, the High falls in Tannery Gully, and prominent escarpment on sides of Hatch Hill and West Hill in Naples section. Separated from overlying High Point ss. by 600 ft. of shales and flags, and correlated with the 25 ft. of ss. that underlies Gardeau flags in Genesee River section. Lies about 600 ft. above Genesee sh. Included in Portage or Nunda group. Carries Portage fauna in base.

D. D. Luther, 1903 (N. Y. State Mus. Bull. 69, pp. 1000–1011). *Grimes ss.*, 25 ft. thick, underlies Gardeau shales and flags (restricted to upper part of Gardeau sh. and flagstones of Hall) and overlies Hatch sh. [On map accompanying this bull. the beds above Grimes ss. are called *West Hill sands*, but in more recent N. Y. repts they are called *West Hill flags and sh.*, also *Gardeau flags and sh.* Luther gives thickness of Grimes in Penn Yan-Hammondsport quads. as 75 ft.]

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 77). Grimes ss. has been differentiated from not far W. of Genesee Valley to Cayuga Co. Named for occurrence in Grimes Gully, near Naples, Ontario Co.

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69). [Table shows *Grimes ss.* underlying Gardeau sh. in Allegany Co.; underlying Westhill sh. in Steuben Co.; and overlying Hatch sh. in both counties.]

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369). *Grimes ss.* underlies Gardeau sh. (=West Hill) and overlies Hatch sh. All included in Portage group.

G. H. Chadwick, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, p. 352), placed *Grimes ss.* below Gardeau and above Hatch, and included Grimes in Chemung group and Hatch in his Naples group.

In south-central N. Y. (Steuben and adjacent counties) the Grimes ss. underlies West Hill fm. (=Gardeau sh. to E.) and overlies Hatch sh.

Grimsby sandstone.

Silurian (early): Ontario and western New York.

M. Y. Williams, 1914. [In Sci., n. s., vol. 39, pp. 915–918, June, 1914, E. M. Kindle listed the following subdivisions of Medina fm. (restricted to "Upper Medina" or Albion ss.) in Niagara Gorge (descending): Thorold ss., *Grimsby ss.* ("name proposed by M. Y. Williams in paper read [but not published] before Geol. Soc. Am., Jan. 1914"), Cabot Head sh., Manitoulin beds, and Whirlpool ss. The first published definition of the name by Williams is in Canada Geol. Surv. Summ. Rept. for 1913, pp. 179–188, 1914, where he stated that it consists of 6 ft. of gray sh. underlain by thick-bedded mottled red and gray ss. 50 ft. thick in Niagara Gorge. Overlain by Thorold ss. and underlain by Cabot Head sh. Named for good exposures along E. side of gorge at Grimsby, Ont.]

See further explanation under *Cataract fm.*

Grindstaff sandstone member (of Tradewater formation).

Pennsylvanian: Southeastern Illinois (Equality and Shawneetown quadrangles).

C. Butts, 1925 (Ill. Geol. Surv. Bull. 47, p. 44). *Grindstaff ss. memb. of Tradewater fm.*—Coarse gray quartzose and conglomeratic ss., 40 to 60 ft. thick, lying 30 to 40 ft. above Caseyville ss. in Equality and Shawneetown quads, SE. Ill. Prominently displayed in Grindstaff Hollow, NE. corner of sec. 28, T. 10 S., R. 8 E., Equality quad. Extends at least 1½ mi. into Shawneetown quad. Lies 5 ft. below Willis coal (Bell?).

†Grindstone grit.

A name applied in some early repts to Berea ss. of Ohio, and in other repts to basal 20 ft. of Berea ss.

Grindstone Creek member (of Millsap Lake formation).

Pennsylvanian: North-central Texas (Brazos River region).

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 106, 107). *Grindstone Creek memb.* top memb. of Millsap Lake fm. Used by G. Scott and J. M. Armstrong in ms. on geol. of Parker Co. Overlies Brannon ls. memb. [Type loc. not stated.]

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, pp. 15, 16, 24). *Grindstone Creek memb.*—Upper memb. of Millsap Lake fm. Was named by G. Scott and J. M. Armstrong in ms. submitted to Tex. Bur. Econ. Geol. in 1933. Includes all strata btw. top of Brannon Bridge ls. (top bed of underlying Lazy Bend memb.) and base of Thurber coal (basal bed of overlying Garner fm.). The lss. of this memb. are here named *Goen ls.* (the younger) and *Santo ls.* (the older), q. v. Type loc. designated by Scott and Armstrong is area W. of Grindstone Creek, in SW. part of Parker Co.

Grinnell argillite.

Pre-Cambrian (Belt series): Northwestern Montana (Glacier National Park) and southeastern British Columbia.

B. Willis, 1902 (Geol. Soc. Am. Bull., vol. 13, pp. 316, 322). *Grinnell argillite.*—Argillite, dark red, shaly, sometimes aren., ripple-marked, sun-cracked. Thickness 1,000 to 1,800 ft. Type loc. Mount Grinnell (at head of Swift Current Valley), where it is 1,800 ft. thick. Also well exposed on Appekunny and Robertson Mtns. Conformably overlain by Siyeh ls. Overlies Appekunny argillite. It is possible more detailed strat. study may develop fact that Grinnell and Appekunny argillites are really phases of one great fm., and that line of distinction btw. them is one diagonal to stratification.

Griswold conglomerate.
Griswold Gap conglomerate. } (In Pocono formation.)
Griswolds Gap conglomerate.

Mississippian: Northeastern Pennsylvania.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. G_5, pp. 56, 57). *Griswold cgl.* (also *Griswold Gap cgl.*).—A true cgl., white, very pebbly, solid, and massive; pebbles very white (quartz), somewhat angular and flattish, rather than ovoid, and range from ½ to 2 in. Matrix is rather coarse, brownish gray, and weathers whitish. Near base, just W. of Waymart, in Rix's Gap, is a calc. layer 2 to 3 ft. thick, in which pebbles of red sh., greenish sh., and fish remains are mixed with the ordinary quartz pebbles. Thickness 35 ft. Forms crest of Moosic Mtn. Has two fine sloping outcrops opposite Griswold's Gap, just E. of Forest City, Susquehanna Co.

I. C. White, 1883 (2d Pa. Geol. Surv. Rept. G_7). *Griswold Gap cgl.* is bottom memb. of Pocono ss. At Campbell's Ledge, Lackawanna Co., it is 130 ft. thick.

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 565–607), called this bed *Griswolds Gap cgl.* and treated it, or its near equiv., as basal memb. of Pocono fm. He stated that it occupies much the same position as *Knapp ss. or cgl.* farther west.

Grizzly formation.

Silurian? (may be Ordovician): Northern California (Taylorsville region).

J. S. Diller, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 370–394). *Grizzly qtzite*, 400 ft. thick. Oldest fm. in Taylor[s]ville region. Tentatively assigned to Sil. (?). Is older than Montgomery ls., of Niagara age.

J. S. Diller, 1892 (Prel. proof-sheet ed. of U. S. G. S. Lassen Peak folio, No. 15). *Grizzly fm.*—Within area represented on map it is composed chiefly of slates, but in Mount Grizzly, near Taylor[s]ville, where the fm. has greatest development, there are, besides slates, both qtzite and ls. The last is of special interest in being Sil., the oldest fossiliferous rock yet discovered in Calif. [The ls. is Montgomery ls., of Niagaran age, which is now treated as a distinct fm., overlying Grizzly fm.]

J. S. Diller, 1908 (U. S. G. S. Bull. 353, on Taylorsville region). *Grizzly fm.*—Gray well-defined but thin-bedded qtzite overlain by lentils of [Montgomery] ls., and interstratified with shaly, often siliceous sl. (argillite) having irregular cleavage. The beds of qtzite range in thickness from 5 to about 20 ft. and run out into sh. in a short distance. The sh. beds are generally thicker than the qtzite, and for most part greenish gray to drab, although sometimes black and more or less flinty, but not much altered. The lighter-colored shales are often sandy and constitute prevailing portion of the fm., although beds of well-marked qtzite are usually present and frequently predominate. The coarser beds of qtzite are near base of fm. and are about 200 ft. thick. Thickness of fm. 400 to 1,000 ft. On E. slope of Grizzly Mtns, near N. end, qtzite prevails immediately beneath a lentil of [Montgomery] ls., but N. of Montgomery Creek shales occupy the corresponding position, and as the section does not continue below the tunnel it does not disclose the coarser beds lying at bottom of Grizzly qtzite horizon. In places is overlain conformably by Montgomery ls. but in most places is uncon. overlain by Taylorsville fm. Rests on ancient metarhyolite.

Since Grizzly fm. underlies Montgomery ls., of Niagaran age, it may be either Sil. or Ord.

Named for exposures on E. and NE. slopes of Grizzly Mtns, Plumas Co.

Grizzly quartzite.

See *Grizzly fm.*

Grizzly Bear formation.

Cretaceous (Upper): Alberta.

S. E. Slipper, 1918 (Canada Geol. Surv. Summ. Rept. 1917, pt. C, p. 8). Included in Belly River series.

Grizzly Mountain rhyolite.

Tertiary: Central Colorado (Sawatch Range).

J. T. Stark and F. F. Barnes, 1935 (Colo. Sci. Soc. Proc., vol. 13, No. 8, p. 477, map). The extrusive material here mapped as *Grizzly Mtn rhyolite* (after the most prominent peak in vicinity) includes the rocks described by Howell (Colo. Geol. Surv. Bull. 17, 1919) as "Grizzly Peak rhyolite" and "Red Mtn rhyolite." All evidence obtained by writers indicates "Red Mtn rhyolite" is merely a part of "Grizzly Peak rhyolite" which has been affected by mineralizing solutions. The name "Grizzly Peak rhyolite" was discarded to avoid confusion with a mtn of that name several mi. to S. The Grizzly Mtn rhyolite is Tert.

†Grizzly Peak andesite.

Pliocene: Western California (San Francisco region).

A. C. Lawson and C. Palache, 1902 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 2, p. 379 and map). A thick accumulation of lava flows, which for most part are of different petrographic type from underlying basalts, and should be classed as andesites. Though of rather varied character they are grouped together under name *Grizzly Peak andesite*. As mapped they include certain subordinate flows of basalt and intercalations of tuff. There are two rather distinct facies of the andesite; the lower one a medium-textured holocrystalline rock; the upper a dense compact rock, frequently glassy, with a prevailingly porphyritic habit, aggregating 175 to nearly 300 ft. [As mapped the Grizzly Peak andesite rests on rhyolite tuff and is overlain by Siestan fm. As mapped it forms Grizzly Peak, in Berkeley Hills.]

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). [The *andesite of Grizzly Peak* is included in Moraga fm., according to definition of Moraga, and as mapped.]

Grizzly Peak rhyolite.

Tertiary: Central Colorado (Chaffee and Lake Counties).

J. V. Howell, 1919 (Colo. Geol. Surv. Bull. 17). *Grizzly Peak rhyolite*—Gray fine-grained, easily weathered rock in which are embedded innumerable fragments of gneiss, schist, and other older rocks. Color light gray to brown. Texture that of rhyolite porphyry to pitchstone. In absence of conclusive evidence it seems fairly safe to consider this rhyolite to be of Tert. (Eocene?) age. [Map shows Grizzly Peak, Chaffee Co., in midst of this mass of rhyolite.]

This name has been discarded by J. T. Stark and F. F. Barnes, as explained under *Grizzly Mtn rhyolite.*

Groat sandstone bed. (In Pierre shale.)

Upper Cretaceous: Northeastern Wyoming and southeastern Montana.

W. W. Rubey, 1930 (U. S. G. S. P. P. 165A). *Groat ss. bed.*—Ferruginous and glauconitic ss. and siltstone, 150 ft. thick in N. part of area. Lies near top of Gammon ferruginous memb. of Pierre sh. Named for exposures along Groat Creek in T. 7 S., R. 56 E., Carter Co., Mont.

Groesbeck dolomite.

Permian: Southwestern Oklahoma and central northern Texas.

F. W. Cragin, 1897 (Am. Geol., vol. 19, p. 357). *Groesbeck dolomites.*—Laminated dolomites overlying Quanah gyp. in Hardeman Co., Tex., and Greer Co., Okla.

Named for Groesbeck Creek, Hardeman Co., Tex.

Gros Cap greenstone.

Pre-Cambrian (Keewatin): Western Ontario (Michipicoten district).

A. P. Coleman and A. B. Willmott, 1902 (Toronto Univ. Studies, geol. ser. No. 2, p. 8; Ont. Bur. Mines Rept. 1902, p. 156). *Gros Cap greenstones,* Huronian.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, p. 151), assigned *Gros Cap greenstone* to Keewatin.

Grosse Isle moraine.

Pleistocene (Wisconsin stage): Southeastern Michigan. Shown on moraine map (fig. 7) in U. S. G. S. Detroit folio (No. 205), p. 9, also on moraine map (pl. 32) in U. S. G. S. Mon. 53. Named for Grosse Isle, near Detroit.

Gros Ventre formation.

Middle Cambrian: Northwestern Wyoming and central southern Montana.

E. Blackwelder, 1918 (Wash. Acad. Sci. Jour., vol. 8, p. 417). *Gros Ventre fm.*—Greenish and gray calc. shales, with gray, striped conglomeratic and oolitic lss., separating overlying Gallatin ls. (as restricted by Hague and his associates) from underlying Flathead qtzite. Contains Middle Camb. fossils. [Gives typical detailed section (which foots 796 ft.) on W. slope of Doubletop Peak, in Gros Ventre Range, where overlying Gallatin ls. and underlying Flathead qtzite are both present.]

Groton granite.

Devonian: Northeastern Vermont (Caledonia County).

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), listed this name in Dev. of "central Vt.," but without definition. Quarried in SW. part of Groton Twp, Caledonia Co.

Grove limestone.

Lower Ordovician (Beekmantown): Western Maryland (Frederick County).

G. W. Stose and A. I. Jonas, 1935 (Wash. Acad. Sci. Jour., vol. 25, No. 12, pp. 564–565). *Grove ls.*—The main quarry rock at Le Gore quarry [Frederick Co.]. Formerly erroneously called *Beekmantown ls.* Rests conformably on Frederick ls. Is probably of Chazy or later age. [Derivation of name not stated in this publication, but authors stated orally that this ls. was named for Grove quarry and Grove Station, on B. & O. R. R., where it is well exposed in syncline above Frederick ls.]

G. W. Stose and A. I. Jonas collected additional fossils from this fm. which proved its lower Beekmantown age.

†Groveland formation.

Pre-Cambrian (upper Huronian): Northwestern Michigan (Crystal Falls and Felch Mountain districts).

H. L. Smyth, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, pp. 114–121, 137–139). *Groveland fm.*—Ferruginous rocks (qtzites, cherts, and subordinate schists) well exposed in central part of sec. 31, T. 42 N., R. 29 W., in vicinity of abandoned Groveland mine, in Felch Mtn dist. The magnetite is always an abundant constituent of fm. The rocks have a general family likeness, which makes it very easy in field to distinguish them from all other members of the Algonkian. There are two varieties. The usual one consists of quartz and the anhydrous oxides of iron, and is generally siliceous, heavy and dark colored; the other, and rarer, is made up essentially of an iron amphibole, quite similar to the grünerite of Marquette range, with quartz and iron oxides as associates. Thickness 500± ft. Immediately overlies Mansfield fm. and is uncon. overlain by Upper Huronian mica schists and qtzites. [On p. 16 of rept above cited, C. R. Van Hise correlated Groveland fm. of Crystal Falls dist. with Negaunee fm.]

According to C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, pp. 304–305 and chart opp. p. 598), the typical Groveland fm. of Felch Mtn dist. is Vulcan fm., the Negaunee fm. is absent there, and "name Groveland is discarded."

Guadalupe group.

Permian: Western Texas.

G. H. Girty, 1902 (Am. Jour. Sci., 4th, vol. 14, pp. 363–368). Not only are these faunas very different from any known in America elsewhere, but they give evidence of being later in geologic time. For this reason I propose to give them a regional name, which shall be employed in a force similar to *Mississippian* and *Pennsylvanian*. For this none more appropriate than one derived from locality where they were first discovered can be found, and term *Guadalupian* is suggested. The strat. limits of *Guadalupian period* will have to be determined on intrinsic evidence. At present it seems to include the whole section at S. end of Guadalupe Mtns, but the central fauna will be that of the "white" and "dark Permian" as described by Shumard. [The faunas to which name was applied were obtained from 1,700 to 1,800 ft. of ls. (afterwards named *Capitan ls.*), underlain by 2,000 to 2,500 ft. of yellow quartzose ss., underlain by 500 or more ft. of thin-bedded black ls., the ss. and basal ls. being afterward named *Delaware Mtn fm.* The basal ls. (now known as *Bone Spring ls.*) is, because of faunal and lithologic differences, now excluded from Delaware Mtn fm., with which it is uncon., and therefore may not properly be a part of Guadalupe group, although included in original definition. At time "Guadalupian" was introduced the Bone Spring ls. had yielded only a few fossils.]

G. H. Girty, 1908 (U. S. G. S. P. P. 58, pp. 10–11). *Guadalupian series.*—Includes Capitan ls. and Delaware Mtn fm. Appears to be younger than Hueco fm. Overlying fm. undet., being absent in Guadalupe Mtns.

Adopted as group term to include, originally, Capitan ls. and Delaware Mtn fm., which are characterized by unique fauna of Perm. age. Now known to uncon. underlie Castile gyp. (also of Perm. age), and considered to be in part younger and in part contemp. with beds that have been described as Hueco ls. The Delaware Mtn fm. of Delaware Mtns is now known to include in its upper part the time equiv. of Capitan ls. of Guadalupe Mtns. (See repts by P. B. King, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 697–793), and W. B. Lang, 1935 (A. A. P. G. Bull., vol. 19, No. 2) and 1937 (A. A. P. G. Bull., vol. 21, No. 7).)

Named for Guadalupe Point, S. end of Guadalupe Mtns, El Paso Co.

Guallava sandstone.

Oligocene: Costa Rica.

W. H. Dall, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, p. 342).

Guanajuato conglomerate.

Tertiary: Mexico.

C. W. Botsford, 1909 (Eng. and Min. Jour., vol. 87, p. 691).
A. Wandke and J. Martinez, 1928 (Econ. Geol., vol. 23, p. 9).

Guanica coral reefs.

Tertiary: Puerto Rico.

C. P. Berkey, 1915 (N. Y. Acad. Sci. Annals, vol. 26, p. 17).

Guantanamo shale.

Oligocene or Miocene: Cuba.

N. H. Darton, 1926 (Wash. Acad. Sci. Jour., vol. 16 p. 327).

Guaracara limestone.

Miocene: Trinidad.

G. A. Waring, 1926 (Johns Hopkins Univ. Studies in geol. No. 7, p. 56).

Guardarraya intrusion.

Age (?): Mexico.

J. E. Spurr and G. H. Garrey, 1908 (Econ. Geol., vol. 3, p. 694).

Guaso limestone.

Eocene: Cuba.

N. H. Darton, 1926 (Wash. Acad. Sci. Jour., vol. 16, p. 327).

Guayabal limestone.

Cretaceous: Puerto Rico.

G. J. Mitchell, 1922 (N. Y. Acad. Sci. Scientific surv. of Porto Rico and Virgin Islands, vol. 1, pt. 3, p. 256).

Guayabal formation.

Eocene: Mexico.

W. S. Cole, 1927 (Bulls. Am. Pal., vol. 14, No. 51, pp. 6, 9).

Guayama series.

Cretaceous: Puerto Rico.

E. T. Hodge, 1920 (N. Y. Acad. Sci. Scientific surv. Porto Rico and Virgin Islands, vol. 1, pt. 2, p. 142).

Guaynabo formation.

Cretaceous: Puerto Rico.

H. A. Meyerhoff, 1931 (N. Y. Acad. Sci. Scientific surv. Porto Rico and Virgin Islands, vol. 2, pt. 3, p. 275).

Gubik sand.

Pleistocene: Northern Alaska.

F. C. Schrader, 1902 (Geol. Soc. Am. Bull., vol. 13, pp. 233–252). *Goobic sands.*—Surficial deposit of fine-grained brownish Pleist. sand or loam, 10 to 15 ft. thick. Rests uncon. on Colville series. [Derivation of name not stated.]

F. C. Schrader, 1904 (U. S. G. S. P. P. 20, p. 93). *Gubik sand.*—Surficial deposit of brownish sand or loam with some silt; 10 to 15 ft. thick. Supposed to be Pleist. Uncon. overlies Colville series. Named for Eskimo name of Colville River, along which it forms the surficial terrane of the coastal plain.

Guelph dolomite.

Silurian: Ontario.

J. Hall, 1852 (Pal. N. Y., vol. 2, pp. 340, 341). *Galt ls.*—The fossils from Galt, Canada West, are peculiar, being nearly all new species, and, with one or two exceptions, different from those within the limits of N. Y. In 1848 I visited the locality and obtained many other species. From nature of the ls., which appeared to succeed the well-characterized ls. of Niagara Falls, and from similarity of some of the fossils with those of Onondaga salt group of N. Y., I was inclined to refer the fm. to base of latter group. A simple inspection of plates 79–84 will show that these fossils are typical of a distinct period from that of Niagara group; and though the few species yet known from base of Onondaga salt group of N. Y. seem scarcely sufficient to indicate a well-marked period, or to claim positive identity in age with those of the Galt ls., yet we are compelled either to regard them thus, or to rank the latter as a group entirely distinct from any yet recognized. The Galt fossils as a group are not only distinct from those of Niagara period, but equally distinct from those of succeeding geological periods of Lower and Upper Helderberg lss. They do in fact make a nearer approach to those regarded as devonian types than to any group of silurian age; and yet we are able to prove their position to be quite below the ls. holding *Pentamerus galeatus* and numerous other silurian species which characterize the lss. at base of the Helderberg. And whether we regard them as of the age of Onondaga salt group or not, we know that they lie above the strata typified by the numerous fossils already described as belonging to Niagara group, and strictly should form no part of that group. It is true, nevertheless, that in many places to W. of Cabot Head the Niagara group is very similar in lithological character to Onondaga salt group, though less argill., and never friable, as some beds of latter are. [In a footnote on p. 341 of vol. cited above appears the following quotation from letter by Mr. [A.] Murray to Mr. [Wm.] Logan, the Geologist of Canada, dated Dec. 24, 1850: "With regard to the age of the group of rocks which appear at Galt, and which Mr. Hall proposes to class as a part of the Gypsiferous [†Onondaga salt group] instead of the Niagara fm., this season's examination has tended to show that his suggestion is founded upon correct data." Other portions of Murray's letter were published by Hall in Pal. N. Y., vol. 3, 1859.]

J. D. Dana, 1857 (Canadian Nat. and Geol., vol. 1, p. 411), included *Galt ls.* in Onondaga period, but placed it beneath Onondaga salt group.

W. E. Logan, 1863 (Canada Geol. Surv. Repts. Prog. 1843–63, pp. 336–344). *Guelph fm.*—In Canada the Niagara rocks are succeeded by a series of strata which appear to be wanting in N. Y. They are largely developed in neighborhood of Guelph and Galt, and we have designated the series as *Guelph fm.* It consists of very fossiliferous light-colored dolomites (drab, reddish, buff, light-gray and whitish), often very porous, has small drusy cavities, and frequently is made up of brilliant crystalline strongly coherent grains. Approx. thickness 160 ft. Overlies brown bituminous strata and black, hard, compact bituminous dol. Underlies Onondaga salt group. The Guelph fm. appears to be absent from N. Y., and in Canada it probably has the form of a great lenticular mass, the limit of which btw. Niagara and Guelph is uncertain, though it appears to extend beyond Ancaster.

E. J. Chapman, 1863 (Canadian Jour., n. s., vol. 45, pp. 215–216). Many fossils of *Guelph fm.* are identical with those of Niagara beds, but others appear to be confined to this fm. At present Guelph fm. can only be regarded as a provisional group, its strata appearing more or less to merge into underlying Niagara beds, and in some localities, also, to offer a passage into Onondaga deposits.

J. D. Dana, 1864 (Manual of geol.), used *Salina period* to replace his Onondaga period, and included in his Salina period, but below his Onondaga salt group, the *Guelph epoch, or that of the Guelph and Galt lss.*

J. Hall, 1865 (Am. Jour. Sci., 2d, vol. 39, pp. 353–355), included *Galt or Guelph ls. of Canada* in Niagara group, stating that as it includes an entirely different set of fossils from Niagara ls. he very naturally inferred it belonged to next higher fm., *Onondaga salt group.* [In 1867 (N. Y. State Mus. Nat. Hist. 20th Ann. Rept., pp. 305–308) Hall still considered the ls. at Galt to be "clearly above the great Niagara ls. of the falls," but he included it in his Niagara group.]

A. L. Arey, 1892 (Rochester Acad. Sci. Proc., vol. 2, pp. 104–107), announced "discovery of the strata of the Guelph fm. in Rochester, N. Y.," where it consists of 4 ft. of dark-gray mag. ls. overlying typical Niagara ls.

H. Ries, 1899 (N. Y. State Geol. 17th Ann. Rept.). The upper memb. of this fm. [Niagara ls., now called Lockport dol.] is known as *Guelph ls.,* but it is not coextensive with lower memb. It forms a lenticular bed about 20 mi. long and extends from Rochester westward.

J. M. Clarke and C. Schuchert, 1899 (Sci., n. s., vol. 10, pp. 874–878), included *Guelph dol.* in Niagaran but excluded it from Lockport dol., as did J. M. Clarke 1900 and 1902; A. W. Grabau 1901, 1902, 1906, 1908, 1909; E. O. Ulrich and C. Schuchert 1902; C. Schuchert 1903; J. M. Clarke 1903; C. A. Hartnagel 1903, 1905, 1908, 1912; and G. H. Chadwick 1908.

J. M. Clarke, 1902 (N. Y. State Mus. Bull. 52, pp. 433–434), referring to fauna collected by Prof. Arey at Rochester, stated: It is thus clear the fauna is not simply a local expression of a late stage of Lockport dol. fauna, but represents the true *Guelph fauna* of Ont. In 1903 (N. Y. State Mus. Bull. 69, p. 865) Clarke recognized two invasions of *Guelph fauna* in N. Y., the first of which entered from the W., penetrated as far E. as Orleans Co., and then retreated; the second invasion reached as far E. as vicinity of Rochester, and was separated from first invasion by an interval during which 30 to 40 ft. of Niagaran dolomites was deposited. In 1903 (N. Y. State Mus. Mem. 5, pp. 9–13) J. M. Clarke and R. Ruedemann named the rocks containing these two invasions of Guelph fauna the *Upper Shelby dol.* and *Lower Shelby dol.,* which they appear to have included in Lockport dol., although Clarke the same year (N. Y. State Mus. Hdb. 19) excluded Guelph from Lockport and included his Upper Shelby and Lower Shelby dolomites in the Guelph. (See under *Shelby dol.*) Several geologists had expressed uncertainty as to whether the Guelph was present at Niagara Falls, but in 1906 (N. Y. State Mus. 58th Ann. Rept., 1904, vol. 1, p. 18) J. M. Clarke stated that Guelph fauna had been found in upper layers of the dolomites lying above crest of the falls and forming the reefs of the upper rapids.

C. A. Hartnagel, 1907 (N. Y. State Mus. Bull. 114), included in Lockport dol. of Rochester and Ontario Beach quads. the beds containing the Guelph faunas. (See his section under *Shelby dol.*) He stated: "The Guelph fauna is an alien fauna from the west, which temporarily displaced the Lockport fauna." In 1908, however, Hartnagel and D. H. Newland (N. Y. State Mus. Bull. 123) excluded Guelph dol. from Lockport dol. but included it in Niagaran.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 28), included Guelph in upper part of Lockport dol., while C. A. Hartnagel in 1912 (N. Y. State Mus. Hdb. 19), as in former years, excluded Guelph from Lockport dol. In U. S. G. S. Niagara folio, No. 190, 1913, the Lockport dol. includes any Guelph element that may be present there.

M. Y. Williams and W. A. Parks, 1913 (Canada Geol. Surv. Guidebook 4), excluded *Guelph fm.* from Niagara, as did Williams in 1914 (Canada Geol. Surv. Summ. Rept. 1913, pp. 179–188).

C. Schuchert, 1914 (Geol. Soc. Am. Bull., vol. 25, p. 308), stated that in highest beds of Lockport dol. in Niagara Gorge are the precursors of Guelph fauna.

R. S. Bassler, 1915 (U. S. Nat. Mus. Bull. 92, vol. 2, pl. 4), included Guelph in the Lockport.

M. Y. Williams, 1916 (Geol. Soc. Am. Bull., vol. 27, pp. 148–149), excluded Guelph from Lockport and called top memb. of Lockport the *Eramosa beds*, on which he stated the Guelph rests conformably. In 1919 (Canada Geol. Surv. Mem. 111, No. 91 geol. ser.) Williams defined Guelph fm. as intermediate btw. Niagara group below and Cayugan group above, and defined top of Lockport dol. (and Niagara group) as consisting of *Eramosa* beds.

E. R. Cumings, 1922 (Hdb. Ind. Geol., pt. 4, p. 456), stated he believed the Guelph faunas, which began to invade in Lockport time, continued to live on in a sea of gradually increasing salinity, long after Lockport time and conditions had passed.

E. O. Ulrich and R. S. Bassler, 1923 (Md. Geol. Surv. Sil. vol.), included Guelph in Lockport (as did C. Schuchert in 1924 ed. of his Textbook of geol., p. 264). On pp. 259–260 of Md. Geol. Surv. Sil. vol. Ulrich and Bassler called attention to "well-established presence of the Guelph fauna in Orleans Co., N. Y., within 12 miles of Lockport, hence well within the area that may justly be regarded as containing the typical expression of the *Lockport dol.* The Guelph fauna has also been found to the east, at Rochester, where most of the fossils described as belonging to this fauna by Clarke and Ruedemann were collected. Its horizon has also been established in the gorge section at Niagara Falls. At all these and other places in N. Y. it occurs in the upper part of the series of dolomitic lss. to which the term Lockport ls. was originally applied. Whatever of stratigraphic significance we may give to the one or more zones containing the Guelph fauna, the fact remains that these zones are included in the Lockport. It is for this reason mainly that we have decided to abandon the term *Chicago group*, and to use instead the older name *Lockport* for the upper of the two *groups* into which the Niagaran series is here divided." [Ulrich and Bassler used their *Lockport group* as a time term, and in Central States included in it all beds from base of Laurel ls. to top of Louisville ls., which they classified as of post-Guelph and pre-Cayuga age.]

The beds to which *Guelph fm.*, *Guelph beds*, *Guelph ls.*, and *Guelph dol.* have been applied have usually been included in Niagara group. In Ontario they have usually been treated as a distinct fm. In N. Y. the beds containing the Guelph fossils are treated by U. S. Geol. Survey as an indivisible portion of upper part of Lockport dol. (See under *Niagara group* and *Lockport dol.*)

Guenette granite aplite.

Pre-Cambrian: Quebec.

F. F. Osborne, 1935 (Quebec Bur. Mines Rept. Minister Mines 1934–35, pt. E, pp. 18, 19, 25, map).

Guernsey formation.

Mississippian: Southeastern Wyoming (Hartville uplift).

W. S. T. Smith and N. H. Darton, 1903 (U. S. G. S. Hartville folio, No. 91). *Guernsey fm.*—Massive gray ls., underlain by ss., with 3 to 20 ft. of conglomeratic qtzite at base. Thickness of fm. 75 to 200 ft. Contains Miss. fossils. Uncon. underlies Hartville fm. and rests uncon. on Algonkian Whalen group and also on intrusive granites of Algonkian (?) age. [Mapped around town of Guernsey.]

†Guertie sand.

See *Gerty sand*, the approved spelling of the geographic name.

†Gueydan formation.

Tertiary (lower Miocene or Oligocene): Southern Texas coastal plain.

T. L. Bailey, March 28, 1924 (Sci., n. s., vol. 59, pp. 299–300). *Gueydan fm.*—Consists of (descending): (1) Brownish-pink latite or andesite tuff; (2) in places a bed of pink and green mottled massive bentonitic clay; (3) yellowish-white trachyte tuff; (4) at base a coarse cgl. 20 ft. thick. Uncon. underlies Oakville ss. and uncon. overlies Frio fm. Named for exposures on Gueydan ranch and survey, in SE. part of McMullen Co., Tex.

T. L. Bailey, 1926 (Univ. Tex. Bull. 2645). *Gueydan fm.*—Volcanic tuffs interbedded with fluviatile deposits which have been derived mainly from these tuffs. Occupies strat. position btw. Frio clay (redefined by writer) and Oakville ss. Divided into 3 members, named (descending) Chusa memb., Soledad memb., and Fant memb.

Same as Catahoula tuff; Catahoula has priority, and "Gueydan" has been discarded.

Gueydan group.

Oligocene and Miocene(?): Southern Texas coastal plain.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 700–727). Miss Ellisor has identified about 80 typical Vicksburg species of Foraminifera from lower Olig. subsurface strata of Tex. The Olig. beds above this Vicksburg zone carry faunas of younger age and constitute a major part of Olig. section in Tex. The name *Vicksburg group* is therefore likely to be misleading. *Gueydan group* is proposed to designate all strata btw. Fayette fm. (Eo.) and Oakville fm. (Mio.). Gueydan of Bailey (applied to the clays and tuffs of SW. Tex. now referred to Catahoula) has been dropped in favor of older name, and *Gueydan* is therefore available and appropriate to apply to all strata btw. Fayette below and Oakville above. In East Tex. the group comprises only Catahoula fm. In SW. Tex. it is divided into Frio fm. below and Catahoula fm. above. In subsurface sections in deep wells along the coast it is divided into (descending): Catahoula (lower Mio. or upper Olig.); unnamed subsurface strata of middle Olig. age (*Discorbis* zone, *Heterostegina* zone, and *Marginulina* zone); Frio (middle or lower Olig.); and subsurface Vicksburg strata (lower Olig.). The subsurface middle Olig. strata may be the down-dip extension of lower and middle part of Catahoula fm. in outcrop.

Guilford slate.

Silurian (?): Southeastern Vermont.

C. H. Hitchcock, 1912 (Vt. State Geol. 8th Ann. Rept., p. 127). Sl. known as *Guilford sl.* in early days was later known as *Leyden phyllite*.

Guilmette formation.

Middle Devonian: Western Utah (Gold Hill district).

T. B. Nolan, 1930 (Wash. Acad. Sci. Jour., vol. 20, No. 17, Oct. 19, pp. 421–432). *Guilmette fm.*—Chiefly dol. but contains a number of thick ls. beds and several lenticular brownish sss. The most characteristic dol. is a fine-grained rock, dark to medium gray on fresh fracture, weathering lighter shades of gray and containing numerous vugs almost completely filled with white coarsely crystalline dol. Also contains striking dark dolomites filled with fragments of tubular corals. Thickness 890 to 1,200 ft. Is uncon. overlain by Madison ls. (early Miss.), and uncon. overlies Simonson dol. Named for exposures in Guilmette Gulch, Gold Hill region.

See also U. S. G. S. P. P. 177, 1934.

Güines limestone.

Oligocene or Miocene: Cuba.

R. H. Palmer, 1934 (Jour. Geol., vol. 42, No. 2, p. 134).

Gulf series (or epoch).

The provincial series of Upper Cret. sediments of Southwestern States and the time covered by their deposition. For definition see U. S. G. S. Bull. 769, p. 59.

†Gulf group.

Tertiary: Gulf Coastal Plain.

See under †*Atlantic group.*

†Gullette Bluff beds. (In Wilcox group.)

Eocene (lower): Southwestern Alabama.

J. E. Brantly, 1920 (Ala. Geol. Surv. Bull. 22, pp. 148–150). *Gullette Bluff beds,* a name applied to all of Nanafalia fm. above unfossiliferous "Coal Bluff beds." Thickness 60 to 175 ft.; at Gullette Bluff 168 ft. Lower 50 ft. characterized by *Gryphaea thirsae.* The top bed of underlying "Coal Bluff beds" consists of 20 ft. of white to yellow cross-bedded massive sands with blue clay lenses. On this the Gullette Bluff beds rest.

Named for exposures at Gullette Bluff, Wilcox Co.

Gunflint iron-formation.

Pre-Cambrian (middle Huronian): Northeastern Minnesota (Gunflint Lake region and Vermilion district).

C. R. Van Hise and J. M. Clements, 1901 (U. S. G. S. 21st Ann. Rept., pt. 3, pp. 401–409, map). *Gunflint fm.*—Iron-bearing; carbonated slates, ferruginous slates, and jaspilites. To SW. changes to coarse amphibolitic and magnetitic quartz rock and a banded rock containing pyroxene and chrysolite. Basal fm. of upper Huronian (Animikie series), of Algonkian system. Underlies upper Huronian sl. [Rove sl.] and lies uncon. above Knife slates.

J. M. Clements, 1903 (U. S. G. S. Mon. 45, pp. 374–387, etc.). *Gunflint fm.*—An iron-bearing fm., consisting of bands of ferruginous carbonates, quartz, magnetitic quartz, magnetitic ore, and augite, hypersthene, hornblende, olivine, grünerite, and magnetite rocks, all apparently representing altered forms of some original ferruginous rocks. Thickness probably 800 to 1,000 ft. Overlain by Rove sl. Rests on rocks of different character and of varying age, from Ely greenstone to W. to Ogishke cgl. and Knife Lake slates still farther W. Occurs at base of Upper Huronian (Animikie) of Algonkian system. Well developed on N. shore of Gunflint Lake.

C. R. Van Hise and C. K. Leith, 1909 (U. S. G. S. Bull. 360) and 1911 (U. S. G. S. Mon. 52), assigned this fm. to upper Huronian, of Algonkian system.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), changed name to *Gunflint iron-fm.,* assigned the fm. to middle Huronian, and stated that it is of Algonkian type.

†Gunnison formation.

Upper Jurassic: Central western Colorado.

G. H. Eldridge, 1894 (U. S. G. S. Anthracite-Crested Butte folio, No. 9). *Gunnison fm.*—Qtzites and shales with a little ls.; at base heavy white qtzite 50 to 100 ft. thick, usually in a single bed; above it, in some cases succeeded by other ss. layers, is a blue fossiliferous ls.; remainder of fm. consists of gray, drab, pink, and purple clays and marls, through which run thin intermittent beds of drab ls. Thickness 300 to 450 ft. Assignment to late Juratrias is based upon its strat. and lithologic correspondence with Atlantosaurus beds on E. flanks of Rocky Mtns and upon similarity of its molluscan fauna to that of those beds, although in this more western region no vertebrate remains have yet been discovered in it. Rests uncon. on eroded Maroon cgls. or on older fms. Underlies Dakota fm.

C. W. Purington, 1898 (U. S. G. S. 18th Ann. Rept. pt. 3, pp. 758–764). *Gunnison sh.*—Upper memb. of Jura; consists of 700 ft. of gray shattered siliceous shales with interbedded layers of friable light-colored ss. Overlies La Plata ss. and underlies Dakota ss. in Telluride quad.

W. Cross, 1899 (U. S. G. S. Telluride folio, No. 57). Lower memb. of Gunnison fm. is here named *La Plata ss.* and upper memb. is named *McElmo fm.* Latter is same as Gunnison fm. restricted of Purington. Thickness 600–900 ft.

According to A. A. Baker, C. H. Dane, and J. B. Reeside, Jr. (U. S. G. S. P. P. 183, 1936), the Gunnison fm. of Cross is same as Morrison fm.

Named for exposures in canyon of Gunnison River, Delta and Mesa Counties.

Gunnison River series.

Pre-Cambrian: Colorado.

T. S. Lovering and others, 1935 (geol. map of Colo.). *Gunnison River series.*—Comprises the oldest sed. and igneous rocks exposed in Colo., which are considered to be older than and uncon. separated from Needle Mtns group of SW. Colo. and the qtzite and schist of Coal Creek, Jefferson Co., eastern Colo., and to be much older than Front Range granite group of Colo. Includes Irving greenstone, Dubois greenstone, River Portal mica schist, and Black Canyon schist of SW. Colo.; Idaho Springs fm. of eastern and central Colo.; Swandyke hornblende gneiss of central Colo.; and unnamed gneisses, schists, and greenstones in different parts of State. Named for exposures in Black Canyon of Gunnison River.

Gunn Peak formation.

Carboniferous (?): Central Washington (Snohomish County).

C. E. Weaver, 1912 (Wash. Geol. Surv. Bull. 7, pp. 34–50). *Gunn Peak fm.*—Metamorphosed qtzites, slates, schists, interbedded volcanic flows, crystalline ls., and conglomeratic qtzite. Thickness 10,000 ft. No fossils, but in composition and general appearance very closely resembles Cache Creek fm. of B. C., which is known from fossils to be Carbf.; therefore provisionally assigned to that period. Named for Gunn Peak region.

Gunpowder granite.

Pre-Cambrian: Northeastern Maryland (Baltimore County).

E. B. Knopf and A. I. Jonas, 1929 (Md. Geol. Surv. Baltimore Co. Rept., pp. 104, 125). *Gunpowder granite.*—Medium-grained potassic granite that contains biotite and muscovite in varying proportions. Intrudes Glenarm series. Is assigned to late pre-Camb. Named for fine outcrops along Gunpowder Falls.

†Gunsight formation. (In Cisco group.)

Pennsylvanian: Central northern Texas.

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, pp. 133–145). *Gunsight fm.*—Shales, sandy shales, and thin lss., approx. 100 ft. thick, underlying Breckenridge fm. and overlying Bunger fm. Top memb. is *Gunsight ls.*, which forms a continuous ledge where not obscured by overlying sands and cgls.

Included in Graham fm.

Named for Gunsight, Stephens Co.

Gunsight limestone member (of Graham formation).

Pennsylvanian: Central and central northern Texas.

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, pp. 133–145). *Gunsight ls.* is top memb. of Gunsight fm. [See 1919 entry under †*Gunsight fm.*]

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31; Univ. Tex. Bull. 2132, pp. 126, 127–137, charts, etc.). *Gunsight ls.*—A memb. of Graham fm. (of Cisco group) in Brazos River Valley. Is Campophyllum bed of Drake. Varies somewhat in different counties, but usually consists of two thin ls. layers separated by 20 to 60 ft. of yellow sh. Overlies South Bend sh. and underlies Wayland sh. [In sections given in this rept the upper ls. is 1 to 20 ft. thick, the lower ls. 1 to 12 ft. thick, and the separating beds 1 to 60 ft. thick.]

Named for Gunsight, Stephens Co.

Gunstock gneiss.

Age (?): Eastern New Hampshire (Winnipesaukee quadrangle, Lake Winnipesaukee region).

L. V. Pirsson and H. S. Washington, 1906 (Am. Jour. Sci., 4th, vol. 22, p. 505). The igneous rocks of Belknap massif are in contact with micaceous gneisses along W. bdy. They constitute a distinct fm. worthy of special study. Since lower valley of Gunstock River is cut in this gneiss we may provisionally, for purposes of reference, term it *Gunstock gneiss*. [Petrographic and chemical descriptions.]

Gunter sandstone member (of Van Buren formation).

Lower Ordovician (Beekmantown): Central Missouri.

S. H. Ball and A. F. Smith, 1903 (Mo. Bur. Geol. and Mines vol. 1, 2d ser., p. 26). *Gunter ss.*—Fine to coarse-grained ss., in places siliceous, in places qtzitic, 0 to 18 ft. thick; the 3d ss. of Swallow. Uncon. overlies Proctor ls. and underlies Gasconade ls. in Miller Co.

Subsequently the lower 35 to 235 ft. of Gasconade fm. was, for faunal reasons, split off from the Gasconade and named *Van Buren fm.* The Gunter is now included in the Van Buren.

C. L. Dake, 1930 (Mo. Bur. Geol. Mines vol. 23, 2d ser., p. 148). Ulrich has questioned vigorously the propriety of using *Gunter* for the basal sss. of next younger beds [Van Buren] above the Eminence in SE. Mo., on grounds they are not of same age as the Gunter of type section at Hahatonka [Gunter or Hahatonka Springs, Camden Co., Mo.]. Since these beds are basal deposit of an encroaching sea, over an eroded landmass, it is to be presumed they are not everywhere of exactly same age, any more than, for example, the basal beds of the St. Peter. That these sands do, however, mark the base of a single encroachment of the sea, seems to writer to be rather clearly established. This seems to be borne out by nearly continuous tracing in deep wells, in which typical Van Buren residues are recovered from just above a ss. that occupies strat. position of the Gunter. It is believed the usage of *Gunter* for the ss. lying btw. the Eminence (including Proctor) and the Van Buren is quite justified in SE. Mo.

Gurabo formation.

Miocene: Dominican Republic.

C. J. Maury, 1919 (Sci., n. s., vol. 50, p. 591).

Gurnee formation. (In Pottsville formation.)

Pennsylvanian: Central northern Pennsylvania (Tioga County).

G. H. Ashley and S. H. Cathcart, 1932 (Pa. Topog. and Geol. Surv. Bull. 102A, p. 6). *Gurnee fm.*—Ss., black sh., and fire clay, with 3-foot coal bed in upper part. Thickness present 30 to 200 ft. Forms upper part of Pottsville in Tioga Co. Overlies Sharon cgl. Type loc. vicinity of Gurnee [Tioga Co.].

Guthrie dolomite.

Permian: Central northern Texas (King County).

M. G. Cheney, 1929 (Univ. Tex. Bull. 2913, p. 26, pl. 1). *Guthrie dol.*—Two beds of white dol., upper of which is 1 to 6 ft. thick and locally fossiliferous. The lower memb. is usually separated from the upper by a sandy gyp. 1 to 5 ft. thick. It grades locally into gyp. This memb. is usually 1 ft. thick, but in some areas attains a thickness of 5 ft. Underlies town of Guthrie, King Co., and outcrops along South Wichita River or Salt River E. of the town. Included in Double Mtn group. Younger than Quanah gyp. and older than McCaulley dol. of Fisher Co.

A. M. Lloyd and W. C. Thompson, 1929 (A. A. P. G. Bull., vol. 13, pl. 9, p. 948). *Guthrie dol.* lies 150 ft. below Childress dol. and 90 ft. above Acme dol., and in midst of Dog Creek sh. interval. The *Acme dol.* can be correlated with reasonable certainty with McCaulley beds of Fisher Co.

G. H. Norton, 1929 (A. A. P. G. Bull., vol. 13, pp. 955–956). Some geologists correlate Guthrie dol. with Aspermont dol.; others believe Guthrie is older than Aspermont.

Guthrie Creek member (of Harrodsburg limestone).

Mississippian: Southern Indiana.

P. B. Stockdale, 1929 (Ind. Acad. Sci. Proc., vol. 38, pp. 233–242). *Guthrie Creek memb. of Lower Harrodsburg ls.*—Calc. sh. to shaly ls., blue gray, weathering light yellow; in places sandy. Top memb. of Lower Harrodsburg. Thickness 2 to 10 ft. Overlies Leesville ls. and underlies the more massive, more regular ls. of the Upper Harrodsburg. Named for exposures along Guthrie Creek, in SE. part of Lawrence Co.

Gutoskey sand.

Eocene (Jackson): Southern central Texas (Austin County).

L. P. Teas, 1933 (A. A. P. G. Bull., vol. 17, No. 12, pp. 1461, 1464). *Gutoskey sand* (subsurface) is in basal 40 ft. of Whitsett fm., and is 17 ft. thick.

Guttenberg limestone member.

Middle Ordovician (Trenton): Northeastern Iowa, northwestern Illinois, southeastern Minnesota, and southwestern Wisconsin.

G. M. Kay, 1928 (Sci., n. s., vol. 67, p. 16). *Guttenberg ls.*—Middle memb. of Decorah fm. At type section (in bluff of Miss. River just NW. of town of Guttenberg, Clayton Co., Iowa) it consists of 15½ ft. of brownish fine-textured ls. Northward from this locality this ls. grades into sh. In NW. Ill. the Guttenberg is the "oil rock" memb. at base of Galena fm. In SE. part of outcrop in Iowa the lss. have been irregularly dolomitized. Fossils are of basal Trenton (Rockland) age. Is overlain by Ion memb. and underlain by Spechts Ferry memb. [See also Kay, Jour. Geol., vol. 37, No. 7, Oct.–Nov. 1929, pp. 639–671, who stated this memb. corresponds to "*Ctenodonta* bed" of Minn. and is of late Black River age.]

This memb. has been slightly redefined by Kay. See 1935 entry under *Spechts Ferry memb.* His 1935 rept included this memb. in Trenton.

G. M. Kay, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 295), showed his Guttenberg memb. as present in SE. Minn. and NW. Ill. On p. 286 he showed his Guttenberg memb. as composing all of his restricted Decorah present near Platteville, Wis.

Guyandot sandstones. (In Sewell formation.)

Pennsylvanian: Southern West Virginia.

M. R. Campbell, 1902 (U. S. G. S. Raleigh folio, No. 77). *Guyandot ss. lentil of Sewell fm.*—Coarse heavy-bedded ss. or cgl., 0 to 100 ft. thick, lying about 150 ft. above base of Sewell fm. and 80 to 100 ft. below Harvey cgl. lentil. Well exposed along Guyandot River from Pineville [Wyoming Co.] to Gilbert [Mingo Co.].

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, p. 196). *Lower Guyandot ss.*—Persistent, massive to current-bedded, medium-grained, grayish white to light gray, 0 to 50 ft. thick. Underlies Sewell A coal, lies 0 to 5 ft. above Sewell ("Davy") coal, and *lies 35± ft. below Guyandot ss.* Forms steep slopes and cliffs.

Guye formation.

Miocene: Central Washington (Snoqualmie quadrangle).

G. O. Smith and F. C. Calkins, 1906 (U. S. G. S. Snoqualmie folio, No. 139). *Guye fm.*—Shales, sss., grits, sl., and cgls. with a little ls. and chert, and with interbedded basalt and rhyolite flows. Thickness 0 to 3,500 ft. Well exposed on Guye Creek. Known only in NW. ¼ of Snoqualmie quad. Not found in contact with other Mio. sed. fm. (Ellensburg). Flora (identified by F. H. Knowlton) indicates probable Mio. age. Uncon. overlain by Keechelus volcanics.

Guyet formation.

Mississippian: British Columbia.

W. A. Johnston and W. L. Uglow, 1926 (Canada Geol. Surv. Mem. 149, p. 19).

Guysborough formation.

Cambrian: Nova Scotia and Canada.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 195).

Guzman formation.

Cretaceous: Puerto Rico.

H. A. Meyerhoff, 1931 (N. Y. Acad. Sci. Scientific surv. of Porto Rico and Virgin Islands, vol. 2, pt. 3, p. 267).

Gwin coal group.

A group of coal beds in upper part of Pottsville fm. (Penn.) of central Ala. Includes Thompson Mill and Gwin coals.

Gwinn series.

Pre-Cambrian (middle Huronian): Northwestern Michigan (Marquette County).

R. C. Allen, 1914 (Jour. Geol., vol. 22, pp. 567, 569). *Gwinn series.*—Consists of (descending): (1) Black ls., gray sl., and graywacke, 30 to 100 ft. thick; (2) iron fm., 50 to 125 ft. thick; (3) black sl. and gray sl.; and (4) cgl. and arkose, 0 to 60 ft. Includes [?] Goodrich qtzite. Uncon. underlies Princeton series and uncon. overlies Archean, the lower Huronian not being recognized in Gwinn dist.

Named for occurrence at and around Gwinn, Marquette Co.

Gwinnup sand.

A subsurface sand, of Penn. age, in Dibrell pool, Coleman Co., north-central Tex., lying at 1,900 ft. depth.

†Gwynedd shale. (In Newark group.)

Upper Triassic: Southeastern Pennsylvania (Bucks and Montgomery Counties).

B. S. Lyman, 1893 (Pa. Geol. Surv. geol. and topog. map of Bucks and Montgomery Counties), and 1895 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 3, pt. 2, pp. 2589–2638). *Gwynedd shales.*—Black, dark-gray, and red or green shales, 3,500 ft. thick. Underlie Lansdale shales and overlie Norristown shales. Exposed at Gwynedd tunnel.

Same as Lockatong fm.

Gym limestone.

Permian (Manzano): Southwestern New Mexico (Deming region).

N. H. Darton, 1916 (U. S. G. S. Bull. 618, pp. 19, 35). *Gym ls.*—Chiefly light-gray ls., in greater part massively bedded, showing brecciated structure in many beds. In Gym Peak (type loc.) and vicinity the lower memb. is dark, and the one next above of much lighter color, with abrupt change btw. them, and thickness there is at least 700 ft. Occurs in central and SE. parts of Florida Mtns and central part of Victorio Mtns and extends part way around N. end of Tres Hermanas Mtns. Total thickness near 1,000 ft. Rests uncon. on Magdalena, Lake Valley, and older fms. and is uncon. overlain by Lobo fm. (Triassic ?) or Tert. aggl. Fossils discussed.

Habana formation.

Upper Cretaceous: Cuba.

R. H. Palmer, 1934 (Jour. Geol., vol. 42, No. 2, p. 128).

Hackberry shale.

Upper Devonian: Northeastern Iowa.

C. L. Webster, 1889 (Am. Nat., vol. 23, pp. 242, 243). *Hackberry group.*—Yellowish-brown argill. shales and sometimes slightly aren. shaly ls. which weathers to stiff yellow or buff clay. Thickness 45 ft. Overlies blue clay of upper Hamilton (Genesee) age. Highest Dev. fm. in State. Contains two rich and varied faunas, one at base and the other occupying remainder of the division. Replaces provisional name "Rockford shales."

As thus originally defined the Hackberry included, according to C. L. Fenton (Am. Jour. Sci., 4th, vol. 48, 1919), Owen substage of Calvin, 1897, and Cerro Gordo substage of Fenton, 1919, and overlies Sheffield fm. of Fenton 1919 (=Hamilton of Webster, 1889), which has since been renamed *Juniper Hill fm.* by A. O. Thomas. The name *Hackberry substage* has also been applied (W. N. Norton, 1897, Iowa Geol. Surv. vol. 6, pp. 138–151) to the lower or Cerro Gordo substage plus the underlying Sheffield of Fenton. The Hackberry of Webster plus the Sheffield of Fenton is Lime Creek sh. of the literature, according to Fenton.

Named for exposures at Hackberry Grove, Cerro Gordo Co.

Hackberry shale. (In Cimarron group.)

Permian: Central southern Kansas and northwestern Oklahoma.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, pp. 3, 46). *Hackberry shales.*—Crumbling shales, chiefly maroon-colored, 0 to 20 ft. thick, overlying Day Creek dol. and underlying Big Basin ss. Included in Kiger div.

F. W. Cragin, 1897 (Am. Geol., vol. 19, pp. 362–363). *Taloga fm.* is proposed to include Big Basin ss. and Hackberry sh. [See under *Taloga fm.*]

R. C. Moore, 1920 (Kans. Geol. Surv. Bull. 6, pt. 2). The sh. underlying Big Basin ss. memb. of Greer fm. has previously been called *Hackberry sh.*, a name that is inapplicable because of prior use for an Upper Dev. div. of Iowa.

Named for Hackberry Creek, Clark Co., Kans. There is no record of any other name having been introduced to replace this one.

Hackett sandstone. (In Hinton formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 297, 353). *Hackett ss.*—Usually greenish gray, sometimes massive, but often made up of thick hard flags separated by streaks of sh. Thickness 10 to 75 ft. Underlies Payne Branch sh. and overlies Hackett sh.; all members of Hinton group [fm.]. Type loc. in Mercer Co., on ridge road btw. Hackett and Island Creeks, 1.6 mi. NE. of Pettry, where it makes a plateau along the ridge. Also observed in Summers Co.

Hackett shale. (In Hinton formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 297, 354). *Hackett sh.*—Red sh. with occasional streaks of ss. or ls.; occasional marine fossils in lower part; thickness 30 to 290 ft. Underlies Hackett ss. and overlies Tophet ls.; all members of Hinton group [fm.]. Type loc. same as Hackett ss. Also observed in Summers Co.

Haddam granite gneiss.

Pre-Triassic: Central southern Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull 6, pp. 115, 143, 145, and map). *Haddam granite gneiss.*—Light-colored, rather fine-grained granitic aggregate of quartz and feldspar, through which are scattered small isolated flakes of biotite. Hornblende sometimes present, also some plagioclase. Small garnets common. In most outcrops is a moderately thick-bedded gneiss. Typical rock is well exposed about Higganum [in Haddam Twp] on both sides of Conn. River.

Hades quartzite.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, pp. 37, 47–53, 281, 287, 290). *Hades qtzite.*—Qtzites, 1,000 ft. thick in Utah and 250 ft. thick in Colo., underlying Jefferson lss. and composing basal fm. of Nevadan series (late Devonic) in Utah and Colo. In Colo. the fm. underlies Elbert shales. Is widely but erroneously termed *Ogden qtzite.* [Page 47.] There seems, therefore, to be but small doubt but that Lodore qtzite is really the eastern extension of the mis-called Ogden qtzite, that the erosion uncon. at its base is the horizon of Early Devonic regional planation, and that rather than propose a new title to take the place of Blackwelder's preoccupied Geneva, Powell's original term Lodore qtzite, should not be discarded. However, should the Lodore section finally prove to include more than the "Ogden" bed, the latter may still be christened the *Hades qtzite,* from the hot, gloomy, and inhospitable canyon on E. side of Duchesne River, where it is so finely exposed in towering cliffs. [Page 50.] This Hades qtzite, as it is recently designated, is believed to be continued eastwardly in the Lodore qtzite of Powell at the Colo. line. [Powell used *Lodore group* (not *Lodore qtzite*), and stated that it consisted of soft sss. and shales with cgls. at base.]

Hagerman lake beds.

Pliocene (upper): Southern Idaho (Gooding and Twin Falls Counties).

H. T. Stearns, 1932 (Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept 1, 1932) and 1936 (Jour. Geol., vol. 44, No. 4, pp. 434–439). *Hagerman lake beds.*—Nearly horizontal and partly consolidated buff to white clay and silt beds, which in most places contain a gravel cap 20 ft. thick and occasional pebbly lenses and sandy beds near top. In places basic tuffs and flows are present, and one thin intercalated subaqueous basalt flow 200 ft. below top is conspicuous for many mi. along Snake River. Near mouth of Salmon Falls Creek the fm. contains a 20-foot bed of diatomite. Thickness 600± ft. Underlies, uncon., the undiff. series of early Pleist. basalts, and is younger than Banbury volcanics. Vertebrate fossils in upper part are late Plio., according to Gidley. Type loc., Hagerman Valley, Gooding and Twin Falls Counties, where it forms prominent bluffs along Snake River.

Hague gneiss.

Pre-Cambrian: Northern New York (Adirondacks).

H. L. Alling, 1918 (N. Y. State Mus. Bull. 199). *Hague gneiss.*—A garnet sillimanite gneiss, included in Grenville series. Max. thickness 50 or 60 ft.; decreases to E. Underlies "Dixon" schist and overlies Trumbull gneiss. Type loc. is Lakeside mine at Hague [Warren Co.]. In Johnsburg Twp., Warren Co., there is 50 ft. of qtzite which writer regards as = Hague gneiss, and which he calls *Hague qtzite.* It is decidedly purer than its equiv. at Hague.

H. L. Alling, 1919 (Am. Jour. Sci., 4th, vol. 48, pp. 52–54). At Rowland Graphite Company's abandoned mine, Johnsburg, Warren Co., the *Hague gneiss* becomes a qtzite; near Conklingville it is highly micaceous. Typically exposed at Hague and at Graphite. Thickness 60 ft. In places underlies and in places is included in "Dixon" schist.

Hague quartzite.

See under *Hague gneiss.*

Hague gas sand.

See under *Sheffield gas sand.*

Haida member. (Of Queen Charlotte series.)

Cretaceous: British Columbia.

C. H. Clapp, 1914 (Canada Geol. Surv. Summ. Rept. 1913, p. 21). [Assigned to Jurassic, but J. D. MacKenzie, on pp. 36 and 43, assigned it to Cret., as he did in 1916 (Canada Geol. Surv. Mem. 88, p. 54).]

R. W. Goranson, 1924 (Am. Jour. Sci., 5th, vol. 8, p. 175). *Haida fm.* is Cret.

Haiku volcanics.

Pleistocene (late): Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Haiku volcanics.*—Basalt and tuff. Included in lower part of Honolulu volcanic series [q. v.]. Occurs in Haiku Valley, along Haiku Stream and the coast near its mouth.

Hailey shale.

Upper Cretaceous: Central Wyoming.

S. W. Williston, 1905 (Sci., n. s., vol. 22, p. 504). *Hailey shales.*—Dark-blue shales containing new armored dinosaur. Thickness 30 to 75 ft. I believe the beds are of Niobrara age, but they may represent Belly River. Have been traced continuously more than 40 mi. Thin to W., where they plainly show littoral and river disturbances. Rest conformably on Benton. [Apparently named for town of Hailey, in E. part of Fremont Co.]

Probably lower part of Frontier fm.

Haileyburnian.

Pre-Cambrian: Ontario.

W. G. Miller and C. W. Knight, 1920 (Canadian Min. Jour., vol. 41, p. 653).

Haileybury formation.

Ordovician: Ontario.

G. S. Hume, 1920 (Am. Jour. Sci., 4th, vol. 50, p. 301).

Haines granite.

Post-Triassic and pre-Tertiary: Northeastern Oregon (Baker quadrangle).

U. S. Grant and G. H. Cady, 1914 (Oreg. Bur. Min. and Geol., Min. Res. Oreg., vol. 1, No. 6, pp. 133–144). *Haines granite.*—Coarse-grained gray hornblende-biotite granite. Intrusive. Clearly later than the Triassic rocks and much earlier than the Tert. basalt. Named for town in Baker dist.

Hakatai shale. (Of Unkar group.)

Pre-Cambrian: Northern Arizona (Grand Canyon).

L. F. Noble, 1914 (U. S. G. S. Bull. 549). *Hakatai sh.*—Red argill. sh. grading upward into aren. red sh. and ss. Nearly all beds contain sun cracks and ripple marks. Thickness 580 ft. Cut by a thick sill of intrusive diabase, which has converted the sh. into sl. and jasper near the contact. Conformably overlain by Shinumo qtzite and conformably underlain by Bass ls., all of which belong to Unkar group. Named for Hakatai Canyon, where typically exposed.

Hale formation. (In Morrow group, Arkansas.)

Hale sandstone member (of Morrow formation, Oklahoma).

Pennsylvanian: Northern Arkansas and northeastern Oklahoma.

G. I. Adams and E. O. Ulrich, 1905 (U. S. G. S. Fayetteville folio, No. 119). *Hale ss. memb. of Morrow fm.*—Soft thick-bedded yellowish-brown ss. and flaggy layers, with some carbonaceous and light-colored shales. Basal part of Morrow fm. Uncon. overlies Pitkin ls. Top is limited by base of Brentwood ls. memb. of Morrow fm.

A. H. Purdue, 1907 (U. S. G. S. Winslow folio, No. 154). Basal 50 ft. of *Hale fm.* usually sandy sh. interbedded with thin layers of ripple-marked ss. Rest of fm. more or less massive calc. ss., relative amounts of sand and lime varying. Thickness 100 to nearly 200 ft. Basal fm. of Morrow group. Underlies Bloyd sh. and overlies Pitkin ls. Usually separated from overlying Brentwood ls. memb. of Bloyd sh. by 5 to 10 ft. of black sh. like rest of Bloyd sh. Of Pottsville age.

In NE. and central eastern Okla. the basal part of Morrow fm. is called *Hale ss. memb.*

Named for Hale Mtn, Washington Co., Ark.

Hales limestone.

Cambrian (probably Upper Cambrian): Central Nevada (northern Nye County).

H. G. Ferguson, 1933 (Univ. Nev. Bull., vol. 27, No. 3, p. 15). *Hales ls.*—Almost wholly ls., of bluish-gray color, thin-bedded but with a few massive members; near base lenses and nodules of chert; at base about 50 ft. of brown shaly ls. transitional from calc. slates of underlying Tybo sh.; in places these transitional slates are absent; in upper part of fm. are one or more beds of qtzite, one of which is 200 ft. thick. Thickness of fm. 3,000± ft. Named for Hales shaft of Tybo mine, which is almost entirely within this fm. Few scanty fossils below the qtzites are pronounced by Resser to probably all be Upper Camb. Overlain by Pogonip ls. in Tybo dist. Grades into overlying and underlying fms.

Half Dome quartz monzonite.

Probably Cretaceous: Yosemite National Park, California.

F. C. Calkins, 1930 (U. S. G. S. P. P. 160, p. 126, map). Name proposed by H. W. Turner, in unpublished ms. Medium-grained light-gray rock; contains nearly equal amounts of biotite and hornblende. Chiefly nonporphyritic, but in part obscurely porphyritic. Included in Tuolumne intrusive series, in which it is next younger than Sentinel granodiorite, and next older than Cathedral Peak granite.

Named from fact that it composes Half Dome, in Yosemite Nat. Park.

Halfway horizon. (In Duchesne River formation.)

Oligocene: Eastern Utah (Uinta Basin).

See under *Randlett horizon.*

Halgaito tongue (of Cutler formation). Also **Halgaito member.**

Permian: Southeastern Utah (San Juan County) and northeastern Arizona.

A. A. Baker and J. B. Reeside, Jr., 1929 (A. A. P. G. Bull., vol. 13, No. 11, pp. 1420, 1423, 1424, 1441, 1443, 1446). *Halgaito tongue of Cutler fm.*—Red sss. and sandy sh., 0 to 430 ft. thick, forming basal part of Cutler fm. in S. part of San Juan Co. and NE. Ariz. Underlies Cedar Mesa ss. memb. of Cutler and overlies Rico fm. In earlier repts called Supai (?) fm. Well exposed near Halgaito Spring, SW. of Mexican Hat (Bluff P. O.), Utah, but btw. Lees Ferry and Kayenta, NE. Ariz.

Halifax formation.

Cambrian or pre-Cambrian: Nova Scotia.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 195).

Halifax chlorite schist.

Upper Cambrian (?): Southeastern Vermont (Windham County).

Geo. D. Hubbard, 1924 (14th Rept. Vt. State Geol., pp. 288–291 and map). *Halifax chlorite schist.*—Characteristic mineral dark-green chlorite, which composes 75 to 85 percent of rock, the remaining 15 to 25 percent being quartz. Believed to be of sed. origin. Thickness of fm. probably 2,000 to 3,000 ft. and possibly more. Overlies Readsboro schist, with which it is interbedded at the contact. We did not become familiar with next fm. above, which outcrops farther E., and do not know nature of the contact on that side. We have found variations from the true green chlorite schist in several places E. of the line placed as our farthest bdy. Whether they should be separated as a new fm. our studies are insufficient to determine. Is=Savoy schist of Mass., which is assigned to Ord. by Emerson.

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), assigned this fm. to Upper Camb. and=Bethel schist, but without discussion of the evidence.

Apparently named for development in Halifax Twp, Brattleboro and Wilmington quads.

Hall series.

Triassic: British Columbia.

C. W. Drysdale, 1917 (Canada Geol. Surv. Mem. 94, p. 27).

Hall.

Name applied to a Pleist. glacial lake in N. Y. (See H. L. Fairchild, Geol. Soc. Am. Bull., vol. 43, No. 3, p. 615, 1932.)

Hall Canyon formation.

Pleistocene (lower): Southwestern California (Ventura Basin).

J. E. Eaton, 1928 (A. A. P. G. Bull., vol. 12, No. 2, pp. 111–141). *Hall Canyon fm.*—A new fm., which lies uncon. above San Pedro fm. (restricted), uncon. below Palos Verdes fm. (uppermost Pleist.), and is absent btw. these 2 fms. at their type loc. Best exposed in Hall Canyon, Ventura Basin. Almost entirely marine in W. part of basin, but almost wholly nonmarine farther E. Is chiefly fine-grained yellow shaly sand, poorly bedded and poorly consolidated, with minor gray-sand layers; lenses of gravel scattered throughout, and these commonly make up large proportion of basal sediments. Lithologically very different from San Pedro fm., but its warm-water faunas are very similar to upper or warm-water faunas of San Pedro, and both are assigned to lower Pleist. Thickness 0 to 2,500 ft. Arnold included Hall Canyon fm. in San Pedro terrace deposits. The Saugus fm. of Kew includes Hall Canyon fm., San Pedro fm. (restricted), and Saugus fm. (restricted) of this rept, the latter of which is Plio.

J. E. Eaton, 1931 (A. A. P. G. Bull., vol. 15, No. 4, pp. 379–381). The term *Hall Canyon* was necessitated by reason of delimiting a lower Pleist. unit which lies in the fuller sections uncon. btw. Arnold's lower and upper San Pedro units, and which had not been previously recognized in Calif. It is highest marine lower Pleist. unit in Calif. Fauna not very distinctive.

Hall City limestone.

Carboniferous: Northern California (Klamath Mountains).

J. S. Diller, 1903 (Am. Jour. Sci., 4th, vol. 15, pp. 342–362). [Mentions (but does not describe or locate in the section, except to say it belongs to southwestern Carbf. belt) *Hall City ls.* On a later page reference is made to Hall City mines, to which one of the Carbf. lss. extends.]

Hallett sand.

A subsurface sand, of Penn. age and 40 ft. thick, in central northern Okla. In Hallett pool, Pawnee Co., it lies at 2,210 ft. depth, the Cleveland sand (25 ft. thick) at 2,140 ft., and the Peru at 2,355 ft.

†Hallopus beds.

A paleontologic name, introduced by O. C. Marsh and used in some early repts, for marine beds forming upper part of Lykins fm. of Front Range, Colo., according to J. B. Reeside, Jr.

†Halymenites sandstone.

Upper Cretaceous: Northwestern New Mexico (San Juan County).

J. J. Stevenson, 1879 (Ann. Rept. Chief of Engrs, 1879, pt. 3, p. 2257). *Halymenites ss.*—Gray to yellowish-gray ss., 50 to 80 ft. thick, lying 70 ft. above base of Laramie group.

Replaced by *Pictured Cliffs ss.*, which carries *Halymenites major* in abundance. (See C. M. Bauer, U. S. G. S. P. P. 98, 1917, p. 274.)

†Hambergian series (also †Hamburgian).

A name applied by C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 51, 53, 79), to Hamburg ls. of Nev. and to supposedly contemp. deposits in other States.

Hambre sandstone. (In Monterey group.)

Miocene (middle): Western California (San Francisco region).

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). *Hambre ss.*—Medium-textured slightly ferruginous sss. with some sandy shales. Thickness 1,200 ft. A fm. of Monterey group. Conformably underlies Rodeo sh. and conformably overlies Tice sh. Named for exposures along Arroyo del Hambre, Contra Costa Co.

Hamburg limestone.

Upper Cambrian: Eastern Nevada (Eureka region).

Arnold Hague, 1883 (U. S. G. S. 3d Ann. Rept., pp. 253, 255–259). *Hamburg ls.*—Dark-gray granular ls., surface weathering rough and ragged, with only slight traces of bedding. Rests on transition beds of shaly ls., 25 to 200 ft. thick, which forms top memb. of Secret Canyon sh. Is overlain by Hamburg sh. Thickness 1,200 ft. Exposed at Hamburg mine, Eureka dist.

†Hamburg shale.

Upper Cambrian: Eastern Nevada (Eureka region).

A. Hague, 1883 (U. S. G. S. 3d Ann. Rept., pp. 253, 255–256). *Hamburg sh.*—Yellow argill. sh., with layers of chert nodules throughout but more abundant near top. Thickness 350 ft. Overlies Hamburg ls. and underlies Pogonip ls. Best exposed opposite Hamburg and Dunderberg mines and in ravine N. of Adams Hill, all in Eureka dist.

Replaced by *Dunderberg sh.*, the name *Hamburg* being retained for the ls.

†Hamburg beds.

†Hamburg clays.

Upper Cretaceous: Western South Carolina.

E. Sloan, 1904 (S. C. Geol. Surv., ser. 4, Bull. 1, pp. 68, 72–75). *Hamburg beds*, divided into upper Hamburg and lower Hamburg, having an aggregate thickness of 181 ft. at Aiken, S. C., and consisting of fine white kaolin; white sands in micaceous kaolinitic matrix; varicolored banded sands; arkose; purple and white kaolin; arkose; subangular boulders and fragments of quartz, sl., and gneiss in arkose matrix. [Detailed section at Aiken given.] Rest uncon. on crystalline rocks and underlie Middendorf beds.

These beds were for a time considered to be of Lower Cret. age and to represent Patuxent fm., but they were later proved by C. W. Cooke and L. W. Stephenson to be of Upper Cret. age and same as †Middendorf fm. of eastern S. C. (See Ga. Geol. Surv. Bull. 40, 1923, and U. S. G. S. P. P. 140F, p. 138, 1926.) Still later "Middendorf" and "Hamburg" were proved to be Tuscaloosa fm., and both of latter names were abandoned. (See C. W. Cooke, U. S. G. S. Bull. 867, 1936.)

Named for exposures at Hamburg, Aiken Co., S. C.

†Hamburg oolite. (In Kinderhook group.)

Mississippian: Southwestern Illinois (Calhoun County).

S. Weller, 1906 (St. Louis Acad. Sci. Trans., vol. 16, pp. 464–467). *Hamburg oolite.*—Fossiliferous oolitic ls., ½ in. to 15 ft. thick at Hamburg, Calhoun Co. May be slightly younger than Glen Park ls. Is time equiv. of upper part of Louisiana ls. Overlain by "Vermicular" ss.

S. Weller, 1914 (Ill. Geol. Surv. Mon. 1, p. 14). *Hamburg oolite.*—White to yellow or flesh-colored oolitic ls., with interbedded layers of sandy sh. Thickness 1 to 15 ft. Underlies Hannibal ss. and sh., and separated from underlying Louisiana ls. by 1 to 8 ft. of brown sandy sh. Included in Kinderhook group.

Preoccupied. Appears to be same as Glen Park ls. memb. of Ulrich.

Named for Hamburg, Calhoun Co.

Hamburg slate.

Pre-Cambrian (middle Huronian): Central northern Wisconsin (Marathon County).

S. Weidman, 1907 (Wis. Geol. Nat. Hist. Surv. Bull. 16, p. 61). *Hamburg sl.*—Under this name is included the sl. fm. having considerable distribution in Berlin and Hamburg Twps, Marathon Co. It consists chiefly of sl. and sh., but graywacke and its schistose phases are abundant. Believed original fm. may have been 500 to 1,000 ft. thick in vicinity of area where now exposed. Probably extends over 75 to 100 sq. mi.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, chart opp. p. 598), assigned this fm. to middle Huronian.

Hamburg moraine.

Pleistocene (Wisconsin stage): Western New York. Shown on moraine map (fig. 8) in U. S. G. S. Niagara folio (No. 190), 1913, p. 17. Named for Hamburg, Erie Co., N. Y.

†Hamburgian.

See †*Hambergian.*

†Hamburg Mountain gneiss.

Pre-Cambrian: Northern New Jersey.

J. E. Wolff and A. H. Brooks, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, p. 439). *Hamburg Mtn gneiss.*—A complex of gneisses, of which most prominent memb. is a course banded hornblendic gneiss, resembling phases of Edison gneiss, with which possibly it might be correlated. In this belt are frequent granitic phases, which are probably intrusive bands.

In U. S. G. S. Franklin Furnace folio, No. 161, 1908, this name was discarded, the rock being an inseparable part of Byram gneiss.

Hamden limestone or member. (In Allegheny formation.)

Pennsylvanian: Southeastern Ohio (Muskingum County).

W. Stout, 1918 (Ohio Geol. Surv., 4th ser., Bull. 21, p. 173). *Hamden ls.*—Hard, dense gray or nearly black fossiliferous ferruginous ls., 1 ft. to 5 ft. 8 in. thick.

Lies just below or within Oak Hill clay, and on or only a few ft. above Lower Kittanning coal. Named because it occurs at strat. horizon of Hamden iron ore of southern Vinton and northern Jackson Counties.

In later repts called *Hamden memb.*

Hamden sand.

A subsurface sand of Buena Vista (Miss.) age, in Jackson and Vinton Counties, SE. Ohio.

Hamill series.

Pre-Cambrian: British Columbia.

J. F. Walker and M. F. Bancroft, 1929 (Canada Geol. Surv. Mem. 161, p. 9).

Hamilton group (where indivisible **Hamilton formation**).

Middle Devonian: New York, Pennsylvania, Maryland, and western Virginia.

L. Vanuxem, 1840 (N. Y. Geol. Surv. 4th Rept., p. 380). *Hamilton group.*—Shales of dark-blue and olive colors and ss. West Hamilton is locality where the group is well characterized. Underlies Moscow shales and overlies Skaneateles shales. Near Cayuga Lake is separated from Moscow shales by encrinal ls. [As thus defined, *Hamilton group* applied to the sh. later named *Ludlowville sh.*]

L. Vanuxem, 1842 (Geol. N. Y., pt. 3, pp. 150–163). *Hamilton group.*—Includes all masses noticed in Ann. Repts under heads of *Skaneateles shales, Dark slaty fossiliferous sh., Compact calc. blue sh., Olive sh., Ludlowville sh., Encrinal ls., Moscow sh., Shales near Apulia and Sherburne,* and *Cazenovia group.* Overlies Marcellus shales and underlies Tully ls. Named for Hamilton, Madison Co., which contains no other rock. Thickness 300 to 700 ft. Extends from near the Hudson to Lake Erie. [Vanuxem's Marcellus of this rept included the lower black shales and 100 to 200 ft. of overlying shaly beds not so highly colored as underlying beds, or apparently the shales later named *Cardiff.*]

J. Hall, 1843 (Geol. N. Y., div. 4, 4th dist., pp. 184–211). *Hamilton group.*—Includes Pyritiferous rock and Third graywacke of Eaton; the Ludlowville, Moscow, and Skaneateles shales; the Dark slaty fossiliferous sh., Compact calc. blue sh., Olive shales, Shales near Apulia and Sherburne; Cazenovia group, Encrinal ls., etc. of Ann. Repts. Rests on Marcellus sh. and is overlain by Tully ls., where present, and by Genesee sl. where the Tully is absent. Along E. shore of Cayuga lake btw. Springport and Ludlowville the group consists of (descending): (1) Moscow sh., (2) Encrinal ls., (3) Ludlowville shales, (4) olive or bluish fissile sh., (5) compact calc. blue sh., (6) dark slaty fossiliferous sh. resting on Marcellus sh. [In later years Hall included Marcellus sh. and Portage and Chemung in his Hamilton group, and still later he excluded them.]

During succeeding years the name *Hamilton* had considerable usage as a time term in each of the following senses: (1) Including Chemung group, Portage group, and Marcellus sh.; (2) including Genesee, Tully, Hamilton, and Marcellus; (3) including Tully, Hamilton, and Marcellus; (4) including Hamilton and Marcellus only. (See †*Hamilton period.*)

In 1885 (N. Y. State Geol. Rept. 1884, pp. 9–22) J. M. Clarke drew top of Hamilton at base of Tully ls. (where top is still placed), but he included Marcellus at base. In 1888 (Trans. Am. Inst. Min. Engrs., vol. 16, pp. 941–947), 1890 (Am. Geol., vol. 6, pp. 205, 206), and subsequent repts, C. S. Prosser definitely placed base of Hamilton at *top* of Marcellus, and gave thickness of Marcellus in central N. Y. as 50 to 82 ft. This definition was followed by G. D. Harris, 1891, by H. S. Williams, 1891, by J. M. Clarke, 1894, 1903, etc., by J. Hall, 1894, 1897, etc., by J. M. Clarke and C. Schuchert 1899, etc., and by nearly all other geologists, and became the established definition of *Hamilton fm.* until 1930 (Cooper). In central N. Y. the Cardiff sh. has been included in Hamilton fm. in some repts, included in Marcellus sh. in some repts, and excluded from both in other repts. The predominant usage, however, has been to restrict Marcellus to the scantily fossiliferous black shales, 62 to 145 ft. thick, and to include the Cardiff in Hamilton fm.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 116–134, 214–236), published the results of a detailed study he had made of the Hamilton strata across N. Y., stating that he found it necessary to "redefine" *Hamilton group* so as to include (ascending) Marcellus sh., Skaneateles fm., Ludlowville fm., and Moscow fm.; and he divided the fms. into many members, to most of which he applied new names. He reported that the occurrence of 3 crinoidal lss. in the Hamilton (Menteth, true Tichenor, and Centerfield, in descending order) had led to many errors in correlating the subdivisions and in drawing the correct boundaries btw. them. He also stated: The results of present study emphasize the close faunal and strat. relationships of the Marcellus with the Hamilton and show that the Marcellus is actually a facies of the Hamilton. Also: The Hamilton beds at type loc. are Skaneateles sh., and the only available good exposures in the Twp are those of the Skaneateles. But according to his map (p. 128) the Ludlowville is present over a large part of Hamilton Twp and to within less than ½ mi. of the village itself. [As first *defined* by Vanuxem the Hamilton rested on Skaneateles sh. and was overlain by encrinal ls. (where that ls. is present), or by Moscow sh. This places it in position of Ludlowville sh.] Cooper also stated that the Marcellus (black) of western N. Y. (Oatka Creek memb.) is characterized by a *Leiorhynchus* fauna; that Cardiff memb. (light-colored) to E. (which he showed is in part contemp. with Oatka Creek memb.) is also characterized by a *Leiorhynchus* fauna; that farther E. the deposits correlated with Cardiff memb. are divisible into (descending) Pecksport memb., Solsville memb., and Bridgewater memb.; that the upper or Pecksport memb. is characterized by a *Leiorhynchus laura* fauna, but that Hamilton species predominate in it; that Solsville memb. is characterized by typical Hamilton fossils in an unusual assemblage; that in underlying Bridgewater memb. the *Leiorhynchus* fauna is common and is associated with many typical Hamilton fossils; and that the underlying Chittenango memb. is nearly barren of fossils. He also stated that the overlying Skaneateles sh. in western N. Y. contains the Second *Leiorhynchus* zone of Cleland, while still higher (in his Ledyard memb. of Ludlowville sh.) occurs the Third *Leiorhynchus* zone of Cleland. Throughout his paper he seemed to recognize the Hamilton fauna as distinct from the Marcellus. He also stated: Writer believes that the Marcellus, and perhaps also the Onondaga, cannot be divorced from the Hamilton.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 190, 192, 369), included Marcellus in Hamilton.

The following recent repts exclude Marcellus from Hamilton: [See list under *Marcellus sh.*]

The following recent repts include Marcellus in Hamilton: [See list under *Marcellus sh.*]

W. Goldring, 1936 (letter dated Jan. 17, 1936). [See under *Marcellus sh.*]

For many years the U. S. Geol. Survey excluded Marcellus sh. from the Hamilton, as did the N. Y. State Survey and most geologists. The N. Y. State Survey has now, however, adopted Cooper's 1930 definition, which includes Marcellus sh. in *Hamilton group*. This is also present classification of U. S. Geol. Survey in N. Y. In south-central Pa., however, it still treats Hamilton and Marcellus as distinct fms.

†Hamilton period.

A term applied by J. D. Dana, in early editions of his Textbook of geology, to include the time covered by deposition of Genesee, Hamilton, and Marcellus shales. He appears to have first used the name in Canadian Nat., vol. 1, No. 6, p. 411, 1857. Subsequently the name was used by others, but it was long ago discontinued, since it conflicts with the earlier and better-established use of Hamilton.

Hamilton Switch sand.

A subsurface sand, of Penn. age, in central eastern Okla. that is correlated with lower sand of Dutcher sand group.

Hamlin shale.

Pennsylvanian: Southeastern Nebraska.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, pp. 8–9). ***Hamlin sh. fm.***, 42 to 46 ft. thick, is top fm. of Admire group. Includes, in section from Forest City, Mo., to DuBois, Nebr. (descending) Oaks sh., Houchens Creek ls., and Stine sh. [Derivation of name not stated.]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 50), adopted this name as defined by Condra, assigned the bed to Perm., but did not state derivation of name.

Hammar Bluff formation.

Post-Miocene: Western Washington (King County).

S. L. Glover, Feb., 1936 (Pan-Am. Geol., vol. 65, No. 1, pp. 77–78). *Hammar Bluff fm.*—Sands and clays, probably lacustrine, of post-Mio. age. The clays are bluish gray when damp and light gray when dry. The sands are free of iron. Source of material may be Puget fm. The beds are gently arched, with crest of anticline near Hammar Bluff, a few mi. E. of Auburn, King Co. Overlain by glacial deposits.

Hammar-Haindl sandstone.

A subsurface sand, of Ord. age and 10 to 50 ft. thick, in Oklahoma City field, NE. Okla. Lies 150± ft. higher than Kinter ss. and 0 to 20 ft. below School Land ss. (See A. A. P. G. Bull., vol. 16, No. 10, pp. 967+.) Derivation of name not stated.

Hammond fire clay. (In Kanawha formation.)

Pennsylvanian: Northeastern West Virginia.

R. V. Hennen and D. B. Reger, 1913 (W. Va. Geol. Surv. Rept. Marion, Monongalia, and Taylor Counties, p. 369). ***Hammond fire clay,*** flinty, 1 to 4 ft. thick, overlies or replaces Upper Mercer coal. Named for Hammond, Marion Co.

Hammondville gneiss.

Pre-Cambrian: Eastern New York (Essex County).

D. H. Newland, 1908 (N. Y. State Mus. Bull. 119, pp. 43–50). *Hammondville gneiss.*—A quartz-plagioclase gneiss; ore-bearing; of doubtful relationships. Dr. I. H. Ogilvie considers this gneiss to be eruptive, but it is believed by Mr. Newman and writer that it does not belong to the intrusive series, or at least that it is not contemporary with the other members of it. Occurs at Hammondville mines, Crown Point Twp, Essex Co.

Hampden diabase. (In Newark group.)

Upper Triassic: Southern central Massachusetts and Connecticut.

B. K. Emerson, 1898 (U. S. G. S. Holyoke folio, No. 50). ***Hampden diabase,*** the "posterior sheet" of Percival. Is younger than Holyoke diabase, and is interbedded in Longmeadow ss. [Derivation of name not stated, but the map shows that, like the Holyoke diabase, it crosses Hampden Co. in belt extending from Ingleside southwestward into Conn., and also occurs farther N. in Holyoke Range, Hampshire Co., Mass.]

†Hampshire formation.

Upper Devonian: Eastern West Virginia, western Virginia, and western Maryland.

N. H. Darton, 1892 (Am. Geol., vol. 10, pp. 13, 17, 18). *Hampshire fm.*—Uppermost series of Dev. sediments in central Appalachian Va. Overlies Jennings fm. and underlies Carbf. Pocono ss. No doubt comprises representatives of the Catskill in their entirety or in greater part. Characterized by thin-bedded, relatively hard, more or less micaceous sss. with sh. intercalations, in greater part of dull-red, dark-gray, and brown color. Thickness 1,000 to 1,400 ft.

Same as Catskill fm., older name, and has been discarded by U. S. Geol. Survey.

Named for Hampshire Co., W. Va.

Hampton shale.

Lower Cambrian: Southwestern Virginia, western North Carolina, and eastern Tennessee.

M. R. Campbell, 1899 (U. S. G. S. Bristol folio, No. 59, p. 3). (Name proposed by A. Keith.) *Hampton sh.*—Over Unicoi ss, lies a bed of sandy sh. which has a thickness of about 600 ft., and which forms most of front of Holston Mtn. Overlying Hampton sh. is another ss. [Erwin qtzite], which appears on summit of the mtn, but it does not extend within limits of this quad.

Named for exposures at Hampton, Carter Co., Tenn., in area mapped by A. Keith.

†Hampton clays.

Pleistocene: Coastal Plain of South Carolina.

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 12, 20). *Hampton clays.*—A fresh-water deposit. In quiet waters, remote from inner or fresh-water shore line, the fine argill. silts deposited to form the white clays of Hampton type, in favored localities, which constituted a broken belt extending from Garnet by Walterboro, by Summerville and thence easterly. While in western area the Hampton clays occur chiefly along a high ridge (60 to 100 ft. M. L. T.), the eastern area affords somewhat similar matter, but as third bottoms, and in depressed basins on the plateaus, at approx. corresponding elevations. Closely identified with the white clay, a more extensive mantle of clay, mottled in highly contrasting pink, red, white, and yellow designs, is substantially coextensive with Lafayette series S. of the littoral line; it roughly conforms to the preestablished topographic irregularities. Its extent may be observed from a point near Jamisons, Orangeburg Co., to Ladsons, Berkeley Co., a distance of approx. 69 mi. At this stage it is probable that the marine Pleist. beds were forming along the ocean beaches. While these white clays accumulated in good bodies in elevated spots, along a favored zone, the argill. silts which were deposited more southerly appear in places interbedded in thin seams with fine varicolored sands, aggregating 20 to 40 ft. in thickness. This appears to have been associated with the formation of an outer reef, barrier, or ridge, designated Ten Mile sands, on seaward slope of which the marine Pleist. deposited. The Ten Mile sands include a capping of reddish loam, which probably represented the terminal expression of the Hampton red clays. The Hampton clays extend from Marion Co. on N. to Beaufort Co. on S. and W. into Aiken, Lexington, Lee, Darlington, and Marlboro Counties.

C. W. Cooke (personal communication 1935). The beds described are Pleist. terrace deposits or beds derived from them.

Probably named for development in Hampton Co.

Hampton granodiorite.

Devonian (?): Southeastern New Hampshire.

A. Wandke, 1922 (Am. Jour. Sci., 5th, vol. 4, pp. 148, 149). [No description. Name is simply listed on pages cited and assigned to Dev. (?). Probably named for exposures at Hampton or in Hampton Twp. Rockingham Co.]

Hampton formation.

Mississippian: Central northern Iowa.

L. R. Laudon, 1930 (Geol. Soc. Am. Bull., vol. 41, p. 174). *Hampton fm.*—Includes beds 3, 4, 5, and 6 of the Kinderhook at Burlington, [SE. Iowa], the Wassonville ls. of Washington Co., the Legrand beds of Marshall Co., and the Chapin, Maynes Creek, Eagle City, and Iowa Falls members of the Kinderhook of north-central Iowa. It carries *in its base* an abundant fauna that can be definitely correlated with upper part of Chouteau of Mo. The upper part of the Hampton carries a fauna derived from this lower fauna. The Hampton is named for county seat of Franklin Co., where it is best exposed. [See also Pan-Am. Geol., vol. 52, Dec. 1929, p. 376, where foregoing is also printed.]

L. R. Laudon, 1931 (Iowa Geol. Surv. vol. 35, pp. 344, 347, 366, 387, 419–431). *Hampton fm.* is proposed for the Kinderhook beds of Iowa that lie stratigraphically above English River fm. and below oldest beds of Osage series. In north-central Iowa is divided into (descending) Iowa Falls, Eagle City, Maynes Creek, and Chapin members. [p. 344.] In eastern and north-central Marshall County, in western Tama Co., and in southern Grundy Co. the Hampton fm. is represented by LeGrand beds, which are correlated, by fossils, with lower part of Eagle City memb., Maynes Creek memb., and upper part of Chapin memb. [pp. 419–431]. In SE. Iowa Hampton fm. is divided into North Hill memb. below and Wassonville memb. above. [p. 366.] Hampton fm. has been proposed for the Kinderhook ls. series exposed in north-central Iowa btw. Sheffield fm. below and Alden ls. above. [p. 387.]

R. C. Moore, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 243, 245), shows major part of Hampton of Iowa as of Burlington and Fern Glen age and basal part only of Chouteau (Kinderhook) age.

L. R. Laudon (on pp. 246–247 of 1935 rept. cited above) stated that not only is the Hampton pre-Osage, but that overlying Gilmore City is also pre-Osage, and that both are of Kinderhook age. He stated that recent work in Iowa has shown conclusively that Hampton fm. should be redefined by excluding from it North Hill memb. as exposed at Burlington and the lower gray ls. ledges of Chapin memb. of north-central Iowa, which are correlatives of the Chouteau of Mo. The redefined Hampton fm. then becomes a distinct lithologic and faunal unit which distributionally follows closely the overlying Gilmore City fm. Fern Glen species are absent in Hampton fauna, which carries all of late Kinderhook species in abundance. The Burlington overlaps the Hampton in SE. Iowa, and Gilmore City fm. lies uncon. on Hampton where exposed near Iowa Falls.

Hampton sand (Archer County, Texas).

See *Lower Freeman sand.*

Hampton moraine.

Name applied to a moraine of Illinoian age in Dakota Co., Minn. (See F. W. Sardeson, Pan-Am. Geol., vol. 59, No. 4, pp. 263–264, 1933.)

Hanaupah formation.

Lower Paleozoic (?): Southeastern California (Inyo County).

F. M. Murphy, 1933 (Calif. State Div. Mines, Rept. 28 of State Min., July–Oct. 1932, pp. 329–356). *Hanaupah fm.*—Predominantly fine-textured slaty or flaggy rocks, generally with irregular lumpy fracture; quartz-biotite schist with irregular streaks of sericite, finely banded with gray, green, or chocolate-brown thin, lenticular, and generally corrugated stripes; regularly banded micaceous schist with megascopic tourmaline and magnetite, and characterized by small oval dark-green spots; flaggy rock in which epidotized stripes alternate with finer ones of light-colored aren. and calc. material; and a few beds of white to pink qtzite. Thickness 1,500± ft. Top fm. of Telescope group (lower Paleozoic?) of S. part of Panamint Range. Conformably overlies Redlands dolomitic ls. and conformably underlies Death Valley fm. (lower Paleozoic?). [Derivation of name not stated but probably derived from proximity to Hanaupah Canyons, shown on his map.]

†Hanbury slate.

Pre-Cambrian (upper Huronian): Northwestern Michigan (Menominee district).

C. R. Van Hise and W. S. Bayley, 1900 (U. S. G. S. Menominee folio, No. 62). *Hanbury sl.*—Black and gray clay slates, gray calc. slates, graphite slates, graywackes, thin beds of qtzite, occasional beds of ferruginous dol. and rarer bodies of ferruginous chert and iron oxide. Thickness 2,000 to 3,000 ft. Top fm. of Algonkian. Overlies Vulcan fm. and uncon. underlies Lake Superior ss.

C. R. Van Hise and C. K. Leith in 1911 (U. S. G. S. Mon. 52) abandoned *Hanbury sl.*, it being a synonym of Michigamme sl., the older name.

R. C. Allen, 1915 (Jour. Geol., pp. 703+). Michigamme sl. is *upper* Huronian and *Hanbury sl.* is older, and is *middle* Huronian.

R. C. Allen, 1919 (Am. Inst. Min. and Met. Engrs. Bull. 153, p. 2593). Major part (5,000+ ft.) of *Hanbury sl.* is upper Huronian. Lower 500 ft. in places is middle Huronian, and name *Loretto sl.* is here proposed for this basal part, which is absent in places.

Named for exposures in Hanbury Hill, just S. of Hanbury Lake, and for development over broad area around Hanbury Lake.

Hance formation. (In Pottsville group.)

Pennsylvanian: Southeastern Kentucky and northeastern Tennessee.

G. H. Ashley and L. C. Glenn, 1906 (U. S. G. S. P. P. 49, pp. 33, 37, 207, and pl. XLA). *Hance fm.*—Mainly sh., some ss., and coal; 600 ft. thick; underlying Mingo fm. and overlying Lee ss. in Cumberland Gap coal field. Top defined by base of Lower Hance coal; base defined by top of Lee ss. Correlated with lower part of Sewell fm.

Named for Hance Ridge, Bell Co., Ky.

Hancock limestone.

Silurian (upper Cayugan): Northeastern Tennessee.

A. Keith, 1896 (U. S. G. S. Morristown folio, No. 27, p. 3). *Hancock ls.*—Interbedded massive and shaly lss., of blue, gray, or dove color; massive beds more frequent at bottom and top, and attain thickness of 20 ft. In general appearance strongly resembles Chickamauga ls. Fossils throughout fm. show it to be of upper Sil. age. Thickness 0 to 450 ft. Underlies Chattanooga sh. and overlies Rockwood fm.

Foregoing is original definition at type loc. The name, however, first appeared in print in 1894, in U. S. G. S. Estillville folio (No. 12), by M. R. Campbell, who accepted Keith's name, correlating the rocks of Estillville quad. with those of Morristown quad. He described the fm. as consisting of blue fossiliferous ls., very sandy at top and bottom, 180 to 275 ft. thick, underlying Chattanooga black sh. and overlying Rockwood fm.

The beds at type loc. are now considered to be of Sil. (upper Cayugan) age, but the fm. as described and mapped in early repts on SW. Va. is chiefly of Helderberg age (Lower Dev.). At present the U. S. Geol. Survey uses *Cayuga ls.* for the beds of Sil. age in SW. Va. and *Helderberg ls.* for the beds of Lower Dev. age in SW. Va.

Named for Hancock Co., Tenn.

Hancock amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name long applied locally to an amygdaloid in upper part of Ashbed group. The mineralized part is the Hancock lode. Named for its occurrence in old Hancock mine, Houghton Co.

Hancock conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name locally in use many years for cgl. No. 17, which is also called *Hancock West cgl.* Occurs near top of Ashbed group. Named for exposures in a ravine just E. of Hancock mine, Houghton Co.

Hancock flow.

Includes Hancock amygdaloid and the underlying trap.

Hancock sand.

A subsurface sand in the Penn. (probably in Bandera sh.) of Chautauqua Co., SE. Kans. Is said to occur 100± ft. below Peru sand and at approx. horizon of Weiser sand of Montgomery Co., Kans.

Hancock West conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan (Houghton and Keweenaw Counties).

A. R. Marvine, 1873 (Mich. Geol. Surv. vol. 1, pt. 2, pp. 77, 83, and chart). Is cgl. No. 17 of Houghton Co.

Is same as Hancock cgl. of Ashbed group.

Probably so named because it lies W. of old Hancock mine, Houghton Co.

Handy Lake volcanics.

Pre-Cambrian: Ontario.

G. Rittenhouse, 1936 (Jour. Geol., vol. 44, No. 4, pp. 455, 469).

Hanford formation.

Lower Cambrian: Newfoundland and New Brunswick.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 196). *Hanford fm.*, Canada and New Brunswick, assigned to Camb.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4). *Hanford fm.*—Fossiliferous green and red sh. with manganiferous lss., and at base phosphorite containing Radiolaria and sponges. Forms upper part of Lower Camb. Discon. overlain by Manuels fm. (Middle Camb.) and discon. underlain by Smith Point fm. (Lower Camb.).

Hanfordian series.

Lower Cambrian: Newfoundland.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4). *Hanfordian series.*—Upper part of Lower Camb. of Newfoundland. Represented by *Hanford fm.* Discon. underlies Middle Camb. (Manuels fm.) and discon. overlies Etcheminian series. [Derivation of name not stated.]

Hanging Rock sandstone.

Pennsylvanian: Central western Indiana (Vermilion County).

F. H. Bradley, 1869 (Ind. Geol. Surv. 1st Ann. Rept., p. 157). Heavy-bedded soft ferruginous ss., 20 ft. thick, locally known as *Hanging Rock ss.* Caps the Hanging Rock and is underlain by black slaty sh. with ironstone nodules. Supposed equiv. of Mahoning ss. [memb. of Conemaugh fm.] of Ohio.

Named for the Hanging Rock, on Big Vermilion River, Vermilion Co.

Hanging Rock sandstone.

Pennsylvanian: Southeastern Illinois (Wabash and Edwards Counties).

A. H. Worthen, 1875 (Ill. Geol. Surv. vol. 6, pp. 51–60), described 2 sss. in upper Coal Measures of Wabash and Edwards Counties, one of which he called *Hanging Rock ss.* and the other *Mount Carmel ss.* Hanging Rock bluff is 3 mi. NE. of town of Mount Carmel, Wabash Co.

†Hanging Rock limestone. (In Allegheny formation.)

Pennsylvanian: Southeastern Ohio.

E. Orton, 1878 (Ohio Geol. Surv., vol. 3, pp. 888, 892–895, pls. opp. pp. 889, 900, 912, 921). *Hanging Rock or Gray ls.*—Light-gray semicrystalline fossiliferous ls., 1 to 12 ft. thick, lying strat. btw. Shawnee and Zoar lss. in Hanging Rock dist. Called "Ferriferous" ls. by E. B. Andrews.

Later repts state that it is same as Vanport ls. memb.

Named for Hanging Rock dist., where it is commercially important.

Hanna formation.

Eocene: Central southern Wyoming (Carbon County).

C. F. Bowen, 1918 (U. S. G. S. P. P. 108, pp. 228, 231, etc.). *Hanna fm.*—Alternating beds of sh., ss., cgl., and numerous coal beds. The sh. is dark-gray, yellowish and carbonaceous; the sss. are white, gray and brown, massive to thin-bedded and cross-bedded; the cgls. and conglomeratic sss. contain pebbles of chert, granite, qtzite, ss., Mowry sh., Cloverly cgl., etc. Contains fossil bones of vertebrates, Eocene fresh-water shells, and abundance of Eocene leaves. Thickness 7,000± ft. Uncon. underlies North Park fm. and uncon. overlies Ferris fm. Is well exposed to W. and N. of town of Hanna, Carbon Co. Is upper part of "Upper Laramie" of Veatch, the lower part of that unit being Ferris fm. of this rept.

Hanna Valley bed. (In Strawn formation.)

Pennsylvanian: Central Texas (Colorado River Valley).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 374, 383). *Hanna Valley bed.*—Clay, 200 or more ft. thick, with some shaly ss. in places. Memb. of Strawn div. Overlies Cottonwood Creek bed and underlies Rough Creek bed.

Named for Hanna Valley, San Saba or Mills Co.

Hannibal shale. (Of Kinderhook group.)

Mississippian: Northeastern Missouri, southeastern Iowa, and western Illinois.

C. R. Keyes, 1892 (Geol. Soc. Am. Bull., vol. 3, p. 289). *Hannibal shales.*—Fossiliferous shales, 70 to 100 ft. thick; upper portion sandy in places and often forms rather compact shaly ss.; lower portion bluish or greenish clay shales. Equiv. of Vermicular shales of Swallow. Underlies Chouteau ls. and overlies Louisiana ls. All included in Kinderhook group.

This continued for many years to be definition of Hannibal sh.

R. C. Moore, 1928 (Mo. Bur. Geol. and Mines, vol. 21, 2d ser., table opp. p. 282), showed Glen Park ls. as underlying Hannibal sh. and overlying Louisiana ls. in Jersey and Calhoun Counties, SW. Ill., and that elsewhere (Pike Co., central western Ill., and Pike and other counties in Mo.) the Hannibal is uncon. on Louisiana ls., the Glen Park being absent. In 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 245) Moore showed Hannibal sh. as present in only W Ill. and NE. Mo., and that in S. Ill. and SE. Mo. the Fern Glen is uncon. on Glen Park, through absence of Chouteau ls. and Hannibal sh.

Named for exposures at Hannibal, Marion Co., Mo.

Hanover limestone.

Mississippian (lower): Southwestern New Mexico.

H. Schmitt, 1933 (Am. Inst. Min. and Met. Engrs. Contr. 39). *Hanover ls.*—Crinoidal ls. forming top part of Lake Valley ls. in Central Mining dist. or Santa Rita-Hanover-Fierro dist. Because of deformation by the centrifugal peripheral thrust during intrusion of Hanover "stock" the Hanover ls. varies in thickness from 80 to 150 ft., the max. measurement having been made at the crest and the minimum on a limb of the peripheral anticline. Average thickness in undisturbed areas 110 ft. No other fms. in vicinity of Hanover are known to be greatly deformed.

Hanover shale.

Upper Devonian: Western New York (Chautauqua County).

See †*Silver Creek sh.*, 1912, 1919, 1923, and 1924 entries.

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60, pp. 96, 98, 193, 198, 199, 357). *Hanover sh.* overlies Pipe Creek sh. and underlies Dunkirk sh. (Canaseraga ss.). Traceable from Lake Erie to Genesee River, where, still overlain by the Dunkirk, it becomes main mass of Wiscoy sh. Basal part of Wiscoy=Pipe Creek sh.

G. H. Chadwick, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, p. 352), included this sh. in Chemung group.

Named for exposures in town of Hanover, Chautauqua Co.

Hanoverian series.

Name proposed by C. [R.] Keyes (Pan-Am. Geol., vol. 65, No. 4, 1936, p. 315) to include Shakopee dol. and New Richmond ss. (=Richmond ss. of Keyes). Named for twp in Allamakee Co., NE. Iowa.

Happy Hollow limestone. (In Scranton shale.)

Pennsylvanian: Southeastern Nebraska, eastern Kansas, and northeastern Oklahoma.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, pp. 40, 58). [See under *White Cloud sh.*]

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, p. 53), restricted *White Cloud sh.* to beds below Happy Hollow ls., named the sh. overlying Happy Hollow ls. *Cedar Vale sh.*, and stated that *Happy Hollow ls.* persists from Nebr. to Okla. with several ft. of sh. btw. it and Rulo ls.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 211–212). *Happy Hollow ls.* is traceable from Cass Co., Nebr., across Kans., and at least to S. part of Osage Co., Okla. Thickness 1 to 8 ft. Overlies White Cloud sh. and underlies Cedar Vale sh. Typically it is a single massive bed of pinkish-brown, somewhat impure ls. that weathers in rounded or irregularly porous surfaces; in places very sandy and locally soft and shaly. Type loc., Happy Hollow Creek, NE. Doniphan Co., Kans. [Moore discarded Scranton sh. and treated Happy Hollow ls. as a fm. in his redefined Wabaunsee group.]

Haragan shale.

Lower Devonian (Helderberg): Central southern Oklahoma.

C. A. Reeds, 1911 (Am. Jour. Sci., 4th, vol. 32, pp. 256–268). *Haragan sh.*—Alternating blue to white shales and thin-bedded earthy lss. which weather into yellowish shales. Resembles somewhat Henryhouse sh., but instead of tendency to massive-bedded alternating series of yellow to pink earthy lss. and some sh. beds, there is predominance of sh. members and only occasionally thin ledges of earthy or crystalline ls. Thickness 0 to 166 ft.; average 100 ft. Originally included in middle of Hunton fm. Underlies Bois d'Arc ls. and overlies Henryhouse sh. Contains New Scotland fossils.

Named for exposures along Haragan Creek, Carter Co., 3 to 4 mi. SE. of Dougherty, Murray Co.

Harbison quartz diorite.

Late Jurassic or early Cretaceous: Southern California (San Diego and Imperial Counties).

W. J. Miller, 1935 (Calif. Jour. Mines and Geol., vol. 31, No. 2, pp. 115–141, map). *Harbison quartz diorite.*—Type in N. part of Harbison Canyon and vicinity, in southern Peninsular Range, where it covers 6± sq. mi., which, with exception of one small area, is only occurrence of the fm. in this area. Cuts Alpine quartz diorite. Is more acidic than the other quartz diorites of region.

Harbledown formation.

Jurassic: British Columbia.

C. H. Crickmay, 1928 (Calif. Univ. Dept. Geol. Sci. Bull., vol. 18, No. 2, pp. 56, 59).

Harbor Hill moraine.

Pleistocene (Wisconsin stage): Southeastern New York (Long Island).

J. B. Woodworth, 1901 (N. Y. State Mus. Bull. 48, pl. 1, map). *Moraine of the Harborhill stage,* included in Wisconsin epoch. Consists of gravels at Harborhill [near Roslyn] and typical till in other places.

A. C. Veatch, 1903 (Jour. Geol., vol. 11, pp. 762–776), and 1906 (U. S. G. S. P. P. 44). *Harbor Hill moraine* of Long Island is late Wisconsin, and younger than Ronkonkoma moraine.

M. L. Fuller, 1914 (U. S. G. S. P. P. 82). Harbor Hill and Ronkonkoma moraines correspond to early Wisconsin of Mississippi Valley region. Thickness of *Harbor Hill moraine* 0 to 30 ft.

Harbor Hill substage.

The time during which *Harbor Hill moraine* was deposited.

Hardesty shale.

Pennsylvanian: Eastern Kansas, northwestern Missouri, and southeastern Nebraska.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 93, 97). [For definition see first entry under *Pedee group.* Derivation of name not stated. The sh. to which this name was applied is basal part of Lawrence sh. of previous usage, which Moore here divided into (descending) Lawrence sh. [restricted], Haskell ls., Stranger fm., resting uncon. on Hardesty sh. This classification was followed by Moore and Condra in their Oct. 1932 revised chart of Penn. of Kans. and Nebr., and by N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21). See Kans.–Nebr. chart compiled by M. G. Wilmarth, 1936.]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 138). *Hardesty sh.* was not properly proposed as a strat. unit, being merely indicated in a chart, and has no standing. It is abandoned. Top of Pedee group is top of Iatan ls., although it is probable that in places there is a certain thickness of sh. btw. Iatan ls. and the post-Missouri discon. that should be included in Pedee group. [See further under *Pedee group.*]

Hardgrave sandstone.

Middle Jurassic: Northern California (Taylorsville region).

J. S. Diller, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 370–394). *Hardgrave ss.*—Red ss., 450 ft. thick, older than Thompson ls. and younger than Foreman beds. [Now known to be much older than Foreman beds.]

J. S. Diller, 1908 (U. S. G. S. Bull. 353). *Hardgrave ss.* varies from fine shaly ss. to cgl. and is almost wholly of tuffaceous character. Most common color is red, ranging from brick red to dull brown, but much of it is gray, and the two colors are intermingled irregularly in same bed. Bedding generally well marked. Thickness 450 ft. Is next younger than Trail fm. Is separated from overlying Thompson ls. by Fant meta-andesite. Is limited in distribution within Taylorsville region almost exclusively to slope of Mount Jura, E. of Taylorsville. One belt lies along W. base of Mount Jura. Named for exposures on Hardgrave's ranch, near Taylorsville.

This fm. has been classified as Lower Jurassic, but according to C. H. Crickmay, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, pp. 80–81), it is Middle Jurassic.

Hardgrave tuff.

Middle Jurassic: Northern California (Mount Jura).

C. H. Crickmay, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 81). [See under *Combe ss.*]

Hardin sandstone member (of Chattanooga shale).

Upper Devonian or Mississippian: Western Tennessee.

J. M. Safford and J. B. Killebrew, 1900 (Elements of geol. of Tenn., pp. 104, 136, 137). *Hardin ss.*—Dark fine-grained bituminous ss., weathering gray or grayish yellow; more or less phosphatic. Chiefly interesting because of close association with Swan Creek phosphate, the latter often becoming this ss. Thickness 12 or 15 ft. Overlies Camden chert and underlies Swan Creek phosphate [according to pp. 104 and 136].

Because of thinness and gradation into overlying sh. is treated as a memb. of Chattanooga sh. Uncon. overlies Pegram ls. in some areas.

Named for Hardin Co.

Harding sandstone.

Middle Ordovician: Colorado.

C. D. Walcott, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 154–167). *Harding ss.*—The lower bed is a shore-line deposit following the advance of the sea upon the land; it is formed of coarse grains of quartz and small quartz pebbles imbedded in a fine aren. matrix, and is 5 ft. thick. The succeeding layers of ss. have more or less calc. matter in the matrix; their fossils all prove the littoral origin of the sediments. The closing deposit of the ss. series is coarse drifted sand, containing numerous fragments of larger fish plates than those below. The change to succeeding shaly beds at top is abrupt, and apparently due to deepening of the water and cessation of aren. deposits. The shaly beds are 2 to 4 ft. thick, and consist of red and purple fine-grained argillaceo-aren. sh. Thickness of fm. at Harding's ss. quarry, about 1 mi. NW. of State Penitentiary, Canyon City, 86 ft. Rests uncon. on Algonkian bedded gneiss and micaceous schists. Overlain by Fremont ls.

Is now considered by E. Kirk to be of approx. late Black River or early Trenton age.

Hardinsburg sandstone. (Of Chester group.)

Mississippian: Southern Illinois, western Kentucky, and northern Tennessee.

A. D. Brokaw, 1916 (Ill. Geol. Surv. Extr. from Bull. 35) and 1917 (Ill. Geol. Surv. Bull. 35). *Hardinsburg ss.*—Moderately fine-grained yellowish-brown ss., with small amount of sh., underlying Sloans Valley [Glen Dean ls.] and overlying Golconda fm. in parts of Saline, Williamson, Pope, and Johnson Counties, SE. Ill. Thickness 80 to 100 ft.

C. Butts, 1917 (Ky. Geol. Surv. Mississippian formations of western Ky., p. 96). *Hardinsburg ss.*—Consists of (descending) shaly ss.; massive coarse-grained ss., 10 ft.; somewhat thinner-bedded ss. 10 ft. Thickness 30 to 60± ft. Underlies Glen Dean ls. and overlies Golconda fm. Named for Hardinsburg, Breckinridge Co., Ky., which is built on this ss.

Hardin School limestone. (In Wichita group.)

Permian: Central Texas (Coleman County).

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501, pp. 254–255). About 50 ft. above base of Santa Anna Branch sh. memb. of Putnam fm., and 125± ft. below top of that memb., is a dense, hard cream-colored ls. about 14 in. thick, which is a good marker. Because of good exposures on hills just N. and W. of Hardin School, in SW. part of Coleman Co., the name *Hardin School ls.* is proposed for it. It lies 9± ft. above another prominent ls., about 18 in. thick, and 5 ft. below a nonpersistent hard gray ls. 1 to 2 ft. thick.

†Hardiston quartzite.

See *Hardyston qtzite.*

†Hardistonville quartzite.

See *Hardyston qtzite.*

Hardman fire clay. (In Allegheny formation.)

Pennsylvanian: Northern West Virginia and western Maryland.

R. V. Hennen and D. B. Reger, 1913 (W. Va. Geol. Surv. Rept. Marion, Monongalia, and Taylor Counties, p. 347). *Hardman fire clay.*—Hard and flinty, 9 ft. thick. Lies immediately under Johnstown ls. and overlies Middle Kittanning coal. Mined 1 mi. N. of Hardman, Preston [Taylor?] Co.

C. K. Swartz et al., 1919 (Geol. Soc. Am. Bull., vol. 30, p. 572). *Hardman fire clay* ("Furnace" clay), underlies Mount Savage iron ore (Johnstown iron ore) and overlies Piney Mtn coal in Allegany and Garrett Counties, Md.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, p. 48, pl. 6). *Hardman ("Furnace") fire clay* underlies Little Montell coal and overlies Piney Mtn coal in Georges Creek Basin, Md.

D. B. Reger, 1924 (W. Va. Geol. Surv. Rept. Mineral and Grant Counties, p. 243). *Hardman fire clay,* 6 ft. thick, usually sandy and impure, underlies Johnstown ls. and overlies Upper East Lynn ss.

Hardwick granite.

Late Carboniferous or post-Carboniferous: Central Massachusetts and southwestern New Hampshire.

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, pp. 239–241, 317–318, pl. 34). *Hardwick gneiss* (pp. 239–241); *Hardwick gneissoid granite and granitite* and *Hardwick granite-gneiss* (pp. 317–318); *Hardwick granite* (on map, where it is described as dark thick-bedded biotite gneiss). [See also Emerson, U. S. G. S. Bull. 597, pp. 238–239, 1917, where it is described, on map, as black biotite granite around Fitzwilliam granite, and is shown as extending northward into N. H.]

Named for occurrence at and around Hardwick, Worcester Co., Mass.

Hardwick granite.

Devonian: Northeastern Vermont (Caledonia County).

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), listed this name in Dev. of "central Vt.," but without definition. Quarried W. of Hardwick, in Hardwick Twp, Caledonia Co.

Preoccupied by Hardwick granite of central Mass. and southern N. H., which is late Carbf. or post-Carbf.

Hardyston quartzite.

Lower Cambrian: Northern New Jersey and northeastern Pennsylvania.

J. E. Wolff and A. H. Brooks, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, pp. 442–443, 454–456). *Hardistonville qtzite.*—Oldest fossiliferous rock of region. Olenellus age established by Beecher and Nason. Usually bluish gray when fresh; weathers yellow or brown; often porous, limonitic; frequently contains considerable pyrite; varies in coarseness from fine cgl. to qtzite; shaly phase often present in upper part. Thickness 1 to 30 ft. Grades into overlying Wallkill blue ls. [Kittatinny ls.]. Overlies Franklin white ls. Exposed at brook section in Hardistonville and on hill 1 mi. S. of Hardistonville.

H. B. Kümmel and S. Weller, 1901 (Geol. Soc. Am. Bull., vol. 12, pp. 149–150). *Hardiston qtzite.*—Was described and named *Hardistonville qtzite* by Wolff and Brooks, from village of that name, near which there are good exposures. The shorter name used above, which is that of the township, seems preferable, however, and is here proposed. Consists of (descending): (1) Sandy shales (transition beds), 10 to 15 ft.; (2) sandy ls., 15 ft. exposed; (3) ss. or qtzite of variable composition and thickness, usually blue gray when fresh, but some beds are light yellow brown and others nearly white. Thickness 100 to 140 ft., if transition beds at top are to be included. The conglomeratic phase is known to exceed 100 ft. at a number of localities. Lower Camb. trilobites in the calc. ss. beds; no fossils in the vitreous qtzites or the arkose beds. Conformably underlies Kittatinny ls. Rests on pre-Camb. crystallines.

H. B. Kümmel and S. Weller, 1902 (N. J. Geol. Surv. Ann. Rept. State Geol. 1901), changed spelling of name to *Hardyston,* the form adopted by U. S. Geog. Bd.

Hare Indian River shale.

Devonian: Mackenzie.

E. M. Kindle, 1921 (Canada Geol. Surv. Summ. Rept. 1920, pt. B, p. 45).

Hare River shales.

Devonian: Mackenzie.

T. O. Bosworth, 1921 (Geol. Mag., vol. 58, p. 287).

Hargett sandstone. (In Chester group.)

Mississippian: Northeastern Mississippi (Tishomingo County).

W. C. Morse, 1935 (Miss. Geol. Surv. Bull. 26, pp. 9, 10). [*Hargett ss. (or a sh. memb.) of Alsobrook fm.* is shown in table on p. 9 as underlying Cripple Deer ss. (or a sh. memb.) of Alsobrook fm., and overlying ls. forming basal part of Alsobrook fm. in Tishomingo Co. The columnar section on p. 10 shows 1 ft. of ss. in middle of Alsobrook fm. Derivation of name not stated.]

Harjo sand.

A series, 10 to 70 ft. thick, of sands, sandy limes or limes, of Penn. age, with sh. breaks recorded, lying at 3,180 to 3,380 ft. depth in Cromwell oil field, Okla. Lies 175 to 250 ft. above Cromwell sand and some distance below Brunner sand, which lies 300 to 370 ft. above Cromwell sand. Named for Hannah Harjo lease of Independent Oil & Gas Co., sec. 21-10-8.

Harlan sandstone. (In Pottsville group.)

Pennsylvanian: Southeastern Kentucky and southwestern Virginia.

M. R. Campbell, 1893 (U. S. G. S. Bull. 111, pp. 28, 31). *Harlan ss.*—Mainly coarse white ss., with sandy sh. and thin coals, 880 ft. thick. At base massive ss. 100 ft. thick. Forms topmost fm. of Coal Measures in Bigstone Gap coal field of Va. and Ky. Overlies Wise fm.

Belongs to upper part of Pottsville group.

Named for Harlan Co., Ky.

Harlem gneiss.

Pre-Cambrian: Southeastern New York.

R. P. Stevens, 1867 (N. Y. Lyc. Nat. Hist. Annals, vol. 8, pp. 116-120), applied *Harlem gneiss* to one of bodies of gneiss shown on his "Section across New York [Manhattan] Island along southern shore of Spuyten-Duyvel Creek and Harlem River." In U. S. G. S. New York City folio (No. 83) the gneiss of this area is mapped as Fordham gneiss.

Harlem clay. (In Conemaugh formation.)

A name applied to the siliceous clay, 1 ft. thick, underlying Harlem coal in Ohio.

Harmon formation. (In Maysville group.)

Upper Ordovician: Southeastern Indiana.

E. R. Cumings and J. J. Galloway, 1913 (Ind. Dept. Geol. and Nat. Res. 37th Ann. Rept., p. 359). *Corryville-Arnheim* (*Rafinesquina fracta zone*).—Lss. and shales, 110 ft. thick, similar to rest of the Maysville; lss. predominating at base, gradually replaced by sh. toward top. Included in Maysville group. Overlies Bellevue and underlies Waynesville div. of Richmond group. If a single name is desired for this div. we propose Harmon, from Harmon's Station [Dearborn Co.], near which, in cuts 8 to 11, the entire fm. is exposed.

E. R. Cumings, 1922 (Hdb. Ind. Geol., pt. 4, Sep. Pub. 21, p. 425). Reason for grouping Corryville, Mount Auburn, and Arnheim together as *Harmon fm.* is that in Ind. the Corryville and Mount Auburn lose their distinctive characters, and the Arnheim, especially in its lower half, is faunistically very much more closely related to the Maysville than to the Richmond.

Harmon Hill gneiss.

Pre-Cambrian: Southwestern Vermont (Bennington region).

C. E. Gordon, 1914 (9th Rept. Vt. State Geol). [In table on p. 345 the pre-Camb. rocks of vicinity of Bennington, Vt., are called "Gneiss of Stamford Mtn and Harmon Hill." On p. 349 is heading: "Petrography of Harmon Hill gneiss."]

†Harney granite.

Pre-Cambrian: Southwestern South Dakota (Black Hills).

H. G. Ferguson and F. N. Turgeon, 1908 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 49, pp. 273–281). *Harney granite* occurs in northern Black Hills. The intrusive granite of Harney Peak region, in southern Black Hills, is a pegmatitic granite, identical with that found in northern Black Hills. The Harney granite appears to be intruded into only the lower schists of the Algonkian. [The name *Harney granite* is used in title of paper.]

U. S. Geol. Survey does not use a geographic name for this local body of granite. (See under *†Harney Peak granite.*)

Harney formation.

Tertiary? (Pliocene?): Southeastern Oregon (Harney Basin).

A. M. Piper, T. W. Robinson, and C. F. Park, Jr. (U. S. G. S. W. S. P. in press). *Harney fm.*—Massive basaltic tuff and breccia, ss., and siltstone; some incoherent gravel; scoriaceous and massive basalt intercalated at a few horizons. Exhumed basalt memb. caps the extensive plain of intermediate altitude in west-central part of area. Rests uncon. on Danforth fm. Is overlain by Pleist. terrace deposits or late basalt. Thickness 0 to 750 ft. Named for Harney Basin, the type section (468 ft. thick) being in E. face of Dog Mtn along bdy btw. secs. 20 and 28, T. 25 S., R. 30 E.

†Harney Peak granite.

Pre-Cambrian: Southwestern South Dakota (Black Hills).

C. R. Van Hise, 1898 (Geol. Soc. Am. Bull., vol. 9, p. 311), referred to the mica schists and mica gneisses about the *Harney Peak granite* of the Black Hills, "described by writer in Geol. Soc. Am. Bull., vol. 1, pp. 206–210, 1890" [but not there named, being simply called *granite of Harney Peak*].

G. M. Schwartz, 1925 (Econ. Geol., vol. 20, pp. 648–653). *Harney Peak granite* forms core of Black Hills uplift. Intrudes pre-Camb. schists. Classed as pre-Camb. by all investigators who have mentioned its age. The parts of the granite seen by writer are largely pegmatitic. It would not be far from correct to refer to all of exposed Harney Peak granite as a pegmatite.

The U. S. Geol. Survey considers a geographic name for this local body of granite unnecessary, and calls it *granite of Harney Peak.*

Haro formation.

Upper Triassic: Northwestern Washington (San Juan Islands).

R. D. McLellan, 1927 (Univ. Wash. Pub. Geol., vol. 2, pp. 93, 112–113). *Haro fm.*—Basal 920 ft. consists chiefly of cgl. with occasional thin beds of reddish ss. and sh.; overlying strata are thin-bedded carbonaceous sh., sl., graywacke, grit, and ls., containing *Halobia,* which is restricted to upper Triassic; the uppermost beds are largely concealed by glacial drift. Thickness of fm. 1,250+ ft. Composes peninsula known as Davidson Head, at N. extremity of San Juan Island. Occupies an area of only 48 acres. So far as known no other rock of this age outcrops in San Juan Island region. [Derivation of name not stated.]

Harper sandstone. (In Cimarron group.)

Permian: Central southern Kansas and northern Oklahoma.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, pp. 3, 18–20). *Harper sss. or beds.*—More or less mottled but prevailingly dull-red or brownish-red argill. and aren. shales and sss., several hundred ft. thick, composing basal fm. of Kiger div. and Cimarron series. Overlies, probably uncon., Wellington sh. and underlies Salt Plain measures. Includes at base transitional beds of calc. sh. which might perhaps be reckoned equally well as constituting the summit of the Wellington.

In Okla. is represented in Enid fm.

Named for exposures in Harper Co., Kans.

Harpers shale. (Also **schist, slate, phyllite,** and **albite schist.**)

Lower Cambrian: West Virginia, Virginia, Maryland, and southeastern Pennsylvania.

A. Keith, 1893 (as reported by G. H. Williams and W. B. Clark, in Maryland, its resources, industries, and institutions, chap. 3, p. 68. The fm. was described, but not named, by Keith in Am. Geol., vol. 10, p. 365, 1892). *Harper's Ferry shales.*—Gray sandy shales, with some ss. beds, scolithus and Lower Camb. fossils. Thickness 1,200 to 1,500 ft. Underlie Antietam ss. and overlie Weaverton [Weverton] ss.

A. Keith, 1894 (U. S. G. S. 14th Ann. Rept., pt. 2, pls. 22 and 23, pp. 333–335). *Harpers sh.*—Bluish-gray and gray sandy shales with some thin beds of ss. Thickness 800 to 1,200 ft. Underlies Antietam ss. and overlies Weverton ss.

In SE. Pa. the lithologic character of this fm. changes, and it is there called *Harpers schist* in some areas, *Harpers phyllite* in other areas, and *Harpers albite schist* in still other areas.

Named for exposures in gorges of Potomac and Shenandoah rivers at Harpers Ferry, W. Va.

†Harpers Ferry shales.

See *Harpers shale.*

Harpersville formation. (In Cisco group.)

Pennsylvanian: Central and central northern Texas.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31, 39). *Harpersville fm.*—Chiefly sh., but in Brazos River Valley includes Saddle Creek ls. memb. at top, Belknap ls. memb. in middle, and Crystal Falls ls. memb. near base. Thickness 200 to 275 ft. Overlies Breckenridge ls. memb. of Thrifty fm. and underlies Camp Creek sh. memb. of Pueblo fm. Chiefly characterized by presence of coal No. 6, one of most important coals in northern Tex. Named for town 10 mi. S. of Breckenridge, Stephens Co.

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, pp. 160–168 and charts). *Harpersville fm.*—In Colorado River Valley includes all strata btw. top of Saddle Creek ls. memb. and base of Waldrip bed of Drake. It consists of basal beds of coarse thick sss. which grade in places to cgls.; of middle beds composed of an alternation of fossiliferous buff and yellow-brown lss., irregularly bedded calc. sss., carbonaceous and ferruginous shales, and thin beds of coal; and of upper beds of a thick, massive coarse persistent ss. in many places capped by a hard gray ls. (Saddle Creek ls. memb.). Includes Crystal Falls ls. lentil 40 to 80 ft. above base, and Belknap ls. lentil 60 to 80 ft. above Crystal Falls ls.

†Harpeth shale.

Mississippian: Central Tennessee.

P. M. Jones, 1892 (Geol. of Nashville and immediate vicinity, Univ. Press, Nashville, Tenn., June 1892, p. 14). *Harpeth sh.*—Blue, apparently compact rock, in fresh exposure heavy-bedded, but weathering easily into sh.; at intervals layers of chert 3 to 4 in. thick, which resist weathering much longer than main body of the sh. Thickness 200 ft. or more. Underlies St. Louis ls. and overlies Dev. Black sh. To this group of rocks Dr. Safford, in his rept of geology of Well's Creek Basin (soon to be published), has given the name "Harpeth sh.," from its fine presentation in the picturesque bluffs, along Big Harpeth River, in Cheatham Co.

Replaced by Ridgetop sh.

†Harpeth and Tennessee River group.

Devonian and Silurian: Western Tennessee.

J. M. Safford, 1851 (Am. Jour. Sci., 2d, vol. 12, pp. 353, 357–358). ***Gray ls. or Harpeth and Tennessee River group.***—Fossiliferous ls. which to W. uncon. separates the black sl. from underlying blue ls. of Nashville group containing ***Spirifer lynx*** and its associates. Along Tenn. River consists of (ascending): (1) Thin-bedded fine-grained impure blue ls., of unknown thickness, 40 to 50 ft. being exposed in bluffs and beds of several creeks in Hardin Co.; (2) mostly light-gray sand and thick-bedded ls. containing crinoidal beds, some of lower strata with bright-green points, middle strata banded by reddish layers, which are generally fine-grained, impure, cherty ls. common on the Glades, and upper portion sometimes affording bluish layers of siliceous ls.; all often of marly nature, easily disintegrating and forming the angular gravel of the Glades.

Includes Pegram, Camden, Harriman, Quall, and Linden fms. (Dev.) and Clifton fm. (Sil.).

Named for Harpeth River, Cheatham and Dickson Counties.

Harrell shale. (Of Portage group.)

Upper Devonian: Central Pennsylvania (Bedford, Blair, Huntingdon, and Center Counties).

C. Butts, 1918 (Am. Jour. Sci., 4th, vol. 46, pp. 523, 532, 536). ***Harrell sh.***—Dove and black fissile (paper) sh., with Burket black sh. memb. at base to W. Thickness 250 ft. Basal fm. of Portage group. Underlies Brallier sh. and overlies Hamilton fm.

C. Butts (U. S. G. S. Hollidaysburg-Huntingdon folio, No. 227, in press). ***Harrell sh.***—Very soft brownish gray or olive-colored highly fissile sh. that cleaves into very thin laminae. East of Tussey Mtn thin beds of black sh. alternate with soft brown or gray sh. Correlated with Cashaqua and Middlesex of N. Y. At base Burket black sh. memb., 80 ft thick. Named for exposures at Harrell, Blair Co. [This village and the station have also been spelled ***Horrell.***]

B. Willard, 1935 (Geol. Soc. Am. Bull., vol. 46, pp. 1209–1213), proposed to restrict this name to the beds overlying Burket black sh. memb.

Harricanaw series.

Pre-Cambrian: Quebec.

T. L. Tanton, 1919 (Canada Geol. Surv. Mem. 109, p. 39).

Harriman chert.

Lower Devonian (Oriskanian): Western Tennessee (Decatur County).

C. O. Dunbar, 1918 (Am. Jour. Sci., 4th, vol. 46, p. 747). ***Harriman chert.***—Nearly white novaculite; weathers buff; very hard and brittle; in layers a few inches to over 1 ft. thick; thoroughly fractured. Thickness 0 to 55 ft. Is heavier-bedded than overlying Camden chert (restricted), with which it is uncon. Overlies, uncon., Quall ls. Is of upper Oriskany age. Named for Harriman Creek, Decatur Co.

Harrington formation.

Lower Triassic: Southwestern Utah (southeast of Frisco district).

B. S. Butler, 1913 (U. S. G. S. P. P. 80). ***Harrington fm.***—Thin-bedded shale with interbedded lss. and lenses of qtzite. Thickness 5,000± ft. Overlain by Tert. intrusives and underlain by Elephant ls. (Penn.). Type loc., Harrington-Hickory mine, SE. of Frisco dist.

Harrington River formation.

Carboniferous: Canada.

W. A. Bell, 1927 (Roy. Soc. Canada Trans., 3d ser., vol. 21, pp. 75–108; table).

Harris moraine.

Pleistocene (Wisconsin stage): Eastern Minnesota (Chisago and Sherburne Counties).

F. Leverett, 1932 (U. S. G. S. P. P. 161, pp. 80–82). Youngest moraine of Rush Lake morainic system. Named for occurrence at Harris, Chisago Co.

Harris formation.

Miocene: Southern California (Santa Maria district).

R. D. Reed, 1933 (Geol. of Calif., p. 189). In Santa Maria dist. it has become customary to refer to the upper, more diatomaceous part of the siliceous sh. series as the *"Harris" fm.*, which may be = the Santa Margarita or may be younger. (According to recent work by G. D. Hanna, the typical *Harris Grade beds* are Plio.; personal communication.) The pre-Harris beds are at least in part = typical Monterey.

Harris sand.

A subsurface sand, 25 ft. thick, in Strawn fm. (Penn.) of Ranger field of central northern Tex., lying 1,700 to 1,800 ft. below Ranger ls.

Harrisburg gypsiferous member (of Kaibab limestone).

Permian: Southwestern Utah and northwestern Arizona.

H. Bassler and J. B. Reeside, Jr., Aug. 15, 1921 (U. S. G. S. Bull. 726C, pp. 90–92). *Harrisburg gypsiferous memb. of Kaibab ls.*—Gray, thin-bedded ls. (some of it containing many small angular fragments of chert) and gray, red, and yellow sh., some gyp. Thickness 137 to 160 ft. [0 to 280± ft. in U. S. G. S. P. P. 129, p. 56, 1922]. Top memb. of Kaibab ls. Uncon. overlain by Rock Canyon conglomeratic memb. of Moenkopi fm. Named for occurrence in Harrisburg dome, 8 mi. E. of St. George, Washington Co., Utah.

Harrisburg Run sand.

Subsurface sand in Bradford dist., NW. Pa., lying btw. Bradford Second and Bradford Third sands, 230 ft. above latter.

Harris City limestone.

Name casually applied by M. N. Elrod (Ind. Dept. Geol. and Nat. Hist. 12th Ann. Rept., 1881, p. 128, 1883) to ls. quarried at Harris City, Sand Creek Twp, Decatur Co., Ind.

Harrison diorite.

Pre-Cambrian (?): Southeastern New York and western Connecticut.

F. J. H. Merrill, 1898 (N. Y. State Mus. 15th Ann. Rept., vol. 1, p. 30). *Harrison diorite* is intrusive into Manhattan schist in town of Harrison [Westchester Co.]. A smaller area of similar rock occurs at Ravenswood, L. I., where it intrudes Fordham gneiss; a mass of it forms Milton Point near Rye; and it is abundant along shore of Long Island Sound btw. Portchester and Greenwich.

F. J. H. Merrill, 1902 (U. S. G. S. New York City folio, No. 83). [*Harrison diorite* classified as Sil. or later, and described as in 1898.]

E. C. Eckel, 1902 (N. Y. State Geol. 20th Ann. Rept., p. r165). *Harrison diorite* is medium-grained granite diorite. Intrusive into Hudson [Manhattan] schist. Covers large part of towns of Mamaroneck, Rye, and Harrison, and extends E. into Fairfield Co., Conn.

C. P. Berkey, 1907 (N. Y. State Mus. Bull. 107). *Harrison diorite* may be later than Precambric, and is tentatively classified as Camb.

V. Ziegler, 1911 (N. Y. Acad. Sci. Annals, vol. 21, p. 1). *Harrison diorite* believed to be distinct from Ravenswood granodiorite, and has been more thoroughly metamorphosed than Ravenswood.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 24). Ravenswood granodiorite is related to *Harrison diorite* and considered to be of essentially same age.

†Harrison beds.

Miocene (lower): Western Nebraska and eastern Wyoming.

J. B. Hatcher, 1902 (Am. Phil. Soc. Proc., vol. 41, p. 117). *Harrison beds.*—Fine-grained rather incoherent sss. permeated by great numbers of siliceous tubes arranged vertically. Characterized by *Daemonelix* and other Mio. mammals. Well shown in bluffs of all small streams that head near summit of Pine Ridge in vicinity of Harrison, Nebr. Cover considerable area. Extend well into Wyo.

Are a part of Arikaree fm., and of lower Mio. age, according to H. F. Osborn, 1909 (U. S. G. S. Bull. 361, pp. 65–75), and H. J. and M. C. Cook, 1933 (Nebr. Geol. Surv. Paper No. 5, p. 44).

Harrison member (of Pottsville formation).

Pennsylvanian: Southeastern Ohio (Vinton County).

W. Stout, 1927 (Ohio Geol. Surv., 4th ser., Bull. 31, pp. 67, 68). *Harrison memb.*, generally an impure iron ore, was named from deposits present in Scioto Co., and was formerly worked for iron smelting at Harrison Furnace. It lies in base of Pottsville fm., but is bedded in the eroded surface of Maxville ls. or, where that is absent, on the Logan strata. Is of variable composition. In places it is a brecciated mass of siliceous fragments cemented by iron compounds. The siliceous material appears to be what was once pieces of Maxville ls. At other places it is a mixture of angular siliceous fragments and well-rounded quartz pebbles, all cemented by iron compounds. Distribution is local in Vinton Co. Thickness 3 in. to 4 ft. 10 in. Underlies Sharon cgl.

Harrison ore bed. (In Pottsville formation.)

See under *Maxville block ore.*

†Harrison series.

Pre-Cambrian: Southern Idaho (Cassia County).

A. L. Anderson, 1931 (Idaho Bur. Mines and Geol. Bull. 14, pp. 24+). *Harrison series.*—Chiefly qtzite, with lesser schist and marble. Descending: (1) White dense vitreous qtzite, in part massive, with ill-defined bedding, and in part distinctly bedded in beds 6 to 18 in. thick, 400 to 500 ft.; (2) qtzite containing much schist and 2 or more marble or ls. members, 2,000 to 3,000 ft.; (3) mainly qtzite; the upper 2,000± ft. slightly micaceous qtzites alternating with numerous thick beds of pure qtzite and a few thin beds of mica schist; the lower 3,000 ft. mainly light-gray to white pure qtzite with thick even bedding, but contains some slightly micaceous members. Total thickness 9,000+ ft. Neither base nor top exposed. Best exposed on flanks of Mount Harrison. Is surely not to be correlated with Belt series, but very likely is older than Belt.

Preoccupied. Replaced by *Albion Range group.*

Harrison Lake formation.

Middle Jurassic: Southwestern British Columbia (Harrison Lake region).

C. H. Crickmay, 1927 (Stanford Univ. Abstracts of Dissert. 1924–26, vol. 1, p. 132).

C. H. Crickmay, 1930 (Geol. Mag., vol. 67, p. 487 and map). *Harrison Lake fm.*—Aggls. and lavas, 9,200 ft. thick, yielding *Cylindroteuthis themis.* Assigned to Middle J. Underlies Echo Island fm. (Middle J.) and uncon. overlies Slollicum series (Triassic). [Mapped on both sides of Harrison Lake.]

†Harrodsburg limestone. (In Meramec group.)

Mississippian: Indiana and northern Kentucky.

T. C. Hopkins and C. E. Siebenthal, 1897 (Ind. Dept. Geol. and Nat. Res. 21st Ann. Rept., p. 296). *Harrodsburg ls.*—Lss., 60 to 90 ft. thick, with some sh. interbedded; formerly known as Encrinital ls. Overlies Knobstone group and underlies Bedford oolitic ls. [Spergen ls.].

Correlation with Warsaw ls. (older name) established. (See C. Butts, 1915, Ky. Geol. Surv., 4th ser., 3d Rept., pt. 2.)

P. B. Stockdale, 1929 (Ind. Acad. Sci. Proc., vol. 38, pp. 233–242), divided Harrodsburg ls. into (descending): (1) Upper Harrodsburg ls., 30 to 50 ft.; and (2) Lower Harrodsburg, 25 to 40 ft. of beds divided into (descending) Guthrie Creek memb., 2 to 10 ft.; Leesville ls. memb., 1½ to 8 ft.; and Ramp Creek memb., 16 to 28 ft.

P. B. Stockdale, 1931 (Ind. Dept. Cons., Div. Geol., Pub. 98, pp. 310–311), suggested redefining Harrodsburg ls. by including his basal Ramp Creek memb. in underlying Borden group. He stated: The complex relationships btw. uppermost Edwardsville (top fm. of Borden group) and overlying Harrodsburg ls. at extreme S. part of State, and uncertainty as to bdy line btw. the two units at many places farther N., suggest that Siebenthal may have been in error in specifically including the "transitional beds" (Ramp Creek memb.) as an integral part of his Harrodsburg fm. This surmise is supported by lithologic contrast btw. Lower and Upper Harrodsburg. Might it not be better to consider Lower and Upper Harrodsburg as two separate fms.; or, perhaps, include Ramp

Creek memb. as a part of the Borden (Edwardsville) and consider Leesville memb. as basal unit of Harrodsburg or as a separate fm.?

Named for Harrodsburg, Monroe Co., Ind.

Harrogate limestone.

Devonian: British Columbia.

F. P. Shepard, 1926 (Jour. Geol., vol. 34, p. 626).

Harrogate formation.

Middle Devonian: British Columbia.

C. S. Evans, 1933 (Canada Geol. Surv. Summ. Rept. 1932, pt. A2, p. 142).

Harshberger limestone. (In Conemaugh formation.)

Pennsylvanian: Southwestern Pennsylvania (Somerset County).

F. and W. G. Platt, 1877 (2d Pa. Geol. Surv. Rept. H_3, pp. 222, 223, and pl. 13). *Harshberger ls.*, 5 ft. thick, is quarried by Mr. Harshberger. At Forwardstown, Somerset Co., Pa., it lies 8½ ft. below lower ls. bed of Berlin ls. and rests on 25 ft. of unnamed ss. It is compact, minutely crystalline, spotted with iron pyrites, and of bluish-black color.

Hart limestone member (of Stratford formation).

Pennsylvanian: Central southern Oklahoma (Pontotoc County).

G. D. Morgan, 1924 (Bur. Geol. [Okla.] Bull. 2, pp. 137–140). *Hart ls. memb.*—A series of alternating lss., shales, and sss. that constitute basal memb. of Stratford fm. In vicinity of Hart the lss. are very prominent, but toward N. and S. some of them thin out while others grade into sh. As a rule arkosic material is not abundant in the lss., but it is always present, and in a few beds constitutes large proportion of the rock. [Regarding age, see *Stratford fm.*]

Named for typical development near village of Hart, W. part of Pontotoc Co.

Hartford limestone.

Pennsylvanian: Western central Kentucky.

C. J. Norwood, 1884 (Ky. Geol. Surv., Repts on western coal field, Ohio Co., p. 174). *Hartford ls.*—Blue shelly ls. 6 ft. thick, lying 15 ft. above coal D.

Apparently named for Hartford, Ohio Co.

†Hartford limestone. (In Shawnee formation.)

Pennsylvanian: Eastern Kansas and northwestern Missouri.

M. Z. Kirk, 1896 (Kans. Univ. Geol. Surv. vol. 1, p. 80). *Hartford ls.*—Ls. which passes under river at Hartford. Separated from underlying Strawn ls. by 60 ft. of sandy sh. and from overlying Wyckoff ls. by 50 ft. of sh.

Same as Topeka ls. (older and better-established name), according to H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines vol. 13).

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 11). *Hartford (Curzon) ls.* is basal memb. of Topeka ls. fm. [See further description under *Curzon ls.*]

R. C. Moore, Aug. 31, 1936 (Kans. Geol. Surv. Bull. 22, pp. 48, 194–197). Hartford ls. of Kirk is lower memb. of Topeka ls. as now classified. It consists typically of 1 to 3 or 4 beds (1 to 20 ft. thick) of massive or irregularly bedded bluish-gray ls. that weathers brown. Where 2 or more beds of ls. are present they are separated by sh. a few in. to several ft. thick. Thickness of memb. as a whole is 1 to 40 ft. Well exposed below highway bridge at N. edge of Hartford, Coffee Co., Kans.

R. C. Moore, Sept. 4 to 7, 1936 (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 41), introduced 2 members into Topeka ls. beneath Hartford ls., as explained under *Jones Point sh.* and *Dashner ls.*

This name was discarded by U. S. Geol. Survey in 1912, because then stated to be same as Topeka ls. (See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936. Also see 1937 entry under *Topeka ls.*)

Named for exposures at Hartford, Lyon Co., Kans.

Hartford clay.

Name applied by R. F. Flint (Geol. Soc. Am. Bull., vol. 44, No. 5, pp. 965–987, 1933) to a late Pleist. clay at and in neighborhood of Hartford, Conn.

Hartgrove limestone member (of Talpa formation).

Permian: Central Texas (Concho County).

W. Kramer, 1934 (A. A. P. G. Bull., vol. 18, No. 12, pp. 1579, 1582). A 2-foot bed of dark gray ls. lying 1,000 ft. above Coleman Junction ls. is here named *Hartgrove memb.*, from exposure on Mack Hartgrove's ranch, where it crops out 0.4 mi. S. of and 37 ft. lower than the ground at Eugene Mays well (middle of W. line of Anton Schmidz survey No. 312, about 4.5 mi. SE of Paint Rock). Has been traced across SE. part of Runnels Co. to 11 mi. N. of SE. corner of that Co. Is persistent ledge maker and hence is considered top memb. of Talpa fm.

†Hartland schist.

Lower Cambrian (?): Western Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 96–100, and map). *Hartland (Hoosac) schist.*—In Conn. is southern continuation of large areas of rock on Hoosac Mtn and in adjacent regions of Mass. The rock is everywhere mica schist of definable character, but exhibits great variation in texture, composition, and field appearance. Where least affected by intrusion it is a highly fissile schist. Ranges in color from clear metallic muscovite to black biotite mixed with graphite. Sericite and chlorite often replace biotite. Garnets almost constantly present. No fossils.

Same as Hoosac schist, the older name.

Named for development in Hartland.

Hartland shale member (of Greenhorn limestone).

Upper Cretaceous: Western Kansas.

N. W. Bass, 1926 (Kans. Geol. Surv. Bull. 11, p. 203). *Hartland sh. memb.*—Chalky sh., with a few thin beds of chalky ls. Thickness 28 to 40 ft. A memb. of Greenhorn ls., underlying Jetmore chalk memb. and overlying Lincoln ls. memb.

Named for exposures along Arkansas River from a short distance W. of Hartland, Kearny Co., to Kendall, Hamilton Co.

Hartley augen gneiss.

Pre-Cambrian: Southeastern Pennsylvania and northern Maryland.

E. B. Knopf and A. I. Jonas, 1923 (Am. Jour. Sci., 5th, vol. 5, pp. 43, 44). The Baltimore gneiss has been intruded by a granite that has produced a lit-par-lit injection in upper part of fm. This granite, which has been metamorphosed into a cataclastic granite gneiss, has been called by writers *Hartley augen gneiss*, from its excellent outcrops at Hartley Mill on Long Green Creek, in eastern Baltimore Co., Md.

This fm. was formerly classified by U. S. Geol. Survey as Archean (?), but "Archean system" having been discarded the fm. is now classified as *pre-Camb.*

Hartmann limestone.

Middle Cambrian: Central northern Utah (Oquirrh Mountains region).

J. Gilluly, 1932 (U. S. G. S. P. P. 173). *Hartmann ls.*—Gray mottled ls. in thin beds, with shaly partings; some oolite toward top. Thickness 650 ft. Conformably underlies Bowman ls. and grades into underlying Ophir fm., the bdy being arbitrarily drawn at top of highest sh. bed in this part of section, all of the shales being included in Ophir fm. Named for exposures on W. side of Hartmann Gulch (sometimes called Graveyard Gulch), just N. of Ophir.

Hartridge shale. (In Pottsville group.)

Pennsylvanian: Northern West Virginia.

D. B. Reger, 1918 (W. Va. Geol. Surv. Rept. Barbour and Upshur Counties, p. 288). *Hartridge black sh.*—Dark-gray to black sh., through which fossiliferous hard black concretions are scattered in large numbers. Thickness 5 to 6 ft. Underlies

Lower Guyandot ss. and overlies Sewell coal. Exposed at Hartridge, Randolph Co.

Hart School bed. (In Moran formation.)

Permian: Central northern Texas (Brazos River region).

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, pp. 179, 180). A ls. bed (2 to 6 ft. thick) in Sedwick ls. memb. of Moran fm. (of Cisco group), occurring 3 to 12 ft. below top of Sedwick memb. Outcrops on road at Hart School, sec. 2969, T. E. and L. survey, 6 mi. N. of Putnam [Callahan Co.]. [See description under *Sedwick ls. memb.* The Moran fm. is now included in Wichita group.]

Hartselle sandstone. (In Chester group.)

Mississippian: Northern, central, and eastern Alabama.

E. A. Smith, 1894 (Ala. Geol. Surv. geol. map of Ala. with explanatory chart). Mountain ls. (Chester), 200 to 2,000 ft. thick, divided into 2 contemp. units, Bangor or ls. phase, including *Hartsell ss.*, and Oxmoor or sh. and ss. phase. In northern Ala. lss. prevail, with one or more interbedded sss., the *Hartsell or Lagrange sss.* To S. and SE. of Wills Valley the lss. are replaced by shales and sss. well exposed at Oxmoor. The Mountain ls. underlies Coal Measures and overlies Fort Payne, which is divided into Tuscumbia ls. above and Lauderdale cherty ls. below. [As thus defined *Hartsell ss.* evidently included Hartselle ss. restricted and the older Cypress ss. of present nomenclature, but apparently did not include Gasper fm. and Bethel ss.]

H. McCalley, 1896 (Ala. Geol. Surv. Rept. Tenn. Valley region, Ala.). *Hartselle ss. group*, 150–400 ft. thick, underlies Bangor lss. and overlies Tuscumbia ls. Consists of massive ss., underlain by variable lss. and interchangeable calc. argill. shales (in one place mostly lss., in another place mostly shales), in places 150 ft. thick; at base variable sss. [As thus defined his *Hartselle ss. group* included the sss. now designated *Hartselle ss. restricted, Cypress ss.*, and *Bethel ss.*, together with intervening beds.]

C. Butts, 1910 (U. S. G. S. Bull. 400, on Birmingham dist.). Bangor ls., divided into (descending): (1) Ls., few ft. to 350 ft.; (2) sh., 30 ft.; (3) *Hartselle ss. memb.*, 100 to 200 ft.; (4) sh., 50 ft.; (5) ls., 160 ft. Rests on Fort Payne chert. [As thus defined *Hartselle ss. memb.* evidently applied to the ss. to which it is now applied. This same definition was employed by Butts in U. S. G. S. Birmingham folio, No. 175, 1910, and by E. A. Smith in Ala. Geol. Surv. Bull. 10, 1911. In some subsequent repts, by other writers, the Hartselle ss. was supposed to be same as Cypress ss.]

C. Butts, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14), divided the rocks that had formerly been called Bangor ls. in NW. Ala. into (descending): (1) Pennington fm., 0 to 200 ft.; (2) Bangor ls. restricted, 100 to 700 ft.; (3) *Hartselle ss. restricted*, 0 to 200 ft.; (4) Golconda fm., 0 to 60 ft.; (5) Cypress ss., 0 to 40 ft.; (6) Gasper fm., 75 to 150 ft.; (7) Bethel ss., 0 to 20 ft.; and (8) Ste. Genevieve ls., 0 to 100 ft., which overlies Tuscumbia ls., "generally with slight uncon. in Miss. and Ohio Valleys." Hartselle ss. restricted correlates with Hardinsburg ss. of Miss. Valley. This restricted definition of Hartselle ss. is the present approved definition.

Named for exposures at Hartselle, Morgan Co.

Hartshorne sandstone.

Pennsylvanian (Allegheny): Eastern Oklahoma and western Arkansas coal field.

J. A. Taff, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, p. 436). *Hartshorne ss.*—Brown to light-gray sandrock, 200 ft. thick, underlying McAlester sh. and overlying Sil. in McAlester dist., Okla. Basal fm. of Coal Measures. Hartshorne coal lies above this ss. and is separated from it by a thin but variable bed of sh.

Underlies McAlester sh. (the base of which in Okla. is at top of 1st ss. below *Upper* Hartshorne coal, and the base of which in Ark. is at top of 1st ss. below *Lower* Hartshorne coal) and overlies Atoka fm. The Hartshorne ss. in Ark. is now defined as the first continuous ss. underlying Lower Hartshorne coal. Some repts have included Lower Hartshorne coal in this ss.

Named for exposures near Hartshorne, Pittsburg Co., Okla.

Hartsville limestone.

Silurian (Niagaran): Southeastern Indiana.

J. A. Price, 1900 (Ind. Dept. Geol. and Nat. Res. 24th Ann. Rept., pp. 84–85). *Hartsville (Louisville) ls.*—Sandy ls., 0 to 12 ft. thick, regarded as strat. equiv. of Louisville ls. Overlain by Dev. Corniferous ls. and underlain by Waldron sh. Regarded as topmost fm. of the Niagara in Decatur, Bartholomew, and Shelby Counties.

E. M. Kindle, 1901 (Ind. Dept. Geol. and Nat. Res., 25th Ann. Rept.). Louisville ls., 4 to 35 ft. thick, is "Hartsville bed" of Price.

T. C. Hopkins, 1904 (Ind. Dept. Geol. and Nat. Res. 28th Ann. Rept., p. 39). Hartsville beds included in Jeffersonville ls. (Dev.).

Named for Hartsville, Bartholomew Co.

Hartville formation.

Pennsylvanian and Mississippian: Southeastern Wyoming (Hartville uplift).

W. S. T. Smith and N. H. Darton, 1903 (U. S. G. S. Hartville folio, No. 91). *Hartville fm.*—Massive gray ls., some beds containing chert nodules, with occasional beds of white, gray, buff, and red ss., composes most of fm. In lower part red sh. and gray ls.; at base 50 ft. of red qtzite streaked with white. Total thickness 650 ft. Conformably underlies Opeche fm. and uncon. overlies Guernsey fm. Contains Penn. fossils in upper part and Miss. fossils in lower part. [Mapped over large area at and around Hartville.]

G. E. Condra and E. C. Reed, 1935 (Nebr. Geol. Surv. Paper No. 9), reported results of a detailed lithologic, faunal, and correlation study of Hartville fm., which they divided into 6 unnamed units, the upper one of which they concluded is probably Perm.; the next underlying 4 fossiliferous units are certainly Penn., while the strat. relations of basal unit suggest it is lower Penn.

Hartwell sandstone.

Pennsylvanian: Western Arkansas coal field.

A. Winslow, 1896 (N. Y. Acad. Sci. Trans., vol. 15, p. 51). *Hartwell ss.*— Ss., 0 to 100 ft. thick, underlying Tomlinson sh. and overlying Belva sh. All included in Sebastian stage. [Is a part of Fort Smith fm.]

Derivation of name not known, but there is a town of that name in Madison Co., NW. Ark.

Hartwell sandstone.

Mississippian: Southern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, p. 244). *Hartwell ss.*—Massive, fine-grained, micaceous, olive green, 25 to 30 ft. thick. Lies about 345 ft. below Pocahontas No. 3 coal. Older than Pageton ss. and younger than Ballard Harmon ss. Exposed at Hartwell, McDowell Co., and quarried ½ mi. SE. of Hartwell. Included in Mauch Chunk series.

Hartwell moraine.

Pleistocene (Wisconsin stage): Western Ohio and eastern Indiana. Shown in part on moraine map (pl. 32) in U. S. G. S. Mon. 53. Belongs to Shelbyville morainic system. Named for Hartwell, a few mi. N. of Cincinnati, Ohio.

Hartwick dolomite.

Silurian (Niagaran): Central eastern Iowa.

C. Keyes, 1912 (Iowa Acad. Sci. Proc., vol. 19, pp. 149, 150). *Hartwick terrane.*—Dol., 80 ft. thick, composing next to top fm. of Niagaran series. Overlain by Monticello dol. of Niagaran series, and underlain by Colesburg dol. of Niagaran series. Separated from underlying and overlying fms. by its fauna.

Named for Hartwick, Poweshiek Co.

Harvard *conglomerate lentil* (*of* Worcester phyllite).

Pennsylvanian: Northeastern Massachusetts (Worcester County).

W. O. Crosby, 1876 (Rept. on geol. map of Mass.), referred in several places to a cgl. and argillite in Harvard and Bolton (cgl. on E. and argillite on W.) as *Harvard cgl.*

W. O. Crosby, 1880 (Boston Soc. Nat. Hist. Occ. Papers No. 3, with map). *Harvard cgl.* is petrologically a part of the argillite [Worcester phyllite] and probably marks beginning of its deposition.

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, p. 18). *Harvard cgl.* underlies Worcester argillite (phyllite) and overlies Worcester qtzite [Oakdale qtzite].

G. R. Mansfield, 1906 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 49, geol. ser. vol. 8, No. 4, pp. 91–271). *Harvard cgl.*, 300 to 400 ft. thick, contains no arkose. Is interbedded with grit and sheared ss. and intimately associated with Worcester phyllite. Apparently thins out to S.

B. K Emerson, 1917 (U. S. G. S. Bull. 597, pp. 61, 66–67, and map). *Harvard cgl. lentil of Worcester phyllite*.—A mass of crushed conglomeratic rock, 500 ft. wide and 1 mi. long, occurs NW. of Harvard village and lies on an isolated block of Worcester phyllite surrounded on all sides by granite. A cgl. mass of similar relations and dimensions forms summit of Vaughn Hill, 3 mi. to SW. The rock is breccia rather than cgl., as component blocks are in general sharply angular. The blocks are as diverse in character as in size. They are mainly qtzite but of several kinds of qtzite. In other specimens the fragments are all sl., but of several kinds of sl. The interstitial matter is fine clay sl. like adjacent argillite.

†Harvard granite.

Late Carboniferous: Massachusetts.

B. K. Emerson, 1889 (Geol. Soc. Am. Bull., vol. 1, p. 560), used, but did not define, this name, which was long ago replaced by him with *Andover granite*.

Harvest Home shale member.

Mississippian: Northwestern Pennsylvania.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61, p. 134), proposed *Harvest Home sh. memb.* to replace *lower Meadville sh.* of early repts on NW. Pa. Well exposed along Rock Creek, Greenwood Twp, Crawford Co., especially at Peterson's Falls, on the edge of which is located the Harvest Home Grove, widely known in Crawford Co.

Harvey conglomerate lentil. (In Sewell formation.)

Pennsylvanian: Southern West Virginia.

M. R. Campbell, 1902 (U. S. G. S. Raleigh folio, No. 77). *Harvey cgl. lentil of Sewell fm.*— Massive cgl., 0 to 50 ft. thick, lying about 100 ft. below Nuttall ss. lentil. Named for exposure at village of Harvey [now Bolt P. O.], on headwaters of Marsh Fork of Coal River, Raleigh Co.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties). *Harvey cgl.*—Massive current-bedded medium-grained to coarse grayish-white to yellowish-gray cliff-forming ss. Thickness 0 to 125 ft. Underlies Lower Iaeger sh. and overlies Sandy Huff sh. Named by M. R. Campbell. [This is definition used in subsequent repts of W. Va. Geol. Surv.]

Harveyville shale. (In Wabaunsee group.)

Pennsylvanian: Southeastern Nebraska and eastern Kansas.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 10). *Harveyville sh.*, middle memb. of Preston ("Emporia") ls. fm. Consists of greenish, bluish sh., locally a subzone nearly black, argill. to calc., quite fossiliferous, 3 to 4 ft. thick to W., 7 ft. thick to E. Underlies Elmont ls. and overlies Reading ls. [Derivation of name not stated.]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 226). *Harveyville sh.*, which is first defined in this rept, includes beds overlying Reading ls. and underlying Elmont ls. It is mostly bluish or yellowish brown and clayey, but locally contains sandy sh. and thin platy ss., with a coal bed locally above the ss. Thickness 1 to 25± ft. *Identified at many places from Nebr. to Okla. and is undoubtedly continuous across Kans.*

Type loc. near Harveyville, SE. part of Wabaunsee Co., Kans. Good section in sec. 25, T. 15 S., R. 13 E.

Haskell limestone.

Pennsylvanian: Eastern Kansas.

R. C. Moore, 1931 (Kans. Geol. Soc. 5th Ann. Field Conf. Guidebook, correlation chart). *Haskell ls.*, new name; underlies Lawrence sh. [restricted] and overlies Stranger ss. and sh. (also new name). Included in Douglas group redefined.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 93, 96). [See under *Douglas fm., Moore, 1932*. On p. 49 the Haskell ls. is described as consisting of 3 ft. of bluish dense even ls.] Named for Haskell Institute, Lawrence.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21). [See 1935 entry under *Stranger fm.*]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 146, 152+). *Haskell ls. memb. of Stranger fm.*—Throughout much of outcrop it is bluish-gray blocky fine-grained ls., occurring as single ledge without sh. partings, and containing banded algae and a few fusulinids and brachiopods. Locally, as at Lawrence, oolitic layers occur at base and top of memb.; the upper oolite furnished types for several pelecypod species of Beede and Rogers. Underlies Robbins sh. [basal part of Lawrence sh. as restricted by R. C. Moore in 1931 and 1932] and overlies Vinland sh. Type loc. on 15th St., NE¼ sec. 5, T. 13 S., R. 20 E., at E. edge of Lawrence.

Haskell sand.

A subsurface sand, 20 ft. thick, of Upper Dev. (Chemung) age, occupying interval btw. 1,550 and 1,570 ft. in Derrick City deep well, McKean Co., NW. Pa., which is Smethport sand of Ashburner, according to C. R. Fettke (Geol. Soc. Am. Bull., vol. 44, No. 3, p. 620, 1933), who spells the name (fig. 2, opp. p. 602, and p. 620) *Haskill;* but Pa. Geol. Surv., 4th ser. Bull. M19, 1933, charts in pocket, spell this name *Haskell.*

Haskew gypsum member (of Blaine formation).

Permian: Northwestern Oklahoma (Harper and Woodward Counties).

N. Evans, 1931 (A. A. P. G. Bull., vol. 15, No. 4, pp. 405–432). *Haskew* is proposed for top gyp. memb. of Blaine fm. Differs from underlying Lovedale, Shimer, and Medicine Lodge gyp. members in several particulars. Does not ordinarily have a dol. bed at base, although a very impure sandy dol. has been observed in a few places. Max. thickness of Haskew memb. in Harper and Woodward Counties, 4 ft. Separated from underlying Lovedale gyp. by 4 ft. of red sh. Clusters of interlocking crystals on surface of this bed are commonly much smaller than those of underlying Lovedale, Shimer, and Medicine Lodge gyp. members, and bed is redder than the other 3. Named for exposures near old store known as Haskew Store, at NE. cor. sec. 2, T. 25 N., R. 19 W.

S. Buckstaff, 1931 (A. A. P. G. Bull., vol. 15, No. 4, pp. 434–437). *Haskew memb.*, not previously recognized, should be accepted.

Haskill sand.

See *Haskell sand.*

Haslam formation.

Upper Cretaceous: Vancouver Island, British Columbia.

C. H. Clapp, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 97).

Hasmark formation.

Upper Cambrian: Central western Montana (Philipsburg region).

F. C. Calkins and W. H. Emmons, 1913 (U. S. G. S. P. P. 78). *Hasmark fm.*—In descending order: (1) Mag. ls., mostly white, 350± ft.; (2) calc. sh., 150 ft.; (3) mag. ls., mostly blue gray, 550± ft. Underlies Red Lion fm. and overlies Silver Hill fm. Named for an abandoned settlement SE. of Philipsburg. The fm. is not very well exposed there, but dearth of geographic names in Philipsburg quad. made it impossible to find one more appropriate.

Hastings series.

Pre-Cambrian: Ontario.

W. E. Logan, 1866 (Canada Geol. Surv. Rept. 1863–66, p. 93, footnote).

C. R. Van Hise and C. K. Leith, 1909 (U. S. G. S. Bull. 360).

The Hastings dist. includes an area btw. Ottawa and St. Lawrence Rivers SW. of city of Ottawa, extending from Peterborough and Hastings Counties on SW. to Lanark and Renfrew Counties on NE.

Hastings Creek formation.

Name applied by H. W. McGerrigle (17th Rept. Vt. State Geol., pp. 182, 185, 1931) to B2 (except summit bed) and B1 of Logan's section of Philipsburg series of Quebec (Lower Ord. and older?). McGerrigle mapped his Hastings Creek fm. (260 ft. thick) in small area in St. Albans quad., NW. Vt. Logan's B1 consisted of white and dove-gray pure lss. with some mag. beds and his B2 consisted of dark lss. with some mag. beds. (See 1931 entry under *Philipsburg series.*)

Hatch shale.

Upper Devonian: West-central New York.

J. M. Clarke and D. D. Luther, 1903 (N. Y. State Mus. Bull. 69, p. 1005 and map). *Hatch shales and flags.*—Light and dark shales with thin flags of blue ss. Thickness 203 ft. Underlie Grimes ss. and overlie Rhinestreet black sh. in Genesee River section. Included in Portage group. Are part of Hall's Gardeau.

J. M. Clarke, 1904 (N. Y. State Mus. Mem. 6, pp. 199–214). *Hatch sands, flagstones, and sss. with intermingled clay shales.*—Thickness 312 ft. in Naples section. *Hatch flags and sandy shales* 209 ft. thick in Genesee River section. Naples fauna. [Clarke and Luther, 1905 (N. Y. State Mus. Bull. 81), gave thickness of 440 ft. in Watkins and Elmira quads.]

D. D. Luther, 1906 (N. Y. State Mus. Bull. 101). Named for Hatch Hill, at Naples, Ontario Co.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 76 and chart). *Hatch sh. and flags* recognized from Genesee Valley to Cayuga Co., where they become involved with the Ithaca.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369). *Hatch sh.* underlies Grimes ss. and overlies Rhinestreet sh. All included in Portage group.

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 201). *Hatch ss. memb.*—Basal memb. of Enfield facies subgroup of Ithaca-Enfield group of fms. in vicinity of Ithaca, N. Y. Thickness 500 ft. Extends from top of Second *Reticularia levis* zone. Contains *Leiorhynchus globuliforme* zone in upper part. Grades into so-called lower Chemung to E.

G. H. Chadwick, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, p. 352). Hatch underlies Grimes and overlies Rhinestreet. Grimes included in Chemung group and Hatch in Naples group.

Hatchetigbee formation. (In Wilcox group.)

Eocene (lower): Southern Alabama and eastern Mississippi.

E. A. Smith and L. C. Johnson, 1887 (U. S. G. S. Bull. 43, pp. 39–43). *Hatchetigbee series.*—All strata btw. base of Buhrstone [Tallahatta fm.] and uppermost of Wood's Bluff fossiliferous beds [called Wood's Bluff or Bashi marl], aggregating about 170 to 175 ft. By far greater part of the beds here included are sandy clays or clayey sands of brownish gray colors, alternating with bands of dark brown or purple color. Top fm. of Lignitic [Wilcox group]. Overlies Wood's Bluff or Bashi series and underlies Buhrstone group.

Is top fm. of Wilcox group, and in Ala. contains deposits of both marine and nonmarine origin, according to C. W. Cooke.

Named for exposures at Hatchetigbee Bluff, on Tombigbee River, in NE. part of Washington Co., Ala.

Hat Creek beds.

Oligocene (middle): Wyoming.

H. F. Osborn, 1918 (Am. Mus. Nat. Hist. Mem., n. s., vol. 2. pt. 1, p. 11), mentioned "*Hat Creek beds,* Wyo., Reed, Hatcher" as included in White River group.

Hathaway formation.

Upper Pliocene or lower Quaternary (mapped as Pliocene): Southern California (San Bernardino Mountains).

F. E. Vaughan, 1922 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 13, No. 9, pp. 344, 375, 376–378, 384, and map). *Hathaway fm.*—A series of land-laid deposits. Bulk of fm. is rather fine for fangl. Upper 1,800 ft. consists of light bluish-gray ss. containing many streaks of angular pebbles derived from igneous and metamorphic rocks to N. This ss. grades downward into light-gray sh. containing hard calc.

streaks, of which 800 ft. is exposed in small canyon just W. of San Gorgonio River and base not seen. Total thickness unknown. In places overlain, in angular discordance, by a basalt flow. In other places overlain by Deep Canyon fangl. or by Cabezon fangl.; and in still other places by Heights fangl. Is younger than Lion ss. and older than Pipes fangl.

Named for Hathaway Creek, Riverside Co., on and near which it is exposed.

Hathaway oil zone.

Subsurface beds of Plio. and Mio. age, encountered in wells in Santa Fe oil field, Los Angeles Co., Calif., that lie lower than Clarke oil zone.

Hato Puerco tuffs.

Cretaceous: Puerto Rico.

H. A. Meyerhoff, 1931 (Scientific survey of Porto Rico and Virgin Islands, vol. 2, pt. 3, p. 272, N. Y. Acad. Sci.).

Hattiesburg clay.

Miocene (lower and middle): Coastal Plain of Alabama, Mississippi, Louisiana, and eastern Texas.

L. C. Johnson, 1893 (Sci., vol. 21, pp. 90–91). More remote from the Great River [Mississippi], and something farther, the less siliceous the fm. becomes, at Hattiesburg, and in that part of Leaf River from Okatoma to Rogers Creek and on the Chickasawhay above Leakesville, a third phase of the Miocene Grand Gulf group is exhibited, abounding in phytogene remains—almost lignitic. This is the *Hattiesburg phase or fm.* Extends into Ala. and has been traced across Miss.

W. H. Dall, 1903 (Wagner Free Inst. Sci. Trans., Phila., vol. 3, pt. 6, pp. 1541–1620). *Hattiesburg clays* underlie Pascagoula clays and overlie Roberts sand.

G. C. Matson, 1916 (U. S. G. S. P. P. 98). *Hattiesburg clay* consists of massive non-marine blue and gray clays with subordinate amounts of sands and sss. Uncon. underlies Pascagoula clay and conformably overlies Catahoula ss. Forms lower part of Fleming clay of Veatch. Thickness 300–350 ft. in Ala. and La. and 450 ft. max. in Miss.

Named for exposures at Hattiesburg, Forrest Co., Miss.

Hatton tuff lentil (of Stanley shale).

Pennsylvanian (Pottsville): Southwestern Arkansas and southeastern Oklahoma.

H. D. Miser, 1920 (Geol. Soc. Am. Bull., vol. 31, p. 125). Tuff of Carbf. age occurs near base of Stanley sh. in Ouachita Mtn region in Polk Co., Ark., and McCurtain Co., Okla. There are 3, and possibly 4 or 5, beds of it, ranging in thickness from 6 to 85 ft. All of them are very similar in lithologic character. Lowest bed is thickest and most widely distributed. Has been mapped in detail in DeQueen quad., lying mostly in Ark., and to it name *Hatton tuff lentil* has been applied, for reason the best known exposure is in a cut of Kansas City Southern Ry ⅓ mi. S. of Hatton [Polk Co., Ark.]. The tuffs are compact, massive, and tough; generally homogeneous except for presence of numerous chloritic pellets that lie parallel with bedding; of dark gray color with a greenish tinge. None of tuffs have yielded fossils, and their assignment to Miss. is based on relations of Stanley sh. to overlying and underlying rocks, whose age has been determined by fossils.

In DeQueen quad, SW. Ark., lies 500± ft. above base of Stanley sh. Age changed to Penn. in 1934. See under *Stanley sh.*

Hauns' Bridge group.

Upper Devonian: Central Pennsylvania (Huntingdon County).

I. C. White, 1885 (2d Pa. Geol. Surv. Rept. T_3, p. 92). *Haun's Bridge group.*—Greenish gray sandy shales and flags with few thin red beds. Thickness 1,000 to 1,100 ft. Chemung shells from top to bottom, but included in Catskill fm. [probably because of red strata]. Overlies Lackawaxen [Saxton] cgl. and underlies 2,500 ft. of red Catskill sh. Named for 1,000-foot exposure at Hauns' Bridge in Juniata Twp, Huntingdon Co.

These strata form upper part of Chemung fm. as now identified in Huntingdon Co. (See U. S. G. S. Hollidaysburg–Huntingdon folio, No. 227, in press.)

Havana shales.

Cretaceous: Cuba.

J. W. Lewis, 1932 (A. A. P. G. Bull., vol. 16, p. 539).

See also *Habana fm.*

Havasupai sandstones.

Permian: Northern Arizona (Grand Canyon).

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, pp. 251, 336). ***Havasupai sss.***—The median ss. section of Aubreyan series, best exposed in rim wall near Bass Camp, W. of El Tovar, Grand Canyon. Thickness 200 ft. Underlies Wompats lss.

Probably named for Havasupai Point, where Coconino ss. is exposed. Appears to be applied to Coconino ss.

Havensville shale. (In Wreford limestone.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., p. 32). ***Havensville sh.***—Middle memb. of Wreford ls. Is essentially an olive-colored argill. sh. with fossiliferous transitional zones at top and bottom. Thickness 5 or 6 ft. in southern Kans.; 15 or 16 ft. SW. of Junction City and SE. of Randolph; and 18 ft. or more at type loc. in cuts on Highway 63 about 2 mi. S. of Havensville, Kans. Overlies Fourmile ls. and underlies Schroyer ls. [R. C. Moore (1936) replaced *Fourmile ls.* with *Threemile ls.*, but Nebr. Geol. Survey continues to use *Fourmile ls.*]

Hawaiiloa volcanics.

Pleistocene (late): Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and Gd. Water Res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). ***Hawaiiloa volcanics.***—Chiefly basalt. Included in lower part of Honolulu volcanic series [q. v.]. Is older than Ulupau tuff. Type loc. Hawaiiloa Hill.

Hawarden shale.

Upper Cretaceous: Northwestern Iowa.

C. [R.] Keyes, 1912 (Iowa Acad. Sci. Proc., vol. 19, p. 148). ***Hawarden terrane.***—Shales, 125 ft. thick, underlying Niobrara terrane and overlying Crill terrane. All included in Coloradan series. [Keyes stated (Iowa Acad. Sci. Proc., vol. 20, p. 200, 1913) that Niobrara terrane in above definition is a bed much higher in section than so-called Niobrara chalk of Iowa as recognized by Meek and Hayden, Calvin, Bain, and others, and that it has recently been traced to typical outcrop of Niobrara ls.]

Probably named for Hawarden, Sioux Co.

Hawke Bay formation.

Hawke Bay quartzite.

Lower Cambrian: Newfoundland.

C. Schuchert and C. O. Dunbar, 1934 (Geol. Soc. Am. Mem. 1, p. 21).

Hawkeye granite.

Pre-Cambrian: Northern New York (Clinton County).

W. J. Miller, 1919 (Jour. Geol., vol. 27, p. 29; also see Econ. Geol., vol. 14, p. 512). [See under *Lyon Mountain granite.*] Named for exposures just E. of Hawkeye post office [Clinton Co.]. Forms summit of Lyon Mtn.

Hawkins formation.

Carboniferous (?): Central Washington (Mount Stuart and Snoqualmie quadrangles).

G. O. Smith, 1903 (U. S. G. S. P. P. 19). *Hawkins fm.*—Volcanic series of flow breccias, tuffs, and amygdaloids; extremely altered; green or purple. Pre-Eocene.

G. O. Smith, 1904 (U. S. G. S. Mount Stuart folio, No. 106). *Hawkins fm.* (Carbf.?) makes up rugged peak known as Hawkins Mtn, Mount Stuart quad. Is younger than Easton schist. Assigned to Carbf.(?).

Hawkins limestone.

Cambrian: Southwestern New Mexico (Grant County).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257–259; Conspectus of geol. fms. of N. Mex., pp. 4, 8). *Hawkins lss.*—Important calc. beds of Mid Cambric age intercalated in basal section of qtzites exposed in Grant Co. Thickness 50 ft. [Derivation of name not given. According to E. Kirk and others Middle Camb. is absent in N. Mex.]

Hawkins Point clays.

Lower Cretaceous; Northeastern Maryland.

L. F. Ward, 1895 (U. S. G. S. 15th Ann. Rept., p. 334). There seems to be one horizon in the Albirupean or upper series of Potomac fm. that occupies a considerable breadth at which the purple mottled tenacious clays occur in vast quantities. I have denominated this belt *Hawkins Point clays,* from their occurrence at Hawkins Point, on the lower Patapsco, where they form an extensive cliff 40 ft. high, with a width along the shore of nearly ½ mi. toward Swan Creek [Anne Arundel Co.].

Belongs to Patapsco fm.

Hawley schist.

Ordovician: Western Massachusetts and southeastern Vermont.

B. K. Emerson, 1892 (U. S. G. S. Hawley sheet, i. e., proof sheets of geol. maps and text intended for a geol. folio, but never completed and published in that form, although cited in U. S. G. S. Bull. 191, 1902). *Hawley schist,* ankerite chlorite schist, with beds of amphibolite and iron ores. Underlies Goshen schist and overlies Savoy schist.

B. K. Emerson, 1898 (U. S. G. S. Holyoke folio, No. 50; also U. S. G. S. Mon. 29, pp. 163–171 and map, pl. 34). *Hawley schist.*—Sericite and actinolitic chlorite schists with many beds of hornblende schist. Thickness 2,000 ft. (?). Uncon. underlies Goshen schist and overlies Savoy schist. [See also B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 43–44).]

Named for exposures in Hawley Twp, Mass.

Hawleyville granite gneiss.

Pre-Cambrian(?): Western Connecticut.

W. M. Agar, 1934 (Am. Jour. Sci., 5th, vol. 27, p. 355), mapped as *Hawleyville granite gneiss* an area of rocks lying NW. of Hawleyville, Conn., but did not mention the town or the fm. name in his text, pp. 354–373.

Hawpatch glacial gravel and sand.

Pleistocene: Southeastern Indiana (Bartholomew County).

M. N. Elrod, 1882 (Ind. Dept. Geol. and Nat. Hist. 11th Ann. Rept., pp. 156–158). *Hawpatch glacial gravel and sand.*—One of most extensive and peculiar beds of gravel in Ind., being 12 mi. long and 3 mi. wide, in Bartholomew Co. Roughly bounded by Flat Rock River on NW. and Haw Creek on SE., and reaching from White River bottoms to Shelby Co. Covered with gravelly black soil.

Hawthorn formation. (Of Alum Bluff group.)

Miocene (lower): Central northern, northern and southern Florida, southern and southeastern Georgia, and South Carolina.

W. H. Dall, 1892 (U. S. G. S. Bull. 84, pp. 81–82, 107–112, 157, 158, 326). *Hawthorne beds.*—Beds of phosphatic rock, more or less broken up and inclosed in a younger matrix, overlying Vicksburg ls. at "Devil's Millhopper," near Gainesville, Ga., and occurring as remnants in place on hilltops near Archer, Arredondo, and other places. Includes (descending) phosphatic oolite, soft ss., ferruginous gravel, sand, or ss., and greenish yellow clays. Rests on Nummulitic beds of Vicksburg group. Underlies Altamaha grit. Max. thickness 125 ft. Included in Chattahoochee group.

Later work by G. C. Matson (U. S. G. S. Bull. 604, p. 13, 1915) led him to believe these beds were same as Alum Bluff, the better-established name, and *Hawthorn fm.* was therefore abandoned. Later work by Julia Gardner led her to opinion (1925) that Hawthorn fm. was=only basal part (Chipola fm.) of Alum Bluff group, and the name still remained abandoned. In 1929 (Fla. Geol. Surv. 20th Ann. Rept.), however, C. W. Cooke and S. Mossom revived *Hawthorn fm.* as designation of a lithologic unit (chiefly phosphatic ls. and fullers earth) within Alum Bluff group (of lower and middle Mio. age), and chiefly if not wholly=Chipola fm. (of different lithology) of Alum Bluff group, but which may include a representative of Oak Grove sand. As redefined by Cooke and Mossom the Hawthorn fm. includes the original Hawthorn "beds" of Dall, but excludes the *Cassidulus*-bearing ls. and chert that Matson and Clapp [Fla. Geol. Surv. 2d Ann. Rept., pp. 69–74, 1909] placed in Hawthorn fm. but which is now known to be Tampa. With it are tentatively included Dall's Jacksonville ls. and Manatee River marl, which it has been found impracticable to map separately, although their faunas seem to be younger than that of typical Hawthorn. Dall's Sopchoppy ls., of Chipola age, is also placed in Hawthorn fm. According to T. W. Vaughan and Julia Gardner the †Jacksonville fm. is of upper Mio. age, and younger than any part of Alum Bluff group. The typical Hawthorn fm. is considered by Gardner, Cooke, and Mossom to be of Chipola (lower Mio.) age.

Named for exposures at Hawthorn, Alachua Co., Fla.

†Hawthorne formation.

See *Hawthorn fm.*, the approved spelling.

Hawxby shale.

Pennsylvanian: Northeastern Kansas and southeastern Nebraska.

R. C. Moore and G. E. Condra (Oct. 1932 revised classification chart of Penn. rocks of Kans. and Nebr., 6th Ann. Field Conf. Kans. Geol. Soc.). [*Hawxby sh.* shown as underlying Falls City ls. and overlying Aspinwall ls., all included in Admire sh. Derivation of name not stated.]

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 9). *Hawxby sh. fm.*—Light bluish-gray calc. sh. cut by thin-bladed material, 10 ft., underlain by 2½ ft. of bluish-gray and locally red sh. with an argill. subzone. Underlies Falls City ls. fm. and overlies Aspinwall ls. fm.; all included in Admire group. [Derivation of name not stated.]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), transferred all beds above Brownville ls. to Perm. (See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.)

E. C. Reed (Asst. State Geol. Nebr.), 1936 (letter dated Oct. 16). Type loc. of Hawxby sh. is Hawxby farm, SE¼ sec. 7, T. 4 N., R. 15 E., Nemaha Co., Nebr., 5± mi. W. of Nemaha.

Haybro formation. (In Mesaverde group.)

Upper Cretaceous: Northwestern Colorado (Yampa coal field).

M. R. Campbell, 1931 (Tentative correlation of named geologic units of Colo., compiled by M. G. Wilmarth, U. S. G. S. separate chart). *Haybro fm.*—Sh., ss., and coal beds, with Hayden Gulch ss. memb. (50 ft. thick) at top in part of Yampa field. In W. part of Daton Peak quad. and N. of Yampa River the Haybro is largely ss. and Hayden Gulch memb. can not be separated. Thickness of fm. 600 to 800 ft. The small coal-mining village of Haybro, on Denver & Salt Lake R. R., on Oak Creek, is built on this fm. Is basal fm. of Mesaverde group in Yampa coal field. Overlies Mancos sh. and underlies Milner fm.

Hay Creek formation.

Lower Cretaceous: Northeastern Wyoming and western South Dakota (Black Hills).

W. P. Jenney, 1899 (U. S. G. S. 19th Ann. Rept., pt. 2, p. 593, fig. 122, and map). *Hay Creek coal fm.*—In Hay Creek coal field, Crook Co., Wyo., consists of (descending): (1) Massive ss., ocher yellow, weathering yellow brown, underlain by gray and drab clay shales with local thin coals and plant remains, 10 to 20 ft.; (2) coal, mined at Larrabee, Young, and Barrett, 2 to 6 ft.; (3) gray clay sh. and sandy sh. with plant remains, 20 to 35 ft.; (4) soft gray or yellow sss. with carbonized plant remains, 5 to 20 ft. Underlies Barrett shales, without positive evidence of uncon., and uncon. overlies Upper Jurassic Beulah clays [Morrison fm.] in Black Hills. [Presumably named for Hay Creek, Crook Co., Wyo., and Butte Co., S. Dak. In Wyo. these beds are mapped along South Fork of Hay Creek.]

Appears to be same as Lakota fm., better-established name.

Hayden Gulch sandstone member (of Haybro formation).

Upper Cretaceous: Northwestern Colorado (Yampa coal field).

M. R. Campbell, 1931 (Tentative correlation of named geologic units of Colo., compiled by M. G. Wilmarth, U. S. G. S. separate chart). *Hayden Gulch ss. memb. of Haybro fm.*—Massive white ss., 50 ft. thick, forming top memb. of Haybro fm. in part of Yampa coal field. In W. part of Daton Peak quad. and N. of Yampa River the Haybro fm. is largely ss. and Hayden Gulch memb. cannot be separated. Named for exposures in Hayden Gulch.

Hayden Peak latite.

Tertiary: Southern Colorado (Bonanza district, Saguache County).

H. B. Patton, 1916 (Colo. Geol. Surv. Bull. 9, pp. 21–63). *Hayden's Peak latite.*—Fine-grained brownish-gray massive rock, with minute inconspicuous feldspar phenocrysts; quartz in groundmass. Occurs on summit of Hayden's Peak and North Hayden's Peak.

W. S. Burbank, 1932 (U. S. G. S. P. P. 169). *Hayden Peak latite.*—Local flows, tuffs, and breccias; probably some intrusives. Thickness 1,000 to 1,500 ft. Believed to be in part contemp. with Bonanza latite and in part younger. Rests on Rawley andesite. Includes Hayden Peak latite of Patton and some underlying rocks mapped by Patton as andesite and Bonanza latite. Occurs on summit of Hayden Peak.

Hayes River beds.

Tertiary: Southern Alaska.

J. E. Spurr, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 172–173, 184). *Hayes River beds.*—Slightly consolidated sands and gravels containing lignite beds. Just below mouth of Hayes River, on the Skwentna, they consist of gray and yellow, partially consolidated sed. beds, some soft, some harder. Farther up the Skwentna, nearly opp. mouth of Hayes River, a bluff 100 to 120 ft. high is composed of these beds. Believed to be younger than Kenai beds; and tentatively referred to Neocene.

Hayes River group.

Pre-Cambrian: Manitoba.

J. F. Wright, 1928 (Canada Geol. Surv. Summ. Rept. 1927, pt. B, pp. 63, 64).

Hayfield shale.

Devonian or Carboniferous: Northwestern Pennsylvania (Erie County).

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69). [In table *Bradfordian (Upper Dev.)* of Erie Co., Pa., is divided into (descending): *Hayfield sh.;* Cussewago ss.; Riceville sh.; Venango group, with Le Boeuf ss. (=Panama cgl.) at base. Corry ss. shown uncon. on Hayfield sh.]

G. H. Chadwick, 1925 (Geol. Soc. Am. Bull., vol. 36, pp. 463, 464). [Repeated 1923 table of subdivisions of Upper Dev. *Bradfordian* in Erie Co., Pa., and expressed opinion that "the Cussewago sand is followed by an increasing thickness of true (non-Bedford) Cussewago sh., which for distinction we will rename *Hayfield sh. (and ls.).*" He also mentioned the thin *Cussewago (Hayfield) ls.* beneath the Hayfield sh.]

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 202), applied *Glade ss.* to the ss. underlying *Hayfield sh. memb. of Knapp fm.* in NW. Pa., but did not explain its relations to Cussewago ss. He treated his Hayfield as top memb. of Knapp fm.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, pp. 103, 116–119), restricted *Hayfield sh.* to upper part of Hayfield sh. of Chadwick, and named the lower part *Tidioute sh. memb.* He stated that latter sh. is present but meagerly developed at Hayfield type loc. (which he stated is Hayfield Twp, Crawford Co.), and that it rests on Cussewago ss., upon which the Hayfield of Chadwick was defined as resting. Caster renamed Hayfield ls. of Chadwick the *Littles Corner ls.*, and included it in his Hayfield sh. restricted. On p. 103 he stated Hayfield sh. is 25 to 40 ft. thick; on p. 116 he gave thickness of 10 to 60 ft. Caster also (p. 116) used *Hayfield monothem* to include his Hayfield sh. restricted and his (underlying) Tidioute sh. memb., and gave its thickness as 60 ft. He assigned it to Miss. G. H. Chadwick, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, pp. 305–354) assigned all of *Bradfordian* to Upper Dev.

Hayfield limestone.

Devonian or Carboniferous: Northwestern Pennsylvania.

See 1925 entry under *Hayfield sh.*

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71), replaced this name with *Littles Corner ls. memb.* "Same as Cussewago ls. of I. C. White."

Hayfield monothem.

See 1934 entry under *Hayfield sh.*

Hay Fork beds.

Miocene: Northwestern California (Trinity County).

J. S. Diller, 1902 (U. S. G. S. Bull. 196, pp. 43–44). [Described deposits near town of Hay Fork, Trinity Co., consisting of sss. and shales, locally associated with coal, and probably extending 10 mi. nearly E. and W., with width of about 1 mi. Contain Tert. fossils and are probably of upper Mio. age. In one place casually alluded to them as *Hay Fork beds.*]

J. S. Diller, 1903 (Am. Jour. Sci., 4th, vol. 15, pp. 342–362). [Described upper Mio. beds of Hay Fork region and throughout text called them *Hay Fork beds.*] "Formed in an estuary near sea level."

Hay Hollow sandstone member (of Nelagoney formation).

Pennsylvanian: Central northern Oklahoma (Osage County).

M. I. Goldman and H. M. Robinson, 1920 (U. S. G. S. Bull. 686Y, pp. 362–363). *Hay Hollow ss.*—Slabby ss., generally 1 ft. or less thick, fine-grained, compact, hard, and of rather warm yellow color. At many places contains peculiar winding cylindrical ss. casts an inch in diam., closely interwoven, which cover surfaces of slabs. As it lies 40± ft. below top of Cheshewalla ss., isolated in midst of a thick series of sh., and weathering out in a well-defined line of large broken slabs, it is easily recognized, but care must be taken not to confuse it with a somewhat similar hard slabby bed which lies 10 or 15± ft. below top of Cheshewalla ss. and also forms conspicuous outcrop in midst of sh. around Sundown Hill and around the point W. of mouth of Hay Hollow. This higher bed, however, is orange-colored, rather than yellow, and generally rich in impressions of fossils, especially bivalves, instead of wormlike markings so common on surface of Hay Hollow ss. Named for occurrence along upper part of Hay Hollow in secs. 25 and 36, T. 28 N., R. 11 E.

Haymaker beds.

Upper Devonian: Western New York (Genesee River region).

G. H. Chadwick, 1934 (Geol. Soc. Am., Prel. list of titles and abstracts of papers to be offered at 47th ann. meeting, Rochester, N. Y., Dec. 27–29, 1934, p. 12). [See 1934 entry under *Cadiz beds.*]

G. H. Chadwick, 1935 (Geol. Soc. Am. Proc. 1934, p. 71). [See 1935 entry under *Northeast sh.* Type loc. not stated.]

Haymond formation.

Pennsylvanian (Pottsville): Western Texas (Marathon region, Brewster County).

J. A. Udden, C. L. Baker, and E. Böse, 1916 (Univ. Tex., Bur. Econ. Geol. and Tech. Bull. 44, p. 46). *Haymond fm.*—Sss. and shales with same characteristics as those of Tesnus fm. Thickness 500 ft. Named by Baker. Lies btw. Dimple fm. below and Leonard fm. above. Is top fm. of Penn.

C. L. Baker, 1928 (A. A. P. G. Bull., vol. 12, p. 1114). Validity of Haymond as distinct fm. is uncertain. It appears to be exact lithologic counter-part of the Tesnus. It may be overthrust on the Dimple.

C. Schuchert, 1927 [See 1927 entry under *Tesnus fm.*]

C. L. Baker, 1928 (A. A. P. G. Bull., vol. 12, p. 1114). Validity of Haymond as distinct fm. is still uncertain. Appears to be exact lithologic counterpart of Tesnus. May be overthrust on Dimple.

P. B. and R. E. King, 1928 (Univ. Tex. Bull. 2801). *Haymond fm.* is 1,800+ ft. thick (total unknown). It clearly overlies Dimple fm. and is a valid fm. It grades into overlying Gaptank fm. Few fossils. Correlates with some part of Strawn of central Tex. Lithologically resembles the much older Tesnus fm.

The U. S. Geol. Survey at present classifies this fm. as of Pottsville age. (See U. S. G. S. P. P. 187, in press.)

Named for exposures NW. and SE. of Haymond, Brewster Co.

Haynesville sand.

See *Oakes sand.*

Haynies limestone.

Pennsylvanian: Southeastern Nebraska, southwestern Iowa, northwestern Missouri, and northeastern Kansas (?).

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 40, 43, 49, 50). *Haynies ls.*, 8 inches to 1 ft. thick in SE. Nebr., 9 inches in SW. Iowa, 1⅔ ft. in NW. Mo., and 2+ ft. in NE. Kans. Underlies Mission Creek sh. and overlies Larsh sh., all included in Deer Creek ls. Named for outcrop in foot of the bluffs SE. of Haynies Station, Mills Co., Iowa.

G. E. Condra, 1933 (Nebr. Geol. Surv. Paper No. 2), used *Plummer ls.*, in Iowa, for the beds formerly called *Haynies ls.*, and stated (p. 5): The "Haynies ls." memb. of the Deer Creek, according to Condra and Moore, is the Plummer ls. of Okla.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 186). *Haynies memb.* seems exactly to correspond to upper bed of Plummer ls. as originally defined, and it is possible Rock Bluff ls., Larsh sh., and Haynies ls. together are=original Plummer ls. [On p. 187 he stated:] Because sh. btw. Ervine Creek ls. and Rock Bluff ls. in Kans. appears to be exactly=Larsh sh., Haynies ls., and Mission Creek sh. of Nebr. it is here called *Larsh-Mission Creek sh. memb. of Deer Creek ls.* It is 2½ to 7 ft. thick. [He omitted *Haynies ls.* from this 1936 classification for Kans.]

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936. Also see 1937 entry under *Topeka ls.* for Condra's latest views.

†Hays limestone member (of Niobrara formation).

Upper Cretaceous: Western Kansas and eastern Colorado.

See explanation under *Fort Hays ls.*

Haystack rhyolite.

Devonian (?): Northeastern Maine (Aroostook County).

H. E. Gregory, 1900 (U. S. G. S. Bull. 165, pp. 107-109, 153-156). *Haystack rhyolite.*—The rhyolites of Haystack Mtn, Aroostook Co.

On 1933 geol. map of Maine, by A. Keith, the mapped areas of rhyolite in the State are assigned to Dev.

Haystack gypsum member (of Blaine gypsum).

Permian: Southwestern Oklahoma (Greer County).

C. N. Gould, 1902 (Okla. Geol. Surv. 2d Bien. Rept., pp. 42, 55). *Haystack gyp.*—Massive gyp., 18 to 25 ft. thick, almost pure white but occasionally grayish, with a few thin bands of gypsiferous ss. Occurs in shales which separate Kiser gyp. below from Cedartop gyp. above. Included in Greer div.

C. N. Gould, 1924 (A. A. P. G. Bull., vol. 8, No. 3, pp. 324–341). Haystack gyp. memb. is provisionally considered=Ferguson gyp. memb.

Named for Haystack Creek, Greer Co.

Hayward sandstone member.

Permian: Central northern Oklahoma.

F. L. Aurin, H. G. Officer, and C. N. Gould, 1926 (A. A. P. G. Bull., vol. 10, pp. 786–799). *Hayward ss. memb.*—Upper 350 ft. of Garber ss., consisting chiefly of heavy ledges of massive red ss., more or less lenticular, generally cross-bedded, and not uncommonly conglomeratic, interstratified with beds of fissile sh. and sandy sh. Overlies Lucien sh. memb. of Garber ss. and is overlain by Fairmont sh. memb. of Hennessey sh. Named for exposures at Hayward, Garfield Co.

Hazel slate. (In Chilhowee group.)

Cambrian (Lower): Eastern Tennessee and western North Carolina.

A. Keith, 1895 (U. S. G. S. Knoxville folio, No. 16, p. 3). *Hazel sl.*—Chiefly black sl., but contains many thin beds of ss. and cgl. In more eastern areas the rock is always a fine black schist. Thickness 600 to 800 ft. Overlies Thunderhead cgl. and underlies Clingman cgl.

Named for Hazel Creek, Swain Co., N. C.

†Hazel sandstone.

Pre-Cambrian: Western Texas.

E. T. Dumble, 1902 (Tex. Acad. Sci. Trans., vol. 4, pt. 2, No. 6, pp. 1–3). *Hazel ss.*—Red ss., 500 ft. thick, in Diablo Mtns. Uncon. overlies schists and underlies heavy-bedded to flaggy cherty or siliceous lss. of various colors, which are supposed to be Algonkian and are correlated with Texan group of Comstock's Llano section and called Texas marbles.

Regarded as an inseparable part of Millican fm.

Named for Hazel mine, Diablo Mtns, El Paso Co.

Hazelton group.

Jurassic (?): Southeastern Alaska (Hyder region) and British Columbia.

W. W. Leach, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 64). *Hazleton (Porphyrite) group,* Jurassic, B. C. [Hazelton is correct spelling.]

A. F. Buddington, 1929 (U. S. G. S. Bull. 807, pp. 17–22, 59, maps, etc.). *Hazelton group* in Hyder dist., Alaska, consists above of tuffaceous graywacke, sl., argillite, qtzite, and rare ls., and below of greenstone, tuff, volcanic breccia, and sparse sl. Is intruded by Coast Range intrusives, of Jurassic or Cret. age. No fossils found. Beds are assigned to Hazelton group because of lithologic similarity to the fms. of that group to SE. and N. in B. C. and because of similar structural relations to Coast Range intrusives. It has been described by G. Hanson (Canada Geol. Surv. Summ. Rept. 1923, pt. A, pp. 32–36, 1924) as consisting of a lower fm. of volcanic tuff, breccia, and flows of green or gray to purplish andesitic rock, and an upper fm. of argillite, qtzite, and tuffaceous ss. The argillite of upper div. carries Jurassic fossils. Schofield and Hanson (op. cit., pp. 10–13) have divided the rocks on B. C. side of Int. Bdy into (descending) Nass fm., Salmon River fm., and Bear River fm. The lower div. in Hyder dist. is continuous with Bear River fm. of B. C.; a bed resembling Salmon River cgl. was seen at one place; and it is very probable Nass fm. is represented in Hyder dist.

†Hazlet sands.

Upper Cretaceous: New Jersey.

W. B. Clark, R. M. Bagg, and G. B. Shattuck, 1897 (Geol. Soc. Am. Bull., vol. 8, pp. 315, 329). *Hazlet sands.*—Chiefly sands, highly ferruginous and brown in color in lower portions and often affording indurated crusts. Above the brown sand is frequently a well-developed dark-colored clay very like lower part of underlying Crosswicks clays. Compose upper part of Matawan fm. Conformably overlain by Mount Laurel sands. Named for Hazlet, Monmouth Co.

W. B. Clark, 1904 (Am. Jour. Sci., 4th, vol. 18, pp. 435–440). The *Hazlet sands* include Marshalltown sand and clay above and Columbus [Englishtown] sand below, and compose upper part of Matawan fm. [Clark et al., also included Wenonah sand, since they extended the name to base of Mount Laurel sand.]

This name is now considered to be superfluous, and its use has been discontinued.

Hazleton group.

Jurassic (?): British Columbia and southeastern Alaska.

See *Hazelton group*, the correct spelling. Named for town of Hazelton, B. C., which was named for the profusion of hazel bushes in its vicinity.

†Headlight porphyry.

A name that has been applied locally to a granodiorite porphyry, of probably earliest Cret. age, in Trinity Co., Calif.

Headquarters granite.

Pre-Cambrian: Southwestern Oklahoma (Greer County).

C. H. Taylor, 1915 (Okla. Geol. Surv. Bull. 20). Fine-grained brownish-red, often porphyritic intrusive granite of Headquarters Mtn, Greer Co. Older than Reformatory granite and younger than the gabbro.

Headquarters schist.

Pre-Cambrian: Southeastern Wyoming (Medicine Bow Mountains).

E. Blackwelder, 1926 (Geol. Soc. Am. Bull., vol. 37, pp. 620, 623, 627). *Headquarters schist.*—Largely greenish gray, chloritic phyllite or schist, with several beds of metaqtzite, glacial metacgl., metadolomite, and schistose basic pyroclastics. Recrystallized but have not lost their most distinctive characteristics. Thickness 2,800± ft. Conformably underlies Heart graywacke, and overlies Deep Lake metaqtzite, probably conformably. Headquarters Park is located on outcrop. Assigned to early Algonkian.

Healdton sand zone.

A series of subsurface sands, 200 to 400 ft. thick, of early Penn. age, in Healdton field, Carter Co., southern Okla., where they lie at 1,730 ft. depth, the Glenn sand lying at 1,130 ft. and the Ord. at 2,220 ft.

Healing Springs sandstone member (of New Scotland limestone).

Lower Devonian: Central western Virginia.

F. M. Swartz, 1930 (U. S. G. S. P. P. 158C). South of Monterey, Va., the New Scotland ls. becomes highly aren. in its lower half, as at Bolar Springs and Dry Run, and finally changes into a heavy-bedded gray calc. ss., as at Clifton Forge, Gala, and in gap W. of Healing Springs, Bath Co. This ss. composes Healing Springs ss. memb of New Scotland ls. Thickness 8 to 20 ft.

Heart metagraywacke.

Pre-Cambrian: Southeastern Wyoming (Medicine Bow Mountains).

E. Blackwelder, 1926 (Geol. Soc. Am. Bull., vol. 37, pp. 620, 623, 631). *Heart metagraywacke.*—Alternation of gray to olive, smoky metaqtzites and chloritic phyllites, much cross-bedded and fine-textured. Thickness 1,500 ft. Conformably underlies Medicine Peak metaqtzite and conformably overlies Headquarters schist. Heart Lake is located on outcrop. Assigned to early Algonkian.

Heartwellville schist.

Upper Cambrian (?): Southwestern Vermont (Bennington County).

Geo. D. Hubbard, 1924 (14th Rept. Vt. State Geol., pp. 278–283, 291, 293, 315, and map). *Heartwellville schist.*—Mica schist. Grades into underlying Whitingham schist through transition zone 5 to 20 ft. thick. Quartz and sericite, in varying proportions, make up 90 to 95 per cent of the rock. Highly siliceous and highly micaceous layers can occur anywhere in the fm. Garnets of a red almandite type occur all through the fm. Is believed to be of sed. origin. Thickness 300 to 1,200 ft. Is overlain by Readsboro schist, from which it is rather sharply separated but with no evidence of erosion. Identity of Greylock [Ord.] and Heartwellville schists is well established, both by position and by mineral composition, structure, and texture.

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), assigned this fm. to Upper Camb., but without discussion.

Named for fact that town of Heartwellville, Bennington quad., lies on a large area of the schist.

Heath formation.

Mississippian: Montana.

H. W. Scott, 1935 (Geol. Soc. Am. Proc. 1934, p. 367). [See first entry under *Big Snowy group.*]

H. W. Scott, 1935 (Jour. Geol., vol. 43, pp. 1016–1032). *Heath fm.*—Black, petroliferous shales and sss., primarily black shales, forming upper fm. of Big Snowy group. Thickness may reach 500 ft. In most sections 3 ss. beds occur in upper half. On SE. flank of Big Snowy Mtns these ss. beds have been grouped under name *Van Dusen sand,* which should be considered a memb. at top of Heath fm. On NE. flank of Big Snowy Mtns ss. beds occupying same strat. zone, at top of Heath fm., have been named, by O. W. Freeman, *Tyler sand.* It also should be treated as a memb. of Heath fm. The fm. conformably underlies Amsden fm. and conformably overlies Otter fm. Type section is on N. flank of Big Snowy Mtns, in sec. 6, T. 12 N., R. 20 E. Fossils listed. Are closely related to fauna of Brazer ls. of Idaho and Moorefield fm. of Ark.; and are not older than Warsaw nor younger than Upper Chester. Fauna is now being studied.

Heber limestone.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, p. 37). *Heber lss.*—Lss., 250 ft. thick; overlie Park sss.; uncon. below Woodside sh.; compose uppermost fm. of Aubreyan series in Utah. [Derivation of name not stated.]

Hebron gneiss.

Probably Carboniferous: Eastern Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 115, 121, 122, 140, 142, and map). *Hebron gneiss.*—Shows great variety in composition and structure. Varies from granitic gneiss to highly fissile schist, and it is only when whole area is considered that term *gneiss* seems appropriate. It forms an irregular band almost completely enclosing the Willimantic gneiss. Crosses Hebron Twp. Is intruded by granite. Grades into Willimantic gneiss on one side and into Scotland and Brimfield schists on the other. The Willimantic gneiss is merely a more injected phase of the Hebron. The Bolton schist grades into Hebron gneiss.

H. E. Gregory and H. H. Robinson, 1907 (Conn. Geol. and Nat. Hist. Surv. Bull. 7, p. 37 and map). *Hebron gneiss* is believed to be of sed. origin and is correlated with Putman gneiss. Willimantic gneiss is igneous.

†Hebron moraine.

A name that was many years ago applied to a moraine of Pleist. (late Wisconsin) age, from Hebron, Ill. Later work proved that this moraine is only a small part of Lake Mills morainic system, and "Hebron" has been discontinued. (See U. S. G. S. P. P. 34, 1904, p. 63; and P. P. 106, 1918, both by W. C. Alden.)

Hecla sandstone. (In Allegheny formation.)

Pennsylvanian: Southeastern Ohio.

E. Orton, 1884 (Ohio Geol. Surv. vol. 5, pp. 96, 124, 128, 1025, 1026). *Hecla ss.*—Massive ss., in Lower Coal Measures, in interval btw. Upper Clarion coal and Putman Hill ls. in Hanging Rock dist., Jackson Co.

W. Stout, 1916 (Ohio Geol. Surv., 4th ser., Bull. 20), stated that Hecla ss. is same as Clarion ss.

Probably named for Hecla, Lawrence Co.

Hector formation.

Pre-Cambrian: Alberta.

C. D. Walcott, 1910 (Smithsonian Misc. Coll., vol. 53, No. 7, p. 428).

Hectozoic.

A time term applied by E. Hitchcock (Geol. Vt., 1861, vol. 1, p. 19) to Quaternary of present usage.

Hedgehog trachyte.

Devonian (?): Northeastern Maine (Aroostook County).

H. E. Gregory, 1900 (U. S. G. S. Bull. 165, pp. 109–110, 161–162). *Hedgehog trachyte.*—The mass constituting Hedgehog Mtn, Aroostook Co.

On 1933 geol. map of Maine, by A. Keith, the trachyte of NE. Me. appears to be included in Dev.

Hedges shale. (Of Pocono group.)

Mississippian: Northeastern West Virginia.

G. W. Stose and C. K. Swartz, 1912 (U. S. G. S. Pawpaw-Hancock folio, No. 179). *Hedges sh.*—Dark-gray to black carbonaceous sh. containing thin seams of anthracite coal. Thickness 170 ft. Underlies Myers sh. and overlies Purslane ss.; all included in Pocono group. Named for occurrence on Hedges Mtn, Berkeley Co.

Hedwig breccia member (of Esmeralda formation).

Miocene (upper): Central Nevada (Manhattan district).

H. G. Ferguson, 1924 (U. S. G. S. Bull. 723). *Hedwig breccia memb.*—Old talus slopes composed of angular fragments of Paleozoic rocks. Thickness 100 ft. Basal memb. of Esmeralda fm. Underlies Round Rock memb. Outcrops in vicinity of Hedwig claim.

Heebner shale. (In Oread limestone.)

Pennsylvanian: Southeastern Nebraska, eastern Kansas, southwestern Iowa, and northwestern Missouri.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 32, 33, 37). *Heebner sh.*, of Oread ls. memb., underlies Plattsmouth ls. and overlies Leavenworth ls. Top part is bluish and argill.; lower part is black, finely bedded, and somewhat carbonaceous. Thickness 5 ft. or more. Named for Heebner Creek and Heebner farm, W. of Nehawka.

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, 2d ser., p. 11). The so-called Heebner sh. of Bull. 1 Nebr. Geol. Surv. is Galesburg sh. memb.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 12), continued to use *Heebner sh.* for the sh. underlying Plattsmouth ls. and overlying Leavenworth ls., and R. C. Moore also used it in Kans. in his 1936 classification.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Hefty formation.

Pre-Cambrian: Southern British Columbia and northwestern Montana (Galton Range).

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, map 2, 114° 30′ to 115°). *Hefty fm.*—Chiefly thick-bedded reddish ss. [Mount Hefty, Mont., is on this map and Hefty fm. is mapped just to W. of it.]

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, pp. 99, 178). *Hefty fm.*—Chiefly heavy-bedded red or reddish-gray ss. and qtzite 775 ft. thick. Underlies, with some abruptness, MacDonald fm. and conformably overlies Altyn fm.

Heidlersburg member (of Gettysburg shale).

Upper Triassic: Southeastern Pennsylvania.

G. W. Stose, 1929 (U. S. G. S. Fairfield-Gettysburg folio, No. 225). Largely red sh. and ss. with some green, gray, and black shales, interbedded with which are many harder gray to white sss. Numerous intrusions of diabase have altered some strata to hard white porcelanite and to white, open-textured sandrock of light weight.

A little of the altered sh. is dark-purplish argillite. Thickness 4,800 ft. Occurs near middle of Gettysburg sh.

Named for exposures in vicinity of Heidlersburg, Adams Co.

Heights fanglomerate.

Quaternary: Southern California (San Bernardino Mountains).

F. E. Vaughan, 1922 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 13, No. 9, pp. 344, 392–393, and map). *Heights fangl.*—Several areas of fangl. are found in this region which were laid down under same conditions as obtain at present day, but they have been uplifted and are undergoing dissection. Banning Heights is floored with such an accumulation, which overlies schists and granite, the Hathaway shales and ss., and the Cabezon fangl. In Hog Canyon, Little San Gorgonio Creek, and Cherry Canyon there is an extensive fangl. at same general elev. as Banning Heights. It is of same sort of material and bears same relationships to surrounding topography. On N. side of range there are several areas of fangl. which are probably of about same age as those described above.

A. O. Woodford and T. F. Harriss, 1928 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 17, pp. 279–288). Heights fangl. of Vaughan is included in our Blackhawk breccia. [See under *Blackhawk breccia*.]

Named for Banning Heights, Riverside Co., which it floors.

Heiskell shale.

Lower Ordovician (Chazyan): Southwestern Virginia and northeastern Tennessee.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27). [*Heiskell sh.* is shown in table, in Pearisburg trough as largely contemp. with Pearisburg ls., as underlying Lowville and uncon. overlying Holston, and as=Ottosee sh. and upper part of Tellico ss. Probably named for Heiskell, Knox Co., Tenn., in SE. corner of Briceville quad.]

Helderberg group (also **Helderberg limestone**).

Lower Devonian: New York, eastern Pennsylvania, western Maryland and Virginia, and northern West Virginia.

Helderberg system of Conrad, 1839, included Oriskany ss. at top and Rochester sh. at base.

Helderberg sss. of Conrad, 1839, was defined as resting on Helderberg lss., as underlying the "gray brachiopodous ss." (which is overlain by black sl.), and as containing *Fucoides cauda galli.*

Helderberg lss. of Conrad, 1839, underlie Helderberg sss. and overlie Second Pentamerus ls., which rests on gypseous shales [Salina fm.].

Helderberg ls. group of Mather, 1840, and of James Hall, 1842, and *Helderberg ls. series* of Mather, 1841, extended from base of Marcellus sh. to top of Salina fm.

Helderberg series of E. Emmons, 1842, and his *Helderberg div.* of 1846, extended from base of Marcellus sh. to top of Manlius ls.

Helderberg ls. of E. Emmons, 1842, applied to beds btw. Marcellus sh. and Schoharie grit, or to Onondaga ls. of present terminology.

Helderberg division of Vanuxem, 1842, *Helderberg series* of James Hall, 1843, and *Helderberg div.* of Mather, 1843, and of E. Emmons, 1846, extended from base of Marcellus sh. to top of Niagara group.

Upper Helderberg group of James Hall, 1851, extended from base of Marcellus sh. to top of Oriskany ss. This definition was used by J. D. Dana in several editions of his Textbook of geology, including 1869 ed., and was for many years followed by Hall and some other geologists.

Upper Helderberg group of C. H. Hitchcock, 1866, excluded Esopus grit.

Upper Helderberg ls. of E. Hitchcock, 1867, applied to beds btw. Marcellus sh. and Schoharie grit, or to Onondaga ls. of present usage.

Lower Helderberg group of James Hall, 1851, extended from base of Oriskany ss. to base of "Tentaculite or water ls.," described as resting on Onondaga salt group. In 1859 (also 1874) Hall drew base of his *Lower Helderberg group* at base of Tentaculite [Manlius] ls., which he described as overlying the Waterlime group. This definition nearly corresponds to that of *Helderberg group* as now commonly recognized, except that it included Manlius. It was not, however, immediately adopted, for some geologists for many years continued to include the "Waterlime group."

Great variability in the use of the names "Upper Helderberg group," "Corniferous group," and "Lower Helderberg group" and in the limits assigned to these divisions continued for many years. In 1899 (Sci., n. s., vol. 10, pp. 874–878) J. M. Clarke and C. Schuchert restricted Helderberg, under name *Helderbergian period or group*, to interval btw. base of Oriskany ss. and top of Manlius ls., or to "Lower Helderberg" of previous repts. In their Helderbergian they included at top 250 ft. of beds (called "Kingston beds") above Becraft ls. These beds—now divided into Alsen ls. and Port Ewen ls.—were transferred to Oriskany group in 1903, by C. Schuchert (Am. Geol.). (Clarke and Schuchert's subdivisions of the Helderberg were: Kingston beds, Becraft ls., New Scotland ls., and Coeymans ls.) In 1908 (Sci., n. s., vol. 28, pp. 346–348) G. H. Chadwick also included the Port Ewen in the Oriskanian, stating that the fauna has many affinities with overlying Oriskany lss. and that Dr. [J. M.] Clarke has therefore recommended the transfer of these beds to the Oriskanian, in spite of preponderance of Helderbergian elements. Chadwick also added another fm. to Helderberg group, designating as *Kalkberg ls.* "certain layers heretofore included variously by writers with the beds above [New Scotland] or below" [Coeymans]. Chadwick's subdivisions for N. Y. (Becraft, New Scotland, Kalkberg, and Coeymans) are those commonly accepted today, although A. W. Grabau in 1919 (Geol. Soc. Am. Bull., vol. 30, pp. 468–470) separated from base of Port Ewen ls. 20 to 50 ft. of cherty lss. "containing a modified Becraft fauna," to which he applied the name *Alsen cherty ls.* He stated that these beds are separated from rest of the Port Ewen, in which they had previously been included, by a big hiatus and discon.

The N. Y. State Survey now divides Helderberg group into (descending) Port Ewen ls., Alsen ls., Becraft ls., New Scotland ls., Kalkberg ls., and Coeymans ls. (See W. Goldring, 1931, N. Y. State Mus. Hdb. 10.)

The U. S. Geol. Survey now includes Port Ewen ls. in Oriskany group, to which it belongs, according to C. Butts.

Where the Helderberg deposits are not subdivided they are called *Helderberg ls.*

Named for fact that the deposits form basal part of Helderberg Mtns in Albany Co., N. Y.

†Helderberg division.
†Helderberg sandstones.
†Helderberg series.
†Helderberg system.
See under *Helderberg group.*

Helderbergian.

See under *Helderberg group.* A time term covering interval during which the rocks of Helderberg group were deposited.

Helen iron-formation.

Pre-Cambrian (Keewatin): Western Ontario.

A. P. Coleman and A. B. Willmott, 1902 (Ont. Bur. Mines Rept. 1902, p. 182, and Toronto Univ. Studies, geol. ser., No. 2, p. 11). *Helen iron fm.* Assigned to Huronian.

C. R. Van Hise and C. K. Leith (U. S. G. S. Bull. 360, 1909, and U. S. G. S. Mon. 52, 1911) assigned this fm. to Keewatin, as did C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184).

Helena limestone.

Pre-Cambrian (Belt series): Western central Montana (Belt Mountains).

C. D. Walcott, 1899 (Geol. Soc. Am. Bull., vol. 10, pp. 199–215). *Helena ls.*—More or less impure bluish-gray and gray ls., in thick layers; 2,400 ft. thick. Underlies Marsh sh. and overlies Empire sh.

Exposed in upper part of city of Helena and on hill slopes to E.

Helenan series.

Name employed by C. [R.] Keyes instead of Helena ls. of other geologists. (See Pan-Am. Geol., vol. 44, 1925, pp. 215, 217.)

†Hellam quartzite.

Lower Cambrian: Southeastern Pennsylvania.

P. Frazer, 1886 (Am. Phil. Soc. Proc., vol. 23, pp. 396, 398–400). *Hellam qtzite, Cambric.*—Same as Potsdam ss. and Formation No. 1. The base of the Paleozoic. A part of it composes Chikis Mtn. Contains *Scolithus linearis.* The *Hellam or Chikis qtzite* is a hard quartzose rock, generally white or gray, tinted by some other color, usually pink, brown, or blue. Is almost always crystalline. In Chester Co. lies uncon. on Archean schists.

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 1, pp. 78, 135, 165–166, 199). *Hellam qtzite* is name adopted by Frazer in his York Co. rept. (C_2) because of extensive spread of the fm. over Hellam Twp, where several large quarries work it out, and its characteristic *Scolithus* fossils are abundant. Chiques ss. is not only oldest name for this fm. but is locality of its finest exposure.

See also *Chickies qtzite.*

Hellam conglomerate member (*of Chickies quartzite*).

Lower Cambrian: Southeastern Pennsylvania.

G. W. Stose and A. I. Jonas, 1922 (Wash. Acad. Sci. Jour., vol. 12, pp. 360–362). *Hellam cgl. memb. of Chickies qtzite.*—Quartz cgl., grainy qtzite with rounded clear and blue quartz grains, and sl., chlorite schist at base in Hellam Hills, York Co. Thickness 600 ft. in Hellam-Chickies Hills; 150 ft. in Welsh Mtn. Is basal memb. of Chickies qtzite. Rests uncon. on pre-Camb. epidotic amphibolite schist or greenstone and aporhyolite. Named for exposures in midst of Hellam Hills, 3 mi. W. of Chickies Rock.

Hell Creek formation.

Upper Cretaceous: Eastern, northern, and central southern Montana, southwestern North Dakota, and northwestern and northern South Dakota.

B. Brown, 1907 (Am. Mus. Nat. Hist. Bull., vol. 23, art. 33, pp. 829–835). *Hell Creek beds.*—Fossil-bearing, fresh-water deposits of alternating sss. and clays 560 ft. thick in W. half of Dawson Co., Mont. Most constant memb. of series is massive ss. at base, 0 to 160 ft. thick. Probably continuous with the dinosaur-bearing beds of Little Missouri and Grand and Moreau rivers, judging from fauna. *These beds, with the underlying and overlying deposits, are typically* exposed on Hell Creek [Garfield Co.] and nearby tributaries of Missouri River. Assigned to Upper Cret. Separated from overlying Fort Union fm. by 100 ft. of lignite beds, here called *Fort Union* (?). Rests uncon. on Fox Hills fm. Lithologically similar in almost every respect to Ceratops beds of Converse Co., Wyo.

W. T. Thom, Jr., and C. E. Dobbin, 1924 (Geol. Soc. Am. Bull., vol. 35, pp. 484–499). *Hell Creek memb. of Lance fm.* as here defined is typically exposed on Hell Creek, Garfield Co., Mont., and is="Hell Creek beds" plus "lignite beds" of Brown (1907), occupying the interval btw. Fox Hills ss. below and the yellow Tullock memb. of the Lance above. In SW. N. Dak. it is overlain by either Ludlow lignitic memb. of the Lance or the contemp. Cannonball marine memb. of the Lance, and it rests on Fox Hills ss. It consists of somber, badland clays, probably accumulated in topset swamps of a great delta, and fluviatile sss., the latter being more numerous and conspicuous toward SW. Remains of a few small mammals have been found in the sss. Dinosaurs (including *Triceratops*) are numerous below the "A" lignite, which marks base of Brown's "lignite beds," but probably have not been found above that horizon. [Mention other fossils.] The Hell Creek and overlying strata are markedly calc. in contrast with the brown memb. of the Fox Hills and older rocks, which are relatively free from lime. In Cedar Creek anticline, Mont., the Hell Creek memb. overlies Colgate ss. memb. of Fox Hills ss.; at mouth of Cannonball River, N. Dak., it rests on Fox Hills ss. [Diagram on p. 484 shows no uncon. above or below Hell Creek memb.]

These rocks are now called *Hell Creek fm.* by U. S. Geol. Survey, and classified as *Upper Cret.*, as explained under *Lance fm.*, last entry.

Heller dacite.

Tertiary (may be upper Miocene): Central Nevada (Tonopah district).

J. E. Spurr, 1905 (U. S. G. S. P. P. 42, pp. 37+). *Heller dacite.*—Vesicular glassy dacite containing numerous inclusions (sometimes large boulders) of pumiceous material, frequently of later andesite, and occasionally of coarse siliceous granite. Composes Heller Butte, near town of Tonopah. Is older than Brougher dacite. Appears to dip under Fraction dacite breccia and to immediately precede the formation of that breccia. The Heller dacite formed numerous small cones along lines of weakness and was poured forth in relatively limited quantities.

According to T. B. Nolan (personal communication, Jan. 3, 1933) this rock may be contemp. with Esmeralda fm. (upper Mio.).

Hellgate formation.

Pre-Cambrian (Belt series): Central western Montana (Missoula to Helena region).

C. H. Clapp and C. F. Deiss, 1931 (Geol. Soc. Am. Bull., vol. 42, p. 679, figs. 2, 3). *Hellgate fm.*—Type section (on N. side of Mount Sentinel, the S. wall of Hellgate Canyon) consists of (descending): (1) Massive, gray-red siliceous qtzite, weathering variegated gray, buff, and lavender, 365 ft.; (2) massive gray and red gray fine to coarse-grained finely banded pure qtzite and sandy qtzite, ripple marked, 280 ft.; (3) massive thick-bedded pink-gray qtzitic ss., weathering buff, 1,160 ft.; (4) massive, gray, fine-grained, siliceous qtzite, ripple-marked, weathering buff, 300 ft.; (5) massive red-gray coarse-grained qtzite, with sandy beds up to 3 ft. in thickness, weathering buff and dull lavender, 95 ft. Conformably underlies McNamara fm. and uncon. (?) overlies Miller Peak fm.; all included in Missoula group.

Hell Gate porphyry.

Pre-Cambrian: Central Colorado (Lake Fork-Ivanhoe region).

J. T. Stark and F. F. Barnes, 1932 (Am. Jour. Sci., 5th, vol. 24, p. 474). Granitic material, which may represent either true intrusion from Silver Plume magma or a porphyroblastic replacement of schist, is well exposed at Hell Gate narrows, 5 mi. W. of the divide on Lake Fork-Ivanhoe section. Similar granitic material alternates with schistose rock for over 10 mi. from the divide in the section down Ivanhoe and Frying Pan creeks. This rock, the origin of which is still in question, has been termed *Hell Gate porphyry.*

J. T. Stark and F. F. Barnes, 1935 (Colo. Sci. Soc. Proc., vol. 13, No. 8, p. 474, map), assigned this fm. to pre-Camb. "It is believed Hell Gate porphyry merely represents a particular stage or phase of migmatization of Sawatch schist by Silver Plume granite, but because of its distinctive appearance in field it has been mapped separately."

Helms formation.

Mississippian and Devonian (?): Western Texas (Hueco Mountains).

J. W. Beede, 1921 (Univ. Tex. Bull. 1852, pp. 8, 30, 36). *Helms group (Miss.)*.—Yellowish thin-bedded rocks. Local facies vary somewhat from place to place, but main features are almost always present. Locally there are thin sss. in top of Helms group. To N. of Long Canyon nearly the whole series is made up of platy drab to dark-buff lss. (which as a rule weather buff), with, locally, considerable chert in concretions, masses, and layers, and some ss., all separated by thin layers of marl that weathers buff. Below is a covered slope largely composed of clay sh. Fossils in most beds, but rare except locally in uppermost part of section. According to S. Weller is of Chester age. Thickness of fm. 400 to 600 ft. [Gives a detailed section 1± mi. S. of Helms Peak, Huéco Mtns.] Uncon. underlies Magdalena group (Penn.). [Originally included in Hueco ls.]

P. B. and R. E. King, 1929 (A. A. P. G. Bull., vol. 13, p. 909). *Helms group*, 400 to 700 ft. thick, includes beds of Chester, lower Miss., and Upper Dev. age.

The upper 500 ft. of Helms fm. of Hueco Mtns contains a Chester fauna (G. H. Girty, unpublished rept.); the remainder of fm. is unfossiliferous.

Hemlock greenstone.

Pre-Cambrian (middle Huronian): Northwestern Michigan (Crystal Falls district).

J. M. Clements, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, pp. 45–63, pl. 9, opp. p. 84). *Hemlock fm.*—Consists almost wholly of typical volcanic rocks, both basic and acid, with crystalline schists derived from them. Sedimentary rocks play very unimportant role; with one exception they have been formed directly from the volcanics and occur interbedded with them. Thickness 23,000(?) ft. On the whole the Hemlock fm. is younger than Mansfield sl., but some of lower Hemlock beds are contemp. with some of upper Mansfield beds. Is overlain by Upper Huronian. Named for fact Hemlock River flows through the fm. for a number of miles.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, pp. 291, 294–296, 300, 323, 507, 607). *Hemlock fm.* (*volcanic*).—Thickness 1,000 to 10,000 ft. Earlier estimated thickness of 23,000 ft. probably illusory. Includes at [pp. 295 and 607 say *near*] top iron-bearing sl. memb., 1 to 1,900 ft. thick, formerly called "Mansfield sl." General strat. position of Hemlock fm. is conformably above Randville dol. and beneath upper Huronian slates, but like most volcanic fms. its relations differ in different parts of dist. Well-bedded cherty slates, iron-bearing lenses, and ls. are interbedded with Hemlock fm. and also both underlie and overlie it. The volcanic rocks are similar in all respects to Keewatin volcanic rocks and to volcanic Clarksburg fm. of Marquette dist. [In chart on p. 598 Hemlock fm. is placed beneath Ajibik qtzite in Crystal Falls dist. and uncon.(?) above Randville dol. Pages 300 and 323 state it is overlain, doubtfully uncon., by upper Huronian in Crystal Falls dist.]

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184) changed name to *Hemlock greenstone*, and stated that it is of Algonkian type.

Hempfield shale member.

Mississippian: Northwestern Pennsylvania.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 141). *Hempfield sh. memb. of Shenango monothem.*—Overlies Shenango ss. memb. and is the *Shenango sh.* of I. C. White's Crawford Co. rept. Is well shown in and about Greenville, Hempfield Twp, Mercer Co.

Hemphill beds.

Pliocene (lower): Texas Panhandle (Hemphill County).

L. C. Reed and O. M. Longnecker, Jr., 1932 (Univ. Tex. Bull. 3231, pp. 16–43, 70–83, map). *Hemphill beds* [also *Hemphill fm.*].—Lower Plio. mammal-bearing beds of Hemphill Co., Tex., consisting chiefly of sands, with lesser amounts of clay, gravel, and caliche. The sands occur throughout the section, while the clays form thin partings. Gravel occurs at base and in upper part. Caliche is confined to uppermost beds. Thickness of fm. 550 ft. Since these beds, according to the fauna, represent a heretofore undescribed fm. of the Lower Plio., the name *Hemphill beds* is here given to them to be applied as a faunal horizon. [Divided into 4 members, which are described in great detail.] Rests uncon. on Perm. (?) red beds.

G. G. Simpson, 1933 (Am. Mus. Nat. Hist. Bull., vol. 67, pp. 98, 99). Clarendon and Goodnight-Hemphill are both distinctly older than Blanco. Hemphill seems to be late Lower Plio., btw. Clarendon and Blanco.

Hempstead gravel member (of Manhasset formation).

Pleistocene: Southeastern New York (Long and adjacent islands) and islands of southern New England (Block, Marthas Vineyard, No Mans Land, and probably Nantucket and Cape Cod).

M. L. Fuller, 1914 (U. S. G. S. P. P. 82). *Hempstead gravel memb.*—Top memb. of Manhasset fm. Description of Herod gravel memb. applies equally well to Hempstead gravel memb. Rests conformably on Montauk till memb. Overlain by glacial deposits of Wisconsin age. Named for exposures in upper parts of many large gravel pits along W. side of Hempstead Harbor, Long Island. Thickness 0 to 75 ft. Occurs on Long Island and on Plum, Gardiners, and Robins Islands. Time of deposition called *Hempstead substage.*

J. B. Woodworth, 1934 (Harvard Coll. Mus. Comp. Zool. Mem., vol. 52). *Hempstead gravel memb.* present on Marthas Vineyard, Block Island, No Mans Land, and probably on Nantucket Island and Cape Cod.

F. G. Wells, 1935 (Geol. Soc. Am. Proc. 1934, p. 121), regarded Manhasset fm. as of Wisconsin age, as do some other geologists.

Hempstead substage.

The time covered by deposition of *Hempstead gravel memb.*

Henderson granite.

Pre-Cambrian: Western North Carolina and northwestern South Carolina.

A. Keith, 1905 (U. S. G. S. Mount Mitchell folio, No. 124, p. 4). *Henderson granite.*—Composed mainly of orthoclase and plagioclase feldspar, quartz, muscovite, and biotite, enumerated in order of importance. Intrusive into all Archean rocks with which it comes in contact. On E. it extends only short distance beyond Mount Mitchell quad. into adjoining Morganton quad., but toward SW. it increases greatly in width and reaches far into S. C. Assigned to Archean.

Named for extensive areas and exposures in Henderson Co., N. C.

Henderson moraine.

Pleistocene (Wisconsin stage): Central Michigan. Shown on moraine map (pl. 32) in U. S. G. S. Mon. 53. Named for Henderson, Shiawassee Co.

Hendricks series.

Hendricks member.

Silurian (Niagaran): Michigan (eastern part of Upper Peninsula).

R. A. Smith, 1916 (Mich. Geol. Surv. Pub. 21, p. 155). *Hendricks series.*—Alternating beds of high calcium and low to high mag. lss. or normal dol. Thickness 145+ ft. Underlies Fiborn ls. and overlies Rochester sh.; all included in Niagara. Named for exposures in Hendricks quarry, sec. 1, T. 44 N., R. 9 W., Mackinac Co.

G. M. Ehlers, 1921 (Geol. Soc. Am. Bull., vol. 32, p. 129). *Burnt Bluff fm.* [new name] includes Fiborn ls. and upper part of Hendricks series of R. A. Smith.

R. B. Newcombe, 1933 (Mich. Geol. Surv. Pub. 38, pp. 23, 37). *Hendricks memb.*, top memb. of Burnt Bluff fm. Overlies Byron memb. [See 1933 entry under *Burnt Bluff fm.*]

Hendricks sandstone.

Upper Devonian: Northern West Virginia.

D. B. Reger and W. A. Price, 1923 (W. Va. Geol. Surv. Rept. Tucker Co., pp. 103, 240, 241, 245–254). *Hendricks ss.*—Fossiliferous ss., conglomeratic in W., fine-grained in E., lying about 100 ft. below top of Chemung series. Marine fauna. Thickness 6 to 10 ft. Ripple marks on upper surface; pebbles of green sh. at base; much iron oxide.

Named for exposure 1 m. NE. of town of Hendricks, Tucker Co., in Black Fork dist., on point of ridge E. of mouth of Falls Run, in highway leading from town of Hambleton along W. slope of Backbone Mtn and over the mtn to Douglas, in Fairfax dist.

Henley beds.

A name used, but not defined, by F. M. Anderson (Calif. Acad. Sci. Proc., 3d ser., vol. 2, 1902, pp. 1–62) for part of the lower beds of Chico age in S. part of Oregon Basin.

Henley shale member. (In Cuyahoga formation.)

Mississippian: Southern Ohio.

J. E. Hyde, 1915 (Jour. Geol., vol. 23, pp. 656, 657, 758, 760, 762, 769). *Henley sh. memb.*—Alternating gray and red shales and sss., the red color and the sss. disappearing to E. Thickness 5½ to over 226 ft. Basal memb. of Cuyahoga fm. in Scioto, Pike, and Ross Counties. Underlies Buena Vista ss. memb. ("City Ledge") and overlies Sunbury sh. Is lower part of Buena Vista memb. of Prosser and Cumings.

Named for Henley, Scioto Co.

Hennessey shale.

Permian: Central Oklahoma.

F. L. Aurin, H. G. Officer, and C. N. Gould, 1926 (A. A. P. G. Bull., vol. 10, pp. 786–799). *Hennessey sh.*—A series of clay shales, approx. 400 ft. thick, in north-central Okla. underlying Duncan ss., overlying Garber ss. and corresponding to lower part of Harper ss. of Kans. These shales are rarely fissile or laminated, but more commonly blocky, and break with conchoidal fracture. Are characterized by numerous bands or streaks of white or light green color, varying in thickness from a few inches to 4 or more ft. Divided into Bison ss. memb. above and Fairmont sh. memb. below. Included in Enid group. Named for exposures at Hennessey, Kingfisher Co.

J. M. Patterson, 1933 (A. A. P. G. Bull., vol. 17, No. 3, pp. 252–256), proposed to redefine Hennessey and Garber, but J. C. Ross objected. See under *Garber ss.*

Henrietta formation (group in Kansas).

Pennsylvanian: Southern Iowa, western Missouri, and northeastern Kansas.

C. R. Keyes, 1897 (Iowa Acad. Sci. Proc., vol. 4, pp. 23–24, 25). *Henrietta ls.*—Several ls. beds separated by shales; 75 ft. thick. Underlies Pleasanton shales and overlies Cherokee shales. *Includes Mystic coal.* Middle fm. of Des Moines stage in Iowa, Mo., and eastern Kans. Includes Pawnee ls. memb. at top, Marmaton fm. in middle, and Fort Scott ls. memb. at base in eastern Kans.

H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines vol. 13). *Henrietta fm.* as here defined is divided in Mo. into (descending) Pawnee ls. memb., Labette sh. memb., and Fort Scott ls. memb. The Lexington (Mystic) coal and the 6 ft. of sh. separating it from Fort Scott ls. are here transferred to Cherokee sh.

This 1915 definition of *Henrietta fm.* was followed generally until 1931, when R. C. Moore (Kans. Geol. Soc. 5th Ann. Field Conf. chart) dropped the name from the Kans. classification, treating its subdivisions as fms. in his Okmulgee group (which he later replaced by Marmaton group and Cherokee group). The 1933 (57th Bien.) and 1935 (58th Bien.) repts of Mo. Bur. Geol. and Mines, however, continued to use Henrietta as defined by Hinds and Greene.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 57–58). At present there seems to be little good reason to continue use of *Henrietta*. The Marmaton group includes *Henrietta fm.* and lower part of Pleasanton sh. [both of which he dropped from Kans. classification].

Named for Henrietta escarpment, near Henrietta, Johnson Co., Mo.

Henrietta diorite porphyry.

Tertiary: Mexico.

S. F. Emmons, 1910 (Econ. Geol., vol. 5, p. 325). [Age not given. Assigned to Tert. by M. L. Lee (Econ. Geol., vol. 7, 1912, p. 328).]

Henry sand.

A subsurface sand lying at 1,850 to 1,900 ft. depth in Lawrence Co., Ill.

Henryan series.

A term employed by C. [R.] Keyes to cover †Henrys Fork group of early repts on Colo. and Utah.

Henryhouse shale.

Silurian (Niagaran): Central southern Oklahoma.

C. A. Reeds, 1911 (Am. Jour. Sci., 4th, vol. 32, pp. 256–268). *Henryhouse sh.*—Along Chimneyhill Creek is bluish to yellowish, thin to moderately thick-bedded earthy ls. and intercalated sh. beds in lower 180 ft., and white marly beds in upper 43 ft. In type area alternating yellowish shales, shaly lss., and bands of reddish ls. occur. Thickness 0 to 223 ft.; average 90 ft. Originally included in middle of Hunton fm. Underlies Haragan sh. and overlies Chimneyhill ls. Contains Niagaran fossils.

Named for Henryhouse Creek, Carter Co., which crosses the outcrop about 3 mi. E. of Woodford.

†Henrys Fork group.

Upper Cretaceous and Upper Jurassic: Northeastern Utah (Uinta Mountains) and northwestern Colorado.

J. W. Powell, 1876 (Geology of eastern portion of Uinta Mtns, pp. 40, 50, 153). *Henry's Fork group.*—Sss., bad-land rocks, cgls., and shales, with carbonaceous shales and lignitic coal. Thickness 500 ft. Underlies Sulphur Creek group and overlies Flaming Gorge group. Type loc. is S. side of Henry's Fork. [Powell's map shows the fm. exposed along lower end of Henrys Fork, in Uinta Co., Utah, at and above where it unites with Green River.]

A. R. Schultz, 1920 (U. S. G. S. Bull. 702, table opp. p. 24), showed Henrys Fork group of Powell as=Frontier, Aspen, Bear River, and upper part of Beckwith fm. of present terminology of SW. Wyo. In Uinta Mtns it appears to correspond approx. to Dakota (?) fm.

A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1936 (U. S. G. S. P. P. 183, p. 36). "Henrys Fork group" of Gilbert in Henry Mtns included part of Morrison fm. (Upper Jurassic) and an overlying ss. here called *Dakota (?) ss.*

Hensell sand. (In Travis Peak formation.)

Lower Cretaceous (Comanche series): Central Texas.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, pp. 141–144, 152). *Hensell sand.*—In descending order: (1) Marly mag. ls., 40 ft.; (2) siliceous ls. underlain by calc. sand, 55 ft.; (3) yellow calc. sand, 15 ft.; (4) cgl., 25 ft.; (5) red sand, 3 ft.; (6) friable yellow sand, 5 ft. Total thickness 143 ft. Included in Travis Peak fm. Underlies upper memb. of Travis Peak fm., which consists of 40 ft. of cgl. and calc. ss. alternating with aren. lss. Overlies Cow Creek beds. Southern equiv. of Bluff Dale sands.

Named for Mr. Hensell's place, at Travis Peak post office, Burnet Co.

Henshaw formation.

Pennsylvanian: Northwestern Kentucky (Shawneetown quadrangle).

Wallace Lee, 1916 (Ky. Geol. Surv., Geol. of Ky. part of Shawneetown quad.). *Henshaw fm.*—Shales, sss., and coals, 175 ft. thick, underlain by 25 ft. of ss. called "Dixon ss." in previous repts. Replaces *Dixon fm.* of previous repts (preoccupied). Is topmost fm. of Penn. in this area. Overlies McLeansboro fm.

Named for Henshaw, Union Co.

Henson tuff. (In Silverton volcanic series.)

Miocene: Southwestern Colorado (Ouray region).

W. Cross and E. Howe, 1907 (U. S. G. S. Ouray folio, No. 153). *Henson tuff.*—Pyroclastic fm.; chiefly well-bedded fine-grained greenish- or brownish-gray sandy andesitic tuffs; no calc. shales or ls. layers, in which respect it differs from Burns tuff. Thickness 75–600 ft. Is uppermost fm. of Silverton [volcanic] series. In Silverton folio upper part was put in Potosi [volcanic] series and lower part in underlying pyroxene andesite. No fossils.

Named for exposures on Henson Creek, Ouray quad.

Heppel formation.

Middle Devonian: Quebec.

F. J. Alcock, 1935 (Canada Dept. Mines Geol. Surv. Bur. Econ. Geol. Mem. 183, p. 83).

Herat shale member (of Ochre Mountain limestone).

Mississippian (upper): Western Utah (Gold Hill district).

T. B. Nolan, 1930 (Wash. Acad. Sci. Jour., vol. 20, No. 17, Oct. 19, pp. 421–432). *Herat sh. memb. of Ochre Mtn ls.*—Thin and poorly exposed horizon of black sh. interbedded with ss., lying 1,700± ft. above base of western facies of Ochre Mtn ls. Named for exposures near Herat claims, Gold Hill quad.

See also U. S. G. S. P. P. 177, 1934.

Herbert conglomerate.

Pennsylvanian (early Pottsville): Southeastern Tennessee (Bledsoe, White, Van Buren, Hamilton, and Cumberland Counties).

W. A. Nelson, 1925 (Tenn. Dept. Ed., Div. Geol. Bull. 33A, pp. 49–50, and under county descriptions). Basal memb. of Bonair ss. Consists of 40 to 150 ft. of soft, light-yellow ss., coarse grained and in places conglomeratic. Underlies Eastland sh. lentil of Bonair ss., and rests on Whitwell sh. Best measurement was taken on Glade Creek just N. of where old road from Herbert, Bledsoe Co., to Sparta crosses this stream.

†Herculean shale member. (In Monterey group.)

Miocene: Central western California (San Pablo region).

C. E. Weaver, 1909 (Calif. Univ. Pub., Bull. Dept. Geol., vol. 5, p. 251). *Herculean sh. memb. of Monterey fm.*, underlies Quercan ss. in San Pablo region. [Derivation of name not stated.]

Replaced by *Hercules sh. memb.*

Hercules shale member (of Briones sandstone).

Miocene (upper): Western California (San Francisco region).

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). *Hercules sh. memb.*—Bituminous sh., 500 ft. thick, forming a memb. of Briones ss. Named for Hercules Station, on San Pablo Bay.

Hercules limestone.

Miners' local name for an ore-bearing ls., 0 to 4 ft. thick, in lower part of Oquirrh fm. (Penn.), Stockton dist., central northern Utah. Lies 90 ft. below Rambler ls. and 150 ft. above St. Patrick ls. Exposed in Hercules claim. (See U. S. G. S. P. P. 173, 1932.)

Herendeen limestone.

Lower Cretaceous: Southwestern Alaska (Alaska Peninsula).

W. W. Atwood, 1911 (U. S. G. S. Bull. 467, pp. 25, 39, etc.). *Herendeen ls.*—Aren. ls., 800 ft. thick, light-gray, locally cross-bedded. Exposed from Herendeen Bay to Port Moller. Underlies Chignik fm. (Upper Cret.) and overlies Staniukovich sh. Contains Lower Cret. fauna.

Herington limestone. (In Sumner group.)

Permian: Eastern Kansas, central northern Oklahoma, and southeastern Nebraska.

J. W. Beede, 1909 (Kans. Acad. Sci. Trans., vol. 21, pt. 2, p. 253). *Herington ls.*—Variable lss., including, in upper part, soft geodiferous, flaggy layers; also harder layers, more massive, very fossiliferous, and of buff shade; and to S. coarser ls. Thickness 12 to 15 ft. Overlies Enterprise shales and underlies Pearl shales. All included in Marion stage.

N. W. Bass, 1929 (Kans. Geol. Surv. Bull. 12, in cooperation with U. S. Geol. Survey). "Marion fm." abandoned and *Herington ls.* elevated to rank of a fm. in Sumner group. Overlies Enterprise sh., probably with slight uncon., and underlies Wellington fm. (redefined to include †Pearl sh. at base). [This is present approved definition of U. S. Geol. Survey.]

R. C. Moore, 1936 (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 12), discarded Enterprise; revived Pearl sh. (restricted) for beds overlying Herington ls.; greatly restricted Wellington fm.; applied *Paddock sh.* to beds immediately underlying Herington ls.; and treated Herington as top memb. of his Nolans ls. (new). These changes have not yet been considered by U. S. Geol. Survey for its publications.

See Kans.-Nebr. Perm. chart compiled by M. G. Wilmarth, 1936.
Named for Herington, Dickinson Co., Kans.

Herkimer sandstone.

Silurian: Central New York.

G. H. Chadwick, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 327–368). *Herkimer ss.*—This name is derived from Herkimer Co., and is here applied to Upper Clinton "gray band" of Eaton, which stretches conspicuously across southern part of this county with a max. thickness of 70 or 80 ft. at type loc. on Steeles Creek, 5 mi. SW. of Herkimer village. Fossils listed. We believe the Herkimer is only a ss. phase of the Phoenix [sh.]. Overlies Vanhornsville ss. and underlies Donnelly iron ore. [Is a part of Clinton fm.]

Herkimer limestone.

Middle Cambrian: Central northern Utah (Tintic district).

W. Lindgren and G. F. Loughlin, 1919 (U. S. G. S. P. P. 107). *Herkimer ls.*—Mottled shaly ls., consisting of bluish-black, dense, carbonaceous ls. mottled by thin discontinuous layers or blotches of yellowish-brown material rich in iron and clay. Thickness 225 to 235 ft. Underlies Bluebird ls. and overlies Dagmar ls. Named for Herkimer shaft, E. of Quartzite Ridge.

Herman Creek lava.

Pleistocene: Southwestern Washington and central northern Oregon.

R. W. Chaney, 1918 (Jour. Geol., vol. 26, No. 7, pp. 577–592), described rocks of gorge of Columbia River, Oreg. and Wash., and applied *Herman Creek lava (andesitic basalt)* to rocks overlying so-called Satsop fm. and underlying gravels and river terraces of recent origin. He repeated this section in Univ. Chicago Cont. Walker Mus., vol. 2, No. 5, 1920. Herman Creek is in Hood River Co., Oreg.

Hermansville limestone.

Lower Ordovician: Northwestern Michigan (Menominee district).

C. R. Van Hise and W. S. Bayley, 1900 (U. S. G. S. Menominee folio, No. 62). *Hermansville ls.*—Coarse-grained ss. with abundant calc. cement alternating with pure dol. or oolitic beds. Thickness 100 ft. max. Of Chazy and Beekmantown age. Overlies Lake Superior ss. Is youngest fm. in Menominee dist.

R. A. Smith, 1914 (Mich. Geol. and Biol. Surv. Pub. 14, geol. ser. 11, p. 22). The Calciferous or Lower Mag. ss. (200 to 250 ft. thick in wells along Green Bay), or perhaps only lower part of it, is represented by *Hermansville ls.*

Named for exposures near Hermansville, Menominee Co.

Hermit shale. (Of Aubrey group.)

Permian: Northern Arizona, southern Utah, and southeastern Nevada.

L. F. Noble, 1922 (U. S. G. S. P. P. 131B, pp. 26, 28, 64+). *Hermit sh.*—Deep brick-red sandy shales and fine-grained friable sss., 267 to 317 ft. thick at Hermit Basin, the type loc. Uncon. overlie Supai fm. as herein redefined, but formerly included in Supai fm. under the designations "sh. of Supai fm." and "upper Supai sh." The beds are separated from Supai fm. because of uncon. at their base and fact that they contain plants and other fossils of Perm. age; the underlying Supai fm. as here redefined being considered of Penn. age, but possibly of Perm. age in its upper part. Lithologically the Hermit sh. resembles many beds of sandy sh. in the Supai, but, unlike the Supai, it contains no massive hard layers of cross-bedded ss., and the more sandy beds in the Hermit are prevailingly reddish, not buff, as they are in the Supai. Thin platy lamination is most prominent structural characteristic of Hermit sh. Thickness varies from possibly less than 75 ft. in region about Tanner Canyon to 500+ft. W. of Bass Canyon. Underlies Coconino ss.

Hermitage formation.

Middle Ordovician (Trenton): West-central Tennessee and southern Kentucky.

C. W. Hayes and E. O. Ulrich, 1903 (U. S. G. S. Columbia folio, No. 95, p. 1). *Hermitage fm.*—Even-bedded, alternating thin layers of argill. or siliceous blue ls. and gray or bluish sh. in lower third, and heavier-bedded siliceous subgranular ls., more or less strongly phosphatic, in middle and upper parts. Thickness 40 to 70 ft. Of early Trenton age. Uncon. overlies Carters ls. and underlies Bigby ls.

Named for occurrence at Hermitage Station, Davidson Co.

Hermon type.

Name applied by A. F. Buddington (N. Y. State Mus. Bull. 281, 1929, pp. 52–81) to a porphyritic granite in NW. Adirondacks (Lewis and Jefferson Counties) intrusive into Grenville series. Derivation of name not stated. Age relations to nonporphyritic Alexandria type of granite not determined.

Hermosa formation.

Pennsylvanian: Southwestern Colorado, southeastern Utah, northeastern Arizona, and northwestern New Mexico.

W. Cross and A. C. Spencer, 1899 (U. S. G. S. La Plata folio, No. 60, p. 8). From section displayed in Animas Valley and at Rico we can assume presence of other sed. fms. below Dolores fm. (oldest exposed) in La Plata dome. These embrace *Rico* and *Hermosa* (Carbf.), the *Ouray* (Dev.), and the Ignacio (Camb.), all in apparent structural conformity.

W. Cross and A. C. Spencer, 1900 (U. S. G. S. 21st Ann. Rept., pt. 2, p. 48). *Hermosa fm.*—The upper part is a complex of shales with occasional lss.; middle part is many bands of massive dark-gray ls., often highly fossiliferous, alternating with sss. and cgls.; lower part is greenish-gray sss. and shales, the latter sometimes nearly black. Thickness 1,800 ft. Underlies Rico fm. and overlies Dev. ls. and qtzite. Named for Hermosa Creek, Colo.

W. Cross and E. Howe, 1905 (U. S. G. S. Silverton folio, No. 120), applied *Molas fm. to 75 ft. of Penn. strata* which intervene btw. Hermosa fm. and Ouray ls. and which are absent in area where Hermosa fm. was first defined.

In SE. Utah and parts of SW. Colo. the intrusive Paradox fm. intervenes below Hermosa fm. and is believed by J. B. Reeside, Jr., and A. A. Baker to be younger than Molas ls.

R. Roth, 1934 (A. A. P. G. Bull., vol. 18, No. 7, p. 945). Since Spencer gave no specific type loc. for *Hermosa fm.*, the type section has been selected as in secs. 26 and 35, T. 37 N., R. 9 W., La Plata Co., Colo., for following reasons: (1) It is easy of access, as main highway btw. Durango and Silverton passes through the area; (2) total thickness (2,146 ft.) is approx. same as max. given by Spencer for the Hermosa; (3) the section is in area considered typical of the Hermosa by Spencer and is well within the area mapped as Hermosa by Colo. Geol. Surv. Fauna of typical Hermosa is of Cherokee age.

Herndon oil sand.

Name proposed by A. F. Crider (A. A. P. G. Structure symposium, vol. 2, 1929, p. 181) for reddish sharp quartz sand, forming oldest producing horizon in Pine Island oil field, Caddo Parish, La. Lies in Trinity group (of Comanche age), 193 ft. below Dixie oil horizon. Named for Texas Co.'s Herndon No. A6 well, which first produced from this sand.

Hernshaw sandstone. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and D. B. Reger, 1914 (W. Va. Geol. Surv. Rept. Logan and Mingo Counties, p. 155). *Hernshaw ss.*—Massive, medium-grained, micaceous and grayish brown. Thickness 20 to 50 ft. Underlies Little Chilton coal and overlies Hernshaw coal. Named for Hernshaw, Kanawha Co.

Herod gravel member (of Manhasset formation).

Pleistocene: Southeastern New York (Long and Fishers Islands) and islands of southeastern New England (Marthas Vineyard, Block Island, and probably Cape Cod).

M. L. Fuller, 1905 (Geol. Soc. Am. Bull., vol. 16, pp. 367–390). *Herod gravel.*—Sandy gravels, with good proportion of pebbles, mainly of granitic rocks, 30 to 100 ft. thick. Uncon. underlies Montauk drift and conformably overlies Jacob sand. Correlated with Illinoian stage of Mississippi Valley.

M. L. Fuller, 1906 (Sci., n. s., vol. 24, pp. 467–469). *Herod gravel* (glacial) occurs at nearly all points from Long Island to Boston.

F. G. Clapp, 1908 (Geol. Soc. Am. Bull., vol. 18, table opp. p. 512). *Herod gravel* is Lower Manhasset and beds overlying Montauk till are Upper Manhasset.

M. L. Fuller, 1914 (U. S. G. S. P. P. 82). *Herod gravel memb.*, basal memb. of Manhasset fm. In some places prevailingly sandy, in others chiefly gravel; in places the lithologic change is abrupt vertically and horizontally; in general more sand toward base and more gravel toward top; in its more normal phases the deposit consists of an alternation of thin layers of sand and gravel, the whole having a gravelly aspect. Underlies Montauk till memb. of Manhasset fm. and overlies Jacob sand. Time of deposition called *Herod substage.* Correlated with beginning of Illinoian stage of Mississippi Valley.

J. B. Woodworth, 1934 (Harvard Coll. Mus. Comp. Zool. Mem., vol. 52). *Herod gravel memb.*—Basal memb. of Manhasset fm.; glacial sand and gravels; 0 to 100 ft. thick. Conformably overlies Jacob sand and conformably underlies Montauk till memb. of Manhasset fm. Present on Marthas Vineyard, Block Island, and probably on Cape Cod.

F. G. Wells, 1935 (Geol. Soc. Am. Proc. 1934, p. 121), regarded Manhasset fm. as of Wisconsin age.

Herod substage.

The time covered by deposition of *Herod gravel memb.*

Herrin limestone. (In McLeansboro formation.)

Pennsylvanian: Southeastern and southwestern Illinois (Saline County).

G. H. Cady, 1926 (Ill. State Acad. Sci. Trans., vol. 19, p. 262). The ls. cap rock of Herrin No. 6 coal, which I shall call the *Herrin ls.*, since it is so commonly associated with Herrin coal, is an impure, earthy dark-gray, dirty-looking ls. that breaks with a splintery fracture. Where exposed along streams it spalls off in angular fragments showing little structure. Contains fossils.

A. H. Bell, C. Ball, and L. McCabe, 1931 (Ill. Geol. Surv. Press Bull. 19), show 2½ ft. of sh. btw. Herrin ls. memb. and Herrin coal in parts of Perry Co., and give thickness of Herrin ls. as 4½ to 6 ft.

Herschel quartzite.

Mesozoic (Lower Cretaceous ?): Southeastern Arizona (Tombstone district).

J. A. Church, 1903 (Am. Inst. Min. Engrs. Trans., vol. 33, pp. 3–37). *Herschel qtzite.*—Dense fine-grained qtzite, 270 ft. thick. Underlies White lime and overlies Lucky Cuss ls. in Tombstone dist.

F. L. Ransome, 1920 (U. S. G. S. Bull. 710D). Herschell qtzite of Church is Mesozoic, probably Comanche (Lower Cret.).

Hersey red shale member (of Pembroke formation).

Silurian (late): Southeastern Maine.

E. S. Bastin and H. S. Williams, 1914 (U. S. G. S. Eastport folio, No. 192, pp. 6–7). *Hersey red sh. memb.*—Chiefly purplish red fossiliferous sh.; includes some gray sh. like that of Leighton memb. Thickness 2,700 ft. Top memb. of Pembroke fm. Separated from older Leighton gray sh. memb. by rhyolite tuff. Named for exposures on Hersey Neck, Pembroke Twp, Washington Co.

Hertha limestone. (In Kansas City group, Kansas.)

Hertha limestone member (of Kansas City formation, Missouri).

Pennsylvanian: Eastern Kansas, southeastern Nebraska, northwestern Missouri, and southwestern Iowa.

G. I. Adams, 1899 (Kans. Acad. Sci. Trans., vol. 16, pp. 58, 59). *Hertha ls.*—Ls. composing lower memb. of Erie fm. and forming escarpment extending W. from Hertha [Neosho Co., Kans.], crossing Labette Creek S. of Galesburg and following its W. bluff for considerable distance, terminating in mounds W. of Altamont. Overlain by Mound Valley ls.

G. I. Adams, 1903 (U. S. G. S. Bull. 211, pp. 34, 35). *Hertha ls.* is here introduced for the lss. succeeding Upper Pleasanton shales (Dudley sh.) as exposed in vicinity of Hertha. Haworth (1898) says this series of beds is probably a continuation of Bethany Falls ls., a term first used by Broadhead (1872) for the fm. at Bethany, Harrison Co., Mo., a distant locality. Should this correlation be established, *Bethany* would displace *Hertha*. Underlies Galesburg sh. Thickness 10 to 20 ft. Thins out in hills NW. of Altamont. Fossils listed.

G. I. Adams, 1904 (U. S. G. S. Bull. 238). *Hertha ls.* overlies Dudley sh. and underlies Ladore sh., which is separated from Galesburg sh. by Mound Valley ls. [Bethany Falls ls.].

H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines, vol. 13). *Hertha ls. memb.*—Basal memb. of Kansas City fm. and of Missouri group. Underlies Ladore sh. memb. and overlies Pleasanton fm. Galesburg sh. memb. rests on Bethany Falls ls., which lies on Ladore sh.

For many succeeding years the definition of *Hertha ls.* was for the ls. overlying Dudley sh. and underlying Ladore sh.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 90, 97), stated that "so-called Hertha ls. at Hertha is really Bethany Falls ls." (which has priority), and introduced *Sniabar ls.* for upper of the lss. called *Hertha* by Hinds and Greene, and *Schubert Creek ls.* for lower ls. called *Hertha* by Hinds and Greene.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, p. 24). J. M. Jewett (Kans. Acad. Sci. Trans., vol. 36, 1933, p. 134) rightly concluded the ls. at Hertha to which Adams in 1903 applied name *Hertha* is Bethany Falls ls. In 1904 (U. S. G. S. Bull, 238, pp. 14 and 16) Adams published maps of area immediately N. of Hertha in which first ls. below the Bethany Falls (=Mound Valley ls.) was indicated as Hertha. This lower ls. is the 6-foot ls. cropping out at Hertha, and not the one shown as Hertha in previous publication. The reason for this confusing change in mapping was not given in text. The early Kans. Surv. followed this second usage of Adams, so that, excepting original definition, the name *Hertha* has been consistently applied to lower ls. of Bronson group [of Newell, not Bronson group of R. C. Moore, 1935, which includes 150 ft. of underlying beds called *Bronson fm.* by Moore]. It was discovered by F. C. Greene, R. C. Moore, and me, in special field investigation of Hertha problem, that lower ls. cropping out at Hertha is continuous across E. Kans., and (contrary to Jewett's 1933 conclusion) is in part=the ls. at Kansas City that has in past been called *Hertha*. It does not seem advisable to suppress *Hertha* on ground it is synonym of Bethany Falls. In Adams' final usage and subsequent work it appears there has been consistent application of *Hertha* to one ls. unit, the lower of the Bronson or "triple system" of early writers. I propose here to retain *Hertha* in formational sense, for the ls. cropping out at Hertha, and for its immediate correlatives. In tracing the Hertha southward from Kans. [Hertha?] it was discovered by Greene, Moore, and me that the unit is added to above, so that over much of E. Kans. it is divisible into 2 members, of unlike lithology, commonly separated by some sh. The upper memb. was thought to be Jewett's Schubert Creek ls., and the lower one, so well developed in NE. Kans. and adjacent parts of Mo., is here termed *Sniabar ls.*, from exposures along Sniabar Creek in SE. part of Jackson Co., NW. Mo.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 79, 80). It is agreed the beds called *Hertha* by Hinds and Greene at Kansas City are same as Hertha ls. at type loc. The names *Elm Branch* [*sh.*], *Sniabar* [*ls.*], *Tennison Creek* [*sh.*], and *Schubert Creek* [*ls.*] are not required and will not be recognized. Critzer ls. may prove useful, but is not here recognized. *Hertha ls.* is considered to comprise first important ls. unit, locally divided by sh. into 2 or more beds, below Middle Creek ls. memb.

of Swope ls. Thickness of sh. interval btw. top of Hertha and base of Middle Creek (or, in S., where Middle Creek disappears, the base of the Bethany Falls) ranges from 2 to 50 ft. or more. The Hertha is basal fm. of Bronson group and rests conformably on Bourbon fm. Black fissile sh. immediately underlies it near Hertha and to S. Thickness of Hertha 4 ft. to locally 30 ft. in N. part of Bourbon Co., where upper and lower members are separated by 15 ft. of sh. The Hertha extends from south-central Iowa to Labette Co., Kans., but is not known to reach Okla. line. Definition and description given by Adams in 1903 and his strat. section in his 1904 paper agree in indicating that rock he intended to name Hertha is the one exposed just E. of Hertha.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Hess thin-bedded limestone member (of Leonard formation).

Permian: Western Texas (Marathon region).

J. A. Udden, 1917 (Univ. Tex. Bull. 1753, p. 43, pl. 3). *Hess fm.*—Lss., mostly thin bedded, but also contain several layers 5 to 10 ft. thick; a good part of ls. is oolitic; some sss. and shales, mostly in lower 400 ft.; ls. cgl. 10 to 40 ft. thick at base. Color of shales and lss. mostly light gray. Thickness 2,150 ft. Extension of the Hess W. from Leonard Mtn is uncertain. It may be present in lower part of Leonard Mtn. Uncon. overlies Wolfcamp and Gaptank fms., from which it is distinguished by small development of argill. and sandy material and by absence of conglomeratic material, except in basal cgl. Distinguished from overlying Leonard fm. by having well-defined bedding planes. Greatest development in old Hess ranch, Glass Mtns.

See also under *Leonard fm.*

P. B. King, 1931 (Univ. Tex. Bull. 3038, pp. 57–69). *Hess fm.* has not been well understood because of its great lateral variation in lithology and thickness. In his section on Leonard Mtn Udden provisionally placed in Leonard fm. massive lss. regarded by us as Hess, though he recognized the possibility that the Hess might be present there. The type sections of the two fms. therefore overlap. The contact is now placed at the natural line of subdivision btw. siliceous shales above and massive lss. below. In E. part of Glass Mtns the Hess is a great mass of ls., prevailingly thin bedded and dolomitic, 2,130 ft. thick. To E. the lss. are partly replaced by varicolored marls and shales. In W. part of Glass Mtns the fm. is less than 100 ft. thick in places, and consists of massive light-gray pure ls. Because of these differences the fm. can be divided into an eastern and a western facies, with div. line lying on Hess ranch E. of Leonard Mtn. Contact btw. Hess and Leonard fms. is here interpreted as conformable, but many puzzling features remain to be explained. Contact is well exposed SW. from Leonard Mtn to Dugout Mtn, where the Leonard is 900 to 1,800 ft. thick and the Hess only a few hundred ft. thick. It is also well exposed NE. from Wood ranch, where Leonard is 250 ft. thick and Hess more than 2,000 ft. thick. In neither area is there any evidence of erosion. Faunas of Hess and Leonard fms. are similar, but there are certain characteristic elements in each not shared by the other, though both are of same facies. Although max. thickness of each fm. appears to be mutually inclusive of the other, the distinctive quality of the two faunas seems to argue against an intergradational relationship. The westward thinning of the Hess is result of an overlap on uplifted Wolfcamp beds and not the result of pre-Leonard erosion or the intergradation of Hess and Leonard facies.

P. B. King, 1934 (Geol. Soc. Am. Bull. vol. 45, pp. 730–732). The Hess fm. of previous repts is contemp. with and grades into lower part of Leonard fm. It is therefore here designated *Hess thin-bedded ls. memb. of Leonard fm.*

Hesse quartzite. (In Chilhowee group.)

Lower Cambrian: Eastern Tennessee and western North Carolina.

A. Keith, 1895 (U. S. G. S. Knoxville folio, No. 16, p. 3). *Hesse ss.*—Fine white massive ss., formed of round quartz grains. Thickness more than 500 ft. Overlies Murray sh. Underlies Apison sh. [In parts of NE. Tenn. is overlain by Shady dol.]

Named for Hesse Creek, Blount Co., Tenn.

Heumader shale. (In Oread limestone.)

Pennsylvanian: Eastern Kansas, northwestern Missouri, and southeastern Nebraska.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 94, 96). *Heumader sh. memb.*—Thin sh. near top of Oread ls., underlying Kereford ls. memb. and overlying Plattsmouth ls. memb. [On p. 52 it is described as consisting of 2 ft. of dark-bluish sh. with thin yellow streaks.]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 48, 167–168). The few ft. of sh. that lies btw. base of Kereford ls., where that memb. is present, and top of Plattsmouth ls. may be termed *Heumader sh.* and classed as a memb. of Oread fm. The sh. is clayey to sandy and usually appears dark gray. Thickness almost 0–10 ft. Where Kereford ls. is absent the Heumader and possibly shaly equivalents of the Kereford are not differentiated. Although strat. continuity with units classified as parts of Oread fm. is recognized, the sh. next above the Plattsmouth is then included with Kanwaka sh. Type loc., Heumader quarry, bluffs of Missouri River just N. of St. Joseph, Mo.

Heuvelton sandstone.

Upper Cambrian: Northern New York (St. Lawrence Valley).

G. H. Chadwick, 1915 (Geol. Soc. Am. Bull., vol. 26, pp. 289–291). *Heuvelton* ("*Twenty-foot*") *ss.*—Name introduced with Prof. Cushing's consent, for the heavy white ss., recognized independently by him and by writer, which from its resistant nature has proved most valuable stratum in Canton quad. for solution of strat. problems. Is characterized by *Scolithus canadensis* and by large gastropods suggestive of Ord. age, but it seems conformable to underlying Theresa mixed beds or fm. as restricted by Ulrich. Assigned to Ord. (?). Is uncon. overlain by Bucks Bridge mixed beds or fm., which is approx.=Tribes Hill.

H. P. Cushing, 1916 (N. Y. State Mus. Bull. 191). There is some evidence that still another fm. will have to be separated from upper part of the Theresa, including: (1) What we have mapped as *Heuvelton ss. lentil of Theresa fm.*; (2) the beds btw. this ss. and base of [overlying] Tribes Hill; and (3) the 30 ft. more or less of sandy beds just under this ss. But evidence is not yet decisive, and lithologically the beds are much like those of the Theresa, with which they form a convenient lithologic unit. [In places in this rept Cushing applied *Heuvelton div.* to the 3 beds enumerated above.]

G. H. Chadwick, 1920 (N. Y. State Mus. Bull. 217, 218). *Heuvelton white ss.*—White vitreous ss., 0 to 25 (?) ft. thick, often with decided platy structure, much ripple marking, and minor cross-bedding. Age uncertain; probably Ozarkian. Seems linked stratigraphically with Theresa (Upper Camb.) below, though its few fossils suggest a later age. This is "20-foot ss." of Prof. Cushing, which according to him is shown by its relations farther W. to be merely a lentil in the Theresa, though on our meridian it constitutes apparent summit of that fm. [But he in several places called it *Heuvelton fm.*, and mapped it separately from Theresa.] No marked strat. break with underlying Theresa mixed beds. Uncon. [discon. on another page] overlain by Bucks Bridge mixed beds.

Probably named for Heuvelton, St. Lawrence Co., NW. N. Y., in Potsdam region.

Hewett's Branch sandstone. (In Allegheny formation.)

Pennsylvanian: Southeastern Ohio.

E. Orton, 1884 (Ohio Geol. Surv. vol. 5, p. 116). *Hewett's Branch ss.*, 25 ft. thick at Carbondale, Athens Co. Underlain by Upper Freeport ls. and separated from overlying Upper Freeport coal by 6 feet of clay and sh.

Hewitt sand.

A subsurface sand, of early Penn. age, in Hewitt pool, Carter Co., central southern Okla.

Hewittville calcilutites (or beds).

Lower Ordovician (Beekmantown): Northern New York (Canton quad.).

G. H. Chadwick, 1920 (N. Y. State Mus. Bull. 217, 218, p. 33). *Hewittville calcilutites* in columnar section; *Hewittville beds* in heading.—Upper 8 to 9 ft. of Bucks Bridge mixed beds or fm. Consist of rather argill., light (smoky) gray, firm and compact dull limy mudstones (calcilutites or exceedingly fine calcarenites); weather vivid tones. Cap Bucks Bridge fm. on W. bank of Raquette River just below concrete dam of lower mills at Hewittville. Elsewhere these beds fail to appear, either because concealed beneath ledges of discon. overlying Ogdensburg fm., or because discontinuous through erosion or lateral change. Questionable whether they belong in Bucks Bridge fm., but since no break is evident at supposed contact it has not seemed wise to separate them until they can be traced farther E. Underlain by sandy and siliceous dol. of rather flaggy structure and highly fucoidal as it weathers.

Hiawatha member (of Wasatch formation).

Eocene (lower): Southwestern Wyoming and northwestern Colorado.

W. T. Nightingale, 1930 (A. A. P. G. Bull., vol. 14, No. 8, pp. 1019–1040). In this paper *Hiawatha memb.* is assigned to Wasatch sediments lying below Tipton tongue fm., of Green River age, in Vermilion Creek gas area. Gray shales constitute predominating part of memb., although there is also a minor amount of green to pink sh. and considerable lignite and dark carbonaceous sh., particularly in highest 1,000 ft. A few interbedded layers of gray to buff ss. are important as known and possible reservoirs for gas and perhaps oil. The sss. are lenticular and range from a few inches to 20 or 30 ft. in a few hundred ft. Thickness of memb. 4,100± ft. The gas-producing sands occur from 2,450 to 4,100 ft. below Tipton tongue, and range from 3 to 45 ft. in thickness. In general the Hiawatha beds are partly fluviatile and partly lacustrine. Named for development on Hiawatha and West Hiawatha domes, Twps 12 N., Rs. 100 and 101 W., Moffat Co., Colo.

W. T. Nightingale, 1935 (A. A. P. G. Bull., June). *Hiawatha memb. of Wasatch fm.* is partly fresh water, partly fluviatile, and partly lacustrine. Thickness 4,054 ft.

Hickman group.

Pleistocene: Southwestern corner of Kentucky.

R. H. Loughridge, 1888 (Ky. Geol. Surv. Rept. Jackson's Purchase Region, pp. 37–41). *Hickman group.*—Thick buff-colored clays with siliceous claystone at top. Believed to be older than Lignitic group. Included in Eocene. [Later studies by E. W. Berry showed these deposits are Pleist. Loughridge's map of Jackson Purchase region is dated 1885, and shows *Hickman* beneath Lignitic.]

Named for bluffs of Mississippi River at Hickman, Fulton Co. and to S.

Hickman sand.

A subsurface sand in Burbank oil field, Okla.

Hickory sandstone.

Upper Cambrian: Central Texas.

T. B. Comstock and E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. lxi, 285). *Hickory series.*—Massive ss. above, coarse cgl. below. One very characteristic and persistent division is a massive white to buff fine pebbly ss., almost qtzite, near top. Thickness 150 to 250 ft. Uncon. overlies Eparchean group and uncon. underlies Riley series. [Later field work showed †Riley series included Hickory ss. Top of Hickory ss. was therefore defined by S. Paige (U. S. G. S. Llano-Burnet folio, No. 183, 1912) as top of highest dominantly sandy beds. Thickness 350 ft.]

Overlies Llano series uncon. and underlies Cap Mtn fm.

Named for Hickory Creek, Llano Co.

Hickory shale.

An abbreviated form of *Hickory Creek sh.* (Penn., Kans.-Nebr.) used by some writers.

Hickory sand.

Drillers' term for an oil sand in NW. Pa. that is said to lie at about same horizon as Snee or Blue Monday sand.

Hickory Creek shale.

Pennsylvanian: Eastern Kansas, northwestern Missouri, and southeastern Nebraska.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 93, 97). [See under *Merriam ls.* On p. 46 *Hickory Creek sh.* is stated to be ½ to 1 ft. thick.]

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pp. 18, 69, 71–72). Plattsburg ls. divided into 3 members (descending): Spring Hill ls. memb., ***Hickory Creek sh. memb.***, and Merriam ls. memb. The Hickory Creek memb. consists of 1± ft. of black carbonaceous sh., which to S. becomes gray or yellowish and argill. Locally absent, and ½ mi. E. of De Soto thickens to 20 ft. In some instances, as at S. edge of sec. 29, T. 13 S., R. 23 E., the sh. is overlain and underlain by a peculiar ochery, shaly ls. or calc. sh. In such case, for convenience, the yellowish shaly layer is considered the div. btw. the upper and lower Plattsburg. Named for stream near Peoria, Franklin Co.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), stated that Newell is author of this name.

Hicks formation.

Upper Cambrian: Western Utah (Gold Hill district).

T. B. Nolan, 1930 (Wash. Acad. Sci. Jour., 5th, vol. 20, No. 17, Oct. 19, pp. 421–432). *Hicks fm.*—Greater part consists of dolomite similar to those of underlying Lamb dol., but the fm. also contains lenticular beds of ss., fossiliferous ls., and in one place sh. Contains early Upper Camb. fossils. Thickness 600 to 1,200 ft. Variation in thickness believed to indicate uncon. with overlying Chokecherry dol., of Lower Ord. age. Named for exposures in Hicks Gulch, in North Pass Canyon, Gold Hill dist.

See also U. S. G. S. P. P. 177, 1934.

Hidden Treasure limestone.

Mississippian (lower): Central northern Utah (Ophir district).

F. M. Wichman, 1920 (Eng. and Min. Jour., vol. 110, No. 12, p. 563). Overlying Gardner dol., but with no distinct bdy separating them, lies what is called in Ophir the *Hidden Treasure ls.* It might be considered as upper part of the Gardner, but on account of its value as an ore-bearing medium, it is advisable to give it a distinct name. It forms summit of Ophir Hill, where all that remains of it is 75 to 100 ft. It consists of coarsely crystalline, rather soft light-gray to brownish ls., with interbedded layers of thin dark-colored ls. similar to that in the Gardner, and at least one bed of dense carbonaceous sh. Fossils abundant.

S. G. Olmstead, 1921 (Econ. Geol., vol. 16, pp. 443, 452, 453). The Upper Pine Canyon ls. in Ophir dist. is locally known as *Hidden Treasure ls.* It consists of 290 ft. of rather pure ls. showing many fossils and some chert nodules. The Lower Pine Canyon ls. is locally known as *Chicago.* It consists of 390 ft. of rather dark-gray blocky ls., characterized by bands of dark chert 1 to 2 in. in thickness, spaced from 1 to several ft. apart.

J. Gilluly, 1932 (U. S. G. S. P. P. 173, p. 145). The Hidden Treasure, Chicago, and Sacramento mines are all in Madison ls. The *Hidden Treasure* ore shoots were in general in upper beds of the Madison. The *Chicago* and *Sacramento* ore bodies showed practically no tendency to be limited to a single strat. horizon but passed up and down through the section as they were followed, although both were in Madison ls. throughout.

Higham grit.

Triassic (?): Southeastern Idaho.

G. R. Mansfield, 1915 (Wash. Acad. Sci. Jour., vol. 5, p. 492). *Higham grit.*—Basal memb. of Nugget ss. in Fort Hall Ind. Res. Thickness 500 ft. Underlies Deadman ls. memb. of Nugget.

G. R. Mansfield, 1916 (Wash. Acad. Sci. Jour., vol. 6, pp. 32, 41). *Higham grit memb.*—Coarse white to pinkish gritty or conglomeratic ss., the component particles of which are coarse and subangular. Locally is almost qtzite. Thickness 500± ft. Basal memb. of Nugget ss. in Fort Hall Ind. Res. Underlies Deadman ls. memb. of Nugget and conformably overlies Ankareh ss. [later named *Timothy ss.*]. Named for Higham's Peak, sec. 23, T. 3 S., R. 37 E., the highest summit in NE. part of the reservation, which is composed of this rock.

G. R. Mansfield, 1920 (U. S. G. S. Bull. 713, pp. 29, 50), (1) treated Higham grit as a distinct fm.; (2) restricted Nugget ss. to upper part ("main ss. memb.") of Nugget ss. as recognized by him in previous repts; (3) introduced *Timothy ss.* to replace *Ankareh ss.* as used by him in previous repts on SE. Idaho; and (4) reported the Higham as resting uncon. on Timothy ss. This is present generally accepted definition of Higham grit.

†High Bluff blue sands.

Upper Cretaceous (Gulf series) : Southwestern Arkansas.

R. T. Hill, 1888 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 2, pp. 72, 75–77, 188). *High Bluff blue sands.*—Fossiliferous dark-blue fine micaceous sandy marls, containing same fossils as overlying Washington greensands, but are more massive and contain more glauconite and lime. Thickness 125 ft. Overlie Big Deciper calc. sands. Absent in places. Named for exposures in High Bluff of Ouachita River, 1½ mi. NE. of Arkadelphia, Clark Co., where they compose basal 50 ft. of section and where they are conformably overlain by Washington greensands.

C. H. Dane, 1929 (Ark. Geol. Surv. Bull. 1, pp. 46, 115). [See under †*Washington greensand.*]

†High Bluff greensand.

Upper Cretaceous (Gulf series) : Southwestern Arkansas.

See explanation under †*Washington greensand.*

Named for exposures in High Bluff of Ouachita River, 1½ mi. NE. of Arkadelphia, Clark Co.

High Bridge gneiss.

R. P. Stevens, 1867 (N. Y. Lyc. Nat. Hist. Annals, vol. 8, pp. 116–120). [On his "Section across New York [Manhattan] Island along southern shore of Spuyten-Duyvel Creek and Harlem River" *High Bridge gneiss* is shown upturned to E. of King's Bridge ls. According to U. S. G. S. New York City folio Highbridge is located on Fordham gneiss.]

Highbridge limestone.

Lower and Middle Ordovician: Central Kentucky.

M. R. Campbell, 1898 (U. S. G. S. Richmond folio, No. 46, p. 2). *Highbridge ls.*—White ls. grading downward into gray ls. and calc. sh.; thickness 200 ft. Underlies Lexington ls. Includes Chazy and Birdseye lss. of early Ky. repts.

A. M. Miller, 1905 (Ky. Geol. Surv. Bull. 2, pp. 8–23), divided Highbridge ls. of Campbell into (descending) Tyrone, Oregon, and Campnelson substages.

A. F. Foerste, 1913 (Ky. Geol. Surv., 4th ser., vol. 1, pt. 1, pp. 377–385), proposed restricting *Highbridge ls.* to Oregon and Campnelson beds, of Chazy age, excluding Tyrone, because of its Black River age. This proposed restriction, however, was not accepted by Miller, who up to 1925 (Ky. Geol. Surv., ser. 6, vol. 21, pp. 126–142) continued to include the Tyrone in Highbridge ls. This is also the U. S. Geol. Survey definition.

Named for exposures at Highbridge, Jessamine Co.

High Bridge granite.

See *Mellen or High Bridge granite.*

High Falls shale (in New York).

High Falls formation (in New Jersey).

Silurian (Salina) : Eastern New York (Ulster and Orange Counties) and northern New Jersey.

C. A. Hartnagel, 1905 (N. Y. State Mus. Bull. 80, pp. 342–357). *High Falls shales.*—Red shales, well shown on farm of Patrick Winn at High Falls [Ulster Co.]. Basal memb. of Salina beds in eastern N. Y. Resemble Vernon sh. Underlie Binnewater qtzites and overlie Shawangunk grit and cgl.

In 1907 (N. Y. State Mus. Bull. 107) Hartnagel gave thickness of *High Falls sh.* at Cornwall as 119 ft., and stated that it graded into overlying Binnewater and rested on Shawangunk without break. Also that the High Falls and Binnewater are=Longwood shales of Darton.

C. P. Berkey, 1911 (N. Y. State Mus. Bull. 146), described *High Falls sh.* as consisting of 67 to 100 ft. of greenish to red argill. to sandy sh., "exposures often brilliant red."

C. Schuchert, 1916 (Geol. Soc. Am. Bull., vol. 27, pp. 540–543), reported great break btw. *High Falls sh.* and Shawangunk cgl. and probable break btw. Binnewater and High Falls fms., and gave thickness of the High Falls in Binnewater-High Falls region as 80 to 90 ft.

In northern N. J. (NW. part of Franklin Furnace quad.) the *High Falls fm.*, as it is there called, consists at base of hard red quartzitic ss. intercalated with some green or gray sss. and softer red shales, which become more abundant in upper part of fm., and it is more than 400 ft. thick. Its thickness in Delaware Water Gap is estimated at 2,300 ft. In N. J., as in N. Y., it rests on Shawangunk cgl.

C. K. and F. M. Swartz, 1931 (Geol. Soc. Am. Bull., vol. 42, p. 657). It has been shown [pp. 622–660] *Bloomsburg red beds* can be followed continuously from type loc. in NE. Pa. southward into Md. and eastward through central and eastern Pa. to Delaware Water Gap, where it was called *Clinton* by Chance and *High Falls* by Stose. It is continuous with Medina-Longwood red ss. of N. J. and High Falls red beds of Hartnagel in SE. N. Y. It is manifest it is same fm. throughout this entire area and should have one name to avoid confusion. The term *Bloomsburg* has priority.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 342). *High Falls shales* are pyritic red shales, 80 to 90 ft. thick, overlying Shawangunk in Kingston-Port Jervis section. The red shales above the Shawangunk in Orange Co., N. Y., and in N. J. are called *Longwood shales*. They are in part or wholly=High Falls sh. and perhaps Binnewater ss.

Highgate slate.

Upper Cambrian (?): Northwestern Vermont (Franklin County).

A. Keith, 1923 (Am. Jour. Sci., 5th, vol. 5, pp. 114–115). *Highgate sl.*—Mainly dark sl., in places black; usually banded. Banding in most places regular, sharp, and clear. The dark and light layers are evenly spaced and from ⅛ to ¼ in. thick. Interbedded with the sl. are many thin seams of fossiliferous blue ls. 1 or 2 in. thick. One-third mi. NW. of Highgate Center these layers thicken and outcrop in the R. R. cut as a strongly banded ls. mass 35 ft. thick. These are probably highest beds in the fm. near Highgate. In lower part at Highgate Falls the light bands consist of fine sandy sh. or ss. seams; there are several beds of tough gray dol., 1 ft. or more thick, that weathers rusty brown; and about 40 ft. above base there is a zone, nearly 6 ft. thick, of sl. filled with small pebbles of ls. up to 4 in. across. Thickness at Highgate Falls at least 300 ft. Contains Upper Camb. fossils. Extends from Canada into town of Milton, a distance of 25 mi. Principal development is in Highgate Twp [St. Albans and Enosburg Falls quads], where it forms broad area. Fine section exposed at Highgate Falls, where it overlies Milton dol. Nothing is known of overlying fms. in this region, but doubtless later Upper Camb. fms. were deposited on Highgate sl.

P. E. Raymond, 1924 (Boston Soc. Nat. Hist., vol. 37, No. 4). So far as can be judged from trilobites at present known, *Highgate fm.* would be termed Ord., rather than Camb., but would be placed about on border btw. the two.

B. F. Howell, 1929 (16th Rept. Vt. State Geol., p. 263). Keith in 1923 [rept cited above] tentatively included in his Highgate sl. the *Paradoxides* beds (Middle Camb.), to which writer in 1926 restricted the name *St. Albans*. *Highgate sh.* as here used is restricted to the Upper Camb. sh. overlying Mill River cgl. (probably Upper Camb.), which in turn rests (almost certainly with uncon.) on St. Albans sh. The name *Mill River cgl.* is proposed by writer, after consultation with Keith.

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 377). In St. Albans region of NW. Vt. the Corliss cgl. (of Beekmantown age) rests uncon. on Highgate sl., and the Highgate rests on Mill River cgl. (Upper Camb.), which in earlier repts was called by me *Milton dol.* and (later) "Missisquoi fm." The Mill River cgl. rests uncon. on St. Albans sl.

C. Schuchert, 1933 (Am. Jour. Sci., 5th, vol. 25, pp. 353–381), assigned *Highgate sl.* to Upper Camb., although Raymond (1924) and McGerrigle (1931) suggested it might be Ord.

C. Schuchert, 1936 (letter dated Feb. 12). I have recently, with help of Prof. Raymond, referred whole of Highgate (formerly Upper Camb.) to oldest Ord., correlating it with *Ceratopyge* fauna of Sweden.

Highgate Springs series.

Middle and Lower Ordovician: Southern Quebec and northwestern Vermont (Franklin County).

W. E. Logan, 1863 (Geol. Surv. Canada, pp. 273–275, 855–859), described the rocks of Highgate Springs region, but did not definitely name them.

H. W. McGerrigle, 1931 (17th Rept. Vt. State Geol., pp. 181–184). The fms. composing *Highgate Springs series* are Chazy, Lowville, Black River, and Trenton in age. Logan and others believed Utica fm. also was present, but it is probable these "Utica" beds are a shaly upper part of the Trenton. Most complete exposure of the series is at Highgate Springs [St. Albans quad.], Vt., where all fms. mentioned above are shown. [Geographic distribution described and fm. mapped in NW. Vt.] Is younger than Philipsburg series.

Highland gneiss.

Pre-Cambrian: Southeastern New York (Highlands of the Hudson).

D. S. Martin, 1888 (geol. map of N. Y. City and vicinity). ***Highland gneiss*** (*Laurentian*). [Oldest fm. shown. Placed beneath ***Atlantic or Manhattan*** *gneiss* (*age disputed*).]

J. M. Clarke, 1908 (N. Y. State Mus. 60th Ann. Rept., vol. 1, pp. 11–12). Oldest fm. of Highlands of the Hudson is a gneiss, provisionally designated ***Highland gneiss***, and probably=Fordham gneiss of New York City dist. It is essentially a series of metamorphosed ancient sediments, chiefly siliceous, now appearing as granite gneisses, qtzite schists, mica schists with occasional interbedded lss. and serpentinous beds, the whole abundantly interjected with sheets, stringers, and dikes, of igneous rocks of many varieties and different dates. Assigned to pre-Cambric.

C. P. Berkey and Marion Rice, 1921 (N. Y. State Mus. Bull. 225, 226, pp. 22, 28). The pre-Camb. ***Highlands gneiss***, Inwood ls., and Manhattan schist and their associated intrusives compose almost all of West Point quad. The ***Highlands gneiss***, which makes about 70 percent of total area, is considered to be age equiv. of Grenville gneiss and associated series of Adirondacks and Canada. The Poughquag qtzite is clearly uncon. on ***Highland gneisses***. [In table on p. 140 the gneiss in West Point quad. is called ***Fordham gneiss***, and it is assigned to "older Grenville."]

Highland morainic system.

Pleistocene (Wisconsin stage): Northeastern Minnesota and northwestern Wisconsin.

A. H. Elftman, 1898 (Am. Geol., vol. 21, pp. 90–109, 175–188). The moraine immediately N. of Lake Superior is named *Highland moraine*, for Highland Station, Lake Co., Minn.

F. Leverett, 1928 (U. S. G. S. P. P. 154). *Highland morainic system.*—The major part of this morainic system was years ago mapped by Elftman as ***Highland moraine***. It is here divided into the following moraines (descending order of age): Nickerson morainic system (including Fond du Lac, Thomson, Cloquet, and Draco moraines) and Kerrick morainic system (including Cromwell and Wright moraines).

Highland formation.

Upper Paleozoic (?): British Columbia.

C. H. Clapp, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 87).

Highland Boy limestone member (of Bingham quartzite).

Pennsylvanian: Central northern Utah (Bingham district).

A. Keith, 1905 (U. S. G. S. P. P. 38, p. 41, map, sections). ***Highland Boy ls. memb. of Bingham qtzite.***—White or light-colored marbles, with considerable silica, both in form of sand grains and chert, and in places beds of mottled blue and white marble. Much of the chert is secondary but some of it is original. Believed to be derived from blue ls. Thickness 0 to 400± ft. Six areas of this ls. occur within short distances of Highland Boy mine. May possibly be=Jordan ls. memb., but seems to lie above Commercial ls. Is lower than Yampa ls. lentil.

Highland Church sandstone member (of Forest Grove formation).

Mississippian: Northeastern Mississippi (Tishomingo County).

W. C. Morse, 1928 (Jour. Geol., vol. 36, pp. 31–43). ***Highland Church ss. memb.***—Massive cliff-forming ss., 25 ft. thick, forming top memb. of Forest Grove fm. Forms typical cliffs about Highland Church, E. of Tishomingo City, Miss. Lower part of Forest Grove fm. consists of 90 ft. of sh. and ss.

W. C. Morse, 1930 (Miss. Geol. Surv. Bull. 23), gave many details regarding this memb.

Highland Croft magma series.

Upper Ordovician (?): Northwestern New Hampshire (Ammonoosuc River region) and White Mountains.

M. Billings, 1934 (Sci., vol. 79, No. 2038, Jan. 19, pp. 55-56). Four major periods of intrusive igneous activity have been recognized in central N. H.: The *Highlandcroft, Oliverian, New Hampshire,* and *White Mtn petrogenic cycles.* The *Highlandcroft cycle* includes diorite, quartz diorite, granodiorite, and granite. They are younger than Partridge sl. and older than Clough cgl.; are definitely pre-Sil., and probably late Ord. The *Oliverian rocks* are largely biotite granite; younger than Lower Dev. but older than major period of orogeny. The *New Hampshire magma series* consists of diorite, quartz diorite, granodiorite, trondhjemite, and granite, younger than Lower Dev. and essentially contemp. with the great period of folding. Youngest of all is *White Mtn ("alkaline") magma series,* which is younger than Lower Dev. and later than the period of orogeny. Thus 3 of the igneous series are younger than Lower Dev., and to them belong 90 percent of the igneous rocks of central N. H. The other 10 percent (the Highlandcroft group) is pre-Sil., probably late Ord. but possibly older. On 1932 geol. map of U. S. only the *White Mtn magma series* is shown as Paleozoic; all others being included in pre-Camb. In other words, Paleozoic intrusives are much more abundant than map shows. [Billings mapped *New Hampshire magma series* and *Highland Croft magma series* over parts of Littleton and Moosilauke quads in Am. Jour. Sci., 5th, vol. 28, Dec. 1934, p. 414.]

M. Billings, 1935 (personal communication April 26). *Highland Croft* was chosen from a large farm about 1½ mi. W.-NW. of Littleton.

See also *Highlandcroft granodiorite.*

Highlandcroft granodiorite.

Upper Ordovician (?): Northwestern New Hampshire (Littleton quadrangle).

M. P. Billings, 1935 (Geology of Littleton and Moosilauke quads., N. H., p. 25 and map of Littleton quad.). *Highlandcroft granodiorite* is proposed for a granodiorite (chiefly greenish gray) and associated intrusives which are younger than Albee, Ammonoosuc, and Partridge fms. and older than Clough, Fitch, and Littleton fms. The large estate called "Highlandcroft," on St. Johnsbury road 1½ mi. W.-NW. of Littleton, is located on largest body of this rock in Littleton and Moosilauke quads. Is probably late Ord. [*Highlandcroft magma series* is used as a center heading and *Highlandcroft granodiorite* as a side heading. The names appear to be synonymous.]

M. Billings, 1935 (letter dated Aug. 27). Lahee's Fitch Hill granite gneiss is precisely the same as our Highlandcroft granodiorite. It belongs to Highlandcroft magma series. In other words, Highlandcroft is used both for a whole magma series and also in a restricted sense for a granodiorite within the series.

Highland Peak limestone.

Middle Cambrian: Eastern Nevada (Pioche region).

L. G. Westgate and A. Knopf, 1927 (Am. Inst. Min. and Met. Engrs. Trans., No. 1647, p. 6) and 1932 (U. S. G. S. P. P. 171). *Highland Peak ls.*—Light-gray to dark-gray or black ls., fine-grained to medium coarse-grained, with many dolomitic beds. Thickness 3,000± ft. Conformably overlies Chisholm sh. and conformably underlies Mendha ls. Named for Highland Peak, in Highland Range, in whose W. slope the fm. is best shown. Composes main part of Bristol-Highland Range from S. edge of Highland quad. N. to about 2½ mi. S. of Bristol Pass. No recognizable fossils but overlying Mendha ls. has been identified as basal Upper Camb., and underlying Chisholm sh. is Middle Camb., so Highland Peak ls. appears to comprise major part of Middle Camb.

High Park lake beds.

Tertiary (late Miocene or Pliocene): Eastern Colorado (Pikes Peak region).

W. Cross, 1894 (U. S. G. S. Pikes Peak folio, No. 7). *High Park lake beds.*—Remnants of a series of local sss. and cgls. lying either on granite or on a thin rhyolite flow, the cgls. characterized by pebbles of extremely hard Algonkian qtzite, granite, and gneiss. No fossils; but beds appear to be older than adjacent volcanic breccia, which in many places rests on Florissant lake beds. Is older than Alnwick lake beds. Named for High Park.

†High Point sandstone.

Upper Devonian: West-central New York.

J. M. Clarke, 1885 (N. Y. State Geol. Rept. for 1884, p. 22 and map; also U. S. G. S. Bull. 16). *High Point Chemung.*—A richly fossiliferous layer of calciferous ss. outcropping on summit of High Point, in Naples, the highest mtn. in Ontario Co. Is youngest Dev. strata in this dist. Thickness 5 to 7 ft. Overlies Lower Chemung (Portage) sss. Fauna is Chemung.

According to J. M. Clarke and D. D. Luther, 1902 (N. Y. State Mus. Bull. 52, pp. 616–631), the High Point ss. carries a Chemung fauna, but corresponds in time to Portage ss., which carries a Naples fauna. In 1904 (N. Y. State Mus. Bull. 63) J. M. Clarke and D. D. Luther named the beds beneath High Point ss. the *Westhill sss.* and the beds above it the *Prattsburg ss. and sh.;* and described High Point ss. as follows: Consists of 100 ft. of light-gray sss. in layers 3 inches to 4 ft. thick, separated by thin beds of hard blue sh., some layers compact and calc., but larger portion laminated and somewhat shaly; contains lenticular beds of impure ls.; sss. are thinner and softer to E.; from 50 to 75 ft. exposed at High Point, Ontario Co.; about 50 ft. below top is "High Point firestone" of calc. ss. and cgl., 7 ft. thick; the High Point ss. is continuous with Portage sss. of Genesee Valley, which carry a Naples fauna, but the High Point and overlying Prattsburg sh. were included in Chemung because of their faunas.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 84). *High Point ss.* is recognized as far E. as Chemung Co.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 369, 402), included *High Point ss.* in Portage group, placed it above West Hill flags, and stated it is same as Nunda ss.

G. H. Chadwick, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2), restricted Chemung but included this ss. in Chemung, placing it below Prattsburg ss. and above Westhill.

The U. S. Geol. Survey has discarded this name, in favor of Nunda ss.

†High Point firestone.

Calc. ss. and cgl., 7 ft. thick, lying about 50 ft. below top of †High Point ss., of N. Y.

High Rock sandstone.

Pennsylvanian: Southwestern Indiana (Daviess County).

G. H. Ashley, 1899 (Ind. Dept. Geol. and Nat. Res. 23d Ann. Rept., 1898, p. 113) casually applied *High Rock ss.* to the massive coarse-grained ss., 65 ft. thick, in Daviess Co., "that culminates at High Rock and extends into Greene Co." He stated that in early repts it was miscorrelated with Mansfield ss.

High Rock sandstone.

Pennsylvanian: Southeastern Kentucky (Magoffin County).

I. B. Browning and P. G. Russell, 1919 (Ky. Geol. Surv., 4th ser., vol. 5, pt. 2, p. 15). *High Rock ss.*—Massive soft coarse-grained white to brownish-white ss. 30 to 50 ft. thick, underlying Fugate coal and overlying Flag coal rider in Magoffin Co. Included in Pottsville. Is persistent enough to be recognized as a distinct fm. Named High Rock ss. because found on several high points exposed in cliffs called "High Rocks" by natives. Is easily confused with Puncheon Creek ss., but is older.

High Tower granite.

Probably Cambrian: Northwestern Georgia (Tate quadrangle).

W. S. Bayley, 1928 (Ga. Geol. Surv. Bull. 43, p. 37, map). *High Tower granite.*—Light-gray or white gneissoid biotite granite. One area of it is in W. part of Tate quad. and the other in SE. corner, where it is best developed around Hightower, Forsyth Co. Younger than Carolina gneiss (Archean), but probably not older than Salem Church granite of W. part of quad. and is probably Camb. The Salem Church granite intrudes Hiwassee schist and Great Smoky fm.

Hightower sands.

Drillers' name *Hightower shallow sand* applies to a sand of Chester (Miss.) age in Ind. that has been correlated with Hardinsburg ss.; and *Hightower deep sand* to a lower sand of Chester age that has been correlated with Mooretown ss. of Cumings.

Highwood syenite.

Eocene (?): Central northern Montana (Fort Benton quadrangle).

W. H. Weed, 1899 (U. S. G. S. Fort Benton folio, No. 55). *Highwood syenite.*—Light-colored coarsely granular feldspathic rocks of Highwood Peak and neighboring laccoliths. Southern part of Highwood Peak is composed of a very typical syenite.

Hignite formation. (In Pottsville group.)

Pennsylvanian: Southeastern Kentucky and northeastern Tennessee.

G. H. Ashley and L. C. Glenn, 1906 (U. S. G. S. P. P. 49, pp. 33, 43, and pl. XLA). *Hignite fm.*—Shales, sss., and coals, 460 ft. thick, lying btw. top of Red Spring coal above and base of Hignite coal below in Cumberland Gap coal field. Underlies Bryson fm. and overlies Catron fm.

Later studies by D. White show Hignite fm. is of late Pottsville age and is represented in time interval of Kanawha fm.

Named for Hignite Creek, Bell Co., Ky.

Hilbig zone.

Eocene (lower): Central Texas.

C. B. Claypool, 1933 (The Wilcox group of central Tex., Abstract of thesis, Univ. Ill.). *Hilbig marine zone* in Rockdale fm. of Wilcox group has been defined in southern Bastrop Co. and traced southward into Guadalupe Co. There is a slight discon. at base of the marine zone. It is considered probable equiv. of Pendleton marine zone of La. [Type loc. not stated.]

Hill sand horizon.

Lower Cretaceous: Northeastern Texas (Cass County) and northwestern Louisiana (Caddo County).

J. S. Ivy, 1936 (Oil and Gas Jour., vol. 34, No. 48, April, p. 72). *Hill sand horizon*, 35 ft. thick, in Glen Rose fm., lies 223 ft. above Dees horizon in Rodessa field, and 80 ft. above *Caddo Levee Board horizon.* Latter horizon consists of 88 ft. of oolitic lss., with some sh. and sand, and lies 55 ft. above Dees sand horizon.

Hillabee chlorite schist.

Post-Carboniferous (?): Eastern Alabama.

W. M. Brewer, 1896 (Ala. Geol. Surv. Bull. 5, pp. 84, 89, 92). *Hillabee (Iwana) green schist belt.*—A belt of light-green, highly pyritiferous altered eruptive rock paralleling "Talladega" sl. proper of Talladega Mtns, on SE. edge, and apparently maintaining its continuity along the line of strike, from Coosa River, near mouth of Weogufka Creek, toward NE. into Cleburne Co. This rock is distinguishable from "Talladega" slates by large percentage of unaltered pyrites it carries, as well as by its massive structure, hardness, and toughness.

E. A. Smith, 1896 (Ala. Geol. Surv. Bull. 5, pp. 118–125). *Hillabee, Iwana, or Millerville green schists.*—Green schists, probably an altered eruptive rock. Occur along SE. border of main mtn belt of Talladega slates in almost continuous outcrops. The names are those of localities where the rocks show in typical form. The highly schistose and slaty varieties may be seen about Hillabee or Millerville, Clay Co. In places the Hillabee schists hold a large percentage of pyrite in crystals disseminated through a siliceous rock. All agree in thinking the schists are result of alteration of some basic eruptive rock. For present, therefore, we have grouped them together under the name *Hillabee*, from locality where they are exposed in typical fashion.

G. I. Adams, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14, map, p. 38). *Hillabee chlorite schist.*—A metamorphosed basic intrusive, in places massive. Occupies position btw. Ashland mica schist and Talladega sl. Is same as Hillabee green schist as mapped by E. A. Smith in Ala. Geol. Surv. Bull. 5. Tentatively classified as post-Carbf. (?).

Named for exposures at Hillabee, on Hillabee Creek, Clay Co.

Hill Creek beds (member of Millsap Lake formation).

Pennsylvanian: North-central Texas.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 106, 107), from ms. of rept. by G. Scott and J. M. Armstrong, on geol. of Parker Co. (See under *Millsap Lake fm.*) Type loc. not stated.

Hilliard formation.

Upper Cretaceous (Montana and Colorado): Southwestern Wyoming (Uinta and Lincoln Counties).

W. C. Knight, 1902 (Eng. and Min. Jour., vol. 73, p. 721). *Hilliard fm.*—Almost entirely sh., varying from drab to gray, with a few bands of ss. Exposed from Kemmerer W. to Ham's Hill and also 1 mi. N. of Hilliard. Thickness 5,000 ft. Well developed near Hilliard. Overlies Frontier fm. and underlies Laramie group.

W. C. Knight, 1903 (Geol. Soc. Am. Bull., vol. 13, pp. 542–544). Hilliard is located on *Hilliard fm.* I cite as typical section the sh. beds W. of Kemmerer and extending as far as E. portal of Oregon Short Line tunnel. Overlies Frontier fm. and underlies Laramie.

A. C. Veatch, 1907 (U. S. G. S. P. P. 56). *Hilliard fm.*—Gray to black sandy shales and shaly sss., not known to contain coal of economic importance. Weathers into region of low relief. Thickness 5,500 (?) to 6,800 ft. Several thick lenses of white ss., containing *Inoceramus exogyroides*, occur 3,000 to 3,800 ft. above base of fm. W. of Frontier. Overlies Frontier fm. and underlies Adaville fm.

Hillman limestone.

Pennsylvanian: Northeastern Pennsylvania (Luzerne County).

C. A. Ashburner, 1886 (2d Pa. Geol. Surv. Ann. Rept. 1885). *Hillman ls.*—Tough, siliceous ls., 2 to 3 ft. thick, exposed in cut of Lehigh Valley R. R. SW. of Hillman Colliery breaker. Lies 10 ft. above Hillman or H coal and 37 ft. below Bowkley or I coal.

†Hill Quarry beds.

Upper Ordovician: Southwestern Ohio and north-central Kentucky.

E. Orton, 1873 (Ohio Geol. Surv. vol. 1, pp. 370–387). *Hill Quarry beds.*—Alternating beds of ls. and sh., 125 to 150 ft. thick. Form topmost div. of Cincinnati beds proper (middle fm. of Cincinnati group). Lie stratigraphically below Lebanon beds (topmost fm. of Cincinnati group), and are underlain by Eden sh. Constitute highest stratum found in Cincinnati hills.

Not a geographic name. Replaced by *Maysville group.*

Named for hill quarries at Cincinnati, Ohio.

Hillsboro sandstone.

Silurian (?): Southwestern Ohio.

E. Orton, 1871 (Ohio Geol. Surv. Rept. Prog. 1870, pp. 271, 301, 306–7). *Hillsboro ss.*—Very fine-grained, purely siliceous ss., of white to yellowish or brown color, 0 to 30 ft. thick, forming top fm. of Niagara group near Hillsboro and at a few other localities in Highland Co. Overlies Cedarville or Guelph ls. and underlies Helderberg ls. (Greenfield stone).

J. E. Carman and E. O. Schillhahn, 1929 (Ohio Jour. Sci., vol. 29, No. 4, p. 169). A restudy of *Hillsboro ss.* of Highland Co. has shown that certain exposures formerly interpreted as ss. layers interbedded in Greenfield and Niagaran dolomites, are really masses of ss. completely enclosed in the dolomites not more than 30 ft. below Sil.-Dev. discon., which here cuts across Greenfield and Niagaran dolomites. The other exposures are of ss. resting on either the Greenfield or the Niagaran at horizon of the discon. The Hillsboro is interpreted as including 2 types of deposits of same age: (1) Discontinuous sand laid down on post-Sil. erosion surface; (2) sand washed down into existing cavities beneath this erosion surface. The Hillsboro is younger than the erosion interval which came after the fm. of Greenfield dol. (late Sil.) and older than Ohio sh. (Upper Dev.), which in Highland Co. lies next above the Sil.-Dev. discon. It is in same hiatus as Sylvania ss. (early Dev.) in NW. Ohio.

A. F. Foerste, 1935 (Denison Univ. Bull., Jour. Sci. Lab., vol. 30, pp. 137–138). *Hillsboro ss.* may represent basal deposits of Lower Dev. and may be of about same age [Helderberg, Lower Dev.] as Sylvania ss. of northern Ohio.

Hillsborough series.

Carboniferous: New Brunswick.

W. J. Wright, 1922 (Canada Geol. Surv. Mem. 129, pp. 7, 18). [Assigned to Carbf., but G. W. H. Norman, 1932 (Canada Geol. Surv. Econ. Geol. ser., No. 9, p. 171), assigned it to Miss.]

Hillsdale limestone. (In Greenbrier limestone.)

Mississippian: Southeastern West Virginia and southwestern Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 451, 487). *Hillsdale ls.*—Blue, hard, and massive at top, with streaks of sandy sh. toward base; calc. portions contain abundant black, nodular chert, weathering gray. Marine fossils. Thickness 50 to 150 ft. Underlies Sinks Grove ls. and overlies Maccrady series [fm.]. Is basal memb. of Greenbrier series [ls.]. Type loc. in Monroe Co., in road just E. of Hillsdale, on W. limb of Hillsdale anticline. Also observed in Greenbrier and Mercer Counties, and northward to Marlinton, Pocahontas Co., W. Va., also in Giles Co., Va., and through SW. Va. and into Ky., where it corresponds to St. Louis ls. of Butts.

Hilton shale member (of Portage formation).

Upper Devonian: Southwestern Virginia and northeastern Tennessee.

J. H. Swartz, 1929 (Am. Jour. Sci., 5th, vol. 17, pp. 436–448). *Hilton sh. memb. of Portage fm.*—Black sh. or argillite, with, in places, some interbedded gray-black sh. Thickness 12 to 50 ft. Is top memb. of Portage fm. in SW. Va. and Rutledge-Rogersville-Sneedville-Klondyke region of NE. Tenn. [Named for exposures at or near Hilton, Scott Co., Va.]

Hinche formation.

Pliocene: Haiti.

W. P. Woodring, 1922 (Haiti Geol. Surv. Stratig. and structure of central plain, p. 10).

Hinchman sandstone.

Upper Jurassic: Northern California (Taylorsville region).

J. S. Diller, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 370–394). *Hinchman tuff* consists of 500 ft. of greenish or gray sandrock, composed in many places of lapilli. Overlies Bicknell ss.

J. S. Diller, 1908 (U. S. G. S. Bull. 353). *Hinchman ss.* consists of 500 to 1,000 ft. of coarse tuffaceous ss. and cgl. of andesitic material, with some shaly beds. Uncon. overlain by Foreman fm. and grades into underlying Bicknell ss.

C. H. Crickmay, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 81; vol. 44, No. 5, pp. 895–903), included Bicknell ss. in *Hinchman arkose*, as he called the fm.

Named for exposures at Curtice Cliff, in lower part of Hinchman Ravine, Plumas Co.

Hinchman tuff. See *Hinchman sandstone.*

Hinckley sandstone.

Pre-Cambrian (Keweenawan): Southeastern Minnesota.

N. H. Winchell, 1886 (Minn. Geol. Nat. Hist. Surv. 14th Ann. Rept., pp. 336–337). *Hinckley sandrock* (*Potsdam?*), is separated from overlying Dresbach sandrock by shales [which he both included in and excluded from his St. Croix, and which he in 1888 named *Dresbach sh.*].

Warren Upham, 1888 (Minn. Geol. Nat. Hist. Surv. Final Rept., vol. 2, pp. 639, 645, and map, pl. 55). *Hinckley ss.*—The ss. quarried at Hinckley is hard and compact medium-grained ss. of light-buff color, nearly level in stratification. This ss. occurs in bluffs of Kettle River. Overlies [so-called] Potsdam ss.

N. H. Winchell, 1899 (Minn. Geol. Nat. Hist. Surv. Final Rept., vol. 4, p. 16). *Hinckley ss.*—White sss. and cgls., varying to red, interbedded with much red sh. Thickness 1,000 ft.

N. H. Winchell, 1901 (Minn. Geol. Nat. Hist. Surv. Final Rept., vol. 6, Atlas, map of Minn.). *Hinckley ss.* underlies Dresbach and passes down into Potsdam red ss. [so-called]. [Mapped on atlas sheets of Carlton and McLeod Counties (where it is 381 ft. thick), also Pine County.]

C. P. Berkey, 1906 (Geol. Soc. Am. Bull., vol. 17, p. 233, pl. opp. 237). *Potsdam or Hinckley sss.* of Minn., 0 to 1,000 ft. thick, underlie Dresbach sh. and rest uncon. on pre-Camb.

F. F. Grout and E. K. Soper, 1914 (Minn. Geol. Surv. Bull. 11). The red clastic series, 2,000 ft. thick, known in wells in E. and SE. Minn., is probably of same age as red sss. and shales outcropping from Lake Superior SW. to Mora, locally called *Hinckley ss.*

C. R. Stauffer, 1925 (Jour. Geol., vol. 33, pp. 699–713). The red clastic series of Minn. consists of *Hinckley ss.* and underlying unnamed shales and sss. The *Hinckley ss.* is a thick coarse red to brown ss., which often contains much partl.' weathered feldspar, together with mica, magnetite, and traces of other minerals. It may be either massive or shaly, and sometimes shows marks of shallow-water deposition. It immediately underlies St. Croix series, and can be recognized over wide areas, even in records of deep wells of southern Minn. Fossils found in cuttings of Waconia well about 40 ft. below base of Hinckley ss. resemble those of Middle Camb. of Mont., Wyo., Utah, and Idaho, and whole deposit may b̓ Camb., but it is also considered=Keweenawan lavas.

A. C. Trowbridge and G. I. Atwater, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 35–36). There are 2 areas in Minn. in which rocks occur that have been classified as *Hinckley ss.* The NE. area, in which occur beds that have been correlated with Bayfield group of the Upper Keweenawan, includes the exposures on St. Louis River at Fond du Lac and to S. around Hinckley, Minn. Correlation of these beds with upper part of main body of Red Clastic series to S. is accepted by all geologists who have worked in region. In eastern and southeastern area, where lowest Upper Camb. and Red Clastic beds are known only from well logs, the term *Hinckley* was applied to a ss. that occurs below the Eau Claire shales. Are these 2 sss. of same age and both properly called Hinckley? The Mount Simon of Wis. [Upper Camb.] and the Hinckley of adjacent parts of Minn. can be correlated with confidence. There appears to be evidence that the Hinckley of NE. Minn., including that at Hinckley, is older than the beds Stauffer called *Hinckley* in southern Minn. We suggest that *Hinckley* as applied to the beds below Eau Claire shales in E. and SE. Minn. be discarded and that *Mount Simon* be used to designate these beds. If Hinckley is to be retained at all it must apply to the rocks exposed near Hinckley, Minn., which are correlated, by all geologists who have worked in region, with upper part of Red Clastic series and are probably of Upper Keweenawan age. If later work should prove that the Hinckley of southern Minn. and Mount Simon ss. of Wis. are same as type Hinckley, then *Hinckley*, which has priority, should replace *Mount Simon*.

G. I. Atwater and G. M. Clement, 1934 (Geol. Soc. Am. Proc. 1933, p. 384). The ss. that outcrops at Hinckley and at Sandstone, Minn., is correlated with Orienta ss. of Bayfield group of Upper Keweenawan of Wis. This correlation was suggested by Thwaites in 1912. The Hinckley represents upper horizons of pre-St. Croixan red clastic series that are encountered in deep wells in SE. Minn. and NE. and central Iowa. The term *Hinckley* as used by Minn. Geol. Survey in deep wells in SE. Minn. is a definitely younger ss.—the Mount Simon ss. of Wis. It is therefore suggested *Hinckley* be restricted to pre-Mount Simon beds that crop out at Hinckley and elsewhere in NE. Minn. The term *Mount Simon* should be applied to the ss. beneath Eau Claire sh. that is now called *Hinckley* by Minn. Survey.

G. I. Atwater and G. M. Clement, 1935 (Geol. Soc. Am. Bull., vol. 46, pp. 1684–1685). The sss. that crop out in central eastern Minn. at Hinckley, Pine Co., and along Kettle River are of upper Keweenawan age and correlate with Amnicon fm. of Oronto group and Orienta fm. of Bayfield group in Wis. Younger Keweenawan beds occur in center of Lake Superior geosyncline in NW. Wis. The Mount Simon ss., which forms base of Upper Camb. in Wis. and Minn., is much younger than Hinckley ss. and the overlying Keweenawan sss., and is separated from them by a great structural and erosional uncon. The name *Hinckley* should therefore be restricted to the ss. that crops out at Hinckley and along Kettle River, and *Mount Simon* should be applied to the ss. that underlies Eau Claire memb. of Dresbach fm. in Wis. and Minn. and overlies Red Clastic series (upper Keweenawan) in Minn.

Hindostan whetstone.

Pennsylvanian: Southwestern Indiana (Orange and Martin Counties).

Name was used by D. D. Owen as early at least as 1839 (2d Rept. Geol. Surv. Ind., pp. 8, 10) but not in stratigraphic sense.

E. T. Cox, 1871 and 1876 (Ind. Geol. Surv. 2d Ann. Rept., pp. 81, 105; 7th Ann. Rept., pp. 6–8). *Hindostan whetstone.*—Whetstone, 20 ft. thick, in 2½-ft. layers, with sh. btw., occurring in middle of Millstone grit. Overlain by 4 ft. of shaly bluish ss., succeeded above by 70 ft. of massive ss. and cgl. Underlain by thin bed of black bituminous sh., succeeded below by thin beds of coal and clay and 38 ft. of ss.

E. M. Kindle, 1896 (Ind. Dept. Geol. and Nat. Res. 20th Ann. Rept.). *Hindostan whetstone* is economically the most important part of Mansfield ss.

Named for village in Martin Co., which was once county seat but has been extinct since 1870.

Hindsville limestone member (of Batesville sandstone).

Mississippian: Northern Arkansas (Eureka Springs and Yellville regions).

A. H. Purdue and H. D. Miser, 1916 (U. S. G. S. Eureka Springs-Harrison folio, No. 202). *Hindsville ls. memb. of Batesville ss.*—Dark-gray ls. interbedded with some ss. Thickness 1½ to 50 ft. In all previous repts on northern Ark. has been included in underlying Boone ls., but is here included in Batesville ss. on paleontologic and lithologic grounds, and because of marked uncon. at its base. Named for exposure near Hindsville, Eureka Springs quad.

Hinsdale gneiss.

Pre-Cambrian: Western Massachusetts and Connecticut.

B. K. Emerson in 1892 used *Hinsdale gneiss* on U. S. G. S. Hawley sheet, i. e., proof sheets of geol. maps and text intended for a geol. folio, but never completed and published in that form, although cited in U. S. G. S. Bull. 191, 1902.

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, pp. 18, 20, 24–25). *Hinsdale gneiss.*—A group of gray biotite gneisses, generally quite coarse and with jet-black biotite in distinct elongate patches, granitoid and yet well foliated. Underlies Hinsdale ls. and is oldest fm. in Berkshire Hills and Connecticut Valley. [See also B. K. Emerson, U. S. G. S. Bull. 597, 1917.]

Named for occurrence at Hinsdale, Berkshire Co., Mass.

†Hinsdale limestone.

Pre-Cambrian: Western Massachusetts.

B. K. Emerson in 1892 used *Hinsdale ls.* on U. S. G. S. Hawley sheet, i. e., proof sheets of geol. maps and text intended for a geol. folio, but never completed and published in that form, although cited in U. S. G. S. Bull. 191, 1902.

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, pp. 18, 24–26). *Hinsdale ls.*—Coarse white to pink, highly crystalline ls. with coccolite or chondrodite so abundantly and evenly scattered through mass that it deserves name *coccolite ls.* or *chondrodite ls.* Exposed 50 ft. W. of Hinsdale Station, where 25 ft. is shown. Overlies Hinsdale gneiss and is older than East Lee gneiss. [In U. S. G. S. Bull. 159, 1899, B. K. Emerson gave thickness 600+ ft.]

Replaced by *Coles Brook ls.*

Hinsdale formation.

Tertiary? (Pliocene?): Southwestern Colorado and northwestern New Mexico.

W. Cross, 1911 (U. S. G. S. Bull. 478, pp. 22, 29, map). *Hinsdale volcanic series.*—In portions of San Cristobal and Uncompahgre quads., and presumably in others not yet examined, a succession of volcanic eruptions later than Potosi volcanic series took place, producing a series of lavas differing notably from the products of earlier eruptions. Potosi volcanic series was much eroded before these later lava flows were extruded. So far as known they closed the long sequence of lavas in San Juan region. They range from a rhyolite very rich in quartz and alkali feldspar but poor in calcic feldspar and in all ferromagnesian minerals to a normal olivine plagioclase basalt. Between these two extremes are several types of lavas possessing some characteristics distinguishing them from earlier lavas. Named for important occurrences in Hinsdale Co. The most extensive deposits of these lavas thus far discovered are on divide btw. Lake Fork and Cebolla Creek, directly E. of Lake City. The section exposed is nearly 1,200 ft. thick. It is too early to sharply define limits of Hinsdale volcanic series.

E. S. Larsen, 1923 (U. S. G. S. P. P. 131G, table opp. p. 184; also Bull. 718). *Hinsdale volcanic series* is later than Fisher quartz latite (Mio.) and Creede fm. (0 to 2,000 ft. thick, and also of Mio. age). Latter fm. rests uncon. on Potosi volcanic series in Creede dist.

W. W. Atwood and K. F. Mather, 1932 (U. S. G. S. P. P. 166). *Hinsdale volcanic series* is of Tert. (?) (Plio. ?) age. [Map shows, in San Juan Mtns, some post-Hinsdale volcanics.] Between the Hinsdale and the Mio. Potosi volcanic series there were outspread the Fisher quartz latite (Mio.) and the Los Pinos and contemp. gravels, of Tert. (?) (Plio. ?) age.

E. S. Larsen, 1935 (U. S. G. S. Bull. 843), changed name to *Hinsdale fm.*, and redefined it so as to include, under the name *Los Pinos memb.*, the gravels and sands originally treated as a distinct fm., under the name *Los Pinos gravel*.

Hinsdale sandstone.

Upper Devonian: Southwestern New York (Cattaraugus County) and northwestern Pennsylvania.

G. H. Chadwick, Oct., 1933 (Pan-Am. Geol., vol. 60, pp. 200, 203). *Hinsdale ss.* is suggested for the "quarry sss." composing basal course of Chadakoin fm. of Olean region.

G. H. Ashley and J. D. Sisler, 1933 (Pa. Topog. and Geol. Surv., 4th ser., Bull. M19, pp. 13–14). According to Chadwick, *Hinsdale* ("*Quarry*") *shaly ss.*, 20 ft. thick, underlies Chadakoin sh. and flags and overlies Girard (=Volusia), and is included in Chemung group of NW. Pa.

G. H. Chadwick, 1935 (Geol. Soc. Am. Proc. 1934, p. 71). [See 1935 entry under *Northeast sh.* Names of beds underlying and overlying Hinsdale ss. changed, and Hinsdale excluded from Chadakoin fm.]

G. H. Chadwick, Feb. 28, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, pp. 326, 350). Near Olean and along Genesee River the *Hinsdale ss.* overlies Volusia beds and underlies Chadakoin beds.

G. H. Chadwick, 1935 (Am. Mid. Nat., vol. 16, No. 6, pp. 860, 862). In eastern Cattaraugus Co. the base of the Chadakoin, there called "pink rock" by drillers, contains the *Hinsdale sss.*

G. H. Chadwick, 1936 (letter dated Jan. 2). Type loc. of *Hinsdale* is Ed Hull quarry, high on the hill face E. of Scott Corners and about 1 mi. N. of Hinsdale village [Cattaraugus Co., N. Y.], which is in sight from it.

Hinshaw sandstone.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, pp. 36, 280). *Hinshaw sss.*—Sss., 100 ft. thick, composing a middle fm. in Laramian series of Utah and Colo. Overlain by 1,200 ft. of unnamed shales and underlain by 1,000 ft. of unnamed shales. [Name used in tables only. Derivation of name not stated. On p. 280 is shown as older than "Navajo sh." and younger than "Picturecliff sss."]

Hinton division.

Lower Ordovician or Upper Cambrian: Central Texas.

T. B. Comstock, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. 301–306). *Hinton div.*—Consists of (descending): (1) Sponge bed. of slabby structure, 15 to 20 ft.; (2) sandy calc. shales or slabby dolomites, 25 to 30 ft.; (3) fossiliferous horizon with solid pavement of large sponges, 10 ft.; (4) calc. shaly beds 0 to 20 ft.; (5) tough, commonly dull-gray to brownish crystalline dolomites weathering gray; (6) 15 ft. of pink, white, or mottled red and white ls. with crystalline facets agreeing well with typical Birdseye ls. of N. Y.; (7) transition set of siliceous lss. of variable thickness and somewhat indefinite composition. Lower div. of San Saba series. Underlies Deep Creek div. and overlies Hoover div. of Leon series.

Named for Hinton Creek, San Saba Co.

Hinton formation.

Mississippian: Southern West Virginia and southwestern Virginia.

M. R. Campbell and W. C. Mendenhall, 1896 (U. S. G. S. 17th Ann. Rept., pt. 2, p. 487). *Hinton fm.*—Heterogeneous mass of variegated shales, sss. of varying character, and impure lss., ranging in thickness from 1,050 to 1,100 ft. Lowest bed is heavy ss., which is prominent feature along railroad from Hinton to Sandstone. Is lowest group of rocks exposed in that portion of New River gorge which lies below Hinton. [Later repts by Campbell state it overlies Bluefield sh.] Underlies Princeton cgl. Is=Greenbrier sh. of Rogers.

The 1928 prel. ed. of Va. Geol. Surv. geol. map of Va. redefined Bluefield sh. and Hinton fm., by restricting Bluefield to the prevailingly calc. beds and transferring to overlying Hinton fm. about 200 ft. of shaly or sandy beds included in Bluefield as defined.

Named for Hinton, Summers Co., W. Va.

Hinton group.

A name that has been applied in some repts to Hinton fm. (Miss.).

†Hinton limestone. (In Hinton formation.)

Mississippian: Southeastern West Virginia.

C. E. Krebs, 1916 (W. Va. Geol. Surv. Rept. Raleigh Co. and western portions of Mercer and Summers Counties, pp. 75, 76, 88). *Hinton ls.*—Massive ls., upper part full of marine fossils. At Hinton, Summers Co., it is 35 ft. thick and top lies 1,060 ft. below top of Mauch Chunk series. Is 55 ft. thick 2 mi. SW. of Hinton, and top lies 340 ft. below top of Mauch Chunk.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 296, 347). Because of conflict with Hinton group [fm.] replaced by *Avis ls.*

Hinton (Upper) limestone. (In Hinton formation.)

Mississippian: Southeastern West Virginia.

C. E. Krebs and D. D. Teets, Jr., 1916 (W. Va. Geol. Surv. Rept. Raleigh and western parts of Mercer and Summers Counties, p. 167). *Upper Hinton ls.*—Hard gray ls., 25 ft. thick, lying 295 ft. below top of Mauch Chunk in section ½ mi. SW. of Meadow Creek, Richmond dist.

Hinton sandstone.

Mississippian: Southern West Virginia.

C. E. Krebs and D. D. Teets, Jr., 1916 (W. Va. Geol. Surv. Rept. Raleigh and western parts of Mercer and Summers Counties, p. 77). *Hinton ss.*—Dark brown, 90 ft. thick. Included in Mauch Chunk series, its top lying 415 ft. below Hinton ls. (marine, and 35 ft. thick) at Hinton, Summers Co.

†Hippurites limestone.

Paleontologic name applied by R. T. Hill in 1887 (Am. Jour. Sci., 3d, vol. 33, p. 298) to the rocks in Tex. that were later named *Edwards ls.*

Hitka formation.

Cambrian: British Columbia and Alberta.

C. D. Walcott, 1913 (Smithsonian Misc. Coll., vol. 57, No. 12, pp. 334, 338).

Hitz limestone member (of Saluda limestone).

Upper Ordovician: Southeastern Indiana and north-central Kentucky.

A. F. Foerste, 1903 (Am. Geol., vol. 31, p. 347). In repts of Ind. Survey the beds at top of Ord. section at Madison are referred to as *Murchisonia hammelli* beds, or as the gastropod layer. Since the most varied fauna so far obtained from this horizon was collected in West Madison, along brow of Hitz hill, on W. side of Madison branch of Panhandle Railroad, the bed may also be called *Hitz bed.* [Some repts have excluded it from the Saluda.]

Adopted as a memb. of Saluda ls. because originally included in Saluda. In Jefferson Co., Ky., is 5 ft. thick and almost pure blue ls. According to E. R. Cumings, 1922 (Hdb. Ind. Geol., pt. 4, Sep. Pub. 21, p. 433), the Hitz ls. belongs to Whitewater fm. and not to Saluda. (See under *Saluda ls.* for explanation of relations of Saluda to Whitewater.)

Named for Hitz Hill, near Madison, Jefferson Co., Ind. Extends from near Floydsburg, Oldham Co., Ky., to southern bdy of Ripley Co., Ind.

Hiwassee slate.

Lower Cambrian: Western North Carolina, northeastern Tennessee, and northern Georgia.

A. Keith, 1904 (U. S. G. S. Asheville folio, No. 116, p. 5 and columnar section). *Hiwassee sl.*—In this region the fm. consists almost entirely of bluish-gray or bluish-black sl., which weathers to greenish, yellowish gray, and yellow. The slates are interstratified at intervals with lenticular layers of blue or dove-colored ls. North and NE. of Hot Springs many of the sl. beds are somewhat sandy, a little coarser-grained, and marked with light-gray siliceous bands of sed. origin. On other side of French Broad River the rocks are finer-grained and more uniform. In many NW. outcrops the slaty character is less pronounced and some layers are almost unaltered shales. A noticeable constituent in some beds is mica in fine scales—an original deposit and not a secondary growth. Bulk of material composing the slates is argill. To this is added here and there the micaceous and sandy material. West of Allen Stand the deposits of sand were enough to make distinct layers 8 to 10 ft. thick, which locally developed into fine cgls. In vicinity of Pigeon River and Crabtree Bald the rocks are so metamorphosed that they consist almost entirely of schists, of several varieties, with interbedded layers of graywacke. Most of the schists are dark gray or black, varied here and there with lighter gray bands. Thickness 700 to 1,500 ft. Overlies Snowbird fm. and underlies Cochran cgl.

In some areas Hiwassee sl. underlies Great Smoky cgl., which is regarded as=Cochran cgl.

Named for exposures on Hiwassee River, Polk Co., Tenn., which has cut a fine section through the fm.

Hobart Hill andesite.

Devonian (?): Northeastern Maine (Aroostook County).

H. E. Gregory, 1900 (U. S. G. S. Bull. 165, pp. 113, 169. 172–173). *Hobart Hill andesites.*—Hornblende andesite forming Hobart Hill, Aroostook Co.

On 1933 geol. map of Maine, by A. Keith, the andesite of NE. Me. appears to be assigned to Dev.

Hobo Gulch formation.

Middle Cambrian: Western central Montana (Elkhorn region).

W. H. Weed, 1901 (U. S. G. S. 22d Ann. Rept., pt. 2, map, pp. 434, 436). *Hobo Gulch fm.* [on map], *Hobo Gulch shaly ls.* [in strat. table], *Hobo Gulch lime-sh.* [in text heading].—Shaly ls., including characteristic ls. flags. Corresponds in position to Pilgrim ls. Consists of (descending): 35 ft. of "crinkled ls." (banded cherty ls.); 100 ft. of nearly black ls.; 18 ft. of sh., with no marked characteristics, that may=Park sh. Overlies Starmount ls. and underlies Cemetery ls. Forms a well-marked group of strata seen in railroad cuts near the tailing dams and in Queen Gulch. [Hobo Gulch is a NE. tributary of Queen Gulch, according to Weed's map, but this fm. is not mapped in vicinity of Hobo Gulch.]

Hoboken serpentine.

See under *Staten Island serpentine.*

Hobson Lake series.

Pre-Cambrian (?): British Columbia.

J. F. Walker, 1930 (Canada Geol. Surv. Summ. Rept. 1929, pt. A, pp. 283, 284).

Hochelagan formation.

Pleistocene: New York and adjacent parts of Canada and Vermont.

J. B. Woodworth, 1905 (N. Y. State Mus. Bull. 84, pp. 206–222, and map). *Hochelagan fm.* proposed to replace *Champlain* (preoccupied) as a name for the late Pleist. marine deposits of northern N. Y., Canada, and Vt. The best studied section of these marine fossiliferous beds is that of Montreal, the ancient site of which city was occupied by the Indian settlement of Hochelaga. It is therefore proposed to call the deposits of this marine invasion the *Hochelagan fm.* and the subepoch or stage of their time of deposition as the *Hochelagan,* a phase which follows the Wisconsin, with its late lacustrine stages contemp. with the departing ice sheet.

Hocking Valley conglomerate facies.

Mississippian: Central Ohio.

J. E. Hyde, 1915 (Jour. Geol., vol. 23, pp. 657, 669, 678). *Hocking Valley cgl. facies of Cuyahoga fm.*—Mostly cgls. and coarse sss., with some sh. Thickness 600 to 625 ft. Includes (descending) Berne memb., 1' to 20 ft.; Black Hand memb., 100 to 150 ft.; Fairfield memb., 200 to 330 ft.; Lithopolis memb., 118 to 200 ft. Underlies Byer memb. of Logan fm. and overlies Sunbury sh. Occurs in Hocking Valley, Fairfield and Hocking Counties.

Includes Cuyahoga fm. and lower part of Black Hand fm.

Hockley Mound sand member (of Willis sand).

Tertiary? (Pliocene?): Southeastern Texas and southern Louisiana.

J. Doering, 1935 (A. A. P. G. Bull., vol. 19, No. 5, pp. 655, 656, 660–665). *Hockley Mound sand memb.*—Uppermost memb. of Willis fm. in SE. Tex., SW. La., and SE. La. Light-colored fine-grained soft sand. Thickness few ft. to 20 to 25 ft. in SE. Tex., SW. La., and SE. La. Named for Hockley Mound, on Willis Plain, 4 mi. SW. of Hockley, Harris Co., Tex. Rests on Willis ferruginous sand memb. of Willis fm. Overlapped uncon. by Lissie fm. and locally by the [later] Beaumont and Recent.

Hodges shale member (of Bloomington formation).

Middle Cambrian: Northeastern Utah and southeastern Idaho.

G. B. Richardson, 1913 (Am. Jour. Sci., 4th, vol. 36, pp. 406, 407). *Hodges sh. memb.*—Drab clay sh., 350 ft. thick, forming basal memb. of Bloomington fm. in northern Utah.

Named for exposures in Hodges Canyon, Rich Co., NE. Utah.

Hodges sand.

A subsurface sand, of Penn. age, in Frye field, Shackelford Co., north-central Tex., lying at 500 ft. depth.

Hodge's Hill sandstones.

Tertiary (Oligocene?): West Indies (Antigua).

J. W. W. Spencer, 1901 (London Geol. Soc. Quart. Jour., vol. 57, p. 498).

Hoffman limestone. (In Conemaugh formation.)

Pennsylvanian: Western Maryland (Allegany and Garrett Counties) and northern West Virginia.

C. K. Swartz, W. A. Price, and H. Bassler, 1919 (Geol. Soc. Am. Bull., vol. 30, p. 573). *Hoffman ls.*—Underlies Middle Hoffman coal and overlies Lower Hoffman coal; all included in Conemaugh fm.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, p. 67, pl. 6). *Hoffman ls.*, of variable thickness, occurs at number of places in Georges Creek valley beneath Middle Hoffman coal, and is named for its relation to that bed.

Hoffman sandstone. (In Conemaugh formation.)

Pennsylvanian: Western Maryland (Allegany and Garrett Counties).

C. K. Swartz, W. A. Price, and H. Bassler, 1919 (Geol. Soc. Am. Bull., vol. 30, p. 573). *Hoffman ss.*—Underlies Lonaconing coal and overlies Upper Hoffman coal; all included in Conemaugh fm.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, p. 68, pl. 6). *Hoffman ss.*—Found at various localities in Georges Creek Valley above Upper Hoffman coal. Thickness 20 to 30 ft. Named for occurrence in Hoffman Drainage Tunnel.

†Hogback sandstone.

Upper Cretaceous: Southwestern Wyoming.

J. W. Powell, 1876 (Geol. of eastern part of Uinta Mtns, pp. 40, 48, 155), applied the descriptive terms *Middle Hogback ss.* and *Upper Hogback ss.* to 2 sss. in upper part of his Point of Rocks group (which is=Adaville fm. and upper part of underlying Hilliard fm.). These sss. are probably in Adaville fm.

Hogback schist.

Pre-Cambrian: Central southern Maine (Waldo County).

E. H. Perkins and E. S. C. Smith, 1925 (Am. Jour. Sci., 5th, vol. 9, pp. 204–228). *Hogback schist.*—Principally quartz-mica schist, very highly metamorphosed. Of sed. origin. Appears to be more highly metamorphosed than the other fms. This may be due to greater age and previous metamorphism or to a difference in original composition of sediments. Lies to E. of Branch Pond gneiss. Forms long ridge known as Hogback Mtn, including Frye Mtn range, in town of Knox [Waldo Co.]. Probably pre-Camb.

On 1933 geol. map of Maine, by A. Keith, these rocks are mapped as pre-Camb.

Hog Creek shale member (of Caddo Creek formation).

Pennsylvanian: Central and central northern Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 387, 397). *Home Creek bed.*—Slightly aren. and slightly fossiliferous bluish clay or sandy clay, with some ss. and conglomeratic ss., in places in massive beds. Thickness thin to 70 ft. Memb. of Canyon div. Overlies 60 ft. of cherty ls. and underlies Home Creek bed.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31, 36; Univ. Tex. Bull. 2132, pp. 117+). *Hog Creek sh. memb.*—Sandy sh. forming basal memb. of Caddo Creek fm. (of Canyon group). To N. grades into thick cross-bedded ss. at top. Underlies Home Creek ls. memb. Rests on Ranger ls. memb. of Brad fm.

Named for Hog Creek, Brown Co., Colorado River region.

Hog Mountain sandstone. (In Mineral Wells formation.)

Pennsylvanian: Central northern Texas (Palo Pinto County).

F. B. Plummer, 1929 (Tex. Bur. Econ. Geol., geol. map of Palo Pinto Co.). *Hog Mtn ss.* underlies East Mtn sh. [restricted] and lies higher than Brazos River ss., all members of Mineral Wells fm. [This ss. lies within East Mtn sh. as originally defined.]

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 106). Hog Mtn ss. of Plummer included in Mineral Wells fm. as here restricted.

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, pp. 31+). *Hog Mtn ss. lentil.*—A reddish-buff medium-grained thick-bedded ss. lying in lower part of East Mtn sh. memb. of Mineral Wells fm., and typically exposed on top of Hog Mtn, 3 mi. SE. of Mineral Wells.

Hogshooter limestone.

Pennsylvanian: Northeastern, central northern and central Oklahoma.

C. N. Gould, D. W. Ohern, and L. L. Hutchison, 1910 (Okla. State Univ. Research Bull. 3, p. 12). Drum ls. splits near Kans. line, and lower memb., which Ohern calls the *Hogshooter,* disappears some 20 mi. N. of Tulsa.

In 1925 the beds overlying Hogshooter ls. were named *Nellie Bly fm.* The Hogshooter rests on Coffeyville fm. In central Okla. it becomes a memb. of Francis fm. Its thickness is 5 to 19 ft.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 91). Winterset ls. extends to southern Okla. and is exact synonym of *Hogshooter ls.,* which should be dropped.

Named for Hogshooter Creek, Washington Co.

Hogshooter sand.

Pennsylvanian (?): Northeastern Oklahoma (Washington County).

W. R. Berger, 1919 (Am. Jour. Sci., 4th, vol. 48, pp. 189–194). *Hogshooter gas sand.*—Channel deposit, 0 to 168 ft. thick. Producing horizon in Hogshooter field, Washington Co. Lies directly on Boone. Varies greatly in thickness and pinches out only a short distance to E. and W. of long axis of the field. Has been determined by several hundred well records to be a continuous body of sand in a N.-S. direction, but very narrow and lenticular in opposite direction. Main body of Hogshooter gas sand is interpreted as having been deposited in the channel of the principal stream flowing southward through the pre-Cherokee valley. The narrow and comparatively thin eastward and westward extensions of Hogshooter sand are believed to be deposits made by tributary streams in lower part of their courses. Similar deposits are known at the surface in central and northern Mo., where 2 main channels have been mapped as the Warrensburg and Moberly channels.

Hoh formation.

Tertiary (Miocene and Oligocene?): Northwestern Washington.

C. E. Weaver, 1915 (Am. Inst. Min. Engrs. Bull. 103, pp. 1424–1427). *Hoh fm.*—Dark-gray shales and sandy micaceous shales with subordinate gray medium-grained sss. which are gritty in places; occasional bands of cgl. Thickness 10,000 ft. Only fm. in Wash. that contains oil. Assigned to Jurassic (?); may be Cret., Jurassic, or older. Overlain uncon. by upper Mio.

C. E. Weaver, 1916 (Wash. Geol. Surv. Bull. 13, p. 278). *Hoh fm.*, 10,000+ ft. thick, occurs on W. side of Olympic Mtns, along W. coast of Olympic Peninsula, in Jefferson and Clallam Counties. Excellent exposures along coast btw. mouth of Hoh River and Hoh Head. Is only fm. exposed along Queets, Hoh, and Soleduck Rivers for 20 mi. from ocean. In Quillayute area is uncon. overlain by upper Mio. deposits. Possibly Jurassic. Certainly pre-Mio. and probably pre-Eocene.

R. H. Palmer, 1927 (Jour. Geol., vol. 35, pp. 276–278; A. A. P. G. Bull., vol. 11, No. 12, p. 1324). *Hoh fm.* covers more than half of Olympic Peninsula. Its strat. position has been so uncertain that either the entire fm. or members of it have been tentatively placed in Cret., pre-Cret., Jura, Trias, and even Carbf. During 1926 a locality was found on the coast 1 mi. N. of Hoh River, where strat. relationships of at least 3 of its members are well exposed. These are (descending): (1) Massive and bedded ss., technically arkosic graywacke, with many cgl. lenses, 2,000± ft., Lower Mio. fossils; uncon. on (2) soft, thinly bedded light-gray ss., 150 to 200 ft., which may be either pre-Temblor Mio. or Olig.; (3) gray sh. with a few sandy and cgl. lenses, 1,000 ft. exposed. There is evidence No. 3 of above section is oldest Hoh memb. exposed anywhere along coast of Olympic Peninsula. No fossils were found in it that are definite age markers, and it may be either pre-Temblor Mio. or Olig. The Hoh fm. underlies Quillayute fm.

Hoing sandstone.

Silurian: Central eastern Iowa.

W. H. Norton, 1928 (Iowa Geol. Surv. vol. 33, pp. 30–31, 431). *Hoing ss.*—Sandy beds (chert, ls., and quartz sand) at base of Sil. Thickness in wells 6–50 ft. Overlies Maquoketa sh. In Des Moines well in Greenwood Park the beds are 22 ft. thick and are separated from Maquoketa sh. by 55 ft. of ls. Believed to correspond to typical Hoing sand of western Ill.

M. A. Stainbrook, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 259, 260). True Hoing sand of Ill., which is Dev., does not occur in Iowa. According to M. Weller (letter) the Hoing sand of Ill. is underlain by upper Davenport memb. (the top of Wapsipinicon) and overlaps older beds of the Wapsipinicon, and underlies Cedar Valley ls. "Writer believes the ls. beneath Hoing sand is lower Davenport, instead of upper Davenport. Independence sh. has same strat. relations as Hoing sand of Ill. but can not be said definitely to be equiv. until fauna, if any, of latter is known."

Hoing sand.

A subsurface unit in Colmar-Plymouth field, McDonough Co., central western Ill., which has been classified as late Ord., as Sil., and as Dev. (Hamilton?). L. E. Workman says (Trans. Ill. State Acad. Sci., vol. 26, No. 3, p. 107, March 1934) it is Dev., and that it consists of ss. and sandy dol. Encountered at 417 ft. depth on J. Hoing farm, near Colmar, McDonough Co. (See Ill. State Geol. Surv. Bull. 23, pp. 51–53, 1917; Bull. 31, pp. 8–55, 1915; Bull. 40, p. 73, 1919.) T. E. Savage, 1922 (Ill. Geol. Surv. Bull. 38, p. 268), stated it was probably derived from deeply weathered residual material that was developed on surface of Maquoketa sh. during long period of land conditions that prevailed in the region btw. end of Maquoketa and beginning of Niagaran time, and that it appears not to have been laid down over extensive area, because many wells pass from Niagaran ls. directly into Maquoketa sh.

See also under *Hoing ss.*, 1935 entry.

Hoko formation.

Pliocene (?): Northwestern Washington.

A. B. Reagan, 1909 (Kans. Acad. Sci. Trans., vol. 22, p. 202). *Hoko fm.*—A series of cgls., 300± ft. thick, occupying territory from Hoko River in its lower course E. to Clallam Bay. Rests uncon. on upturned and eroded sss. and shales of Clallam fm. The boulders contain Mio. fossils. The fm. is certainly pre-Pleist., so that evidence places it in Plio. [Relations to Quinault fm. and his Raft River fm. not explained.]

R. Arnold and H. Hannibal, 1913 (Am. Phil. Soc. Proc., vol. 52, p. 604). The Hoko River Plio., so called, of Reagan is an area of Monterey ss. and cgl. uncon. on Astoria series.

Holbrook sandstone.

Lower Triassic: Eastern Arizona (Holbrook region).

D. Hager, 1922 (Mg. and Oil Bull., vol. 8, Nos. 1, 2, 3, Jan., Feb., Mar., pp. 26, 33–34, 73, 81–94). *Holbrook ss.*—Thinly cross-bedded sss. with a few sh. intercalations; the ss. dark gray on fresh fracture and contains black specks and mudstone pellets; all weathers dark red and changes laterally to massive cross-bedded ss. Top memb. of Moenkopie fm. in Holbrook area. Exposed in form of cliffs just N. of railroad btw. Winslow and Holbrook. Uncon. underlies Shinarump cgl. and lies on red gypsiferous shales of the Moenkopie.

†Holden group.

Pennsylvanian: Northwestern Missouri.

G. C. Broadhead, 1873 (Mo. Geol. Surv. Prel. Rept. on Iron Ores, pt. 2, pp. 169, 194). *Holden group.*—Shales, lss., and sss, 59 ft. thick, including beds Nos. 55 to 64 of detailed section of lower Coal Measures from Sedalia to Kansas City. Underlies Mound group and overlies Lexington group.

Is lower part of Pleasanton fm.

Named for exposures at Holden, Johnson Co.

Holdenville shale.

Pennsylvanian: Central and central southern Oklahoma.

J. A. Taff, 1901 (U. S. G. S. Coalgate folio, No. 74). *Holdenville sh.*—Blue and yellow clay sh., with thin siliceous lss. and sss., 260 ft. thick. Underlies Seminole cgl. and overlies Wewoka fm.

Named for Holdenville, Hughes Co., which is located on the sh.

Holderness formation. (In Mesaverde group.)

Upper Cretaceous: Northwestern Colorado (Yampa coal field).

M. R. Campbell, 1931 (Tentative correlation of named geologic units of Colo., compiled by M. G. Wilmarth, U. S. G. S. separate chart). *Holderness fm.*—N. of Yampa River mostly friable ss. 200± ft. thick, but S. of that stream thickens rapidly to W. to 900 ft. and includes beds of massive ss., sh., and coal. Is thickest in Holderness Gulch, Daton Peak quad. Is top fm. of Mesaverde group in Yampa coal field. Underlies Lewis sh. and overlies Twentymile ss.

Holdrege formation.

Pleistocene (Nebraskan): Southern Nebraska.

A. L. Lugn and G. E. Condra, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, p. 190). *Holdrege fm.* (*Nebraskan*).—Lowermost gravel-sand deposit in southern Nebr., 50 to 100+ ft. thick. Conformably underlies Fullerton fm. (Aftonian).

A. L. Lugn, 1934 (Nebr. State Mus. vol. 1, Bull. 41, pp. 326, 342–344). *Holdrege fm.*—Largely fluvial inwash-outwash deposits of sand and gravel, generally coarse near base and finer toward top. Thickness 0 to 120± ft. Is = Nebraskan till and David City fm., both of Nebraskan age. Not known to outcrop in Platte River valley or south-central Nebr. May be exposed at some places along Republican Valley. Is certainly exposed at several places in Niobrara Valley. Is known almost entirely from well logs. Underlies Fullerton fm. and rests uncon. on Tert. or Cret. Occurs more or less continuously over area of 15,000± sq. mi. Named for the Trees deep test for oil and gas near Holdrege, Phelps Co.

Hole-in-the-Wall member.

Pre-Cambrian (Belt series): Northwestern Montana (Glacier National Park).

C. L. and M. A. Fenton, 1931 (Jour. Geol., vol. 39, No. 7, pp. 670–679). *Hole-in-the-Wall memb.*—Basal memb. of Boulder Pass fm. Consists of (descending): (1) Metargillite, medium-bedded, finely banded, green, with large ripple marks in upper part and *Collenia* in lower part, 16 ft.; (2) metargillite, qtzite, and minor cgl. beds, main mass being of red to buff sandy metargillites, mud-cracked, ripple-marked, and in spots cross-bedded, well exposed on slope above Granite Park chalet, 300 to 350 ft.; (3) argillite, green to buff, finely banded, grading down into gray-buff argill. ls., mud-cracked and ripple-marked, 75 ft. Overlies Siyeh fm., and underlies Purcell lava. [Derivation of name not stated but probably Hole-in-the-Wall Falls, Flathead Co.]

†Holiknuk series.

Upper Cretaceous: Southern Alaska.

J. E. Spurr, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 159–161, 182). *Holiknuk series.*—Alternating beds of ss., argill. or siliceous ls., sh., and arkose; cgl. at base containing pebbles apparently derived from uncon. underlying Tachatna series. Some plants and invertebrates. Referred to Cret. Essentially contemp. with Kolmakoff series. [Apparently named for Holiknuk River.]

G. C. Martin, 1926 (U. S. G. S. Bull. 776, chart opp. p. 474), referred these rocks to Upper Cret. and discarded the name. He stated that they are W. continuation of part of Spurr's Kolmakoff series.

Holland sandstone.

Lower Devonian: Northwestern Ohio.

E. Orton, 1888 (Ohio Geol. Surv. vol. 6, p. 20) and 1890 (Ohio Geol. Surv. 3d Organization, 1st Ann. Rept., p. 24). *Monclova or Holland ss.* occupies same position in series as Sylvania ss.

Named for Holland, Lucas Co.

Holland sand.

A subsurface sand occurring btw. Big lime and Oswego lime in vicinity of Ochelata, N. E. Okla., and correlated with Labette sh. (Penn.).

Holland Patent.

Upper Ordovician: Eastern New York (Mohawk Valley).

R. Ruedemann and G. H. Chadwick, 1935 (Sci., n. s., vol. 81, No. 2104, p. 400). *Holland Patent* introduced for upper Utica or zone of *Climacograptus pygmaeus* in Mohawk Valley.

Hollenberg limestone. (In Sumner group.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., pp. 63–66). Only a few ft. of basal part of Pearl sh. is exposed in Nebr., but a short distance S. of State line, as btw. Hollenberg and Hanover, Washington Co., Kans., its lower sh. and a ls. capping this sh. are well shown, from which we have traced them southward to near Okla. line. A second ls., 18 to 20 ft. above the Hollenberg bed, outcrops at some places. The lower sh. memb. of Pearl sh. is 38 to 40 ft. thick in northern Kans. and about 50 ft. farther S. in Kans. The *Hollenberg ls.* (named for exposures along the Little Blue 3½ mi. SE. of Hollenberg) is very persistent and a good horizon marker, 3 to 4 ft. thick. It is a gray fossiliferous zone which forms large yellowish flat blocks. In places it is filled with Foraminifera, ostracodes, and 3 genera of small gastropods.

R. C. Moore, 1936 (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 12), restricted *Pearl sh.* to beds beneath this ls., applied *Newbern sh.* to the beds overlying this ls., and treated the ls. and his Newbern sh. as lower part of Donegal ls. (new).

Holliday shale.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, p. 38). *Holliday shales.*—Shales, 900 ft. thick, composing Pintoan series, the basal div. of Cambric section in Utah. [Derivation of name not stated.]

Hollis quartzite.

Pre-Cambrian: Eastern Alabama (Lee County).

G. I. Adams, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14, map, pp. 33–34). *Hollis qtzite.*—Qtzite, in places having nature of quartz schists, exposed at and near Hollis, Lee Co., and 10 mi. to SW. No fossils. Infolded in Archean rocks. Tentatively assigned to Algonkian.

In view of fact that "Archean system" and "Algonkian system" have been discarded, this fm. is now classified by U. S. Geol. Survey as *pre-Camb.*

Hollow dolomite. (Buried.)

Silurian (Niagaran): Central Kansas (Harvey County).

L. A. Johnston, 1935 (Tulsa Geol. Soc. Digest, 1934, pp. 12–17, pl. 1). *Hollow dol.*—Highly crystalline porous dol. containing many large vugs, some of which are due to chemical solution of fossils. Upper part usually sandy and sometimes has phosphatic inclusions. Recrystallization has destroyed most fossils. Occasionally the lower part of this zone is cherty and in such places fossils are more easily found. This is major producing zone of Hollow field and can be traced throughout the basin where the Siluro-Dev. group is present. Thickness 0–40 ft. Few fossils. Microfossils resemble those of Hopkinton of southern Ill. and lower Hunton of Okla. According to Laudon is lithologically similar to Niagaran of northern Miss. Valley. Differs lithologically from the uncon. overlying Ediger ls. In 4 wells overlies a coarsely crystalline pink and white crinoidal ls., 10 ft. thick, resembling Chimneyhill of Okla. Was named by F. A. Bush, unpublished paper delivered before Tulsa Strat. Soc. in 1933, in which *Ediger ls.* also was proposed.

Holly Creek clay.

Lower Cretaceous (Comanche series): Southwestern Arkansas.

H. C. Vanderpool, 1928 (A. A. P. G. Bull., vol. 12, pp. 1079–1080). *Holly Creek clay.*—Series of nonfossiliferous aren. rocks, 0 to 300 ft. thick, consisting of red clays, thin sand beds, and gravel lenses. One gravel lentil in particular has been named Ultima Thule lentil. It occurs locally just above Dierks ls. lentil. Southward from outcrop this red series thins within a short distance, and is represented in La. by lss. which form part of Glen Rose ls. It seems desirable that this series of beds, occurring btw. two such well-defined marine zones, should have a distinct name. The name *Holly Creek* is therefore proposed, because of excellent exposures near Little Holly and Holly Creeks, SE. of Dierks, Howard Co., Ark. The beds grade into underlying Dierks ls. lentil and are overlain by DeQueen ls.

Holly Springs sand. (In Wilcox group.)

Eocene (lower): Mississippi and western Tennessee and Kentucky.

E. N. Lowe, 1913 (Miss. Geol. Surv. Bull. 10, pp. 23–25). The middle div. of Wilcox fm. might appropriately be called *Holly Springs sands.* Thickness perhaps 350 ft. Is prevailingly sands, coarse-grained, cross-bedded, white to yellow, red, or purple; micaceous; become grayish or greenish beneath the surface. Typically developed at and for several mi. E. of Holly Springs [Marshall Co., NE. Miss.]. Underlies Grenada beds and overlies Ackerman beds, the lowest div. of the Wilcox.

In present usage of names the Wilcox is treated as a group and Holly Springs sand as middle fm. of that group.

Holmesville shale. (In Chase group.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., p. 43). *Holmesville sh.*—Basal memb. of Doyle fm. Type loc. 1½ mi. W. and ½ mi. N. of Holmesville, Gage Co., Nebr., where it consists of (descending): (1) Gray, red and gray, argill. sh., 10 or 11 ft.; (2) blocky ls., 1 ft.; (3) gray sh., 7 ft. The ls. persists for a considerable distance into Kans. Thickness 20± ft. in

Nebr., increasing to 35 ft. in parts of Butler Co., Kans. Underlies Towanda ls. and overlies Fort Riley ls.

Holmesville moraine.

Pleistocene: Northeastern Ohio. Named for Holmesville. (See G. G. Cole, Sci., vol. 47, p. 469, 1918, and G. W. White, Jour. Geol., vol. 40, pp. 246–247, 256, 1932.)

Holocene.

A term that has been applied to post-Pleist. deposits designated as Recent series by U. S. Geol. Survey and most other geologists, and also applied to Tert. deposits. For former use see B. Smith, N. Y. State Mus. Bull. 300, 1935; for latter use see J. B. Perry, Boston Soc. Nat. Hist. Proc., vol. 15, 1872, p. 55. The term was adopted by Portuguese Committee of 1885 Int. Geol. Congress, but has seldom been used in United States.

Holston marble. (Also **Holston limestone.**) (In Blount group.)

Lower Ordovician (Chazy): Eastern Tennessee, western North Carolina, and western Virginia.

A. Keith, 1895 (U. S. G. S. Knoxville folio, No. 16, map). *Holston marble.*—[Described on map legend as: "Lentils of variegated marbles of many colors in blue and gray ls." The name does not appear in columnar section or in text of this folio, but marble beds in Chickamauga ls. are briefly described.]

A. Keith, 1901 (U. S. G. S. Maynardville folio, No. 75, p. 3). *Holston marble.*—In lower part of Chickamauga fm. are many beds of more or less coarsely crystalline marble. These do not appear NW. of Clinch syncline, except in a most local way. In that syncline and southward, however, marble is usually well developed in all areas of the fm. On account of distinctive appearance and economic importance is mapped under name of Holston marble. Is 600 to 650 ft. thick near Clinch Mtn and thins in all directions from that area. The position of the marble beds in the ls. varies much from place to place. Usually there is considerable thickness of blue and gray ls. below the marble; N. of Clinch Mtn, however, and on S. side of Black Oak Ridge, the marble beds are thicker and rest on Knox dol. Varies considerably in color from red, brown, gray, and pink, most of rock, however, being dark bluish gray and variegated reddish brown or chocolate. Is lentil in Chickamauga ls.

Later repts define Holston marble as underlying Athens sh. and uncon. overlying Lenoir ls. Ulrich (1929) stated that in places in E. Tenn. and SW. Va. his newly proposed *Whitesburg ls.* intervenes btw. Athens sh. and Holston marble. The Holston is now in most areas treated as a distinct fm. in Blount group, instead of as a memb. of Chickamauga ls., which is being rapidly split up into smaller units, as more detailed work is done.

Named for exposures on Holston River, Knox Co., Tenn.

Holt shale. (In Topeka limestone.)

Pennsylvanian: Northwestern Missouri, southeastern Nebraska, northeastern Kansas, and southwestern Iowa.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 42, 52, 53). *Holt sh.*—A thin but persistent bed of sh. in Topeka ls. memb. of Shawnee fm. Is bluish and argill. above and black and fissile in middle and lower parts. Thickness in Nebr. 1–2½ ft.; in Iowa 1⅝ ft.; in Kans. 2½ ft.; at Forest City, Mo., 2⅓ ft. Underlies Coal Creek ls. bed and overlies Dubois ls. bed, all included in Topeka ls. Named for good exposures in Holt Co., Mo., just below Forest City and NW. of Oregon.

Holt moraine.

Pleistocene (Wisconsin stage): Northwestern Minnesota.

F. Leverett, 1932 (U. S. G. S. P. P. 161, pp. 117–118). Village of Holt, Marshall Co., stands on this moraine.

Holtsclaw sandstone. (In Osage group.)

Mississippian: Western and northern Kentucky and southern Indiana.

C. Butts, 1915 (Ky. Geol. Surv., 4th ser., vol. 3, pt. 2, p. 151). *Holtsclaw ss.*—Bluish-gray or buffish, loosely cemented soft fine-grained thick-, to massive-bedded ss., 15 to 25 ft. thick in Jefferson Co., Ky. Top fm. of Osage group. Underlies Warsaw ls. and overlies Rosewood sh. Is "Knob" ss. of early repts. Contains Keokuk fossils.

E. R. Cumings, 1922. [See under *Rosewood sh.*]

P. B. Stockdale, 1931 (Ind. Dept. Cons., Div. Geol., Pub. 98, pp. 54, 124), abandoned this name. See summary of book cited, under *Carwood fm.* and *Rosewood sh.*

Named for Holtsclaw Hill, Jefferson Co., Ky.

Holy Cross schist.

Pre-Cambrian: Central Colorado (Sawatch Range).

J. T. Stark and F. F. Barnes, 1935 (Colo. Sci. Soc. Proc., vol. 13, No. 8, pp. 466–479, map). *Sawatch and Holy Cross schists.*—[Mapped separately, but described together, as follows:] Foliated rocks, ranging from dense black biotite or hornblende schists, through banded injection gneisses, to granitoid rocks with only faint traces or "ghosts" of schist remnants, are by far the most abundant rocks of Sawatch Range. These various types of foliates are everywhere gradational one into another, the type depending upon extent to which the original metamorphosed sediments have been invaded and replaced by granitic juices, stringers, and sills of Pikes Peak or Silver Plume massives. In extreme cases all traces of schistosity have been removed, resulting in a thoroughly granitoid rock. All outcrops that retain any evidence of original schistose character have been mapped as schist. The Sawatch and Holy Cross schists are separated more on basis of field appearance than on any difference in origin or composition. The Holy Cross schist is universally and intimately injected by stringers and sills of brilliant pink pegmatite, and is distinct in appearance from Sawatch schist, in which the pegmatite is commonly white or gray. Not known on what the difference of color is based, since Silver Plume massive is apparently responsible for injection of both types of schist. Are pre-Camb. and may belong to Idaho Springs fm. [The *Mountain of the Holy Cross* occurs in midst of mass mapped as *Holy Cross schist and migmatite*. The other schist seems to have been named for Sawatch Range.]

Holyoke formation.

Pre-Cambrian (upper Huronian): Northwestern Michigan (Marquette district).

M. E. Wadsworth, 1890 and 1891 (Lake Superior along the south shore, by Julian Ralph, pp. 77–99; 1st ed., 1890; 2d ed., 1891). *Holyoke fm.*—Cgls., qtzites, and schists of Cascade, Republic, Holyoke, and elsewhere in Marquette dist. Overlies Republic fm. and uncon. underlies Potsdam ss.

M. E. Wadsworth, 1893 (Mich. Geol. Surv. Rept. 1891 and 1892, pp. 63–66). *Holyoke fm.*—Qtzite with cgl. at base. Uncon. underlies Negaunee fm. and uncon. overlies Mesnard fm., which is believed to be uncon. on Republic fm., but which may be same as Republic fm. [On later pages of this vol. Holyoke fm. is defined as resting uncon. on Republic fm. and as including at base a cgl. they called *Holyoke cgl.*] Named for occurrence at Holyoke, in Cascade range.

J. M. Clements, 1899 (U. S. G. S. Mon. 36, p. 20). Upper Marquette series is Wadsworth's Holyoke fm.

See also C. R. Van Hise and C. K. Leith, 1909 (U. S. G. S. Bull. 360, pp. 145–149).

Holyoke diabase. (In Newark group.)

Upper Triassic: Central Massachusetts and Connecticut.

B. K. Emerson, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 451–456). The sheet of *Holyoke diabase* came up through a fissure in Chicopee sh. and flowed westward out over Longmeadow brownstone and Sugarloaf arkose. Greatly thickens to W.

B. K. Emerson, 1898 (U. S. G. S. Holyoke folio, No. 50; see also U. S. G. S. Mon. 29). [See 1898 entry under *Longmeadow ss.*] Is "main sheet" of Percival. Thickness 350 to 400 ft. Is older than Hampden diabase.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 92, 94, 97, 265–271). After Talcott diabase had been deeply covered, the accumulation of sediment was again interrupted by an eruption of lava through a fissure on the earth's crust, which opened along bottom of the basin. The lava flowed E. and W. on bottom of the bay, and solidified into a sheet which may have been 2 or 3 mi. wide and about 400 ft. thick in its thickest central part. This is the "main sheet" and is called *Holyoke diabase.* This sheet was covered with sand and mud layers to a considerable thickness when Hampden diabase ("posterior bed") outflowed. At N. the same buff arkose that underlies Holyoke diabase also rests on it. The diabase continues to rest on Sugarloaf arkose to Holyoke, and from there to S. line of State it rests on Longmeadow ss. and Chicopee sh. The "Deerfield" diabase is a sheet of Holyoke diabase. The Holyoke is a fm. in Newark group. Named for occurrence in Mount Holyoke Range. Mass.

Holyoke conglomerate.

Pre-Cambrian (middle Huronion): Northwestern Michigan (Marquette district).

See 1893 item under *Holyoke fm.*

Holzmark sand.

A subsurface sand in Fayette ss. (Eocene) of Pettus dist., Tex. (See A. A. P. G. Bull., vol. 15, No. 7, pp. 780, 781, 1931.)

Home Creek limestone member (of Caddo Creek formation).

Pennsylvanian: Central and central northern Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 387, 398). *Home Creek bed.*—Ls., 25 to 50 ft. thick, friable in upper part, massive blue beds in lower part, and some clay and ss.; one clay bed 10 to 30 ft. thick to N. Is memb. of Canyon div. Overlies Hog Creek bed and underlies Bluff Creek bed.

C. S. Ross, 1921 (U. S. G. S. Bull. 726G, p. 306). *Home Creek ls. memb. of Canyon fm.*—Is 40 ft. thick in Lacasa area. Consists of 3 lss. separated by shales. Is top memb. of Canyon fm. Replaces Plummer's "Eastland" ls., which name is preoccupied. Town of Caddo, Stephens Co., is built on this ls.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31, 36; Univ. Tex. Bull. 2132, pp. 118+). *Home Creek ls.,* a series of thin lss. 10 to 50 ft. thick, forming top memb. of Caddo Creek fm. from Llano Mtns NE. into Young Co.; but to NE. of Finis, Jack Co., it can not be traced with certainty, because it changes laterally into calc. sands. Overlies Hog Creek sh. memb. in both Colorado River and Brazos River valleys.

Named for Home Creek, Coleman Co.

Homer limestone member (of Wayan formation).

Cretaceous (Lower ?): Southeastern Idaho.

G. R. Mansfield, 1921 (Geol. Soc. Am. Bull., vol. 32, pp. 249–266), referred 4 times (and showed its distribution on geol. map) to *Homer ls. memb.* of Wayan fm., Lower Cret. (?), SE. Idaho, but did not define it. In Jour. Geol., vol. 29, 1921, pp. 458, 459, Mansfield casually referred twice to same unit, and also mapped it.

G. R. Mansfield, 1927 (U. S. G. S. P. P. 152, p. 107). *Homer ls. memb. of Wayan fm.*—Occurs in NE. part of Cranes Flat quad. and extends into adjacent regions N. and E. Its strat. position is not known definitely. Ordinarily the surface underlain by it is strewn with white pieces of rock, which by their arrangement on the slopes suggest the attitude of the beds. Locally, as on slope NE. of Sugarloaf Mtn, the ls. forms massive ledges. At this place some of upper beds are dull gray, coarsely crystalline, and crowded with poorly preserved fossils [listed].

Named for exposures in valley of Homer Creek, Cranes Flat quad.

Homer limestone member (of Holdenville shale).

Pennsylvanian: Central southern Oklahoma (Pontotoc County).

G. D. Morgan, 1924 (Bur. Geol. [Okla.] Bull. 2, pp. 104–105). [Name was also used by Morgan, but not defined, in Okla. Geol. Surv. Circ. No. 12, pl., p. 9, 1923.] *Homer ls. memb.*—Dark-gray or almost black ls.; constituting a reef of *Chaetetes* in NE. part of Stonewall quad. To S. Fusulinas appear in the ls., become abundant, and the ls. finally changes to almost a pure *Fusulina* ls. Is in lower part of Holdenville fm., 17 to 70 ft. below Sasakwa ls. memb.

Named for exposures ½ mi. W. of Homer School, in sec. 25, T. 4 N., R. 6 E., Stonewall quad.

Homestake limestone.

Carboniferous: Southwestern Utah (Iron Springs region).

C. K. Leith and E. C. Harder, 1908 (U. S. G. S. Bull. 338, p. 24). *Homestake ls.*—Carbf. ls., 50 to 500 ft. thick, uncon. underlying Pinto ss. (Upper Cret.). [Mapped at and around Homestake mine, Iron Springs quad.]

Homestake formation.

Pre-Cambrian: Southwestern South Dakota (Lawrence County).

J. O. Hosted and L. B. Wright, 1923 (Eng. and Min. Jour.-Press, vol. 115, pp. 793–799, 836–843, with maps). *Homestake fm.*—Cummingtonite and chloritic schists, with contorted quartz stringers; in places dolomitic. Outcrops usually red and massive, the red color due to iron oxide. Greater part of fm. is cummingtonite schist. Original fm. was a siliceous, ferruginous, dolomitic ls., somewhat banded and in places well preserved. Underlies Ellison fm. Thickness 70 ft. Believed to be of Keewatin age.

Derivation of name not stated, but probably is Homestake mine, Lead dist.

Homewood sandstone member (of Pottsville formation).

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q, p. 67). *Upper Homewood ss.*—Top memb. of Beaver River group. Is a massive yellowish white conglomeratic ss., 75 to 155 ft. thick. Is separated from overlying Brookville coal by 4 ft. of fire clay. Is 155 ft. thick at Homewood Station, Beaver Co., Pa., where it cuts out overlying Clarion coal group up to a higher horizon than Ferriferous (Vanport) ls. Lies 20 to 80 ft. above Connoquenessing (*Lower Homewood*) ss. [The Upper Homewood ss. of above rept has for many years been called *Homewood ss. memb. of Pottsville fm.*, the use of *Lower Homewood* for the Connoquenessing ss. having been discontinued.]

J. P. Lesley, 1878 (2d Pa. Geol. Surv. Rept. Q, pp. 308–316). *Piedmont (Upper Homewood)* ss. underlies Brookville coal and is separated from underlying Mount Savage coal by 20 to 80 ft. of sh.

Homewood (Lower) sandstone. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

C. E. Krebs and D. D. Teets, Jr., 1916 (W. Va. Geol. Surv. Rept. Raleigh and western parts of Mercer and Summers Counties, p. 56). *Lower Homewood ss.*—Underlies Stockton A coal and overlies Stockton coal. Thickness 48 ft. 4 in.

†Hominy formation.

Pennsylvanian and Permian: Central-northern Oklahoma.

C. N. Gould, 1905 (U. S. G. S. W. S. P. 148, map). [In this rept an area in NE. Okla. is mapped as *Hominy fm.*, but text does not mention the name. Page 32 of rept, however, states that: The fms. exposed in Hominy dist. include the southern extension into Okla. of Pottawatomie, Douglas, Shawnee, Wabaunsee, Cottonwood, and Neosho fms. of Kansas geologists, and have a thickness of over 1,500 ft. In 1906 (U. S. G. S. Bull. 298, p. 252) M. L. Fuller and S. Sanford published a description of a well near Cleveland, Pawnee Co., Okla., which contains the following statement: The rocks outcropping for 25 mi. W. and E. and 40 mi. N. have been grouped together as *Hominy fm.* (*Penn.*), including Pottawatomie, Douglas, Shawnee, Wabaunsee, Cottonwood and Neosho fms. of Kansas geologists, and have a thickness of over 1,500 ft.]

Named for Hominy, Osage Co.

Hominy sand.

Lower (?) Ordovician: Central northern Oklahoma (Osage County) and eastern Oklahoma (Tulsa and Okmulgee Counties).

L. H. White, 1926 (Okla. Geol. Surv. Bull. 40B, pp. 8, 13–14). *"Burgen" ss.* (*"Hominy" sand*).—The "Burgen" ss. was first called "Hominy" sand because it was thought to be principal source of deep production around town of Hominy, Osage Co. Since that time, however, it has developed that most of that production was probably coming from the underlying "Siliceous" ls. The "Burgen" ss. uncon. overlies Arbuckle ls. ("Siliceous lime") and underlies Tyner fm.

R. W. Clark, 1926 (Okla. Geol. Surv. Bull. 40F). The *Hominy sand* lies at depth of 2,880 ft. in sec. 19, T. 14 N., R. 13 E., and at 3,548 ft. in sec. 33, T. 13 N., R. 11 E.

F. C. Edson, 1927 (A. A. P. G. Bull., vol. 11, p. 969). *"Hominy" ss.* underlies Tyner fm. and uncon. overlies Siliceous ls.

W. F. Cloud, 1930 (Okla. Geol. Surv. Bull. 40RR). *Burgen ("Hominy") sand* is 10–75 ft. thick in Tulsa Co. It lies on weathered surface of Arbuckle ls., and consists of hard massive ss., light gray to yellowish brown.

Hominy lime.

A subsurface ls., of Penn. age, in central northern Okla. that is supposed to correlate with Lecompton ls. memb. of Pawhuska fm. and to be same as †Pawhuska lime.

Honaker limestone. (In Virginia, **Honaker dolomite.**)

Middle Cambrian: Southwestern Virginia, northeastern Tennessee, and western North Carolina.

M. R. Campbell, 1897 (U. S. G. S. Tazewell folio, No. 44, p. 2). *Honaker ls.*—Varies in character from blue flaggy ls. to dark impure ls. and massive gray dol. Thickness 900 to 1,000 ft. Overlies Russell fm. and underlies Nolichucky sh. West of this quad. the Honaker ls. is subdivided by a small band of calc. sh. (Rogersville sh.) into two distinct lss., the upper of which has been named Maryville and the lower Rutledge ls. In passing eastward the Rogersville sh. becomes more and more calc. until, on W. edge of this quad. the three blend into a single ls. with about same thickness as the aggregate farther W.

Named for exposures at Honaker, Russell Co., Va.

Honaker sand.

A subsurface sand in southern San Juan Co., SE. Utah, that lies in Hermosa fm. (Penn.). Is reported to occur just below water level at foot of Honaker Trail.

Hondo sandstone member (of Chupadera formation).

Permian: Southeastern New Mexico (Pecos Valley region).

W. B. Lang, 1937 (A. A. P. G. Bull., vol. 21, No. 7). *Chupadera fm.* of Pecos Valley region here divided into (descending): (1) *San Andres ls. memb.* (replaces Picacho ls. of Fiedler and Nye); (2) *Hondo ss. memb.*, and (3) Yeso memb. The Hondo ss. consists of coarse white quartz grains, variably streaked yellowish to brownish red and cemented by iron and lime. In places it is cross-bedded, and iron concretions and nodules are abundant in upper part. Thickness usually 50± ft. Has been commonly referred to in the field as "Glorieta ss.," but it has never been definitely shown that this ss. is wholly or in part the ss. of Glorieta Mesa. Crops out near bottom of valley of the Hondo and its tributaries. Of great value in subsurface correlation. [The adoption of *Hondo ss. memb.* involves a slight redefinition of both San Andres ls. and Yeso as originally defined and heretofore used.]

Honerine limestone.

Miners' local name for an ore-bearing ls., 8 to 12 ft. thick, in lower part of Oquirrh fm. (Penn.), Stockton dist., central northern Utah. Lies 40 ft. below Maverick ls. of miners and 10 ft. above their Little Honerine ls. Exposed in Honerine claim. (See U. S. G. S. P. P. 173, 1932.)

Honesdale sandstone group. (In Catskill formation.)

Upper Devonian: Northeastern Pennsylvania.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. G_5, pp. 66–68, 132, 140). *Honesdale ss. group.*—Underlies Cherry Ridge group and overlies Montrose red sh. At Honesdale, Wayne Co., is easily divisible into (descending): *Honesdale white ss.*, 25 ft.; *Honesdale red ss.*, 40 ft.; *Honesdale gray ss.*, 25 to 50 ft. At Montrose, Susquehanna Co., this group of rocks forms the high bank near Fair Grounds, but no division can be made. *Montrose sss.* is a term I have freely employed in my township repts, uncertain how much of the section in hilltops around Montrose (over the red sh.) ought to be restricted to Honesdale ss. group. Vanuxem in

1844 applied term *Montrose ss.* (*Oneonta*) to distinguish one div. of his Catskill, but seems to have looked upon it as lowest div. of the fm., whereas I find 500 ft. of Catskill measures still beneath drainage level at Montrose. [On pp. 132 and 140 he says Honesdale ss. series of Wayne Co. is same as Montrose series of Susquehanna Co.]

I. C. White, 1882 (2d Pa. Geol. Surv. Rept. G_6). *Honesdale ss. group* is 500 ft. thick near W. line of Monroe Co. and 987 ft. thick on Lehigh River. [Another rept gave thickness of 987 ft.]

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 571, 581–584, 606), described geographic distribution and fossils of nonmarine *Honesdale ss.*, as he called it, and replaced *Montrose red sh.* of White with *Damascus red sh.*, the name *Montrose* being preoccupied in N. Y. He stated: *Honesdale ss.* underlies Cherry Ridge red beds, overlies Damascus red sh., and passes into marine beds to west.

Honey Creek limestone.

Upper Cambrian: Central southern Oklahoma (Arbuckle and Wichita Mountains).

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pp. 624, 642, 661, 666, pl. 27). *Honey Creek ls. memb. of Reagan ss.*—Certain thin lss. originally included in basal part of Arbuckle ls. but now transferred to underlying Reagan fm. Is calc. upper part of the Reagan. [Thickness and type loc. not stated.]

H. D. Miser, 1926 (Okla. geol. map), followed Taff's original definitions of Arbuckle ls. and Reagan ss. and included this ls. in Arbuckle ls.

E. O. Ulrich, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 3, pp. 742+). The beds formerly called by writer Honey Creek ls. memb. of Reagan ss. are here raised to rank of fm. and called *Honey Creek fm.* Named for Honey Creek, a tributary of Washita River which rises in Arbuckle Mtns and flows northeastward around W. end of East Timbered Hills. Along Honey Creek, on S. side of East Timbered Hills, in sec. 1, T. 2 S., R. 1 E., Okla., the upper part of *Honey Creek fm.* consists of 44 ft. of thin-bedded argill. and shaly ls., often yellow, with some cgl., probably intraformational, (the *Ptychaspis* zone), which is absent ¼ mi. E. of Honey Creek. The *lower part* consists of 80 ft. of uneven plates of crystalline ls., many of them very fossiliferous, separated by clayey and more or less glauconitic seams, with grains of glauconite scattered through the lss. Trilobites of *Pterocephalia* zone are abundant in lower 20 ft., and *Eoorthis* zone next above; also a layer with crinoid fragments near base and another or two in upper third. In this section the Honey Creek is uncon. overlain by Royer fm., the intervening Fort Sill fm. being absent, and is separated from underlying Reagan ss. by a hiatus corresponding to Cap Mtn fm. of [central] Texas. In Wichita Mtns the fm. is 250 ft. thick.

The U. S. Geol. Survey has adopted *Honey Creek ls.* (Upper Camb.) as a distinct fm., for the thin sandy lss. that form basal part of Arbuckle ls. as defined by Taff in Wichita Mtns, Okla., but in Arbuckle Mtns, Okla., older lss. come in below the Honey Creek. The latter is 124 ft. thick at type loc. It does not include the 60 ft. of calc. sss. which Taff treated as top memb. of Reagan ss. (See C. L. Dake and J. Bridge, Geol. Soc. Am. Bull., vol. 43, No. 3, pp. 725–741.)

C. E. Decker, 1933. (See under *Timbered Hills group.*)

Honna formation.

Cretaceous: British Columbia.

J. D. MacKenzie, 1914 (Canada Geol. Surv. Summ. Rept. 1913, p. 44).

Honolulu volcanic series.

Pleistocene (middle? and late) and Recent (?): Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). Most of *Honolulu volcanic series* lies at or near city of Honolulu. It rests with great erosional uncon. on Koolau volcanic series, of Tert. and possibly early Pleist. age. It has been subdivided into the following mapped subdivisions:

Recent or latest Pleist. lavas and pyroclastics:

Basalts and pyro-explosion deposits of Tantalus and Sugar Loaf:

Tantalus basalt.	Sugar Loaf basalt.	Contemporaneous pyro-explosion deposits. Locally called "black sand."	Occur at Honolulu

Basalts and pyroclastics of Koko fissure:
- Kaupo basalt.
- Kaohikaipu volcanics.
- Koko volcanics. (Overlie Kalama volcanics.):
  - tuff.
  - basalt.
- Kalama volcanics.
- Manana tuff.

Recession of sea to present level.

Do not occur near Honolulu. — Contemporaneous

Late and middle (?) Pleist. lavas and pyroclastics. (Probably all post-middle Pleist.):

Lavas and pyroclastics of Waipio (60±-foot) stand of the sea and Wamainalo (+25-foot) stand of the sea:
- Punchbowl volcanics:
  - basalt.
  - tuff.
- Castle volcanics.
- Kamanaiki basalt.
- Black Point basalt. (Overlies Diamond Head tuff.)
- Mauumae volcanics.
- Kaimuki volcanics. (Rest on Diamond Head tuff.)
- Diamond Head tuff.
- Training School volcanics.
- Maunawili volcanics.
- Ainoni volcanics.
- Salt Lake tuff. | Makalapa tuff. (From different vents.)

Relatively contemporaneous, but erupted from different vents. Occur at and near Honolulu.

Halt of sea at 40-foot (?) level, known as Waialae stand.

Lavas and pyroclastics of Kaena (+95-foot) and Laie (+70-foot) stands of the sea:
- Kaau volcanics:
  - tuff.
  - basalt.
- Ulupau tuff.
- Moku Manu volcanics:
  - tuff.
  - basalt.
- Makawao breccia.
- Pali volcanics:
  - basalt.
  - breccia.
- Nuuanu volcanics (3 basalts).
- Kaneohe volcanics.
- Aliamanu tuff.
- Haiku volcanics:
  - basalt.
  - tuff.
- Kalibi volcanics.
- Rocky Hill volcanics.
- Mokulea basalt.
- Mokapu basalt.
- Hawaiiloa volcanics.

Relatively contemporaneous. Occur at and near Honolulu.

Recession of the sea to a level below 55 ft. known as Kahipa stand. Erosion of deposits of previous stand of the sea.

Halt of sea at 55 ft. above present sea level known as Kahuku stand.

Hoodoo quartzite.

Pre-Cambrian (Belt series): Southern central Idaho (Casto region).

C. P. Ross, 1932 (Idaho correlation chart compiled by M. G. Wilmarth). *Hoodoo qtzite.*—White massive qtzite, 3,650+ft. thick, uncon. underlying schist of unknown thickness, believed to be of Algonkian age, and overlying Yellowjacket fm., both included in Belt series. Type loc., Hoodoo Creek.

C. P. Ross, 1935 (U. S. G. S. Bull. 854). *Hoodoo qtzite.*—White, relatively pure and massive qtzite, 2,000 to 4,000 ft. thick, overlying Yellowjacket fm. Named for exposures along Hoodoo Creek, in NW. part of Casto quad. Upper fm. of Belt series. A. L. Anderson suggests (Idaho Bur. Mines and Geol. Pam. 34, p. 10, June 1930) the rocks here named *Yellowjacket fm.* and *Hoodoo qtzite* may correspond to lower and middle members of Prichard fm. as identified by him in Orofino region.

Hood River conglomerate.

Miocene (upper) or Pliocene (lower): Northwestern Oregon and southwestern Washington.

J. P. Buwalda and B. N. Moore, 1927 (Sci., n. s., vol. 66, p. 236). *Hood River fm.*, proposed for the unique cgl. and ss. strata underlying Dalles fm. in Columbia River gorge. Heretofore called "Satsop fm." but older than typical fossiliferous Quat. marine Satsop fm. of Wash. coast, and is approx. upper Mio. or lower Plio. Type section in cut immediately E. of Columbia River highway bridge across Hood River. In E. part of gorge this cgl. underlies Dalles beds and can be traced into central Wash., where it lies at base of Ellensburg fm.

J. P. Buwalda and B. N. Moore, 1928 (Pan-Am. Geol., vol. 49, p. 313) and 1929 (Geol. Soc. Am. Bull., vol. 39, pp. 116–117). From its relation to Dalles beds the "Satsop" of Columbia River gorge is of equiv. or greater age and not correlative of Quat. Satsop fm. of Oreg. and Wash. coasts.

J. P. Buwalda and B. N. Moore, 1930 (Carnegie Inst. Wash. Pub. 404, pp. 21, 22). *Hood River cgl.*—Gravels in gorge of Columbia River, in places several hundred ft. thick, and heretofore known as "Satsop gravels" but now known to be older than type Satsop of Chehalis Valley, 100 mi. distant. Overlies Columbia River basalt and in places underlies, probably conformably, The Dalles beds. Type section at E. end of Columbia River highway bridge spanning Hood River, just E. of town of Hood River, Oreg. Is probably a phase of The Dalles fm., as suggested by Bretz, but it appears to be rather distinct from the volcanic series.

Hooker slate.

Lower Cambrian: Southwestern Vermont (Rutland County).

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 402). *Hooker sl.*—Notably black sl. with less cleavage than usual in this region. No fossils known, but it appears to be more closely associated with Lower Camb. fm. than with overlying Ord. fms. Underlies Lower Ord. Poultney sl. with a great hiatus btw. and overlies Beebe ls. Named for Hooker Hill, 2 mi. N. of Castleton [Castleton quad.].

Hoopes sand.

A subsurface Ord. sand in Okla. that is known by several other names. See under *Kinter ss.*

Hoosac schist.

Lower Cambrian (?): Western Massachusetts, southwestern and southeastern Vermont, and western Connecticut.

B. K. Emerson, 1892 (U. S. G. S. Hawley sheet, i. e., proof sheets of geol. maps and text intended for a geol. folio, but never completed and published in that form, although cited in U. S. G. S. Bull. 191, 1902). *Hoosac schist.*—Feldspathic mica schist or thin-bedded gneiss. Underlies Rowe schist and overlies Dalton phyllite in Green Mtn region, Mass., and Becket gneiss in Hawley quad., Mass.

J. E. Wolff, 1894 (U. S. G. S. Mon. 23, pp. 23–107). *Hoosac schist.*—Albite schist. Conformably overlies the cgl. on top of Hoosac Mtn., Mass., extending northward for miles into Vt. Underlies Rowe schist. Is in contact with Stockbridge ls. and with Vermont fm. [in NW. Mass.].

B. K. Emerson, 1898 (U. S. G. S. Holyoke folio, No. 50; also U. S. G. S. Mon. 29, pp. 66–76, pl. 34). *Hoosac schist.*—Albitic sericite schist, finer-grained than uncon.

underlying Becket gneiss, and iron and potash absent. Grades into overlying Rowe schist.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 40–41). *Hoosac schist.*—A dark graphitic mica schist, in many places highly garnetiferous, especially at base. In a few places it carries staurolite and kyanite. Is commonly porphyritic. In N. part of area it becomes a gneiss. Equiv. in part at least to Berkshire schist. Thickness 1,500 ft. in Westfield Valley; 4,000 ft. in Hoosac Mtn. Is Ord.

Age changed to Lower Camb. (?) in 1932, because L. M. Prindle and E. B. Knopf, who have studied and mapped the fm., consider it to be Lower Camb. or older. (Am. Jour. Sci., 5th, vol. 24, Oct. 1932.)

Hooser shale. (In Council Grove group.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., pp. 20, 25). *Hooser sh.*, new name for basal part of Easly Creek sh. of Condra 1927. It consists of (descending): (1) Olive sh., calc., argill., fossiliferous, weathers buff, 2 ft.; (2) sh., weathered buff, with boxwork at places, 1 ft.; (3) sh., grayish, with calc. concretionary sub-zone near base and reddish subzone below middle, 8 ft. Thickness averages about 11 ft. from Nebr. to Okla. Underlies Middleburg ls. and overlies Eiss ls. Type loc. highway cut and ravine just E. of Hooser.

G. E. Condra, 1935. (See under *Bader ls.*)

Hoover division.

Upper Cambrian or Lower Ordovician: Central Texas.

T. B. Comstock and E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. lxii, 295–306). *Hoover div.*—Consists of (descending): (1) Fine-grained gritty crystalline lss.; (2) compact, thin, slabby, fossiliferous ls., blue, red, gray, dull brownish, and yellow (called "Burnet marble" by earlier geologists, from great development of series near town of Burnet and neighboring parts of Burnet Co.); (3) dark fucoidal ls. Is upper div. of Leon series. Underlies Hinton div. of San Saba series and overlies, apparently uncon., Wyo div.

Is a part of Ellenburger ls.

Named for Hoover Valley, Burnet Co.

Hoover gas sand.

A subsurface sand of Chester (Miss.) age in Ind. that has been correlated with Hardinsburg ss. An older Chester sand, called *Hoover oil sand*, has been correlated with Cypress ss.

Hoover sand series.

A series of subsurface Penn. sss. and interbedded strata in central and northern Okla., reported to be 150 to 700± ft. thick and to correspond approx. to Elgin ss.

†Hop Brook limestone.

A name applied by B. K. Emerson (U. S. G. S. Bull. 159, p. 52, 1899) to Coles Brook ls. as exposed in bottom and steep banks of Hop Brook at Sodom, E. part of Berkshire Co., Mass.

Hope limestone.

Silurian (?): Central southern Maine (Hope Township, Knox County).

C. T. Jackson, 1837 (1st Rept. Geol. Maine, pp. 57–58). *Hope ls.* is in the talcose sl. Is indistinctly stratified and is cut through by many small trap dikes, while at points of contact the ls. is frequently converted into dol. Extensively quarried in Hope Twp. Most compact variety is known in commerce as *Lafayette lime.*

Hope gypsum. (In Sumner group.)

Permian: Central Kansas.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, pp. 10, 11). *Hope gyp.*—A gyp. bed in Geuda salt measures, about 100 ft. lower than Greeley gyp.

G. P. Grimsley, 1899 (Univ. Geol. Surv. Kans, vol. 5, pp. 58–61), gave further description of this gyp. bed, and named a gyp. occurring 10 ft. lower the *Solomon gyp.*

Named for Hope, Dickinson Co.

Hopewell sandstone.

Carboniferous: Canada.

H. M. Ami, 1900 (Canada Rec. Sci., vol. 8, p. 162).

Hopewell formation.

Pleistocene: Jamaica.

C. Schuchert, 1935 (Hist. geol. of Antillean-Caribbean region, p. 417).

Hopkinton dolomite.

Silurian (Niagaran): Eastern Iowa.

S. Calvin, 1906 (Jour. Geol., vol. 14, pp. 572, 574). *Hopkinton ls.*—Dol., very fossiliferous in places, 220 ft. thick, constituting lower phase of western Niagara and heretofore designated as Delaware (preoccupied). Includes zones btw. base of Niagara and top of *Pentamerus*-bearing beds.

T. E. Savage, 1906 (Iowa Geol. Surv. vol. 16), included in Hopkinton "stage" the "*Cerionites* and crinoid beds," overlying the *Pentamerus oblongus* beds.

According to E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22), the Hopkinton dol. is of post-Clinton and pre-Guelph age. According to E. O. Ulrich, 1924 (Wis. Acad. Sci. Trans., vol. 4, pp. 91–93) it is doubtfully of middle Clinton age. The U. S. Geol. Survey, also E. O. Ulrich, now treat Guelph as upper part of Lockport dol.

A. C. Trowbridge, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 61). Due largely to recent work of E. H. Scobey (unpublished thesis, Univ. Iowa Library) the Alexandrian (Medina, Lower Sil.) Edgewood and Kankakee fms. of Ill. have been recognized in Iowa and separated from the Hopkinton. The upper part of the Hopkinton remaining after removal of the Edgewood and Kankakee is probably= Joliet, Waukesha, and Racine of Ill. [Niagaran]. [In fig. 2 of this rept. the Hopkinton is placed in Niagaran.]

Named for Hopkinton, Delaware Co.

Hoppin slate.

Lower Cambrian: Massachusetts.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, p. 36). *Hoppin sl.*—Chiefly red sh. or sl., with layers and nodules of white ls., overlying greenish sh. or sl., beneath which is a basal white qtzite. Not greatly altered. Lower Camb. fossils. Thickness probably not less than 600 ft.; base not seen. Exposed at 2 places in Narragansett Basin, one at Hoppin Hill, North Attleboro, and the other in Wrentham, ½ mi. S. of West Wrentham village, just N. of Rhode Island bdy. Overlapped by Wamsutta fm. (Carbf.).

Hordes Creek limestone lentil (of Admiral formation).

Permian: Central Texas (Colorado River region).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 421, 422). *Hordes Creek bed.*—Impure lss., 10 to 30 ft. thick, with some layers of ss. and clay. Memb. of Albany div. Overlies Lost Creek bed and underlies Indian Creek bed.

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, pp. 192, 193, and charts). *Hordes Creek ls. lentil* is in lower part of Admiral fm. (basal fm. of Wichita group). Overlies Lost Creek sh. memb. and underlies Indian Creek sh. memb.

Named for Hordes Creek, Coleman Co.

Hornerstown marl. (In Rancocas group.)

Eocene (lower): New Jersey Coastal Plain.

W. B. Clark, 1907 (Johns Hopkins Univ. Circ., n. s., 1907, No. 7, Whole No. 199, p. 3). The term *Hornerstown marl* is here proposed to replace *Sewell*, which is found to be preoccupied. Is basal fm. of Rancocas group. Underlies Vincentown sand.

Named for occurrence at Hornerstown, N. J.

Horn River shales.

Devonian: Mackenzie.

E. J. Whittaker, 1922 (Canada Geol. Surv. Summ. Rept. 1921, pt. B, p. 52).

Hornsboro sandstone.
Hornsboro zone.

Triassic (Upper); Northeastern South Carolina (Chesterfield County).

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 11, 12). *Hornsboro ss.*, also *Hornsboro zone* (Jurassic and Triassic).—This fm. is bounded on N. by N. C. line, from a point about 3 mi. E. of Hornsboro to a point about 1.2 mi. W. of Hornsboro; the delimiting line then proceeds southeasterly about 1 mi., thence easterly 5 mi., and thence to initial point on N. C. line; from easterly half of this area a narrow strip has been removed through erosion by the Clay Creek waters, which expose the underlying Edgefield-Chesterfield slates. The Hornsboro rocks comprise brown-red and gray sss., varying in places to a purple-brown indurated clay. Numerous intrusive masses of diabase have greatly disturbed, and partly metamorphosed to secondary forms, portions of the red sss. The bodies exhibited in this State are not sufficiently homogeneous to afford valuable quarries. In N. C., where these beds attain much greater thickness, as in Jupiter area, workable beds of coal are included by the Jura-Trias. In many places the coal seams have been disconnected by diabase intrusions, and exhibit so much pyrite that profitable mining is impossible. The close of Jura-Trias in S. C. was characterized by intrusion of a vast series of diabase dikes, prominent in the Jura-Trias and in Edgefield-Chesterfield fms., but progressively less toward the Piedmont.

Named for exposures around Hornsboro, Chesterfield Co.

Horse Bench sandstone lentil (of Green River formation).

Eocene (middle): Northeastern Utah (Uinta Basin).

W. H. Bradley, 1931 (U. S. G. S. P. P. 168, p. 16). *Horse Bench ss. lentil.*—Nearly equal groups of thin-bedded and ripple-marked ss. beds that alternate with a smaller amount of hard greenish gray micaceous and sandy mudstone. Thickness 0 to 55 ft. Is much more resistant than the associated rocks. Lies 475± ft. below top of Green River fm. in area W. of Bitter Creek. Is=part of Evacuation Creek memb. E. of Bitter Creek. Is underlain by grayish-brown sh. and shaly marlstone, much of it sandy and either laminated or flaky. Is overlain by hard, drab, either uniformly colored or faintly banded mudstone, which weathers spheroidal and contains some soft, brown, flaky sh. Named for fact it forms the broad table-land btw. Minnie Maud Creek and Jack Canyon known as Horse Bench, in NE. part of Carbon Co.

Horse Creek limestone member (of Moran formation).

Permian: Central Texas (Colorado River region).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 387, 419). *Horse Creek bed.*—Mostly hard massive light-gray ls., 5 to 15 ft. thick, with clay parting in places. Memb. of Cisco div. Underlies Santa Anna bed and overlies Watts Creek bed.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31; Univ. Tex. Bull. 2132, pp. 177–183 and charts). *Horse Creek ls. memb. of Moran fm.* (of Cisco group), 5 to 15 ft. thick; underlies Santa Anna sh. memb. and overlies Watts Creek sh. memb. of Moran fm. in Colorado River Valley.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 170). Horse Creek ls. of Drake is preoccupied (see under Strawn fm.) and discarded. Moran fm. transferred to Wichita group (Perm.).

Named for Horse Creek, Coleman Co.

Horse Creek clay and shale. (In Strawn formation.)

Pennsylvanian: Central Texas (Colorado River region).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 374, 379). *Horse Creek clays and shales.*—Upper 100 ft. usually blue clay, slightly sandy, and containing a few clay ironstone nodules; lower 50 ft. black clay sh. or, in places, shaly black clay of nodular structure. Memb. of Strawn div. Underlies Bull Creek ss. and overlies Fox Ford bed.

Named for valley of Horse Creek, San Saba Co.

Horse Creek coal group. (In Pottsville formation.)

Pennsylvanian: Central Alabama.

Same as Mary Lee coal group.

Horsefly gravels.

Tertiary: Canada.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 220).

Horseneck sand.

A subsurface sand in Conemaugh (?) fm. (Penn.) of W. Va., that is considered to be younger than Saltsburg ss. memb. Named for Horseneck Creek, Pleasants Co., W. Va. Some geologists correlate it with Clarion ss. memb. of Allegheny fm.

Horsepen. (In Pottsville group.)

Pennsylvanian: West Virginia.

D. White, 1895 (Geol. Soc. Am. Bull., vol. 6, p. 316). "Horsepen" is used for present convenience, without any intention to add to geol. nomenclature, to indicate a group of coals above Pocahontas coal in lower half of Pottsville sections of Tug River and Great Flat Top Mtn. They are more or less exposed near schoolhouse at Horsepen [and at other mentioned localities].

Horse Spring formation.

Tertiary (?): Southeastern Nevada and northwestern Arizona.

C. R. Longwell, 1921 (Am. Jour. Sci., 5th, vol. 1, p. 53) and 1928 (U. S. G. S. Bull. 798). *Horse Spring fm.*—Fine playa and lake deposits of ls., compact clays, sss., gyp., and volcanic tuffs. A variant thickness of light-colored ls. is most persistent and characteristic horizon marker of fm., but it varies considerably in color and other physical properties. Some of the soft white beds are almost pure magnesium carbonate, and the deposits are locally called "the magnesite," being interbedded with thin dol. layers and pink calc. sss., 200 to 300 ft. thick. No fossils. Assigned to Tert. (Mio. ?). Thickness of fm. 1,000 to 2,800 ft. Grades into underlying Overton fangl. (Tert., Mio.?), and is uncon. overlain by Muddy Creek fm. (Plio.?). Well exposed on E. side of Horse Spring Valley, near St. Thomas Gap, Clark Co., Nev.

The finding, later, of a Cret. flora in lower part of Overton fangl., led to reclassification (in March 1936) of the Overton as *Cret. and Tert. (?)*; and, because of physical relationships of the Horse Spring to the Overton, the age designation of the Horse Spring was changed to *Tert. (?)*.

†Horsetail Creek beds.

Tertiary (lower Oligocene): Northeastern Colorado.

W. D. Matthew, 1901 (Am. Mus. Nat. Hist. Mem., vol. 1, pt. 7, pp. 355–374, 444). *Horsetail Creek beds.*—Lower part of White River fm.—the *Titanotherium* beds. Consist of hard white or grayish-white clays with considerable horizontal cleavage and some ss. layers. Older than Cedar Creek and Martin Canyon beds.

H. F. Osborn, 1909 (U. S. G. S. Bull. 361, p. 103) and 1918 (Am. Mus. Nat. Hist. Mem., vol. 2, pt. 1, p. 9). *"Horsetail Creek beds"*=Chadron fm. (lower Olig.).

Named for Horsetail Creek, Logan and Weld Counties.

Horsethief sandstone. (Of Montana group.)

Upper Cretaceous: Northwestern Montana and southern British Columbia.

E. Stebinger, 1913 (Am. Inst. Min. Engrs. Bull. 81, p. 2337). *Lennep or Horsethief ss.*—Massive gray ss., 0 to 300 ft. thick, overlying Bearpaw sh. and underlying Lance fm.

E. Stebinger, 1914 (U. S. G. S. P. P. 90, pp. 62–68). *Horsethief ss.*—Gray to buff coarse-grained, much cross-bedded, massive ss. in upper half, and slabby gray ss., becoming shaly toward base, in lower half. In places contains beds of heavy magnetite-bearing ss. Thickness 360 ft. Fossils mainly brackish, but in places it contains a marine littoral fauna. Overlies Bearpaw sh. and underlies continental deposits composing St. Mary River beds of Dawson, which occupy approx. strat. position of Lance fm. of Wyo. Believed to correlate with Lennep ss. of central Mont.

Type loc. is Horsethief Ridge, Blackfoot quad.

Horsethief formation.

Pre-Cambrian: British Columbia.

J. F. Walker, 1926 (Canada Geol. Surv. Mem. 148, p. 14).

Horsethief Creek formation.

Pre-Cambrian: British Columbia.

C. S. Evans, 1933 (Canada Geol. Surv. Summ. Rept. 1932, pt. A2, p. 117).

Horsetown formation.

Lower Cretaceous (Shasta series): California and Oregon.

C. A. White, 1885 (U. S. G. S. Bull. 15, pp. 19–32). [See definition under *Knoxville fm.*]

J. S. Diller and T. W. Stanton, 1894 (Geol. Soc. Am. Bull., vol. 5, pp. 435–464). [See explanation under *Knoxville fm.*]

The Horsetown fm. ranges in thickness up to 6,000 ft. It overlies Knoxville fm. and underlies Chico fm. The upper part may be of early Cenomanian age, and therefore Upper Cret., but U. S. Geol. Survey classifies the whole unit as Lower Cret.

Named for exposures at Horsetown, Shasta Co. Also well exposed on North Fork of Cottonwood Creek.

Horton series.

Mississippian: New Brunswick and Nova Scotia.

J. W. Dawson, 1873 (Rept. on fossil plants of Lower Carbf. and Millstone grit. fms. of Canada, Canada Geol. Surv., 1873).

According to C. Schuchert and C. O. Dunbar, 1933 (Textbook geol., pt. 2, p. 227), corresponds to Pocono group of Appalachian region.

Horton sand.

A subsurface sand in Pottsville fm. (Penn.) of Knox, Knott, and Pike Counties, SE. Ky.

Horton Bluff formation.

Carboniferous: Nova Scotia.

W. A. Bell, 1929 (Canada Geol. Surv. Mem. 155, p. 30).

Hortontown basic eruptives.

Southeastern New York (Poughkeepsie quadrangle).

C. E. Gordon, 1911 (N. Y. State Mus. Bull. 148, pp. 11, 37–39). *Hortontown basic eruptive.*—Several outcrops of a massive compact greenish rock in orchard by the house and near the barn on farm of Albert Lawrence at Hortontown. The only occurrence within Poughkeepsie quad. that indicates that an eruptive has penetrated and altered the overlying Paleozoics. [In table on p. 11 *Hortontown hornblende rock* is placed opposite Camb. and Ord.]

Hortonville slate.

Middle Ordovician (early Trenton): Southwestern Vermont (Rutland County).

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 369). *Hortonville sl.*—Dark or black sl. with portions sufficiently altered to be called phyllite. Also contains a few small seams of siliceous material giving a local banded appearance. As a rule the bedding is obscured by the cleavage. Is well exposed around Hortonville [Castleton quad.]. Though unfossiliferous is correlated with Snake Hill fm. of N. Y. [which is early Trenton]. Younger than Hyde Manor ls.

Hoskinnini tongue (of Cutler formation). Also **Hoskinnini member.**

Permian: Southeastern Utah (San Juan County) and northeastern Arizona.

A. A. Baker and J. B. Reeside, Jr., 1929 (A. A. P. G. Bull., vol. 13, No. 11, pp. 1422, 1423, 1441, 1443, 1446). *Hoskinini tongue of Cutler fm.*—Red sss. and sandy sh., 0 to 75 ft. thick, forming top part of Cutler fm. in Monument Valley and other areas in southern San Juan Co., Utah, and NE. Ariz. Uncon. underlies true Moenkopi fm. and overlies De Chelly ss. memb. of Cutler fm. In earlier repts all these beds were included in Moenkopi fm. (Lower Triassic), but they are Perm. Exposed on N. face of Hoskinini [Hoskinnini] Mesa, several mi. W. of Oljeto trading post, in Moonlight Wash, btw. Lees Ferry and Kayenta, NE. Ariz.

Hosmer sand.

Hosmer oil sand.

Hosmer Run oil rock.

Hosmer Run oil sand.

Terms applied by J. F. Carll (2d Pa. Geol. Survey Rept. I, pp. 45-46, 1875) to the First oil sand of Hosmer Run, Warren Co., Pa., which lies 410 to 455 ft. below the Olean cgl. (basal memb. of Pottsville fm.).

Hosmer conglomerate.

Hosmer Run conglomerate.

Devonian or Carboniferous: Northwestern Pennsylvania (Warren County).

J. F. Carll, 1883 (2d Pa. Geol. Surv. Rept. I_4, pp. 250, 254, 259, 268). *Hosmer Run cgl.*—Massive conglomeratic ss. of flat-pebble type, the largest pebbles, white and yellow, being in upper part. Thickness 15 or more ft. on Hosmer Run, near E. line of Spring Creek Twp, Warren Co. Probably same as Wrightsville cgl.

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 2), shortened this name to *Hosmer cgl.*

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 93). Relation of *Hosmer Run cgl.* of oil-pit region NW. of Garland, Pa., and Woodcock ss. is obscure, but it appears unlikely that they are synonymous. The Hosmer Run is probably referable to Tuna cgl. horizon, which is probably a little lower in section than Woodcock.

Hosselkus limestone.

Upper Triassic: Northern California (Taylorsville and Redding region).

J. S. Diller, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 370–394). *Hosselkus ls.*—Fossiliferous ls., 140 ft. thick, considered to be younger than Swearinger sl. and older than Trail beds.

J. S. Diller, 1908 (U. S. G. S. Bull. 353). *Hosselkus ls.*—Dark-blue to light-gray ls., thin-bedded, in some places decidedly slaty; fossiliferous. Thickness 140 ft. Well developed in Redding region, where upper part is lighter colored and more massive and contains a spiriferlike shell, and lower part is thinner bedded and darker, with small coiled forms. Conformably overlain (not underlain, as originally assumed) by Swearinger sl., and uncon. underlain by Robinson fm. In Redding region it is separated from Robinson horizon by 1,000 ft. of andesitic and rhyolitic lavas, which are overlain by 1,500 ft. of shales, sss., and tuffs of Triassic age.

Named for fact it forms prominent ledges on divide btw. Genesee Valley and Hosselkus Creek, 1 mi. NE. of Hosselkus ranch, Plumas Co.

Hosselkus series.

G. H. Ashley, 1923 (Eng. and Min. Jour.-Press, vol. 115, pp. 1106–1108), proposed *Hosselkus series* as a geographic name for *Upper Triassic series*.

Hosta sandstone member (of Mesaverde formation).

Upper Cretaceous: Northwestern New Mexico (Gallup region).

J. D. Sears, 1934 (U. S. G. S. Bull. 860A). *Hosta ss. memb. of Mesaverde fm.*—The ss. that appears in midst of Gibson coal memb. NW. of Walker's store thickens rapidly to N. and E., and within 10 mi. to NE. it is 250± ft. thick. To this unit writer is here applying the name *Hosta ss. memb.*, because it caps the prominent Hosta Butte. It also forms the major cliff or rim and the top of the northward-sloping ridge behind it. To N. the ss. is split into 2 distinct tongues by a wedge of marine sh. that forms Satan tongue of Mancos sh. The upper ss. of Hosta memb. is of earliest Montana age and the underlying rocks are of Colorado age.

Hota formation.

Cambrian: British Columbia and Alberta.

C. D. Walcott, 1913 (Smithsonian Misc. Coll., vol. 57, No. 12, pp. 335, 338).

Hotauta conglomerate. (Of Unkar group.)

Pre-Cambrian: Northern Arizona (Grand Canyon).

L. F. Noble, 1914 (U. S. G. S. Bull. 549). *Hotauta cgl.*—Arkose cgl. characterized by lack of sorting and transportation. Thickness 0 to 6 ft. in Shinumo quad. Rests on Vishnu schist (Archean), the upper surface of which is very uneven, through erosion, representing a great uncon. Is basal fm. of Unkar group (Algonkian). Conformably overlain by Bass ls. Named for Hotauta Canyon, Shinumo quad., in lower part of which the geologic section was measured.

Hotson sand.

A subsurface sand, 8 to 20 ft. thick, in central northern Okla., correlated with part of Eskridge sh. (top of Penn.). In Garber pool it is reported to lie at 1,430 ft. depth, the Hoy sand at 1,100 ft., and the Walker at 1,500 ft.

Hot Springs formation.

Quaternary: Yellowstone National Park.

W. H. Weed, 1896 (U. S. G. S. Yellowstone Nat. Park folio, No. 30), mapped *Hot Spring fms.*, and described them in text under heading *Hot Spring deposits.*

A. Hague et al., 1899 (U. S. G. S. Mon. 32, pt. 2, pl. 10), mapped *Hot Springs fm.*, and this name was adopted in 1904, for the Atlas to accompany Mon. 32; but the Atlas as printed used *Hot Spring fm.*

Named for the Hot Springs, which formed the deposit.

Hot Springs sandstone.

Pennsylvanian: Southwestern Arkansas (Hot Springs quadrangle).

A. H. Purdue, 1910 (Jour. Geol. vol. 18, pp. 282–283). *Hot Springs ss.*—Gray qtzitic ss., in beds 3 to 8 ft. thick, the basal 10 ft. conglomeratic. Thickness 100 ft. Overlies Arkansas novaculite in vicinity of Hot Springs [intervening Fork Mtn sl. apparently absent] and underlies Stanley sh.

Age of Stanley sh. and Hot Springs ss. was changed to Penn. in 1934. (See H. D. Miser, A. A. P. G. Bull., vol. 18, No. 8, 1934.)

Houchen Creek limestone.

Pennsylvanian: Southeastern Nebraska and northeastern Kansas.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 84, 89). *Houchen Creek ls.*—Massive to irregular, or separated by bluish sh. partings; characterized in most exposures by presence of large masses of algal growth. Thickness 4 to 8+ ft. in Nebr., 3+ ft. in NE. Kans. Been traced to Kansas Valley, N. of Belvue [Pottawatomie Co., Kans.]. Underlies Hughes Creek sh. and overlies Stine sh., all included in Elmdale sh. memb. Named for exposures on Houchens Creek, sec. 29, T. 6 N., R. 13 E., Nemaha Co., Nebr.

R. C. Moore and G. E. Condra, 1932 (Oct. 1932 revised classification chart of Penn. rocks of Nebr. and Kans.), transferred Houchen Creek ls. and Stine sh. to Admire sh., and introduced *Oaks sh.* for the bed overlying Houchen Creek ls. Whether Oaks sh. is a part of Hughes Creek sh. as originally defined, or a newly discovered unit, was not stated.

G. E. Condra, 1935. (See under *Hamlin sh.*, where the name was spelled *Houchens Creek ls.*)

Houghton conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. R. Marvine, 1873 (Mich. Geol. Surv. vol. 1, pt. 2, pp. 80–81 and chart). *Houghton cgl.* is cgl. No. 14 of Houghton Co.

Belongs to Central Mine group.

Named for occurrence in Houghton mine, Houghton Co.

Houghton moraines.

Pleistocene (Wisconsin stage): Northern central Michigan (Roscommon County).

W. A. Ver Wiebe, 1927 (Mich. Acad. Sci., Arts, and Lett. Papers, vol. 7, p. 161). *Houghton moraine* extends across S. side of Houghton Lake from sec. 4, T. 22 N., R. 4 W. to sec. 33, T. 22 N., R. 3 W. *Houghton ground moraine* lies on SW. side of Houghton Lake.

Hounsfield bentonite.

Middle Ordovician (Black River): Central New York (Jefferson County).

G. M. Kay, 1930 (Sci., n. s., vol. 72, p. 365). *Hounsfield bentonite.*—Type section in small quarry just N. of Dexter-Brownville road, 2 mi. E. of town of Dexter, Jefferson Co.; Hounsfield Twp is 1 mi. S. of the locality. In the quarry it occurs as a bed of gray white homogeneous clay, reaching ⅜ in. in thickness, lying [uncon. in 1931 rept.] above Leray ls. and [uncon.] below Watertown ls., in Chaumont fm., of Ord. (upper Black River) age. In Ont. the Hounsfield occurs within the intermediate Glenburnie memb. of Chaumont fm. near Kingston and in Coboconk ls. of Lake Simcoe dist. In upper Miss. Valley it occurs consistently within 2 ft. of base of Spechts Ferry memb. of Decorah fm. The presence of the bed has been reported in Minn. and Tenn. The fact that Hounsfield bentonite has been found to occupy the position that it has in type Black River section establishes new basis for correlating beds in other regions within which the bentonite occurs with those in type section.

G. M. Kay, 1931 (Jour. Geol., vol. 39, No. 4, p. 362), showed uncon. btw. Hounsfield bentonite and overlying Watertown ls. and underlying Leray ls. at its type loc., and on p. 374 he applied *Hounsfield bentonite* in N. Y., Ont., Ky., Tenn., Mo., and Iowa columns of his correlation chart.

House Mountain shales.

Upper Ordovician: Central western Virginia.

J. L. Campbell, 1879 (Am. Jour. Sci., 3d, vol. 18, p. 29), listed, in table of geol. fms. of Virginia Valley, *House Mt. shales* (of Trenton age) as overlying *Lexington lss.* (of Trenton age), and underlying Medina cgl. Not defined. All of definition of both.

J. L. Campbell, 1880 (The Virginias, vol. 1, pp. 41–45). *House Mtn shales*=Hudson River and Utica. Overlie Lexington lss., of Trenton age, and underlie Medina cgl.

Appears to correspond to Martinsburg sh.

Houston marl.

Upper Cretaceous: Northeastern Mississippi (Chickasaw County).

E. W. Hilgard, 1860 (Geol. and Agric. Miss., pp. 96–97). *Houston marl.*—Bluish-gray marl dug from cisterns at Houston, Chickasaw Co. Outcrops of the marl (which extends eastward to Kilgore's Ridge, and probably southward to the Tibby) are scarce, but it is generally not far underground in dist. of its occurrence, as is known in each neighborhood where wells have been dug. Belongs to Rotten ls. group [Selma chalk].

Houston andesite.

Tertiary: Southwestern New Mexico (Mogollon district).

H. G. Ferguson, 1927 (U. S. G. S. Bull. 787). *Houston andesite.*—A single flow near base of Cranktown ss. Is porphyritic, but phenocrysts are smaller and less numerous than in the other andesites higher in the series. Thickness about 40 ft.

Named for exposures in valley of Houston Canyon, in SE. part of Mogollon dist.

Houston group.

Pleistocene: Coastal Plain of eastern Texas.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 780). *Houston group* is proposed to embrace the Pleist. strata of the flat Gulf coastal plain from top of Plio. sands of Citronelle group to base of Recent coastal silts and wind-blown sands overlying the Pleist. deposits in some areas. Outcrop along coastal border of Gulf of Mexico. Are bounded on N. by Hockley escarpment and equiv. rolling ridgeland, and on S. by the beach and wind-blown sands along present shore line. Average thickness 1,500 ft. Named for city of Houston, which is located in middle part of Pleist. section at about contact of the upper clays with the lower sands. Includes Beaumont and Lissie fms.

Houten sandstone.

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, p. 257, and Conspectus of geol. fms. of N. Mex., pp. 2, 8). *Houten sss.*—Middle sandy portion of Raton series [Raton *fm.*, of Eocene age] in NE. N. Mex. Thickness 600 ft. Underlies Maxwell sh. and overlies Maya cgl. [See under *Maxwell.* Keyes has also applied this name in Colo. Derivation of name not stated.]

Howard limestone. (In Shawnee group, Kansas.)

Howard limestone member (of Shawnee formation, Missouri).

Pennsylvanian: Eastern Kansas, northwestern Missouri, southeastern Nebraska and southwestern Iowa.

E. Haworth, 1898 (Kans. Univ. Geol. Surv. vol. 3, pp. 67, 105). *Howard ls.* proposed by G. I. Adams in field notes, for ls., 3 to 8 ft. thick, overlying Severy shales and underlying what seems to be equiv. of Osage shales [not true †Osage but the higher Scranton sh.] in Chautauqua, Elk, and Greenwood Counties, Kans.

H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines vol. 13), defined *Howard ls. memb. of Shawnee fm.* as underlying Scranton sh. memb., and overlying Severy sh. memb., and this has been the generally approved definition for many years. In Kans. the Shawnee is treated as a group and the subdivisions as fms.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 204). Type loc. of Howard ls. is near Howard, Elk Co., Kans. It is typically exposed in NE¼ sec. 7, T. 29 S., R. 11 E., and is here included in Wabaunsee group.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Howard arkose.

Tertiary (Miocene?): Central Washington (Snohomish County).

C. E. Weaver, 1912 (Wash. Geol. Surv. Bull. 7, pp. 34–50). *Howard arkose fm.*—Coarse, angular, arkosic cgl. with interbedded tuffs, lavas, and andesitic breccias. Thickness 500 to 700 ft. No fossils. Is Tert. and much younger than Eocene arkose of Monte Cristo dist.; may be Mio. Named for Howard Creek, just below Howard Lake. Uncon. overlies West Index andesitic series.

†Howard sandstone member. (In Tuscarora sandstone.)

Silurian: Central Pennsylvania (near Mount Union and Lewistown).

F. M. Swartz, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 101). *Howard ss. memb.* is proposed for red and green beds at top of Tuscarora ss. in sections near Mount Union and Lewistown. This memb. may represent bulk of Albion group of western N. Y.

F. M. Swartz, 1934 (Geol. Soc. Am. Bull., vol. 45, p. 109), replaced this name, which is preoccupied, with *Castanea ss.*, which he excluded from Tuscarora ss.

Howe limestone.

Pennsylvanian: Southeastern Nebraska and northeastern Kansas.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 84, 86, 88). *Howe ls.*—Dark-gray massive dense ls., with considerable free calcite. Weathers buff to yellowish, granular, vesicular or cavernous, and very irregular. At places carries geodes. Thickness 4 to 5 ft. in Nebr. and NE. Kans. Underlies Roca sh. and overlies Bennett sh., all included in Elmdale sh. memb. Named for exposures S. of Howe, Nebr.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 8), introduced into Nebr. section *Red Eagle ls. fm.*, to include (descending) Howe ls., Bennett sh., and Glenrock ls.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), transferred this unit to Perm. This change in Perm.-Penn. bdy has not been considered by U. S. Geol. Survey for its publications.

Howell formation.

Middle Cambrian: Western Utah (House Range).

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804, pp. 9, 11). *Howell fm.*—Dark, more or less massive ls. and pinkish argill. shales, 640 ft. thick. Basal fm. of Middle Camb. in House Range. Underlies Dome fm. and overlies Pioche fm. Type loc., slopes of Howell Peak, on W. side of House Range, about 5 mi. W. of Antelope Springs.

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1812), gave a résumé of House Range section in which he recognized btw. Howell fm. and underlying Pioche sh. 205 ft. of bluish gray aren. ls. which he called Langston (?) fm.

†Howenstein limestone. (In Allegheny formation.)

Pennsylvanian: Northeastern Ohio.

G. F. Lamb, 1910 (Ohio Nat., vol. 10, p. 130). *Howenstein ls.* caps Brookville coal in Stark and Mahoning Counties.

Same as Putnam Hill ls. memb.

Named for Howenstine, Stark Co.

Howson andesite.

Pliocene (?): Central Washington (Snoqualmie quadrangle).

G. O. Smith and F. C. Calkins, 1906 (U. S. G. S. Snoqualmie folio, No. 139). *Howson andesite.*—Hornblende-andesite lava; porphyritic; mostly light gray, some pink. Thickness 250 ft. Assigned to Plio. (?). Probably not older than Plio. or late Mio. Occurs N. and NE. of head of Howson Creek.

Hoxbar formation.

Pennsylvanian: Central southern Oklahoma (Carter County).

W. L. Goldston, Jr., 1922 (A. A. P. G. Bull., vol. 6, No. 1). *Hoxbar member.*—Top memb. of Glenn fm. Upper part is characterized by white sss. separated by light-blue to yellow and red shales; near top 4 mi. SE. of Ardmore is a coal seam 2 to 4 ft. thick. Basal sediments are characterized by several brown lss., one of which is a prolific *Fusulina cylindrica* horizon. Thickness of memb. 4,000 ft. To SE. it becomes less calc. and lss. grade into shales and shales into sss. and cgls. Fossils listed. Overlies Deese memb. Occurs W. of Hoxbar.

G. H. Girty and P. V. Roundy, 1923 (A. A. P. G. Bull., vol. 7, No. 4, pp. 331–347). We are convinced it was not Taff's intention to include in Glenn fm. the beds called *Hoxbar memb.* by Goldston. These beds are younger than Glenn and possibly represent part of Franks cgl.

H. D. Miser, 1925 (Okla. Geol. Surv. Bull. 35, p. 26, footnote). Glenn fm. as mapped on Okla. geol. map. corresponds to Glenn fm. of Goldston, except that his Springer memb. N. of Ardmore is included in Caney sh. His Springer memb. around Criner Hills S. of Ardmore is held by G. H. Girty and P. V. Roundy to be younger than the Springer N. of Ardmore, and is mapped as part of Glenn.

S. Powers, 1927 (A. A. P. G. Bull., vol. 11, No. 10, pp. 1067–1085), mapped *Hoxbar fm.* as overlying Glenn fm.

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z, pp. 7–21). *Hoxbar fm.* uncon. underlies Pontotoc series and overlies Deese fm. It is 4,000± ft. thick, and is here divided into several named members. [See Okla. correlation chart.] Basal memb. is here named *Confederate ls. memb.*

C. W. Tomlinson, 1929 (Okla. Geol. Surv. Bull. 46). *Hoxbar fm.*, 4,000± ft. thick, coincides very nearly with Goldston's Hoxbar memb. of Glenn fm.

C. W. Tomlinson, 1934. (See 1934 entry under *Confederate ls. memb.*)

Named for exposures W. of Hoxbar, Carter Co.

Hoy sand.

A subsurface sand, 12 to 20 ft. thick, in central northern Okla., reported to correlate with part of Matfield sh. (Perm.). In Garber pool (Garfield Co.), however, the sand is reported to lie at 1,100 ft. depth, the Kisner at 700, the Whitney at 800, and the Hotson at 1,430 ft.

Hoyt dolomite. (A distinct formation to south.)

Hoyt limestone member (of Theresa dolomite).

Upper Cambrian: Eastern New York (Saratoga and Dutchess Counties).

See explanation under *Little Falls dol.* and *Theresa dol.* Named for exposures at Hoyt's quarry, 3 mi. W. of Saratoga Springs, central eastern N. Y.

Hozomeen series.

Carboniferous: Southern British Columbia and central northern Washington.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, maps 14 and 15, 120°30′ to 121°30′). *Hozomeen series.*—Greenstone, cherty qtzite, phyllite, and ls. pods. [Hozomeen Range, B. C., appears to consist largely of these rocks, and Mount Hozomeen, Wash., lies in midst of them.]

C. Camsell, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 118).

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, pp. 500, 508).

Huacalote rhyolite.

Age (?): Mexico.

S. F. Emmons, 1910 (Econ. Geol., vol. 5, p. 322).

Huautla basalt.

Oligocene: Mexico.

R. H. Palmer, 1927 (A. A. P. G. Bull., vol. 11, pp. 1180, 1201).

Hubbardston granite.

Late Carboniferous or post-Carboniferous: Central Massachusetts.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 231–236 and map). *Hubbardston granite.*—Chiefly coarse white ragged, highly feldspathic granite of pegmatitic texture, though never distinctly porphyritic or fine grained. Locally the rock becomes a white sugary granulite, full or red garnets, graphite, and great sheets of silky white fibrolite, much of it changed to muscovite. There is also a dark fine-grained biotite granite or gneiss phase resembling Hardwick granite. Named for occurrence at Hubbardston.

Hubbardton slate.

Lower Cambrian: Southwestern Vermont (Rutland County).

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 401). *Hubbardton sl.*—Mainly green sl. with variable amount of purple sl. In some places (notably in W. part of Taconic Range) the purple is more common than the green in upper part of fm. and very similar to that of Bull sl. Thickness estimated at 300 ft. No very sharp div. line btw. this sl. and underlying Stiles phyllite, and bdy is placed where the small qtzite layers end, which is also the horizon where the special colors of the Stiles end. Underlies Barker qtzite. Named for occurrence in village of Hubbardton [Castleton quad.].

Huckleberry clay. (In Pottsville formation.)

A bed of clay, 0 to 6 ft. thick, underlying Huckleberry coal and lying 0 to 12 ft. above Anthony coal and Sciotoville clay in Olive Hill field of Ky. and in Sciotoville field of SE. Ohio. (See Ohio Geol. Surv., 4th ser., Bull. 26, 1923, pp. 150–151, where the names of the clay and coal are quoted.) Derivation of name unknown.

Huckleberry andesites.

Age (?): Northern California (Lassen National Park).

H. Williams, 1932 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 21, No. 8, pp. 251, 252, 254). *Huckleberry andesites.*—Markedly different from glassy andesites that form bulk of Brokeoff Cone. Occur near Huckleberry Lake. [Not mapped separately.]

†Hudson system.

Cambrian: Eastern New York.

T. A. Conrad, 1839 (N. Y. Geol. Surv. 3d Rept., pp. 57–63), described the rocks of Hudson River region, N. Y., as "Cambrian or Hudson system."

†Hudson period.

Time term applied by J. D. Dana and other early geologists to epoch covering deposition of rocks underlying Oneida cgl. and overlying Trenton ls.

†Hudson formation.
†Hudson group.
†Hudson shales.
†Hudson terrane.
†Hudson River slate group.
†Hudson River group.
†Hudson River beds.
†Hudson River shales.
†Hudson River formation.
†Hudson River slates.
†Hudson River shales and sandstones.
†Hudson River series.

Terms variously used in early N. Y. repts to include (1) beds of Upper Ord. age only; (2) beds of Upper and Middle Ord. age; and (3) beds ranging in age from Upper Ord. to Upper Camb., both inclusive. The following are the earliest definitions:

W. W. Mather, 1840 (N. Y. Geol. Surv. 4th Rept., pp. 212, 256–258). ***Hudson River sl. group.***—Slates, shales, and grits with interstratified lss., all of which occur under various modifications, with siliceous and calc. breccias and hypogene and plutonic rocks. In places is uncon. overlain by Shawangunk grit. Occurs in SE. counties of N. Y.

W. W. Mather, 1841 (N. Y. Geol. Surv. 5th Rept., pp. 90–96). ***Hudson sl. series*** (also *Hudson River sl. series*).—Includes all rocks btw. top of Frankfort sl. group and base of Potsdam ss. [As thus defined includes Upper Ord. to Upper Camb., inclusive.]

E. Emmons, 1842 (geol. map of New York). ***Hudson River group or Lorrain[e] shales*** underlies Gray ss. [Oswego ss.] and Shawangunk grit and overlies Utica sl. [As thus defined is all of Upper Ord. age, and later than Utica sl., which is also Upper Ord.]

L. Vanuxem, 1842 (Geol. N. Y., pt. 3). ***Hudson River group.***—Includes shales and sss. of Pulaski and Frankfort sl. and ss. Overlies Utica sl. and underlies Gray ss. of falls of Salmon River and Oswego. Thickness 700 ft. [This definition of "Hudson River group" has been the most widely used.]

In some subsequent repts the Utica sl. also was included, and "Hudson River group" became synonymous with *Upper Ord.* The names "Hudson" and "Hudson River" were also carried into many other States and into Canada for supposedly contemp. deposits. The name in all senses has been discarded by most geologists.

Hudson trilobite beds.

Upper Cambrian: Western Wisconsin.

L. C. Wooster, 1878 (Wis. Geol. Surv. Rept. 1877, pp. 36–41). ***Hudson trilobite beds*** are quite rich in trilobites and brachiopods, including one new sp. of former and several undet. spp. [Seem to be named for Hudson, St. Croix Co. Lie higher than Eau Claire trilobite beds.]

L. C. Wooster, 1882 (Geol. Wis., vol. 4, pp. 101–140). ***Hudson trilobite beds*** lie at best-defined horizon in Potsdam ss., 200 ft. higher than Eau Claire trilobite beds. Overlain by Lower Calcareous Band, 10 ft. thick.

A. C. Trowbridge et al., 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 160). Franconia section at Hudson is type loc. of Hudson trilobite beds of Wooster.

Probably is part or all of Hudson memb. of Trowbridge et al.

†Hudson schist.

Ordovician, Cambrian, and pre-Cambrian: Eastern New York.

F. J. H. Merrill, 1902 (U. S. G. S. N. Y. City folio, No. 83). ***Hudson schist.***—The schist of N. Y. dist. is given name *Hudson* because it continues northward and connects stratigraphically with the great area of sl. and sh. along Hudson River which has been called respectively *Hudson sl.* and *Hudson sh.* The Hudson schist, Hudson sl., and Hudson sh. represent different phases of alteration of same original rock, and together they form *Hudson fm.* The Hudson fm. continues into New England, and is there a schist, which has been called *Berkshire schist.* [The Hudson schist of N. Y. City quad. is described as mica schist, consisting of biotite and quartz with garnet, staurolite, fibrolite, and cyanite.] Overlies Stockbridge dol. and underlies Newark fm.

According to E. B. Knopf (1927) and other geologists this schist is same as Berkshire schist, which has priority as a name for this schist; and "Hudson" also is objectionable because of its varied applications. Is not considered same as Manhattan schist of New York City region, which is pre-Camb. The Berkshire schist is now classified as of Ord., Camb., and pre-Camb. (?) age. (See under *Berkshire schist.*)

Hudson member (of Franconia sandstone).

Upper Cambrian: Western Wisconsin (St. Croix County).

A. C. Trowbridge, W. H. Twenhofel, G. O. Raasch, F. T. Thwaites, Sept. 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., fig. 1, pp. 81, 92, 134, 140, 159, 160, 431, 446, 449, 454, etc.). *Hudson memb. of Franconia fm.*—At Goodenough Hill, Juneau Co., consists of (descending): (1) Fine-grained white ss., 13 ft.; (2) covered, 19 ft.; (3) fine-grained pink to brown ss., 24.2 ft.; (4) greensand, 5 ft. Underlies Bad Axe memb. of the Franconia and rests on Goodenough memb. of the Franconia. At Hudson it consists of 85 ft. of medium-grained, green to gray glauconitic ss., underlying Bad Axe and overlying Goodenough members. The Franconia section at Hudson, St. Croix Co., is type loc. of Hudson trilobite bed of Wooster and of Hudson memb. of Franconia as defined by Twenhofel, Raasch, and Thwaites. [On p. 309 of this book G. O. Raasch stated that Hudson memb. is *Ptychaspis-Prosaukia* zone.]

Above definition was repeated and somewhat amplified by Twenhofel, Raasch, and Thwaites in Geol. Soc. Am. Bull., vol. 46, No. 11, Nov. 30, 1935, pp. 1701, etc. See under *Mazomanie ss.*

Hudson Bridge limestone. (In Palo Pinto formation.)

Pennsylvanian: North-central Texas (Wise County).

G. Scott and J. M. Armstrong, 1932 (Univ. Tex. Bull. 3224, p. 21). *Hudson Bridge ls.*—Hard, crystalline ls., dark brown to gray, with local pink splotches and occasionally large masses of chert in top bed. Thickness 7± ft. Outcrops about 3 mi. SE. of Bridgeport, on S. side of West Fork of Trinity River, in E. end of Rebecca Coleman survey, along margin of Trinity River flood plain, and crosses the road 200 yds S. of Hudson Bridge. Is believed to be of lower Palo Pinto age. Probably belongs in Keechi Creek shales. Writers believe it should be included in Palo Pinto fm. Is oldest exposed bed in Wise Co.

†Hudsonian substage (of Wisconsin stage).

Pleistocene (late): Great Lakes region.

M. M. Leighton, 1931 (Jour. Geol., vol. 39, pp. 51-53). *Hudsonian substage (late Wisconsin).*—Includes Port Huron to Des Moines [lobe] and younger moraines. This name was chosen for the last substage because the ice fields about Hudson Bay were approx. equally developed. The early and middle Wisconsin substage is here named *Quebecan.*

M. M. Leighton, 1933 (Sci., vol. 77, p. 168), withdrew *Hudsonian* and replaced it with *Mankato.*

†Hudson River.

See under †*Hudson fm.*

Hueco limestone.

Permian (?): Western Texas and southern New Mexico.

G. B. Richardson, 1904 (Univ. Tex. Min. Surv. Bull. 9, pp. 32–38). *Hueco fm.*—Mainly massive gray fossiliferous nonmag. ls., locally including beds of sh. and ss. Thickness at least 5,000 ft. Represents the Penn. in Diablo Plateau, Franklin, Cornudas, Diablo, Finlay, and Hueco Mtns. Fossils assigned to Penn. by G. H. Girty. Relations to Delaware Mtn fm. (Perm.) not determined, but supposed to be older.

Later studies by many geologists resulted in differentiating the great mass of lss. called *Hueco ls.* in early repts on Franklin and Hueco Mtns into Helms fm. (Miss.) at base, Magdalena ls. (Penn.), and an uncon. overlying series of beds, of Perm. (?) age, to which some geologists restricted the name *Hueco ls.*, and which included Powwow cgl. at base, and near top the Deer Mtn red sh. memb., 150± ft. thick. This restricted definition is that now employed by U. S. Geol. Survey and geologists generally.

Named for exposures in Hueco Mtns, El Paso Co.

Hueconian.

A name that has been applied, provincially, to the time during which Hueco ls. of western Tex. was deposited.

Huerfano formation.

Eocene (lower and middle): Southeastern Colorado (Huerfano County).

See under *Poison Canyon fm.*

†Huerfano series.

See explanation under *Poison Canyon fm.*

Huerto andesite. (Of Potosi volcanic series.)

Miocene: Southwestern Colorado.

E. S. Larsen, 1917 (Colo. Geol. Surv. Bull. 13, pp. 20, 36). *Huerto fm.*—Underlies Piedra fm. and overlies Alboroto fm. in Platoro-Summitville dist. Included in Potosi volcanic series.

W. H. Emmons and E. S. Larsen, 1923 (U. S. G. S. Bull. 718). *Huerto fm.*—A series of andesitic flows and tuff breccias, 0 to 2,000+ ft. thick, which commonly overlies Alboroto fm. rather regularly. Is absent in Creede dist., where the overlying Piedra deposits rest uncon. on the Alboroto. Named for occurrences on Huerto Peak, in S. part of San Cristobal quad., W. of Huerto Creek.

E. S. Larsen, 1935 (U. S. G. S. Bull. 843), changed name to *Huerto andesite.*

Huethawali limestones.

Pennsylvanian (?): Northern Arizona (Grand Canyon).

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, pp. 251, 336). *Huethawali lss.*—Lower 200 ft. of lss. of Aubreyan series, typically exposed in esplanade at head of Bass Canyon, W. of El Tovar. Older than Havasupai sss.

Derivation of name not stated, but probably Huethawali Peak, which is just W. of head of Bass Canyon.

Hughes Creek shale.

Pennsylvanian: Southeastern Nebraska and northeastern Kansas.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 84, 85, 89). *Hughes Creek sh.*—Blue argill. sh., dark shales, and thin lss. Thickness 35 to 50 ft. in Nebr. and NE. Kans. Underlies Long Creek ls. and overlies Houchen Creek ls., all included in Elmdale sh. memb. Named for Hughes Creek, Nemaha Co., Nebr.

R. C. Moore and G. E. Condra, 1932 (Oct. 1932 revised classification chart of Penn. rocks of Nebr. and Kans.), transferred Houchen Creek ls. and underlying Stine sh. to Admire sh., and introduced *Oaks sh.* for the bed overlying Houchen Creek ls. This left Hughes Creek sh. the basal memb. of Elmdale sh. Whether the Oaks sh. is a part of Hughes Creek sh. as originally defined, or a newly discovered unit, was not stated, but it appears that it and the true Americus ls. were included in Hughes Creek sh. of previous repts.

G. E. Condra, 1935. (See under *Long Creek ls.*)

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), transferred this unit to Perm. This change in Perm.-Penn. bdy has not been considered by U. S. Geol. Survey for its publications.

Hughes River flint. (In Conemaugh formation.)

Pennsylvanian: Northwestern West Virginia.

R. V. Hennen, 1911 (W. Va. Geol. Surv. Rept. Wirt, Roane, and Calhoun Counties, p. 258). In Wirt Co. the Brush Creek ls. is replaced by *Hughes River flint*, a reddish-gray and white ledge of chert or flint underlain by dark sh. full of marine shells. Not recognized in Roane Co.

Probably named for occurrence on South Fork of Hughes River.

Huginnin porphyrite.

Pre-Cambrian (Keweenawan): Northern Michigan (Isle Royale).

A. C. Lane, 1898 (Mich. Geol. Surv. vol. 6, pt. 1, pp. 98, 141, 205–206, 207, 208, 209, 212, plates 1, 13). *Huginnin porphyrite* is shown as older than Minong trap.

Belongs in Central Mine group.

Named for exposures in bed of Huginnin Creek, about 50 ft. from shore of Huginnin Cove and about 200 ft. from mouth of the creek, in Isle Royale.

Huishi-Schwatka group.

Triassic to Tertiary: Yukon, Canada.

E. J. Lees, 1934 (Roy. Canadian Inst. Trans., vol. 20, pt. 1, p. 28).

Hulah sandstone member (of Nelagoney formation).

Pennsylvanian: Central northern Oklahoma (Osage County).

M. I. Goldman and H. M. Robinson, 1920 (U. S. G. S. Bull. 686Y, pp. 362, 365). *Hulah ss.*—Hard ss., averaging 4± ft. thick; usually weathers yellow or orange. In places rather fossiliferous—nowhere more so than at type loc., where *Productus* is very abundant. Named for good development at top of small ridge at E. edge of town site of Hulah, near center of SE¼ sec. 5, T. 28 N., R. 12 E. The interval separating it from top of Mission ss. ranges from 40 to 55 ft. and averages 50± ft. In that interval lie Possum ss. (above) and Gap ss. (below).

P. V. Roundy, K. C. Heald, and G. B. Richardson, 1922 (U. S. G. S. Bull. 686Z, pp. 398–399, pl. iv). [See under *Revard ss. memb.*]

The U. S. Geol. Survey at present treats *Hulah ss.* as a memb. of Nelagoney fm.

Hull meta-andesite.

Upper Jurassic: Northern California (Taylorsville region).

J. S. Diller, 1908 (U. S. G. S. Bull. 353). *Hull meta-andesite.*—Greenish to reddish meta-andesite resembling Fant meta-andesite. Prevailing type is greenish and essentially nonporphyritic; occasionally in Little Grizzly Creek region it is decidedly amygdaloidal. Is only partially crystalline. Much of it is in more or less well-defined sheets representing lava flows and tuff. In places is decidedly slaty. It penetrates Mormon ss. and Foreman fm. Most likely erupted near close of Jurassic.

Named for exposures E. of Hull diggings (called Taylor diggings on Taylorsville map).

Hull limestone.

Middle Ordovician (Trenton): Ontario and northern New York.

P. E. Raymond, 1914 (Canada Geol. Surv. Summ. Rept. 1912, p. 348), named these beds, of Trenton age, *Hull fm.*, and used the name in 1916 and 1921 repts of Canada Geol. Surv.

G. M. Kay, 1929 (A. A. P. G. Bull., vol. 13, No. 9, p. 1214), defined *Hull ls.* as middle fm. of Trenton group, as 35 ft. thick, and as underlain by Rockland ls. and overlain by Sherman Fall ls. In 1935 (Geol. Soc. Am. Bull., vol. 46, pp. 227–229) he defined *Hull fm.* as consisting of ls., 97 ft. thick at Lowville, NW. N. Y., and 100 ft. thick at Deer River, N. Y.

Named for exposures at Hull, Quebec.

Hull porphyry.

Pre-Cambrian: Northwestern Iowa.

C. [R.] Keyes, 1914 (Iowa Acad. Sci. Proc., vol. 21, p. 187; Sci., n. s., vol. 40, p. 144). *Hull porphyries*, 475 ft. thick, included in Keweenawan series.

Probably named for Hull, Sioux Co.

Hull agglomerate.

Middle Jurassic: Northern California (Mount Jura).

C. H. Crickmay, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 81, and No. 5, pp. 895–903). ***Hull aggl.*** (also ***Hull fm.***).—Named by J. S. Diller, 1892 [where?]. Mostly massive, coarse, green aggl., with small amounts of red and purple matter; in places a fine red or green tuff. Thickness 700 ft. No fossils. Of late Middle Jurassic age. Occurs at many places on slopes of Mount Jura, especially on S. end of mtn and on SW. slope from 4,500 to 5,000 ft. elev., in lower end of Hinchman Ravine, SE. and NW. slopes of mtn and north ridge.

Humber limestone.

Age (?): Newfoundland.

J. B. Jukes, 1839 (Rept. on geol. Newfoundland, p. 4).

Humber grit series.

Carboniferous: Newfoundland.

T. Landell-Mills and others, 1922 (Geol. Soc. London, Abstr. Proc. No. 1083, p. 53).

Humber member.

Upper Ordovician: Toronto, Canada.

W. A. Parks, 1924 (Geol. Soc. Am. Bull., vol. 35, pp. 103–104).

See quotation under ***Dundas fm.*** Type loc. not stated.

Humber Arm series.

Middle and Upper Ordovician: Newfoundland.

C. Schuchert and C. O. Dunbar, 1934 (Geol. Soc. Am. Mem. 1, pp. 86, 99).

Humber River.

Ordovician: Ontario.

A. F. Foerste, 1924 (Canada Geol. Surv. Mem. 138, p. 52).

Humboldt formation.

Pliocene: Northern Nevada.

C. King, 1878 (U. S. Geol. Expl. 40th Par., vol. 1, pp. 434–443). ***Humboldt group*** (*Pliocene*).—Friable gray, white, and drab sss., marly lss., reddish gravels, marly sands, loosely compacted pumiceous tuff, etc., extending, in patches, from W. base of Wasatch Mtns, Utah, to Humboldt River and Mtns, Nev. There is little doubt that all these exposures of Plio. were deposited in one lake. Fossils rare. The beds along Humboldt River are 300 ft. thick. The Humboldt Valley S. of its bend at Lassen's Meadows cuts a canyon through these Plio. strata for 25± mi. exposing cliffs on either bank from 150 to 300 ft. high.

J. C. Merriam, 1914 (Univ. Calif. Pub. Bull. Dept. Geol., vol. 8, No. 12, p. 278). "***Humboldt Pliocene***" of King's Shoshone Lake of Middle Basin area seems to indicate Mio. at what may be considered type loc. Whether other evidence may indicate that a large portion of deposits mapped as Plio. by King really represents that period remains to be demonstrated. It seems probable a considerable part of these deposits may be Mio.; other portions are probably Pleist.

G. D. Louderback, 1924 (Univ. Calif. Pub. Dept. Geol. Sci., Bull. 15, p. 36). There is no question about fact that best exposures of what King called ***Humboldt Pliocene*** and what Russell has called ***Lake Lahontan*** (***Quaternary***) ***lake beds*** are identical.

The U. S. Geol. Survey still tentatively classifies Humboldt fm. as Plio., although recognizing that deposits of Pleist. and Mio. age may have in places been included in the unit designated by that name. Much more work on this problem is needed.

Humboldt limestone.

Pennsylvanian: Southeastern Kansas.

R. Hay, 1887 (Kans. Acad. Sci. Trans., vol. 10, p. 7). The immense bed [in Wilson Co.] we have called ***Dun ls.*** is probably same as the thick ***Humboldt ls.*** of Neosho Valley. It has same irregularity of structure and apparently same fossils.

Probably named for Humboldt, Allen Co.

Humboldt oolite. (In Kinderhook group.)

Mississippian: Central northern Iowa (Humboldt County).

F. M. Van Tuyl, 1925 (Iowa Geol. Surv. vol. 30, pp. 109–114). *Humboldt oolite.*—In vicinity of towns of Humboldt and Rutland oolitic lss. of Kinderhook age appear at surface over small areas. The largest of these appears in E. bank of West Fork of Des Moines River in SW. part of town of Humboldt. The rock is gray in color, and texture is typically oolitic. [Fossils listed.] Is believed to represent either a more oolitic and more fossiliferous facies of Alden ls. [top of Kinderhook group] or a younger fm. not preserved in Hardin Co. Is probably younger than Gilmore City ls. of Pocahontas Co. [Van Tuyl does not state that he is naming the beds, but he does use the term *Humboldt oolite* in his description, and the name is in index to the volume.]

Humboldt formation.

Pennsylvanian: Southwestern New Mexico (Central mining district).

H. Schmitt, 1933 (Am. Inst. Min. and Met. Engrs. Contr. 39, pp. 2, 13). Upper Magdalena fm. of A. C. Spencer is here divided into *Humboldt fm.* above, 261 ft. thick, and *Mountain Home sh.* below, 130 ft. thick. These names are introduced for convenience of mapping, and will probably be replaced by Geol. Survey in rept. in preparation by A. C. Spencer. The Upper Magdalena fm. rests on blue ls. (Lower Magdalena ls. of Spencer). [His Mountain Home sh. was named for a mine. Derivation of Humboldt not indicated and not apparent.]

Humbug formation.

Mississippian (upper): Central northern Utah (Tintic district and Oquirrh Mountain region).

G. W. Tower, Jr., and G. O. Smith, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, pp. 625–626). *Humbug intercalated series.*—Alternating beds of fossiliferous lss., limy sss. and sandy lss. Overlies Godiva ls. in Tintic dist. Total thickness 250 ft.

G. F. Loughlin, 1919 (U. S. G. S. P. P. 107), applied *Pine Canyon ls.* to the 1,000 ft. of Miss. lss. underlying Humbug fm. in Tintic dist., and reported that G. H. Girty states the fossils from Humbug fm. are upper Miss., and those from Pine Canyon ls. are lower Miss. in all but upper 300 ft., which are tentatively regarded as upper Miss.

J. Gilluly, 1932 (U. S. G. S. P. P. 173, pp. 7, 26–29). *Humbug fm.*—In Stockton and Fairfield quads, Utah, consists of interbedded ls. and lenticular ss. and qtzite in beds as much as 100 ft. thick but ordinarily from 2 to 10 ft. thick. Grades into overlying "Great Blue" ls. and into underlying Deseret ls. ("Lower Blue ls." of Spurr, and of upper Miss. (Brazer) age, according to Girty). Total thickness 650 ft. Lower limit of fm. arbitrarily placed at base of lowest considerable qtzite or ss. in Miss. section. Top limit is also an arbitrary line and is probably not drawn at same horizon in all places. Is same as "Lower Intercalated series" of Spurr.

Named for mine formerly called Humbug mine but now known as Uncle Sam mine.

†Humbug limestone.

A name applied by G. W. Crane (Am. Inst. Min. Engrs. Bull. 106, pp. 2149–2151, 1915) to 378 ft. of nearly pure coarse-grained gray ls., with a few intercalated beds of yellowish-buff aren. ls., said to underlie his Humbug ss., overlie his Tetro ls., and to represent lower part of Humbug fm. of U. S. G. S. of Tintic dist., Utah, but now known to be older than latter fm. and to represent upper part of Pine Canyon ls.

Humbug sandstone.

A name applied by G. W. Crane (Am. Inst. Min. Engrs. Bull. 106, pp. 2149–2151, 1915) to 224 ft. of calc. ss. with a few intercalated beds of aren. ls., said to overlie Humbug ls. and to be only upper part of Humbug fm. of U. S. G. S., but now known to correspond to all of Humbug fm. of U. S. G. S. in Tintic dist., Utah.

Humphrey shale. (In Wabaunsee group.)

Pennsylvanian: Northeastern Kansas, southeastern Nebraska, and southwestern Iowa.

A. J. Smith, 1905 (Kans. Acad. Sci. Trans., vol. 19, p. 151). [See 1905 entry under *Olpe sh.*]

R. C. Moore, 1920 (Kans. Geol. Surv. Bull. 6, pt. 2). [See 1920 entry under *Olpe sh.*]

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 63, 77, etc.). *Humphrey sh. memb. of Wabaunsee fm.* underlies Emporia ls., overlies Burlingame ls., and is here divided into (descending) Auburn sh., 20 ft.; Wakarusa ls., 6 ft.; and Soldier Creek sh., 25± ft. The beds form a natural memb. of about same rank as Willard sh., which overlies Emporia ls. [This is definition adopted by R. C. Moore and G. E. Condra in their Oct. 1932 revised classification chart of Penn. rocks of Nebr. and Kans.]

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8), dropped *Humphrey sh.* and treated Auburn, Wakarusa, and Soldier Creek as fms.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 218, 221). *Humphrey sh.* discarded. Writer concludes type Humphrey does not include Condra's Soldier Creek sh. It included from top of Burlingame ls. up to base of Reading ls.

Named for exposures on Humphrey's ford, 6 mi. SE. of Emporia, Kans.

Humphrey sand.

A subsurface sand, 19 ft. thick, occupying interval btw. 1,567 and 1,586 ft. in L. B. Autman well No. 1, 2 mi. S. of village of Humphrey, Humphrey Twp, Cattaraugus Co., N. Y. (See C. R. Fettke, Geol. Soc. Am. Bull., vol. 44, No. 3, p. 622, 1933.)

Humphrey Creek shale. (In Wabaunsee group.)

A name applied by R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3), to the beds designated *Humphrey sh. memb. of Wabaunsee fm.* by G. E. Condra in 1927. Later in 1932 (revised classification chart of Penn. rocks of Kans. and Nebr. dated Oct. 1932) Moore and Condra designated the unit *Humphrey sh.*

Hundred sandstone. (In Washington formation.)

Permian: Northern West Virginia.

R. V. Hennen, 1909 (W. Va. Geol. Surv. Rept. Marshall, Wetzel and Tyler Counties, p. 214). *Hundred ss.*—Massive ss. in places, but outside of Church and Clay dists., Wetzel Co., is generally red sh. and sandy beds. Thickness 30 ft. Lies 5 ft. below Upper Washington ls. and 2 to 5 ft. above Hundred coal. Has been called Dunkard ss. by Grimsley. Named for village of Hundred, Wetzel Co.

Hundred-foot sand.

Drillers' term for a sand, probably of late Catskill age, in western Pa. Lies lower than Murrysville sand and higher than Nineveh 30-foot sand.

Hunker series.

Age (?): Canada.

R. G. McConnell, 1900 (Canada Geol. Surv. Rept. on Klondike gold field, pp. 8–9).

Hunker Creek series.

Cambrian: Canada.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 198).

Hunt sandstone. (In Bluestone formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 293, 317). *Hunt ss.*—Green massive or shaly ss., 10 to 20 ft. thick, lying a few ft. below Hunt coal ("the uppermost coal in Bluestone group" and exposed just W. of Hunt School, Mercer Co.), and overlying Hunt sh. All members of Bluestone group [Bluestone fm.], and all exposed in Stony Gap section, Mercer Co., on N. side of Big Ridge, about ¾ mi. S. of Belcher School, where the ss. is 15 ft. thick.

Hunt shale. (In Bluestone formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 293, 317). *Hunt sh.*—Red and variegated, 35 ft. thick. Underlies Hunt ss. and overlies Bratton ss. All members of Bluestone group [Bluestone fm.]. [See additional under *Hunt ss.*]

Hunt sand.

A subsurface sand (of Chester Miss. age) in Ind., that has been correlated with Sample ss. memb. of Gasper oolite.

Hunter Canyon formation. (In Mesaverde group.)

Upper Cretaceous: Western Colorado (Book Cliffs coal field).

C. E. Erdmann, 1934 (U. S. G. S. Bull. 851, pp. 22, 33). *Hunter Canyon fm.*—Assemblage of massive brown, buff, and gray cliff-making fluviatile sss. and gray clay sh.; about 60 percent ss. Thin coals near top. Thickness 375 to 1,400 ft. Top fm. of Mesaverde group. Uncon. underlies Eocene (?) deposits and overlies Mount Garfield fm. Named for Hunter Canyon.

Hunters Island iron-bearing series.

Pre-Cambrian: Northeastern Minnesota (Vermilion district).

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, p. 118). The rocks of E. extension of N. arm of Vermilion range are known locally as *Hunters Island iron-bearing series.* [The map of Vermilion dist. in Mon. 52 (pl. 6) shows the rocks of the area designated as Hunters Island as consisting of Ely greenstone, Archean granite, Ogishke cgl., Agawa fm., and Knife Lake sl.]

Huntersville chert. (In Oriskany group.)

Lower Devonian: Southeastern West Virginia (Pocahontas and Greenbrier Counties).

P. H. Price, 1929 (W. Va. Geol. Surv. Rept. Pocahontas Co., pp. 106, 108, 233, 236–237, 397, etc.). *Huntersville chert.*—Yellow, gray, to dark, sandy chert, 30 to 65 ft. thick, forming top div. of Oriskany series in Pocahontas and Greenbrier Counties, to which counties it appears to be confined in W. Va. Contains sparse marine fauna of Oriskany age. Directly underlies Marcellus sh. and directly overlies Ridgeley ss. Type loc. in vicinity of Huntersville [SE. part of Pocahontas Co.], where it has been quarried for road material. The Shriver chert, which underlies Ridgeley ss., is not present in county.

Hunter Valley.

Probably lower Mesozoic: Sierra Nevada, California.

N. L. Taliaferro, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 149). *Hunter Valley cherts and tuffs,* 1,500 ft. thick, included in Tuolumne group. Underlie Penyon Blanco aggls. and overlie pillow basalts.

Huntingdon stone.

Name listed in U. S. G. S. Bull. 191, and credited to E. T. Cox, 1879 (Ind. Geol. Surv. 8th, 9th, and 10th Ann. Repts, for 1876, 1877, 1878, p. 66). On p. cited Cox simply mentioned "the celebrated Huntington stone," which is quarried for lime at Huntington (the correct spelling), Huntington Co., Ind.

Huntingdon formation.

Eocene: Southern British Columbia and central northern Washington.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, map 17). *Huntingdon fm.*—Ss., cgls., sh., and thin coal beds. [Mapped at and to N. of Huntingdon, B. C., and in Wash.]

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 519). *Huntingdon fm.*—Heavy masses of medium-grained gray-tinted cgl. alternating with ss. and sh.; cgl. most abundant at base. Thickness 1,000 ft. Occurs on Sumas Mtn, N. of Huntingdon R. R. Station, B. C. Eocene fossils. Is uncon. on Chilliwack series, also on Sumas diorite and Sumas granite.

Huntington series.

Triassic (?): Northeastern Oregon (Blue Mountains).

W. Lindgren, 1901 (U. S. G. S. 22d Ann. Rept., pt. 2, p. 579). *Huntington series.*—Lss., calc. shales, and clay slates, with some gyp. and red and green volcanic tuffs. Thickness probably several thousand ft. Rests on old volcanic rocks, largely old rhyolites and tuffs. Overlain by marine Triassic. Occurs in vicinity of Huntington. Indeterminate fossils. Regarded as Triassic.

Huntington dolomite.

Silurian (Niagaran): Northeastern Indiana.

E. M. Kindle, 1904 (Ind. Dept. Geol. and Nat. Res. 28th Ann. Rept., p. 408). *Huntington ls.*—Light-gray or cream-colored granular dolomitic ls. of saccharoidal texture, 150 to 200± ft. thick; about 80 ft. exposed at Huntington. Contains Guelph fauna, a younger fauna than Noblesville dol., which contains Lockport fossils, and also differs decidedly in physical appearance from the Huntington. Both belong to the Niagara. It will be convenient to designate the beds exposed in the Huntington quarries as *Huntington ls.* The same ls. is also exposed in the lime quarries NE. of Delphi. At one place near Delphi it is uncon. overlain by beds of Hamilton age.

E. R. Cumings and R. R. Shrock, 1928 (Ind. Dept. Cons., Div. Geol., Pub. 75, pp. 53, 94–113). *Huntington dol.*—The name *Huntington ls.* was proposed by Kindle for "the beds exposed in the Huntington quarries." Since several distinct fms., complicated by a great coral reef plexus, are now exposed in the quarries at Huntington, the authors have been forced to redefine the type section of Huntington dol. (ls.). As redefined it consists of the exposures of yellowish to grayish saccharoidal dol. along the dredged rock channel of Little River, from NE. cor. of SW. cor. of NE¼ sec. 13, T. 28 N., R. 10 E., eastward nearly to W. line of sec. 8, T. 28 N., R. 10 E., where a cherty fm., here named *New Corydon ls.*, comes in above the Huntington dol. The Huntington is typically a massive to slabby evenly bedded yellowish, gray, or pinkish granular dol. of saccharoidal texture. At 2 localities, however (certain exposures at Huntington and near Georgetown), the fm. is represented by nearly pure pink, crystalline ls. Exact thickness of fm. not known. In quarry at Ridgeville 70 ft. are exposed; 90 ft. in bluff on S. side of Wabash River 3 mi. W. of Logansport; at least 100 ft. exposed in quarries at Delphi; and our meager data at Huntington indicate thickness of 150± ft. We feel certain the fm. thickens from Monon northwestward, but how much we are not prepared to say. Fossils listed. Rests on Liston Creek ls., probably conformably. Grades upward into New Corydon ls. It is practically certain it extends beneath the drift to Chicago dist.

Named for Huntington, Huntington Co.

A. F. Foerste, 1935 (Denison Univ. Bull., Jour. Sci. Lab., vol. 30, p. 159). *Huntington fm.* has not been identified S. of N. half of Randolph Co.

Hunton limestone.

Silurian and Devonian: Southeastern Oklahoma.

J. A. Taff, 1902 (U. S. G. S. Atoka folio, No. 79). *Hunton ls.*—Nearly pure white ls. and limy marls. At base variable beds of white oolite, in parts of which coarse and fine spherical granules appear as if originally sorted and stratified. Elsewhere spherules ranging in size from that of a small pea to fine grains appear intermingled; in places the oolite is silicified. Succeeding the oolite are bluish and cream-colored granular and fine-textured lss. and marly beds attaining thickness of 100± ft.; many of these beds are crystalline and hard, while others are composed largely of comminuted shell fragments. Near top are marly beds which carry abundance of well-preserved fossils. Uppermost 50 ft. of fm. is for most part hard and thin-bedded. Many nodular cherty concretions and numerous fossils, some of which are beautifully silicified, occur in these beds. Overlies Sylvan sh. and underlies Woodford chert.

J. A. Taff, 1903 (U. S. G. S. Tishomingo folio, No. 98). *Hunton ls.*, 0 to 200 ft. thick, is divisible into 3 members (descending): (1) Crystalline and in part cherty bluish to white ls. with occasional thin marly strata, in places overlain by several ft. of very cherty ls.; (2) 100 ft. of white or cream-colored and occasionally pinkish rather soft ls. interstratified with more friable marly lime and, rarely, calc. clay, with a few ft. of marly white ls. at top; (3) whitish massive crystalline ls., which in places includes a bed of oolite at or near base and thin-bedded compact ls. at top; thickness few ft. to 25± ft. Upper memb. contains Oriskany and perhaps

Onondaga fossils; middle memb. contains Helderberg fossils; and basal memb. contains Niagara fossils in thin-bedded compact ls. at top and Clinton fossils in underlying beds.

C. A. Reeds, 1911 (Am. Jour. Sci., 4th, vol. 32, pp. 256–268). Hunton ls. of Taff is here divided into 4 fms. in Arbuckle Mtns (descending): (1) Bois d'Arc ls., 0 to 90 ft., of Becraft (Oriskany) age, according to C. Schuchert (1922) and E. O. Ulrich (1927); (2) Haragan sh., 0 to 166 ft., of New Scotland age; (3) Henryhouse sh., 0 to 223 ft., of Niagaran age; and (4) Chimneyhill ls., 0 to 53 ft., of Alexandrian age. Overlies Sylvan sh. with uncon. The Bois d'Arc ls. corresponds to upper Hunton of Taff; the Haragan and Henryhouse correspond to middle Hunton of Taff; and the Chimneyhill corresponds to lower Hunton of Taff.

C. N. Gould, 1927 (Univ. Okla. Bull., Proc. Okla. Acad. Sci., vol. 6, pt. 2, p. 235). *Hunton* will probably remain as a group name, for purposes of mapping.

Named for exposures near former hamlet of Hunton, SW. part of Coal Co.

†Huntsville.

Mississippian: Northeastern Alabama.

E. A. Smith, 1892 (Sketch of geology of Ala., Birmingham, Ala., Roberts & Son, pam. of 36 pp.). *St. Louis or Huntsville.*—A subdivision of the Sub-Carbf. in Tennessee River Valley. More calc. than beds below. Is=upper Siliceous of Safford and St. Louis group of western geologists. Overlies Lauderdale (Keokuk) and underlies several hundred ft. of Sub-Carbf. lss. [*Huntsville* used in table only.]

The Mississippian rocks in vicinity of Huntsville, Ala., consist of (descending) Bangor ls. restricted, Hartselle ss., Golconda fm., Gasper oolite, Ste. Genevieve ls., and St. Louis ls. (See C. Butts, Ala. Geol. Surv. Spec. Rept. No. 14, 1926, pl. 49, sec. 14.)

Named for exposures at Huntsville, Madison Co.

†Huron group.

Upper Devonian and Mississippian: Michigan (Lower Peninsula).

A. Winchell, 1861 (Mich. Geol. Surv. 1st Bien. Rept. Prog., pp. 71, 139). *Huron group.*—Consists of (descending): (1) Fine bluish gritstones (Pt. aux Barques), 14 ft.; (2) shales, lss., and flagstones, 18 ft. [180 in Am. Jour. Sci., 2d, vol. 33, pp. 353–354]; (3) green sh., 10 ft.; (4) black bituminous sh., 20 ft. Underlies Marshall group and overlies Hamilton group of lss. and shales. Thickness of Huron group 224 ft. Assigned to Portage epoch.

A. Winchell, 1865 (Am. Jour. Sci., 2d, vol. 39, pp. 350–353), gave thickness of *Huron group* as 600 to 700 ft.

A. Winchell, 1871 (Am. Phil. Soc. Proc., vol. 11, pp. 73–82). Huron gritstones, 15 ft. thick, belong to Marshall group.

Includes Coldwater sh., Berea ss., and Antrim sh.

Probably named for outcrops along Lake Huron in Mich.

Huron shale.

Upper Devonian: Northern Ohio.

J. S. Newberry, 1870 (Ohio Geol. Surv. Rept. Prog. 1869, p. 18). *Huron sh.*—Black bituminous sh., 350 ft. thick, designated by former Geological Board as "Black Slate." Overlies Hamilton ls. and underlies Dev. bluish or greenish Erie sh. Extends from lake shore at mouth of Huron River S. to mouth of Scioto.

E. M. Kindle, 1912 (Am. Jour. Sci., 4th, vol. 34, pp. 187–213). Typical *Huron sh.* of Huron River section and to S. consists of black and blue shales characterized by spherical concretions, and is overlain by Cleveland sh. (black and blue shales characterized by cone-in-cone structure) and underlain by Olentangy sh. In Cleveland region the typical Cleveland sh. (black) is underlain by Chagrin sh. (gray, with much ss. in upper part), which in turn rests on Huron sh. (black and gray). The Chagrin sh. of Cleveland section represents lower part of Cleveland sh. and upper part of Huron sh. of Huron River section.

H. P. Cushing, 1931 (U. S. G. S. Bull. 818, on Cleveland, Berea, and Euclid quads), defined Cleveland sh. as resting uncon. on Chagrin sh. (described as containing concretions in lower part and as resting on black shales of Portage age). The relations of Huron sh. to Cleveland and Chagrin shales are still under investigation.

Named for exposures on Huron River, northern Ohio (Huron and Erie Counties).

Huron gritstone.

Mississippian: Michigan (Saginaw Bay region).

A. Winchell, 1871 (Am. Phil. Soc. Proc., vol. 11, pp. 73–82). *Huron gritstones,* 15 ft. thick, belong to Marshall group.

G. P. Grimsley, 1904 (Mich. Geol. Surv. vol. 9, pt. 2, p. 79), included *Huron grindstone* in top of Coldwater sh.

†Huron group.

Mississippian: Indiana.

T. C. Hopkins, 1902 (Geol. Soc. Am. Bull., vol. 13, pp. 519–520). *Huron group.*—Alternating beds of ss. and ls., known in some older repts as *Chester,* forming topmost part of Lower Carbf. [Miss.] in southern and west-central Ind. Underlain by Mitchell ls. and overlain by Mansfield ss. [Penn.].

Replaced by Chester group, older name.

Named for Huron, Lawrence Co.

Huron Bay slates.

Age (?): Northeastern Michigan.

T. B. Brooks (Mich. Geol. Surv. vol. 1, pt. 1, 1873, p. 155) stated: The *Huron Bay slates* with associated rocks may be regarded as belonging to L'Anse series, although more than 10 mi. away in NE. direction.

Huronian series (or **epoch**).

As used for many years, this term was defined as the lower provincial series of the system of pre-Camb. rocks in Great Lakes region known as "Algonkian system," and the time covered by their formation. The U. S. Geol. Survey uses the name in the broad sense, i. e., including upper, middle, and lower Huronian. For definition see U. S. G. S. Bull. 769, pp. 105–108. (See also under †*Animikie group.*) The U. S. Geol. Survey, however, no longer uses "Algonkian system," tentatively excludes Knife Lake series from the Huronian (in which it was formerly included), and classifies the Huronian as pre-Camb.

Huronic period.

C. [R.] Keyes, 1914 (Iowa Acad. Sci. Proc., vol. 21, p. 201). Time btw. Algomic period above and Laurencic period below.

Represents earliest part of Huronian epoch of U. S. Geol. Survey.

Hurrah slate.

Post-Ordovician (?): Northwestern Alaska (Seward Peninsula).

P. S. Smith, 1910 (U. S. G. S. Bull. 433, pp. 50, 59+, maps). *Hurrah sl.*—Carbonaceous qtzites and black sl., 200 to 800± ft. thick. In places basal few ft. to 50 ft. is black nondolomitic ls. Overlies Sowik ls. and underlies Puckmummie schist. Most continuous exposures are on lower 2 or 3 mi. of Big Hurrah Creek and in shafts and other mine developments of Big Hurrah mine, located at junction of Big and Little Hurrah Creeks. No fossils. Assigned to post-Ord. (?).

Hurry-up sand.

A subsurface sand in Conemaugh fm. (Penn.) of western Pa. that probably corresponds to Mahoning ss. memb. The name has also been applied to sands that probably correspond to Saltsburg and Mahoning ss. members combined. In W. Va. the name has been applied to a much younger sand that is believed to correspond to Waynesburg ss. memb. of Washington fm. (Perm.). In Palo Pinto Co., Tex., the name has been applied to a thick subsurface Penn. sand in base of Millsap Lake fm., lying uncon. on Smithwick sh.

Hushpuckney shale.

Pennsylvanian: Eastern Kansas and northwestern Missouri.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 85, 90, 97). [See under *Swope fm.*] Named by Newell.

J. M. Jewett, 1932 (pp. 99, 101, 103 of book cited above). *Hushpuckney sh.* will be proposed by Newell to include sh. underlying Bethany Falls ls. and overlying Middle Creek ls., all members of Swope fm. It is a black sh. a few ft. thick. In Kans. it is coexistent with Middle Creek ls.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pp. 26–27). *Hushpuckney sh.*—Middle memb. of Swope ls. Here named for a creek S. of Fontana, Miami Co., Kans. Typically shown at a R. R. cut, center N. side sec. 13, T. 19 S., R. 23 E. Consists typically of 2 parts, upper half gray argill. sh. and lower half black platy sh. Locally a thin layer of argill. greenish sh. underlies the black sh.; and less commonly the upper part consists of carbonaceous blocky sh. Thickness 4½ to 5½ ft. Overlies Middle Creek ls. memb. and underlies Bethany Falls ls. memb.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Hutchison salt bed. (In Sumner group.)

Permian: Central Kansas.

I. Perrine, 1918 (A. A. P. G. Bull., vol. 2, pp. 73–90). *Hutchison salt beds* belong in upper part of Marion fm.

N. W. Bass, 1929 (Kans. Geol. Surv. Bull. 12). *Hutchison salt bed,* 25± ft. thick, lies in Wellington fm. as here redefined, about 580 ft. below top and 412± ft. above top of Herington ls.

Probably named for Hutchison, Reno Co., central Kans.

Hutchison limestones.

A term applied by C. [R.] Keyes to 25 ft. of Dev. ls. in Iowa that belongs to top of Cedar Valley ls. (See Pan-Am. Geol., vol. 56, pp. 318, 348, 1931. It occupies same interval as that to which name *Lucas ls.* had already been applied, and thickness corresponds to that of latter ls.)

Hutshi group.

Tertiary: Yukon Territory.

D. D. Cairnes, 1910 (Canada Geol. Surv. Mem. 5, p. 38).

Hyampom lake beds.

Miocene: Northwestern California (Trinity County).

J. S. Diller, 1902 (U. S. G. S. Bull. 196, pp. 41–43). Near mouth of canyon [where Hay Fork enters] the coal-bearing series, which for convenience we will call *Hyampom beds,* has an exposed thickness of 250 ft., the upper 100 ft. being cgl. and the lower portion sandy, containing here and there concretions. Some of sss. are rather hard, strike N. 85° E., with a dip of 30° SE., and contain coaly beds. Near base of series is 25 ft. of cgl., and bottom part, about 30 ft. thick, is not exposed. Limited to Hyampom Valley, 3 or 4 mi. long and of less breadth. Rests uncon. on underlying beds. Flora identified by F. H. Knowlton as upper Mio.

Hyco quartz porphyry.

Pre-Cambrian: South-central Virginia and central northern North Carolina (Person and Granville Counties).

F. B. Laney, 1917 (Va. Geol. Surv. Bull. 14, pp. 15, 19, 20–23, and map). The acid volcanics of Virgilina dist. originally were rhyolite or quartz porphyry and rhyolitic tuffs, but in their present condition are largely sericite schists which may or may not show more than remnants of their original minerals and texture. In this rept these rocks are described under name *Hyco quartz porphyry.* The fm. consists largely of quartz-sericite schist, which represents a mashed and otherwise metamorphosed quartz porphyry or rhyolite, and which was tuffaceous in certain areas. It appears to be oldest of the volcanic rocks, at least its areal distribution indicates that it underlies the other volcanics. Assigned to Ord. (?). Underlies Aaron sl. In SE. part of Virgilina dist. its place is apparently taken by Goshen schist.

A. I. Jonas, 1917 (Va. Geol. Surv. prel. ed. of geol. map of Va.). [Under the block of pre-Camb. extrusive rocks younger than Glenarm series and designated as "aporhyolite" is statement: "In Virgilina area called Hyco quartz porphyry and tuffaceous facies is called Goshen schist."]

Named for Hyco River, Halifax Co., Va., along which occur its largest and most typical exposures.

Hyde granite.

Pre-Cambrian: Northwestern New York (Hammond quadrangle).

A. F. Buddington, 1934 (N. Y. State Mus. Bull. 296, pp. 85, 86–88). ***Hyde granite*** forms area SW. of Hickory Lake in bend btw. Hickory Creek. Is fine-grained pink rock with marked gneissic structure. Intrudes Grenville series. [Appears, from pp. 120–122 and 136, to be named for Hyde School.]

Hyde Manor limestone.

Middle Ordovician (Trenton): Southwestern Vermont (Rutland County).

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 368–9). ***Hyde Manor ls.***—Of decided blue color. Consists of massive beds interlayered with thin slabby strata. Considerable schistosity is evident. The fm. is strongly folded. Fossils rather common; good brachiopod fauna of Trenton age. Occurs near N. end of Taconic Range. Underlies Hortonville sl. [Thickness of fm. not given.]

Named for exposures at well-known summer resort, called Hyde Manor, S. of Sudbury, Brandon quad.

Hyder quartz monzonite.

Jurassic or Cretaceous: Southeastern Alaska (Hyder district).

A. F. Buddington, 1929 (U. S. G. S. Bull. 807, pp. 29–39, 58–59, maps, etc.). ***Hyder quartz monzonite.***—The quartz monzonite composing Hyder batholith. Included in Coast Range intrusives. Named for exposures at Hyder.

†Hydraulic limestone.

Descriptive term applied by Swallow to a ls. in middle of Cherokee sh. of Mo. and Kans. that is now known as *Ardmore ls. memb.* The term has also been applied, in a titular sense, to lss. of different ages in other parts of the country, which are used in making cements.

Hygiene sandstone member (of Pierre shale).

Upper Cretaceous: Central northern Colorado (Boulder district and northward).

N. M. Fenneman, 1905 (U. S. G. S. Bull. 265). *Hygiene ss. memb. of Pierre fm.*—Thick-bedded, frequently cross-bedded ss.; much of it dark greenish gray and gritty, remainder light gray; the whole calc. when fresh. Near Boulder it is very thin; to N. it is 250 ft. thick. In places it consists of 2 sss. separated by a sh. parting that thickens to 200 or 300 ft. The upper div. of Hygiene ss. is characterized by large calc. concretions several ft. in diam. The Hygiene lies 1,000 to 3,000 ft. above base of Pierre fm. Typically developed in ridge which passes within 1½ mi. of village of Hygiene [Boulder Co.]. It crosses Little Thompson Creek on Culver ranch, 6 mi. SW. of Berthoud, where a seepage of oil has long been known. At its outcrop W. of Berthoud it is several hundred ft. thick. [As thus defined includes Terry ss. memb.]

M. W. Ball, 1924 (A. A. P. G. Bull., vol. 8, pp. 81–87). The name Hygiene ss. has heretofore been misapplied to a series of sands occurring through strat. interval of 1,700 ft. or more. The assumption seems to have been that only one ss. is present in the Pierre, and every ss. outcrop was called Hygiene and connected up in a single line across the map. A. T. Schwenneson, E. W. Krampert, and C. H. Henley [unpublished repts] restricted the name to basal ss. of the series, since this seems most likely to have been the ss. noted near Hygiene, and the term is so used here. The other sss. have been named and mapped by Schwenneson, Krampert, and Henley [unpublished], in descending order: ***Richard ss.***, Larimer ss., Rocky Ridge ss., and Terry ss. The ***Hygiene ss.*** as restricted is 100 ft. thick, and lies 383 ft. below Terry ss.

K. F. Mather, J. Gilluly, and R. G. Lusk, 1928 (U. S. G. S. Bull. 796B). ***Hygiene ss. memb. of Pierre sh.***—As now restricted is 0 to 100 ft. thick, lies 200 to 400 ft. below Terry ss. and 2,400 to 3,100 ft. above Niobrara fm. It is not distinguished, either lithologically or faunally, with certainty from the other ss. members of the Pierre.

Hyndman formation.

Pre-Cambrian: Central Idaho (Hailey region).

L. G. Westgate and C. P. Ross, 1930 (U. S. G. S. Bull. 814, pp. 10–17). *Hyndman fm.*—Massive qtzite with a green hornfels memb., 600 ft. thick, in upper part, and a schist memb., 1,100 ft. thick, in lower part. Total thickness of fm.

6,600± ft. Is oldest sed. fm. in Wood River region and probably of Algonkian age. Underlies East Fork fm. (also of Algonkian age). Excellently exposed in Hyndman Peak and in cirques at its southern base, in Hailey quad.

Hyneman sand.

A subsurface sand of Chester (Miss.) age in Ind. that has been correlated with Cypress ss.

†Hypozoic era and †Hypozoic series.

Names that have been applied to all pre-Camb. stratified rocks and the time covered by their formation. For definition see U. S. G. S. Bull. 769, pp. 12, 21, 30. Included in Proterozoic era of U. S. Geol. Survey.

Iaeger sandstones. (In New River formation.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, pp. 186–191), named, in descending order, the following subdivisions in upper part of "Middle Pottsville series or New River group," beneath Panther cgl.: (1) Iaeger B coal; (2) *Upper Iaeger ss.* (massive to current-bedded, medium-grained, grayish white to brown, cliff-making, 30 to 50 ft. thick); (3) interval 60 to 70 ft.; (4) Iaeger A coal; (5) *Upper Iaeger sh.* (dark gray, argill., laminated, with plant fossils at base, 5 to 85 ft. thick); (6) Iaeger coal; (7) *Middle Iaeger ss.* (massive, medium-grained to coarse, grayish white to light gray, 30 to 40 ft. thick); (8) Lower Iaeger coal; (9) fire clay and sh. 0 to 5 ft.; (10) *Lower Iaeger ss.* (massive to flaggy, medium-grained, micaceous, gray to brown, 20 to 30 ft. thick); (11) *Lower Iaeger sh.* (dark gray, argill., laminated, 20 to 40 ft. thick); (12) Harvey cgl. The Iaeger members are named for their occurrence at Iaeger, McDowell Co.

Iaeger shales.

See under *Iaeger sandstones.*

Iatan limestone. (In Douglas group, Kansas.)

Iatan limestone member (of Douglas formation, Missouri).

Pennsylvanian: Southwestern Iowa, northwestern Missouri, eastern Kansas, and southeastern Nebraska.

C. R. Keyes, 1899 (Am. Geol., vol 23, p. 306). *Iatan ls.*—Middle memb. of Lawrence sh. [broad and abandoned usage of Lawrence] in Mo. and eastern Kans. Underlies Andrew sh. memb. of Lawrence and overlies Weston sh. memb.

H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines vol. 13), divided Douglas fm. of NW. Mo. and SW. Iowa into (descending) Oread ls. memb., Lawrence sh. memb., Iatan ls. memb., and Weston sh. memb. This classification prevailed for many years. For recent innovations, see under *Weston sh. memb.*, also Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Named for exposures at Iatan, Platte Co., Mo.

Iberville formation.

Ordovician: Quebec.

T. H. Clark, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 1, p. 5).

Ice River formation.

Age (?): British Columbia.

L. D. Burling, 1912 (Wash. Acad. Sci. Jour., vol. 2, p. 357).

Ice River intrusive complex.

Post-Cretaceous: Alberta.

J. A. Allan, 1913 (12th Int. Geol. Cong. Guidebook 8, p. 185).

Iconium member (of Wellington formation).

Permian: Central northern Oklahoma (Logan and Lincoln Counties).

J. M. Patterson, 1933 (A. A. P. G. Bull., vol. 17, No. 3, pp. 243, 249, etc.). *Iconium memb.*—Upper or shaly part of Wellington fm. in Logan and Lincoln Counties, occurring btw. top of Fallis memb. of Wellington and base of Garber ss. Thickness

470± ft. Lower 270 ft. is 65± percent. sh., with ss. and dolomitic beds well spaced. Lower 200 ft. contains more ss. beds with the sh. beds. Grades into overlying Garber, top of Iconium being placed at base of massive ss. of Garber. The shales of Iconium are red, blocky, nonlaminated, and contain calc. or dolomitic material in form of septarian concretions and veined geodes. The sss. are friable, reddish brown to gray, micaceous, cross bedded, and relatively fine grained. Fossil wood. A few thin calc. or dolomitic beds, usually red, in lower part. Two important ss. beds in upper part are here named *Evansville ss. bed* and *Lowrie ss. bed.* Named for little town of Iconium, near S. quarter cor. of sec. 10, T. 16 N., R. 1 E., Logan Co. The town is 80± ft. above base of Iconium memb.

Idaho formation.

Pliocene and Pleistocene: Southeastern Oregon and western and southern Idaho.

E. D. Cope, 1884 (Phila. Acad. Nat. Sci. Proc. 1883, vol. 35, p. 135; fauna described on pp. 153–166). Still another late Tert. lake existed in eastern Oreg. and western and southern Idaho. No body of water represents it at present time, and the remains of fishes found in its sediments belong to species different from those of the Oregon basin, both recent and extinct. It is to be supposed that this lake was separate from all of the others (Lahontan, Bonneville, and Klamath), and of earlier age, although one of the Plio. series. It may be called *Lake Idaho*, and its sediment the *Idaho fm.*

W. Lindgren, 1898 (U. S. G. S. 18th Ann. Rept., pt. 3, pp. 632–634). [See under *Payette fm.*]

W. Lindgren, 1900 (U. S. G. S. 20th Ann. Rept., pt. 3, pp. 93–94, 97–98). [See under *Payette fm.*]

V. R. D. Kirkham, 1931 (Jour. Geol., vol. 39, No. 3, pp. 198–201, 235–239). Writer presents evidence to support following ideas: (1) A series of terrestrial deposits and lake beds exists in Columbia River basalt, 600 or more ft. below its upper surface, which present a characteristic lithology and a flora of Mio. age. (2) A series of terrestrial deposits and lake beds, in places several thousand ft. thick, overlies Columbia River basalt and Owyhee rhyolite and presents a characteristic lithology and a flora and fauna of Plio. and later age. According to original definitions of *Payette fm.*, none of upper series may be included in it, but the series underlying the basalt and rhyolite can be shown to be true *Payette.* According to original definition of *Idaho fm.*, all of upper series should be included in it. For convenience of discussion, *basin beds* will refer to all lake beds and terrestrial sediments overlying the upper flow of Columbia River basalt or the rhyolite, and *intermontane beds* will refer to all lake beds and terrestrial sediments underlying several hundred ft. of Columbia River basalt or rhyolite. These in no case occur in the plains area. The basin beds (Idaho fm.) overlie Columbia River lava on both N. edge and S. border of the plains without marked angular uncon. but with considerable discon. *Idaho fm.* is here redefined and applied to all *basin beds* in mapped area (Canyon, Gem, Payette, and parts of Ada, Adams, Owyhee, and Washington Counties, Idaho) and in contiguous areas in Idaho and Oreg., and *Payette fm.* is applied to all *intermontane beds* in this area. Idaho fm. consists of lake beds and terrestrial beds which dip toward the downwarp axis and attain a thickness of several thousand ft. in middle of basin. It includes all lake beds overlying Columbia River basalt and Owyhee rhyolite but excludes the Pleist, Upper Mesa and Lower Mesa fms. and alluvium. Interbedded with the upper members is Snake River basalt. The basal beds and upper beds are predominantly sandy, but by far the greater thickness of fm. is light-colored sh. A few beds of volcanic ash and diatomite are conspicuous. The basal sss. are in places well cemented and resistant, but on whole the fm. is poorly consolidated. Most of fm. is well stratified. Plant fossils point to Plio. age. Invertebrate and vertebrate fossils indicate Plio. and Pleist. age. The "Payette fm." mentioned by Washburne is included in Idaho fm. as here defined. Writer does not conceive of a great Lake Payette and a smaller Lake Idaho, as do Lindgren, Russell, Washburne, and others, but visualizes temporary shallow lakes of varying sizes from time to time alternating with intervals of desiccation. Bryan and Buwalda admitted small lakes but also strongly urged flood plains, deltas, and alluvial fans. Idaho fm. includes Poison Creek fm. of Buwalda and *Emmett fm.*, a name proposed by writer in June 1928, for a part of what was originally called *Idaho fm.*

The U. S. Geol. Survey classifies Idaho fm. as Plio. and Pleist., and Payette fm. as Mio.

†Idaho granite.

A term that has been loosely applied to the granitic rocks of Idaho batholith of Idaho.

Idaho Springs formation.

Pre-Cambrian: Central northern Colorado (Georgetown quadrangle).

S. H. Ball, 1906 (Am. Jour. Sci., 4th, vol. 21, p. 374). *Idaho Springs fm.*—Biotite-sillimanite schists, biotite schist, and quartz gneiss, with lenses of silicate rocks. The schists and quartz gneiss are interbedded with and grade into one another, while the lime silicate rocks, although interbedded with the others, appear only to grade into the quartz gneiss. Probably of sed. origin. Oldest memb. of pre-Camb. series in Georgetown quad., and forms the network into which the other fms. were injected. Typically exposed in hills surrounding Idaho Springs.

On 1935 geol. map of Colo. this fm. was assigned to Gunnison River series, which includes all of oldest exposed rocks in Colo.

Idalia clay.

Tertiary: Southeastern Missouri.

C. F. Marbut, 1902 (Mo. Univ. Studies, vol. 1, No. 3, pp. 18, 21, 32). *Idalia clay.*—Black or dark and gray to drab clay sh., 60 to 80 ft. thick, found only in Crowley ridge and usually only in lower part. Overlain uncon. by Benton sands and underlain uncon. by Paleozoic. Assigned to Tert.

Named for exposures at Idalia, Stoddard Co.

Ideal gypsum.

See under *Childress dol. and gyp.*

Idolo beds.

Eocene: Mexico.

E. T. Dumble and E. R. Applin, 1924 (Pan-Am. Geol., vol. 41, p. 341).

Ignacio quartzite.

Upper Cambrian: Southwestern Colorado.

W. Cross and A. C. Spencer, 1899 (U. S. G. S. La Plata folio, No. 60, p. 8). [See 1st entry under *Hermosa fm.*]

W. Cross, 1901 (U. S. G. S. Bull. 182, p. 35). Earliest Paleozoic fm. of Silverton quad., Colo., is a qtzite with some sandy shales 100 to 200 ft. thick, which is seen on W. side of Animas River from the monzonite contact to Molas Lake, and imperfectly on E. side of the Animas. This qtzite has been traced down the Animas to below Rockwood, and is called *Ignacio qtzite,* from its characteristic development on the bench where lake of that name is situated. A southerly dip carries this qtzite onto S. slope of Needle Mtns, where a few indistinct fossils indicate its Camb. age. The rather shaly beds, often calc. [Elbert fm.], succeeding the qtzite have not yielded fossils. If there are any Sil. strata in this section they are probably represented by these calc. shales and sss. The Ignacio qtzite overlies Algonkian qtzites and slates.

Ignek formation.

Jurassic (?): Northern Alaska (Canning River region).

E. D. Leffingwell, 1919 (U. S. G. S. P. P. 109, pp. 103, 120, map). *Ignek fm.*—Black sh. and subordinate ss., coal, or red beds. Thickness 2,500± ft. Youngest Mesozoic fm. in region. Probably overlies Kingak sh. (Lower? Jurassic). Type loc. is on S. side of Red Hill, in Ignek Valley, at W. end of Sadlerochit Mtns. Occurs at both ends of Sadlerochit Mtns and probably along N. front, but not identified elsewhere. Fauna differs from that of Kingak sh. Is tentatively assigned to Jurassic (?).

Ilchester granite.

Pre-Cambrian (?): Eastern Maryland.

W. H. Hobbs, 1889 (Am. Jour. Sci., 3d, vol. 38, pp. 225–228). *Ilchester granite.*—One of youngest of a series of eruptions in the gneiss and crystalline schist of eastern Md. Medium to coarse grained rock, with a porphyritic aspect caused by the large microcline crystals scattered through the holocrystalline to granophyric groundmass. Occurs at Ilchester, Md.

Iles formation. (In Mesaverde group.)

Upper Cretaceous: Northwestern Colorado.

Named by E. T. Hancock, but publication of his rept was delayed, so that name first appeared in U. S. G. S. Press Memo. 16037, Oct. 1, 1923, on map of Hamilton and Seeping Spring Gulch domes and vicinity, Moffat Co.

E. T. Hancock, 1925 (U. S. G. S. Bull. 757). *Iles fm.*—An alternation of thick beds of ss. and sandy sh. with a few thin coal beds near base and near top. Is lower fm. of Mesaverde group in Axial and Monument Butte quads. Thickness 1,350 ft. Trout Creek ss. is top memb., and basal bed consists of 15 to 25 ft. of ss. Rests conformably on Mancos sh. and is conformably overlain by Williams Fork fm., the upper fm. of Mesaverde group of this area. Forms nearly all of Iles Mtn.

Illahe formation.

Oligocene: Northwestern Oregon (Salem Hills, Willamette Valley).

T. P. Thayer, 1933 (Pan-Am. Geol., vol. 59, No. 4, p. 317). *Illahe fm.*—Near-shore marine tuffaceous sediments containing lower-middle Olig. fossils. Occurs in S. part of Salem Hills, SW. of Salem, Oreg. Probably grades eastward into the subaerial Mehama volcanics. The basaltic Stayton lavas, about 400 ft. thick, which are correlated with the Mio. Columbia basalts, lie on the eroded surface of the gently folded Illahe fm. In the Cascades the Stayton lavas rest uncon. on Mehama volcanics. [Derivation of name not stated.]

Illecillewaet quartzite.

Pre-Cambrian: British Columbia.

R. A. Daly, 1913 (12th Int. Geol. Cong. Guidebook 8, p. 134).

Illinoian stage of glaciation, also **Illinoian drift** (Pleistocene).

Illinoian drift is name applied to third drift of Labrador and Patrician parts of Laurentide ice sheet, the term *Illinoian stage* being applied to time during which this drift was deposited. The name was proposed by F. Leverett, but was first published by T. C. Chamberlin (Jour. Geol., vol. 4, pp. 872–876, 1896), who credited it to Leverett, as *Illinois* till sheet. Leverett defined the term in Chicago Acad. Sci. Geol. and Nat. Hist. Surv. Bull. 2, pp. 11–16, 1897, and in Jour. Geol., vol. 6, p. 173, 1898. The *Illinoian drift* is underlain by Yarmouth soil and interglacial deposits and overlain by Sangamon soil and interglacial deposits. Named for its development in Ill.

†Illinois till sheet.

See under *Illinoian stage.*

†Ilo formation.

Upper Cretaceous: Northwestern Wyoming (Park County).

D. F. Hewett, 1914 (U. S. G. S. Bull. 541, pp. 91, 103, etc.). *Ilo fm.*—Buff and yellow sss. with minor sandy sh. and clay. No coal beds. Saurian bones and fresh-water invertebrates. Thickness 1,790 ft. in Shoshone River section. Underlies (uncon.?) Fort Union fm. and overlies Meeteetse fm. Is Cret. or Tert. Well exposed in open valley NW. of Ilo, a settlement 50 mi. SE. of Cody, hence name.

Same as Lance fm., which is now classified as Upper Cret. in most areas.

Image member. (In Queen Charlotte group.)

Jurassic: British Columbia.

C. H. Clapp, 1914 (Canada Geol. Surv. Summ. Rept. 1912, p. 21).

Imlay moraine.

Pleistocene (Wisconsin stage): Southeastern Michigan. Shown on moraine map (pl. 32) of U. S. G. S. Mon. 53. Named for Imlay, Lapeer Co.

Imperial formation.

Miocene (late lower): Southern California (Imperial County).

G. D. Hanna, 1926 (Calif. Acad. Sci. Proc., 4th ser., vol. 14, No. 18, pp. 434–435). There appears to be good reason to suspect that more than one Plio. fm. is represented on flanks of Coyote Mtn (which is also called *Carrizo Mtn*). Very little reason exists for placing the coral reef, the lowermost exposed fossiliferous stratum, with the great oyster reefs of upper part. For a long time the deposits about Coyote Mtn have been called "Carrizo Creek beds," or "Carrizo fm.," the latter proposed definitely in 1914 by Kew; but F. E. Vaughan has shown that these names are inapplicable because of prior use elsewhere. This is to be regretted, but it seems that current usage demands a different name. Since we are unable as yet to correlate definitely any of the fossil-bearing strata with any named fm. elsewhere, I would propose that it be known as *Imperial fm.* The type loc. should be taken as the coral reef exposed in Alverson Canyon on S. side of the mtn. This coral reef has a distinctive fauna. It is succeeded by about 200 ft. of very fossiliferous calc. sss. for which I propose the name *Latrania sands.* Above the Latrania sands are enormous deposits of clay, here named *Coyote Mountain clays.* Above the clays, and interbedded with them near the top to some extent, are extensive deposits of oyster shells for which the name *Yuha Reefs* has been selected. According to above nomenclature, Conrad's fossil mollusks came from the Yuha Reefs; Kew's echinoderms are from the Latrania sands; and Vaughan's corals from Imperial fm. It is believed that further work will necessitate further subdivision rather than a consolidation of above fms. [According to foregoing the name *Imperial fm.* was proposed as a substitute for *"Carrizo Creek beds,"* but as defined it was also restricted to the coral reef forming basal part of *"Carrizo Creek beds."*]

W. P. Woodring, 1931 (Carnegie Inst. Wash. Pub. 418, pp. 1–25), redefined *Imperial fm.*, restricting it to marine deposits, and dividing it into an upper or siltstone memb. (1,400± ft. thick) and a basal cgl. memb. (a few inches to 700 ft. thick). He correlated the basal cgl. memb. with Imperial fm. of Hanna in narrow sense, and the siltstone memb. with Latrania sands, Coyote Mountain clays, and interbedded Yuha Reefs of Hanna. He assigned his Imperial fm. to late lower Mio., and his overlying Palm Spring fm. (nonmarine) to middle or upper Mio.

Incarnacion fire clay.

Pennsylvanian: Central northern New Mexico.

C. L. Herrick, 1904 (Jour. Geol., vol. 12, p. 242). *Incarnacion fire clay*, basal bed of Sandia fm. near Socorro, N. Mex. Uncon. overlies Incarnacion granite. Named for mining dist. in which it occurs.

Incarnacion granite.

Age (?): Central New Mexico.

C. L. Herrick, 1904 (Jour. Geol., vol. 12, pp. 237–251). Near Socorro the *Incarnacion granite* uncon. underlies Sandia fm. Named for mining dist. in which it occurs.

Inch Arran latites.

Devonian: New Brunswick.

W. V. Howard, 1926 (Geol. Soc. Am. Bull. vol. 37, p. 487).

Independence shale member (of Wapsipinicon limestone).

Middle Devonian: Central eastern Iowa.

S. Calvin, 1878 (Am. Jour. Sci., 3d, vol. 15, pp. 460–462). *Independence shales.*—Fossiliferous, argill., fine-grained shales charged with bituminous matter. Thickness 20 to 25+ ft. Basal div. of Dev. at Independence. Underlies Dev. lss.

In subsequent repts (up to 1928) W. H. Norton placed Independence sh. below his Davenport beds and above his Otis beds, and this assignment was followed by G. F. Kay and E. T. Apfel, 1929 (Iowa Geol. Surv. vol. 34, pp. 17–18).

T. E. Savage, 1925 (Jour. Geol.), classified Wapsipinicon ls. (of which this sh. was considered a memb.) as Upper Dev.; E. O. Ulrich (1911) as Middle Dev.

The Rept. 9th Ann. Field Conf. Kans. Geol. Soc., 1935, fig. 1, assigned this sh. to Upper Dev., excluded it from Wapsipinicon ls., and treated it as a distinct fm. overlying Davenport memb. of Wapsipinicon, which was excluded from Upper Dev. On p. 24 A. C. Trowbridge stated they are undecided whether it is Upper or Middle Dev.

M. A. Stainbrook, 1935 (pp. 249–254 of 1935 rept cited above). *Independence sh.* lies conformably below Cedar Valley ls. and uncon. on Davenport ls. Carries large Upper Dev. fauna.

†Independence limestone.

Pennsylvanian: Southeastern Kansas.

E. Haworth and W. H. H. Piatt, 1894 (Kans. Univ. Quart., vol. 2, pp. 115–117). *Independence ls.*—Heavy ls., 40 ft. thick at Independence. Overlain by 80 to 150 ft. of shales with interbedded sss. May be same as Oswego ls., but differs in character.

Preoccupied. Replaced by Drum ls. according to G. I. Adams, 1903 (U. S. G. S. Bull. 211, p. 37); but R. C. Moore states (Kans. Geol. Surv. Bull. 22, 1936, p. 109) †Independence ls. of Adams is Dennis ls.

Named for Independence, Montgomery Co.

Independence gas sand.

A subsurface sand, of early Penn. (Cherokee) age, 0 to 100± ft. thick, in Independence field, central northern Okla., reported to occur at horizon of Bartlesville sand, but to be a distinct body.

Index granodiorite.

Jurassic (?): Central Washington (Snohomish County).

C. E. Weaver, 1912 (Wash. Geol. Surv. Bull. 7, pp. 34–50). Very closely resembles Mount Stuart granodiorite, but in this rept will be designated *Index granodiorite*. Constitutes by far the larger part of areal geology of Index mining dist. Assigned to Jurassic (?).

C. E. Weaver, 1916 (Wash. Geol. Surv. Bull. 13). *Index granodiorite*, Jurassic or Cret., intrudes Gunn Peak fm. Outcrops typically near town of Index, Snohomish Co. To SW. of Index is uncon. overlain by Tert. lavas.

Indian conglomerate.

Eocene (?): Southern California (southern part of Santa Ynez quadrangle, Santa Barbara County).

R. N. Nelson, 1925 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 15, No. 10, pp. 344, 350–352, pl. 46, and map). *Indian cgl.*—Rudely sorted pebbles and boulders, up to 1 foot diam., in coarse-grained ss. matrix, firmly cemented. In Indian Canyon, where the fm. is over 500 ft. thick, the cgl. is in beds 8 ft. thick, or less, separated by massive, thick-bedded sss. which sometimes attain aggregate thickness of 25 ft. Near its base, in places, are lenses of ss. A characteristic feature is large percentage of acid porphyry pebbles. Varies in thickness from 25 ft. in Mono Creek to 500 ft. in Indian Canyon. Rests, with probable uncon. in places at least, on Cret. rocks, and is conformably overlain by Mono sh. Best developed in Indian Canyon, whence its name. Assigned to Eo.

M. F. Keenan, 1932 (San Diego Soc. Nat. Hist. Trans., vol. 7, No. 8, pp. 53–84). Paleontologic evidence points to Cret. (Chico) age of Indian cgl. and Mono sh., instead of Eo.

Indian sand.

A subsurface sand in western Pa. that is correlated with Morgantown ss. memb. of Conemaugh fm.

Indiana oolitic limestone.

Mississippian: Indiana.

C. E. Siebenthal, 1901 (Ind. Dept. Geol. and Nat. Res. 25th Ann. Rept., pp. 390–393), and C. E. Siebenthal and W. S. Blatchley, 1908 (Ind. Dept. Geol. and Nat. Res. 32nd Ann. Rept., pp. 305, 307). *Indiana oolitic ls.*—Oolitic ls. overlying

Harrodsburg ls. and underlying Mitchell ls. Formerly called Bedford oolitic stone, Spergen Hill ls., White River stone, etc.

Trade name for Spergen ls. Named for its commercial importance in Ind.

Indiana travertine.

A trade term applied to a very coarse-grained stone containing many large cavities, occurring at intervals in upper part of Spergen ls. of Ind., which is known to the trade as "Indiana oolitic ls."

Indiana till.

A term applied by C. [R.] Keyes to an early till sheet (of pre-Nebraskan age, he stated) in Ind. and Ill. (See Pan-Am. Geol., vol. 58, pp. 203, 217, 1932.)

Indianan till.

C. [R.] Keyes, 1926 (Pan-Am. Geol., vol. 45, p. 151). East of Mississippi River probably most of so-called Kansan till comes from Labradoran center, and it should therefore be distinguished from Kansan till by some such title as *Indianan till*.

Indian Cave sandstone.

Pennsylvanian: Eastern Kansas.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 50, 201). *Indian Cave ss.* = lower and major part of Towle sh. (basal subdivision of Admire group of Moore) and in places cuts out upper beds of underlying Wabaunsee group [restricted]. [This is all of definition.]

Indian Creek bed. (In Strawn formation.)

Pennsylvanian: Central Texas (Colorado River region).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 374, 386). *Indian Creek bed.*—Shaly sandy clay, thickness not stated. Memb. of Strawn div. Overlies Antelope Creek bed or, where that is absent, Comanche Creek bed. Underlies Ricker bed. [Named for Indian Creek, Brown Co.]

Drake applied *Indian Creek* to 2 units, one in Admiral fm. (Perm.), and the other in Strawn fm. (Penn.). E. H. Sellards (Univ. Tex. Bull. 3232, pp. 105, 170, 173, 1933) retained the name for the Penn. unit and discarded it for the Perm. unit, altho the Perm. name has had greater usage.

Indian Creek shale member (of Admiral formation).

Permian: Central Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 421, 423). *Indian Creek bed.*—Clay, more or less sandy throughout, at many places slightly shaly, and at some places carbonaceous; of bluish, purplish, and yellowish colors. Thickness 75 to 100 or more ft. Memb. of Albany div. Overlies Hordes Creek bed and underlies bed No. 5 (25 to 60 ft. of ls. with some marly clay).

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, pp. 192, 193, and charts). *Indian Creek sh. memb.* is included in Admiral fm. (basal fm. of Wichita group). Overlies Hordes Creek ls. lentil and underlies "bed No. 5" of Drake.

Named for Indian Creek, Coleman Co.

See also under *Indian Creek bed* (Penn.).

Indian Fields formation.

Silurian (Niagaran): East-central Kentucky.

A. F. Foerste, 1905 (Ky. Geol. Surv. Bull. 6, p. 145) and 1906 (Ky. Geol. Surv. Bull. 7, pp. 10, 60). *Indian Fields fm.* introduced, for convenience, to include Oldham ls. at top, Plum Creek clay in middle, and "those layers of ls., usually 1 to 2 ft. thick, beneath Plum Creek clay which are regarded as belonging above the line of uncon. marked, in east-central Ky., by *Whitfieldella subquadrata* and oolitic iron ore bed." Included in Crab Orchard div., of Niagaran age. Overlain by Alger fm. and underlain by Brassfield ls.

Named for Indian Fields, Clark Co.

Indian Gap limestone. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

C. E. Krebs and D. D. Teets, Jr., 1916 (W. Va. Geol. Surv. Rept. Raleigh and western parts of Mercer and Summers Counties, pp. 52, 108, 326, 340). *Indian Gap* (*Winifrede?*) *ls.*—Dark-gray hard ls. 1 to 2 ft. thick, with marine fossils. Directly overlain by 1 to 5 ft. of fossiliferous limy sh. Lies 5 to 10 ft. below Chilton rider coal, 65 to 149 ft. below Winifrede coal, and 28½ ft. above Chilton coal. Occurs at Indian Gap, Raleigh Co.

Indian Gulch.

Mesozoic: Sierra Nevada, California.

N. L. Taliaferro, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 149). *Indian Gulch aggls., tuffs, sss., and cgls.*, 3,500 ft. thick. Basal fm. of Mariposa group on Merced River and southward into Indian Gulch quad. Underlies Mariposa slates.

Indian Hill series.

Upper Cretaceous: Southeastern Massachusetts (Marthas Vineyard).

N. S. Shaler, 1888 (U. S. G. S. 7th Ann. Rept., map, pl. 20, p. 340). *Indian Hill series* [on map].—There are two sets of deposits on Marthas Vineyard the relations of which are not as yet determined. One of these is the hidden series, which is certainly known from the drift in dist. about Indian Hill and on shores of Cotamy Bay. It is shown only by abundant fragments of its beds contained in glacial drift in region about Indian Hill and the rarer fragments which are found on Chappaquiddick Island and neighboring shores of Cotamy Bay. These fragments, which on certain fields about Indian Hill constitute a large part of the glacial detritus, are the wastes from deposits of highly ferruginous ss., often taking on the form of an impure siliceous hematite. The fragments can not have been transported more than a few hundred ft. from their original position. The obscure fossils lead to belief the beds are Lower Cret. or older.

According to L. W. Stephenson (personal communication) the fossil invertebrates collected at Indian Hill are of Upper Cret. age.

Indian Hollow sands.

Pleistocene: Northwestern Pennsylvania (Warren County).

See under *Clarendon gravel*.

Named for Indian Hollow, Warren Co.

Indian Ladder beds.

Upper Ordovician: Eastern New York (lower Mohawk Valley).

J. M. Clarke, April 15, 1911 (N. Y. State Mus. Bull. 149, pp. 10–12). *Indian Ladder beds* (upper part of Frankfort sh. as previously identified in eastern N. Y.). Several hundred ft. of strata characterized by rapid alternation of shales and thin sss. with argill. ls. beds. Carry different fauna from lower beds of Frankfort sh., which contain a eurypterid fauna throughout. Named for exposures at Indian Ladder [near Meadowdale, Albany Co.]. Field work in charge of H. P. Cushing, W. J. Miller, and R. Ruedemann.

R. Ruedemann, December 15, 1911 (Geol. Soc. Am. Bull., vol. 22, p. 720, abstract of paper read by title at Dec. 1910 meeting). *Indian Ladder beds*, upper part of Frankfort sh., carry different fauna from underlying beds and are present only in the east [Mohawk Valley].

R. Ruedemann, 1912 (N. Y. State Mus. Bull. 162), restricted Frankfort sh. to the fm. as exposed in Utica region, which is absent in Mohawk Valley, the sh. in lower Mohawk Valley formerly called *Frankfort* being much older, and named by him *Schenectady fm.* He recognized *Indian Ladder beds* as distinct fm. in Mohawk Valley, equiv. in age to part of Frankfort sh. but faunally entirely different. Thickness 0 to 300± ft. Rest on Schenectady fm., of Trenton age.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 43). *Indian Ladder beds* consist of thin sss. and shales with massive ss. at top. Formerly included in "Hudson River group," of which they form uppermost div. in lower Mohawk Valley. Are characterized by distinct fauna and differ lithologically from underlying Schenectady beds. Distinct fm. from Frankfort sh. but equiv. to it in time.

H. P. Cushing and R. Ruedemann, 1914 (N. Y. State Mus. Bull. 169). *Indian Ladder beds* of western trough at Saratoga Springs and vicinity are 300+ ft. thick, and contain a faunule hitherto known only from Eden beds about Cincinnati, but of age roughly corresponding to Frankfort beds of central N. Y. Are of basal Lorraine age. Rest uncon. on Schenectady fm., of middle and upper Trenton age.

R. Ruedemann, 1925 (N. Y. State Mus. Bull. 258), restricted Frankfort sh. to Utica Basin and to rocks older than *Indian Ladder beds* of lower Mohawk Valley, which rest uncon. on Schenectady beds. In 1929 (Geol. Soc. Am. Bull., vol. 40, p. 414) he repeated assignment of *Indian Ladder beds* to basal Lorraine.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 292). *Indian Ladder beds.*—Fauna not represented anywhere else in east N. Y. It is of Cincinnatian (Frankfort) age. The beds are 400+ ft. thick.

Indian Mills sandstone. (In Bluefield formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Tazewell and Giles Counties).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 300, 400). *Indian Mills ss.*—Usually greenish gray, fine-grained, partly massive, partly shaly; 30 to 100 ft. thick. Underlies Bradshaw sh. and overlies Indian Mills sh.; all members of Bluefield group [fm.]. Type loc. on N. side of Indian Creek just W. of Indian Mills, Summers Co. Also observed in Mercer and Monroe Counties, and in Tazewell and Giles Counties, Va.

Indian Mills shale. (In Bluefield formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 300, 401). *Indian Mills sh.*—Green or red and variegated; 20 to 70 ft. thick; marine fossils. Underlies Indian Mills ss. and overlies Raines Corner ls.; all members of Bluefield group [fm.]. Type loc. same as Indian Mills ss. Also observed in Monroe Co.

Indian Point formation.

Silurian (Niagaran): Quebec (Gaspé Peninsula).

C. Schuchert and J. D. Dart, 1926 (Canada Geol. Surv. Bull. 44, p. 52).

S. A. Northrop, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, p. 271). Faunas of Bouleaux, West Point, and Indian Point fms. of the middle Sil. Chaleur series are of Lockport and Guelph age.

Indian River group.

Age (?): Canada.

R. G. McConnell, 1900 (Canada Geol. Surv., Rept. on Klondike gold fields, p. 8).

Indian River series.

Cambrian: Canada.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 198). [See also A. H. Brooks, 1906 (U. S. G. S. P. P. 45, p. 213), for Indian River series, Yukon Terr.]

Indian River slate.

Lower Ordovician (Chazy): Southwestern Vermont (Rutland County) and eastern New York (Washington County).

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 403). *Indian River sl.*—The fm. that furnishes the well-known red sl. of N. Y. sl. industry. Is mainly bright red sl. with, locally, a few thin seams or layers of fine green qtzite. Red color is due to iron oxide. Conformably overlies Poultney sl. and conformably underlies an unnamed black sl. Named for Indian River, a few mi. S. of Granville [Washington Co.], N. Y., where several red sl. quarries are located on banks of the stream.

Indian Spring red beds. } (In Tonoloway limestone.)
Indian Spring sandstone. }

Silurian: Northern Maryland.

C. K. Swartz, 1923 (Md. Geol. Surv. Sil. vol., pp. 46–49). *Indian Spring ss.*—Lies about 120 ft. above base of Tonoloway fm. Is thin and inconspicuous at Pinto, but increases in thickness eastward. In vicinity of Hancock it is argill. and about 5 ft. thick. East of Hancock it becomes very hard and dense and breaks into irregular fragments. Seems to occupy strat. position of Bloomfield ss. of Claypole. The red beds here called *Indian Spring red beds* are associated with it in North Mtn, becoming conspicuous in easternmost exposures. Named for occurrence at Indian Spring, Washington Co. [In tables in book cited the Indian Spring red beds are placed beneath Indian Spring ss.]

Indian Springs shale. (In Chester group.)

Mississippian: Southwestern Indiana.

C. A. Malott and J. D. Thompson, Jr., 1920 (Sci., n. s., vol. 51, pp. 521–522). *Indian Springs sh.*—Olive sh., 20 ft. thick, which characteristically underlies Golconda ls. Overlies Cypress ss. [Later repts give thicknesses from 5 to 58 ft.]

Probably named for Indian Springs, Martin Co.

Indian Springs member (of Bird Spring formation).

Mississippian (upper): Southeastern Nevada (Las Vegas quadrangle).

C. R. Longwell and C. O. Dunbar, 1936 (A. A. P. G. Bull., vol. 20, No. 9, pp. 1200–1207). In Good Springs dist., Nev., the basal memb. of Bird Spring fm. consists of thin-bedded ss., sh., and ls. with local cgl. This basal memb. changes considerably in character. Near Indian Springs, 50 mi. NW. of Las Vegas, yellow, orange, and reddish shales are interbedded with lss. and subordinate sss. in a section 700 ft. thick. Because of its peculiar lithologic character and fauna, this zone appears to have formation value, but writers refer to it in this paper as *Indian Springs memb. of Bird Spring fm.* Overlies Monte Cristo ls. and underlies lower Penn. zone of *Fusulinella.* Fossils assigned to upper Miss. (Chester) by Girty.

†Indian Territory division.

Name applied by R. T. Hill (Geol. Soc. Am. Bull., vol. 2, 1891, p. 504) to *Washita group* of Okla.

Indidura formation.

Cretaceous: Mexico (Coahuila Peninsula).

W. A. Kelly, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 7, p. 1028).

Indio formation. (Of Wilcox group.)

Eocene (lower): Southern Texas.

A. C. Trowbridge, 1923 (U. S. G. S. P. P. 131D). *Indio fm.*—The strata overlying the marine Midway fm. and underlying Carrizo ss. in Gulf Coastal Plain of Tex. adjacent to Rio Grande. Consists chiefly of thin-bedded and laminated argill. sand and aren. sh., but includes some layers of massive clay and lenses and layers of ss. The clay and sh. are greenish or bluish gray and light chocolate brown, and most of them are gypsiferous. The ss. is gray, yellow, green, and brown, is not notably cross bedded, and is of various textures. Includes some beds of lignite and many calc. and aren. concretions. Thickness 648 to 700± ft. Is basal fm. of Wilcox group.

The overlying Carrizo sand and Bigford fm. were formerly considered to be of Wilcox age, but are now assigned to Claiborne group by most geologists. This leaves the Indio the only representative of Wilcox group in Tex.

†Indio formation.

Miocene (middle or upper): Southern California (Riverside County).

J. P. Buwalda and W. L. Stanton, 1930 (Sci., n. s., vol. 71, pp. 101–106). *Indio fm.*—Several thousand ft. of strongly folded and erosionally bevelled terrestrial deposits, consisting of clays, probably playa deposits, arkosic sss. and fangls. with considerably worn fragments in subequal thicknesses. Form entire exposed section in Indio Hills. Type section along a NE.-SW. line through Indio Hills about 2 mi. NW. of Thousand Palm Canyon. At all localities overlies the marine Carrizo fm., probably uncon. No fossils, but strat. relations to Carrizo fm. and well-indurated character of Indio fm. indicate probable age not greater than middle Mio. and not less than lower Plio.; in short, approx. middle Neocene.

W. P. Woodring, 1931 (Carnegie Inst. Wash. Pub. 418, pp. 1–25), replaced this preoccupied name with *Palm Spring fm.*

Industry sandstone.

See under *Kittanning ss. memb.*

Inglefield sandstone.

Pennsylvanian: Southwestern Indiana.

M. L. Fuller and G. H. Ashley, 1902 (U. S. G. S. Ditney folio, No. 84). *Inglefield ss.*—Massive ss. with thin sh. partings; 20 or more ft. thick. Underlain by Ditney fm. and overlain by Pleist. glacial deposits. [Later repts give thicknesses up to 150 ft.]

Supposed equiv. of Merom ss., and name was dropped by E. R. Cumings, 1922 (Hdb. Ind. Geol. pt. 4, Sep. Pub. 21, p. 525).

Named for Inglefield, Vanderburg Co.

†Ingles conglomerate member.

Silurian: Southwestern Virginia.

M. R. Campbell, 1925 (Va. Geol. Surv. Bull. 25). *Ingles cgl. memb.*—Basal 40 ft. of Price fm. (Miss.). Consists of white quartz cgl.; in places entirely white or gray ss., but white quartz pebbles generally occur in the ss., either scattered through it in thin and irregular layers or in a thick bed of well-rounded quartz pebbles cemented by gray or white quartzose sand. Exposed on Ingles Mtn, back of Radford.

Later work developed fact that the ss. on Ingles Mtn is Clinch ss. (Sil.). See C. Butts, 1933 (Va. Geol. Surv. Bull. 42, p. 36).

Ingleside formation.

Pennsylvanian: Central northern Colorado (Larimer County region).

R. M. Butters, 1913 (Colo. Geol. Surv. Bull. 5, pp. 68, 75, etc). *Ingleside fm.*—Alternating lss. and hard fine-grained sss., gray to almost white, through pink to almost red; basal Ingleside is a light-colored ss. somewhat harder than the rest. Name is considered necessary to avoid confusion by use of *Lyons* in too broad a sense. Is quite different from the Lyons as described by Fenneman, especially in fact it contains the ls. bands, some of them very pure. Is also in a different and lower horizon than the Lyons. It lies conformably on Fountain fm. Possibly it should be regarded as merely a lithological unit in the Fountain, showing a change in conditions of sedimentation transitional to Lykins conditions. Contact with Fountain is hard to place, but appears to be at top of last prominent band of arkose cgl., though there are bands of ss. in the Fountain similar to those in the Ingleside. It extends geographically from beyond State line to the N. to a point a little N. of Lyons. Typically developed at Ingleside quarries and at Owl Canyon [3 mi. N. of Ingleside]. Thickness 100 to 125 ft. Underlies Lyons ss.

W. T. Lee, 1927 (U. S. G. S. P. P. 149) published the following as his interpretation of the section at Ingleside, Colo.:

Lykins fm. (basal part):
1. "Crinkled ss.," brecciated ls., gyp., and red sh., 75± ft.
2. sh., red, soft, 175 ft.

Lyons ss., 25 ft. (ss., yellowish pink, cross-bedded, ridge making).

Satanka (?) sh., 375 ft. (red sh., poorly exposed, with thin layers of ridge-making ss.). "Possibly belongs with underlying fm."

Ingleside fm.:
1. ss., ledge making, red to yellowish pink (Tensleep ss. of Darton), 65 ft.
2. ls., pink to gray, with many solution cavities and masses of calcite, 25 ft.
3. ss., red, intensely cross bedded, 25 ft.
4. ls., gray, brittle, impure, in places variable, 22 ft.
5. ss., red, massive, cross bedded, 40 ft.
6. ss., limy, gray, quartzose, 6 ft.
7. sh., soft, red.
8. ss., red, ledge making, 100± ft.

Fountain fm.

Pl. 1 of above rept showed Satanka (?) sh. as thinning out before reaching Spring Canyon, Larimer Co., where the Ingleside was shown as overlain uncon. by Lyons ss. as restricted by Lee.

Ingleside chert. (In Franciscan group.)

Jurassic (?): Western California (San Francisco region).

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). *Ingleside chert.*—Radiolarian chert, prevailingly dull brownish red, especially in its thicker and more evenly bedded portions, but also includes some yellow and green rock, and locally rock of other colors. Contains thousands of thin beds of earthy sh. In many places the rock is true jasper. Max. thickness about 530 ft. Is overlain by Bonita ss. and underlain by Marin ss. Next to top fm. of Franciscan group.

Named for exposures in San Miguel Hills, E. of town of Ingleside, San Francisco Co.

Ingonish gneiss.

Pre-Cambrian (?): Cape Breton Island.

W. J. Wright, 1914 (Canada Geol. Surv. Summ. Rept. 1913, p. 274).

Ingraham gas sand.

A subsurface sand, 25± ft. thick, of Miss. age, in central Okla., which lies lower than Jefferson gas sand and higher than Chattanooga sh.

Ingram sand.

See under *Quinn sand.* This sand has also been spelled *Ingraham sand.*

†Inoceramus beds.

Paleontologic name applied by C. A. White (Geol. Iowa, vol. 1, 1870, p. 289) to Niobrara ls., because of presence of many species of *Inoceramus.*

Inola limestone member (of Boggy shale).

Pennsylvanian: Northeastern Oklahoma (Rogers County).

S. W. Lowman, 1932 (Summaries and abstracts of technical papers presented before Tulsa Geological Society 1932, unpaged; paper dated Dec. 19, 1932). *Inola ls.*—A ls. in lower part of Boggy sh., occurring in black sh. interval btw. salt sand or Enterprise [Bluejacket] ss. of Okmulgee underground and upper Earlsboro or Red Fork sand of Seminole underground. Named for an outlier on a hill E. of town of Inola [Rogers Co.].

C. W. Wilson, Jr., 1935 (A. A. P. G. Bull., vol. 19, No. 4, pp. 503–520), treated this ls. as a memb. of Boggy sh.; gave its thickness as 0 to 10 inches; and showed that it lies 80 to 150 ft. below Taft ss. memb., 40± ft. above Bluejacket ss. memb., and 10 ft. above Crekola ss. memb.

Institute limestone.

Pennsylvanian: Eastern Kansas.

E. Haworth, 1894 (Kans. Univ. Quart., vol. 2, pp. 122, 124). *Institute ls.*—Thin ls. system exposed at Haskell Institute, Lawrence. Included in Lawrence shales.

This ls. was renamed *Haskell ls.* by R. C. Moore (1931), who now includes it in his Stranger fm.

Interior formation.

Upper Cretaceous: Southwestern South Dakota and northwestern Nebraska.

F. Ward, 1922 (S. Dak. Geol. Nat. Hist. Surv. Bull. 11, pp. 18–20 and map). *Interior phase of the Pierre.*—Thin-bedded sandy sh., predominantly yellow brown, but variegated with browner and purpler colors in upper portions, forming top 35 ft. of the Pierre in SE. part of Pennington Co. and SW. part of Jackson Co., S. Dak. Fossils warrant placing the beds in the Pierre, although in field they were called Fox Hills. If accepted as Pierre the strong color contrast and sandier texture require explanation. They grade into underlying typical Pierre, which consists of dark gray-blue sh. containing occasional thin calc. concretionary lenses. They uncon. underlie Chadron fm. (Olig.). The Nebr. Geol. Surv. has called these beds *"Rusty memb." of the Pierre* (E. F. Schram, personal communication).

H. R. Wanless, 1923 (Am. Phil. Soc. Proc., vol. 62, p. 194). *Interior fm. of Ward* consists of 0 to 45 ft. of lavender and blue clays weathering to rusty-brown color, diversified by calc. nodules with cone-in-cone structure and concentrically banded nodules of pink or red color strongly impregnated with oxides of iron. Ward believes these clays represent Fox Hills. Prof. Toepelman suggests they may be a slightly sandy phase of Pierre. Writer is inclined to agree with Toepelman that they were formed by weathering and leaching, rather than that their characters are primary, as Ward suggests. Rest on Pierre with very irregular surface. Named by Ward because of development in vicinity of town of Interior, S. Dak.

F. Ward, 1926 (Am. Jour. Sci., 5th, vol. 11, pp. 350–352). Type loc. of *Interior fm.* is a few mi. W. of Interior, Jackson Co., S. Dak., where thickness is almost 30 ft. Is 45 ft. thick 21 mi. N. of type loc. In my 1922 rept there was some disagreement as to whether the beds were basal Fox Hills or upper Pierre, the latter position finally being agreed upon. [Discusses pros and cons.] Since then author has seen additional exposures, and conclusion reached is that Interior fm. is really Fox Hills. [Gives reasons for this opinion.]

†Intermediate series.

A descriptive term applied in some early repts on SW. Colo. to the series of Mio. volcanic rocks underlying Potosi volcanic series and overlying San Juan tuff, and now known as *Silverton volcanic series.*

Intermediate limestone.

Devonian: Canada.

R. G. McConnell, 1887 (Canada Geol. Surv. Ann. Rept., vol. 2, pp. 15D, 19D–21D).

Intervale clay slate.

Silurian (?): East-central New Hampshire (North Conway quadrangle).

M. Billings, 1928 (Am. Acad. Arts and Sci. Proc., vol. 63, map, p. 80). One small area of clay sl. has been found in North Conway quad. It may be either the less intensely metamorphosed equiv. of Montalban schists or it may be a fragment of a westward extension of the great Sil. sl. belt of central Maine. Writer favors latter interpretation; but more field work in adjacent areas is needed to settle the question. It is proposed to call this group *Intervale clay slates,* because the known occurrence in North Conway quad. is on S. slope of Mount Pequawket, just E. of Kearsarge Village trail at elev. of 1,500 ft. Two mi. NE. of Intervale [village], in vicinity of the trail, the sl. strikes N. 75° E. and dips vertically. Uncon. underlies Moat volcanics (Dev.?). Tentatively assigned to Sil. (?). Was called *Kearsarge andalusite group* by Hitchcock, but writer believes it does not belong to Hitchcock's "Kearsarge andalusite group."

Inwood limestone.

Pre-Cambrian: Southeastern New York.

F. J. H. Merrill, 1890 (Am. Jour. Sci., 3d, vol. 39, pp. 389–390). The position and strat. of the ls. areas of Westchester Co. have been carefully studied by Professor Dana, who has estimated thickness of the bed in Tremont and Harlem River valley at 600 to 750 ft. Writer's measurements indicate thickness varies from 600 to 800 ft., it being apparently greater on New York [Manhattan] Island than in Morrisania. The eastern bed at Tuckahoe is but 150 ft. thick. For this rock I propose the name *Inwood ls.,* from the locality on N. Y. [Manhattan] Island in vicinity of which it is well exposed. [This village of Inwood is W. of Fordham and in Harlem quad.] Underlies Manhattan schists and overlies Fordham gneiss, from which it is in a few places separated by 5 to 10 ft. of thinly bedded qtzite [later named *Lowerre qtzite*]. Included in Manhattan group.

F. J. H. Merrill, 1898 (N. Y. State Mus. 15th Ann. Rept., vol. 1, pp. 21–31). Max. thickness of *Inwood ls.* unknown, but is about 700 ft. thick in Harlem River. No fossils. Exact age indeterminate, but is probably Calciferous-Trenton [Beekmantown to Trenton]. Underlies Manhattan schist and overlies Lowerre qtzite (0 to 16 ft. thick).

F. J. H. Merrill, 1902 (U. S. G. S. New York City folio, No. 83). [Stockbridge ls. (of Camb. and Ord. age) was extended into this area and used to replace *Inwood ls.,* now considered to be pre-Camb.]

C. P. Berkey, 1907 (N. Y. State Mus. Bull. 107, pp. 361–378), assigned Manhattan schist and *Inwood ls.* to pre-Camb., and named the underlying qtzite *Lowerre qtzite.* Under description of Sprout Brook Valley he in several places called the Inwood ls. the *Sprout Brook ls.*

C. P. Berkey, 1911 (N. Y. State Mus. Bull. 146, pp. 47–57). *Inwood ls. (or dol.)* assigned to *Cambro-Ordovicic (?).* Generally supposed to be = Wappinger ls.

C. P. Berkey and J. R. Healy, 1912 (Columbia Univ. Contr., vol. 20, pp. 1907–1912). *Inwood ls.* conformably underlies Manhattan (Hudson) schist and uncon. overlies Fordham gneiss. Thickness 750 ft. Is essentially a coarse marble, more strongly mag. than usual. Has no fossils and is of undet. age. Other names for it are Tuckahoe marble, Sing Sing marble, and Stockbridge dol. Whether or not it is = Stockbridge dol. of Mass. no one is in position to say.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 21). Berkey holds that in all probability these fms. [Lowerre, Inwood, and Manhattan] are pre-Cambric and offers good evidence that they are not metamorphosed Paleozoic sediments.

J. F. Kemp, 1912 (Int. Geol. Cong., 11th sess., Stockholm, Compt. rend., vol. 1, pp. 702–711). Manhattan mica schist and *Inwood ls.* assigned to pre-Camb. and equivalence with Huronian of Lake Superior suggested.

C. R. Fettke, 1914 (N. Y. Acad. Sci., vol. 23, pp. 194–248). Berkey and writer think *Inwood ls.* is pre-Camb., but Merrill, Dana, Mather, and others believe it is Cambro-Ord. Berkey thinks Sprout Brook ls. is=Inwood ls.

C. P. Berkey and Marion Rice, 1921 (N. Y. State Mus. Bull. 225, 226). *Inwood ls.* tentatively assigned to pre-Camb., but its age is uncertain. We are inclined to consider it a part of Grenville. [Correlated with later Grenville (pre-Camb.) on their correlation chart, p. 140.]

E. B. Knopf and A. I. Jonas, 1929 (U. S. G. S. Bull. 799). *Inwood ls.* correlates with Cockeysville marble of Md. and SE. Pa., which U. S. Geol. Survey classifies as Algonkian.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 210), assigned this ls. to pre-Camb.

The terms "Algonkian system" and "Archean system" have been discarded, and Inwood ls. is now classified simply as *pre-Camb.*

Inwood sandstone.

Silurian (?): Southeastern Pennsylvania (Lebanon County).

C. K. and F. M. Swartz, 1931 (Geol. Soc. Am. Bull., vol. 42, p. 635). Swatara Gap is 11 mi. NW. of Lebanon, Pa. At S. end of the gap is Inwood Station, on Phila. & Reading Ry. The section E. of Swatara Creek shows Marcellus fm., Onondaga ls. (20 ft.), Inwood ss. (49 ft.), Bloomsburg red beds, [and other fms. down to Tuscarora ss.]. The *Inwood ss.* is greenish-gray argill., somewhat arkosic ss. Concealed above. Age unknown, probably Cayugan.

Inyan Kara group.

Lower Cretaceous: Western South Dakota, northeastern Wyoming, and (in wells) southeastern Montana.

W. W. Rubey, 1930 (U. S. G. S. P. P. 165A). *Inyan Kara group.*—An extremely variable group, consisting of discontinuous beds of ss., sandy sh., cgl., lignite, and variegated siltstone. In general, though not in detail, the higher sss. are more heavily iron stained and slabby and the lower ones lighter gray and massive. Continental fossils throughout greater part but marine fossils in upper 20 ft. Thickness 150 to 350 ft. Includes (descending) Fall River ss. (the so-called Dakota ss. of previous repts on NE. Wyo. and SE. Mont.), Fuson fm., and Lakota ss. Named for exposures along Inyan Kara Creek, NE. part of Moorcroft quad., Wyo.

Inyo marble.

Lower Cambrian: Eastern California (Inyo Range).

H. G. Hanks, 1886 (Calif. State Min. Bur. 6th Ann. Rept. State Min., pt. 1, p. 25). The *Inyo marble* caps White Mtn. Is a dol. of finest quality, as pure and white as finest Carrara marble. Is found at numerous localities in Inyo Range from White Mtn southward 100 mi. or more.

The rocks that cap White Mtn were mapped by E. Kirk (U. S. G. S. P. P 110, pl. 1, 1918) as Lower Camb.

Inyo series.

Middle and Lower Triassic: Southern California (Inyo Range).

J. P. Smith, 1910 (Jour. Geol., vol. 18, table opp. p. 217). *Inyo series* includes black ls. of Inyo Mtns (*Parapopanoceras* beds), of Middle Triassic age, and gray lss. of Inyo Mtns (*Meekoceras* beds), of Lower Triassic age.

G. H. Ashley, 1923 (Eng. and Min. Jour.-Press, vol. 115, pp. 1106–1108), proposed *Inyo series* as geographic name for *Lower Triassic series.*

Inyo granite.

J. H. Maxson, 1934 (Pan-Am. Geol., vol. 61, No. 4, p. 311), in a brief note entitled "Strat. of Inyo Range," stated that the rocks were invaded on E. side of the range by *Inyo granite* (*late Jurassic*). Not defined, and apparently not intended as a geol. name.

Inyoan series.

Lower Triassic: Southeastern California and Nevada.

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 52, 59, 79). In SW. Nev. and adjoining parts of Calif. early Triassic sedimentation is important. The *Inyoan series*, as it may be called, of Death Valley region, attains thickness of 1,200 to 1,500 ft. and is characterized by well-defined fauna. The section consists mainly of early Triassic shales, of which five subdivisions are easily differentiated. Composes all early Triassic of Nev., and is divided into five unnamed fms. (descending): 10 ft. of lss., 800 ft. of shales, 15 ft. of lss., 400 ft. of shales, and 100 ft. of cgl. The name *Koipatoan series* is given to Middle Triassic and *Staran series* to late Triassic.

Named for Inyo Co., Calif.

Iola limestone. (In Kansas City group, Kansas.)

Iola limestone member (of Kansas City formation, Missouri).

Pennsylvanian: Eastern Kansas, southeastern Nebraska, northwestern Missouri, and southwestern Iowa.

E. Haworth and M. Z. Kirk, 1894 (Kans. Univ. Quart., vol. 2, p. 109). *Iola ls.*—Thick-bedded ls., 30 to 40 ft. thick, underlain by Chanute shales and separated from overlying Carlyle ls. by 75 ft. of sh.

H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines vol. 13). The ls. exposed at Carlyle is Plattsburg ls., but the ls. that has been called *Carlyle* is an older bed—the Farley ls. bed in Lane sh. memb., which overlies Iola ls. ("Crusher ledge").

R. C. Moore, 1932 (Nebr. Geol. Surv. Bull. 5, 2d ser., issued before Mar. 1932, p. 17), showed Iola ls. of "current nomenclature" as younger than true Iola ls., and called it *Argentine ls.*, which he showed as lying on Lane sh. "(=upper part of so-called Chanute sh. of current nomenclature)." He divided Iola ls. into (descending) Raytown ls., Muncie Creek sh., and Paola ls. The rest of so-called Chanute sh. of "current nomenclature" he divided into (descending) Chanute sh., Drum ls., Dewey ls., and Quivira sh.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3, pp. 92, 97). *Iola ls.* is typically developed at Iola, [Allen Co.], Kans., and is not changed in this revised classification of the rocks of Kans. The upper or main body of ls. is termed *Raytown ls.* An underlying black fissile sh. is termed *Muncie Creek sh.*, and a blue dense bed with "middle" characteristic is designated *Paola ls.* All of these units are recognized in Kansas City section. [Derivation of new names not stated.]

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, p. 51). So-called Iola ls. of Kansas City area is Frisbie-Argentine ls. members of Wyandotte ls., and pinches out before Iola is reached. On tracing type Iola ls. N. from Iola I found main upper part of it is continuous with Raytown ls. of Hinds and Greene, and this was confirmed in field by R. C. Moore and J. L. Rich. The Iola overlies Chanute sh., underlies Lane sh., and is divided into following 3 members: Raytown ls., Muncie Creek sh., and Paola ls.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 112–113). *Iola ls.* at Iola (where it is 30 ft. thick and extensively quarried) is chiefly light bluish-gray, irregularly thin-bedded fine-grained ls. containing many thin veinlets of calcite. It rests on Chanute sh. and is overlain by Lane-Bonner Springs sh. At Kansas City and vicinity the ls. ("Crusher ledge") that has long been called Iola is now known to be an entirely different fm. that belongs above Lane sh. and is now known as *Argentine ls.* The main part of true Iola is represented in NE. Kans. and NW. Mo. by Raytown ls., formerly included in Chanute sh. The Iola is now divided into 3 (descending) members—Raytown ls., Muncie Creek sh., and Paola ls. It extends into south-central Iowa and into Platte Valley, Nebr. In southern Kans. it becomes very thin and is locally absent. It is not found along State line either in Kans. or Okla., but is thought to be = Dewey ls. of Okla.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

†Iola shale.

Pennsylvanian: Eastern Kansas.

E. Haworth, 1894 (Kans. Univ. Quart., vol. 2, p. 124). *Iola sh.*—Sh., 75 ft. thick, underlying Carlyle ls. and overlying Iola ls. in Cherryvale-Lawrence section.

Conflicts with Iola ls. For present interpretation of relations see 1936 entry under †*Carlyle ls.*, and also Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Probably named for Iola, Allen Co.

†Iola beds.

Pennsylvanian: Eastern Kansas.

L. C. Wooster, 1905 (The Carbf. rock system of eastern Kans.). *Iola beds.*—Include Vilas sh., Allen [Plattsburg] ls., Concreto or Lane sh., Iola ls., and Chanute sh.

Preoccupied and conflicts with adopted classification. Includes upper part of Kansas City group and lower part of Lansing group.

Ion member.

Middle Ordovician (Trenton): Northeastern Iowa, northwestern Illinois, southeastern Minnesota, and southwestern Wisconsin.

G. M. Kay, 1928 (Sci., n. s., vol. 67, p. 16). *Ion memb. of Decorah fm.*—Calc. sh. and argill. lss., the lss. irregularly dolomitized in SE. part of their outcrop in Iowa. The beds become more argill. to N. and more calc. to SE. Thickness 16 ft. Top memb. of Decorah fm. Rests on Guttenberg ls. memb. Type loc. about 1 mi. SW. of hamlet of Ion, Allamakee Co., Iowa. Fossils are of basal Trenton (Rockland) age. [See also Kay, 1929 (Jour. Geol., vol. 37, No. 7, Oct.-Nov., pp. 639–671), who stated this memb. corresponds to Fucoid bed and *Chasmatopora* bed of Minn.]

G. M. Kay, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 295), showed his Ion, Guttenberg, and Spechts Ferry members as present in Minn. and NW. Ill.

Ione formation.

Eocene: Northern California (Gold Belt region).

W. Lindgren, 1894 (U. S. G. S. Sacramento folio, No. 5). During Neocene period the auriferous gravels accumulated on slope of Sierra Nevada, and at same time there was deposited in the gulf then occupying the Great Valley a sed. series consisting of clays and sands to which name *Ione fm.* has been given. The largest development occurs S. of American River. The strata form characteristic flat-topped hills, and consist of a succession of light-colored clays and white or yellowish-white sss. Is usually overlain by a few ft. of reddish Pleist. gravel and rests on Chico fm.

H. W. Turner, 1894 (Am. Geol., vol. 13, pp. 229–249). *Ione fm.* consists of white shales, clay, and sand of Mio. age. Is best developed in Amador and Calaveras Counties, where it is separable into:

1. Ione clay rock or tuff, 100+ ft.
2. Ione ss., 100+ ft.
3. White clay and sand beds containing coal seams, 860+ ft.

Howel Williams, 1929 (Calif. Univ. Pub. Dept. Geol. Sci. Bull., vol. 18, No. 5, pp. 112, 124+). *Ione sands.*—Very siliceous sands with anauxite; usually pure white, but often stained brown, pink, or purple. Thickness 100 to 150 ft. Underlie Butte gravels, with minor discon., occasionally with erosion uncon. Overlie Marysville fm. with minor discon. The term *Ione* is applied to these sands in sense adopted by Dr. V. T. Allen, who has permitted this brief advance statement of his work. Previous to Allen's work the term had been used so widely to include deposits of very different lithology and often of different ages, that it had long since lost all accurate connotation. Allen has redefined the term, restricting it to the quartz-anauxite sands of the Meganos. His work indicates clearly that this peculiar lithological unit is of surprising uniformity throughout wide belt along foothills of Sierra Nevada, and that it probably represents a single persistent horizon. He has shown that Ione sands are probably the age equivalents of the "Bench gravels" of the Sierra, and that they were chiefly derived by the erosion of an intensely weathered granitic series. The fm. is often characterized by strong current bedding.

V. T. Allen, 1929 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 18, No. 14, pp. 347–419). *Ione fm. restricted* to lower two members of type section, i. e., to the white clay and sand beds containing coal seams and the overlying white or red ss. The upper clay rock or rhyolite tuff formerly included is now considered to probably be Mio., and is here excluded. It is separated from underlying Ione fm. restricted by an extensive erosion period. The lower clays of the Ione were not formed from rhyolitic tuffs, as heretofore supposed. As here restricted the fm. is a lithologic unit serviceable in mapping and valuable in correlation, and it can be traced for more than 200 mi. The work of writer lends support to belief the Ione is contemp. with the white quartz gravels of Sierra Nevada. The Ione is composed of delta deposits formed at mouths of many westward-flowing streams. The presence of marine fossils in upper part shows that it accumulated on shores of an Eocene sea. From 1913 to 1916 R. E. Dickerson made valuable contributions to our knowledge of the Ione by finding Eocene marine fossils in it. He designated the Ione as the *Siphonalia sutterensis* zone, which he considered the uppermost part of Tejon Eocene. He concluded the Ione is the marine or estuarine equiv. of the auriferous gravels of Sierra Nevada. In 1921 B. L. Clark referred Dickerson's uppermost Eocene *Siphonalia sutterensis* zone to the Meganos Middle Eocene. This reference applied especially to the marine Ione, such as Dickerson described from Oroville Table Mtn and Marysville Buttes, but not to type section. Perhaps latter was excluded because of its limited fauna and poor preservation of the forms obtained.

Allen's 1929 restricted definition of Ione fm. is present adopted usage. The "Ione clay rock or tuff" at top of Turner's Ione fm. has been named *Valley Springs fm.* and assigned to Mio.

Named for exposures at Ione, Amador Co., where it overlies Mariposa sl. It has been described as younger than Tejon, as=upper part of Tejon, and as older than Tejon and=Meganos fm.

†Ione clay rock or tuff.

See under *Ione fm.*, H. W. Turner, 1894.

†Ione sandstone.

See under *Ione fm.*, H. W. Turner, 1894.

†Ionia sandstone.

Pennsylvanian: Southern Michigan (Ionia County).

A. Winchell, 1871 (Mich. Geol. Surv. Rept. Prog., btw. pp. 26 and 33). *Ionia ss.* is=Woodville ss. Borings have demonstrated correctness of this opinion of mine published 10 years ago.

For further information see *Woodville ss.*

Ionia moraine.

Pleistocene (Wisconsin stage): Southern Michigan. Shown on moraine map (pl. 32) of U. S. G. S. Mon. 53. Named for Ionia, Ionia Co.

†Iota subdivision.

A Greek name applied by F. W. Cragin (U. S. G. S. Bull. 266, 1905) to middle 50 ft. of Malone fm. of Malone Mtn, El Paso Co., Tex.

Iowa marble.

Mississippian: Central northern Iowa.

C. A. White, 1870 (Iowa Geol. Surv. vol. 2, pp. 312–313). Some of upper layers of Kinderbook div. in Le Grand quarries, Marshall Co., furnish a beautifully banded stone which has become known as *"Iowa marble."*

Iowa terrane.

A term applied by C. [R.] Keyes to Iowan drift (Pleist.). He also uses *Iowa stage* (instead of *Iowan stage*).

Iowa series.

Mississippian: Mississippi Valley region.

S. Weller, 1920 (Jour. Geol., vol. 28, No. 4, pp. 282+, and No. 5, pp. 408–416). *Lower Mississippian or Iowa series*, as it may be called for want of any comprehensive name already in use. Extends from top of Ste. Genevieve ls. (exclusive of Shetlerville fm., which belongs in Chester series) to base of Kinderhook group.

Probably named for Iowa.

Iowa City marble.

Trade name. Same as Iowa marble of the trade.

Iowa Falls dolomite.

Mississippian: Central northern Iowa.

F. M. Van Tuyl, 1925 (Iowa Geol. Surv. vol. 30, pp. 52, 92, 97). *Iowa Falls dol.*—Heavily bedded (except at very top, where layers are comparatively thin), yellowish to brownish, slightly vesicular beds of dol. Thickness 20 to 50 ft. Few fossils. Overlies Eagle City beds and underlies, with evidence of discon., Alden ls. Included in Kinderhook group. Named for exposures in gorge of Iowa River at Iowa Falls, Hardin Co.

L. R. Laudon, 1931 (Iowa Geol. Surv. vol. 35, pp. 388, 406, 412–419). *Iowa Falls memb. of Hampton fm.* is here used exactly as defined by Van Tuyl. Thickness 77 ft. Very local, exposures being practically confined to a few mi. of Iowa River Valley in Hardin Co.

R. C. Moore, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 243, 245). Eagle City ls. and Iowa Falls dol. are with little question Burlington. They contain Burlington fossils, as identified by both Van Tuyl and Laudon, mingled, it is true, with forms of Kinderhook aspect.

Iowan stage of glaciation, also **Iowan drift** (Pleistocene).

Iowan drift is name applied to third drift of Keewatin part of Laurentide ice sheet; *Iowan stage* being the name applied to time during which this drift was deposited. This drift was named for its exposures in eastern Iowa. The name "*East Iowan*" was originally applied by **T. C.** Chamberlin (Geikie's Great ice age, 3d ed., 1894, pp. 724–775) to the *second* drift sheet, the name *Kansan* being then applied to the *oldest* drift. In 1895 (Jour. Geol., vol. 3, pp. 270-277) Chamberlin, at suggestion of Upham, shortened the name of *second* drift sheet to *Iowan*. In 1896 (Jour. Geol., vol. 4, pp. 872–876), as result of further studies, he shifted the name *Kansan* to the *second* drift (which is the drift that covers NE. Kansas), and shifted the name *Iowan* to a younger drift (supposed to be the *fourth* drift), the name *Illinois* (from unpublished rept of F. Leverett) being applied to the *third* drift. The *Iowan* drift has generally been regarded as later than Illinoian drift (the name applied to third drift of Labrador part of Laurentide ice sheet), but Leverett later expressed opinion that the Iowan drift, also the loess to which the names *Iowan* and *Peorian* have been applied, may be of same age as Illinoian drift.

G. F. Kay and M. M. Leighton now include Peorian loess and Iowan glacial stage in the Wisconsin stage. (See under *Wisconsin stage.*)

†Iowan loess (Pleistocene).

Name formerly applied to the loess deposit in Iowa and Ill., "mainly interglacial, succeeding the development of the Sangamon soil and weathered zone on the Illinoian till, and also succeeding the development of the pebbly concentrate on the Iowan drift." (See under *Peorian loess.*)

G. F. Kay and M. M. Leighton, 1933 (Geol. Soc. Am. Bull., vol. 44, pp. 669–673, August 31), include in Wisconsin stage the Iowan drift and Peorian loess, and recognize *Iowan loess* as a part of Peorian loess. (See under *Wisconsin stage.*)

Iowa Point shale. (In Calhoun shale.)

Pennsylvanian: Southeastern Nebraska, northeastern Kansas, and northwestern Missouri.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 40, 43, 51, 102). *Iowa Point sh.*, top bed of Calhoun sh., consists of (at type section in Missouri River bluff just E. of Iowa Point, Kans.), (descending): (1) Bluish argill. bedded to massive sh., with carbonaceous flakes and plant leaves; (2) blue to brownish sh. with some sand, becoming a loose ss. at places; (3) bluish to brownish bedded argill. sh. Thickness 10± ft. at Iowa Point, Kans., Forest City, Mo., and SE. Nebr. Underlies Curzen ls. (basal bed of Topeka ls.) and overlies Meadow ls.

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, 2d ser., p. 47), stated that true Meadow ls. belongs down in Stanton ls., and he applied *Sheldon ls.* to the ls. underlying Iowa Point sh. and overlying Jones Point sh.

R. C. Moore and G. E. Condra, 1932 (Oct. 1932 revised classification chart of Penn. rocks of Kans. and Nebr.), restricted *Calhoun sh.* to beds above Sheldon ls., below Topeka ls., and included Jones Point sh. and Sheldon ls. in Deer Creek ls. (redefined). Calhoun sh. restricted thus occupies interval of beds previously named *Iowa Point sh.* In 1933 (Nebr. Geol. Surv. Paper No. 2, p. 5) Condra stated Iowa Point sh. was discarded for Calhoun restricted.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 11). *Calhoun sh. fm.* divided into (descending) Iowa Point sh., Sheldon ls., and Jones Point sh.; and R. C. Moore followed this classification in his 1936 rept. (Kans. Geol. Surv. Bull. 22).

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936. For Condra's latest interpretation of strat. position of this sh. see 1937 entry under *Topeka ls.*

Ipava shale and sandstone. (In Carbondale formation.)

Pennsylvanian: Central western Illinois (Fulton County).

T. E. Savage, 1927 (Am. Jour. Sci., 5th, vol. 14, pp. 307–316), applied *Ipava sh. and ss.* to the clay, sh., and sss. composing that part of Carbondale fm. beneath Springfield (No. 5) coal and above Vergennes ss. in Fulton Co. Derivation of name not stated, but probably is the town in Fulton Co.

Ipperwash limestone.

Devonian: Ontario.

C. R. Stauffer, 1915 (Canada Geol. Surv. Mem. 34, p. 11).

Ipperwash limestone member.

Devonian: Ontario.

W. Malcolm, 1915 (Canada Geol. Surv. Mem. 81, p. 42). Ipperwash ls. memb. of Hamilton fm.

Ira slate.

Lower Ordovician (Beekmantown): Southwestern Vermont (Rutland County).

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 398). *Ira sl.*—Dark-gray or black sl. with very little banding or means of determining bedding, but a few ft. of sl. in lower part contains gray siliceous seams. Secondary quartz is developed in these beds and they are tightly squeezed and dissected by folding so that locally the fm. resembles finely banded gneiss. Sedimentary contact btw. the sl. and underlying Williston ls. is sharp. Upper contact with West Rutland marble is equally sharp, with complete change from muddy sediments to pure ls., and it appears to be uncon. with the West Rutland. The sl. disappears at N. end of Taconic Range, but to S. it expands into a belt 1 or 2 mi. wide. Thickness probably 700 or 800 ft. Is well developed in town of Ira, which adjoins West Rutland on S., Castleton quad.

Irasburg conglomerate.

Lower Ordovician: Northeastern Vermont (Orleans and Washington Counties) and Quebec.

C. H. Richardson, 1906 (5th Rept. Vt. State Geol., p. 82). *Irasburg cgl.*—As it contains beds of siliceous ls. lithologically identical with Waits River ls. it should both mark the basal memb. of Lower Trenton series and the great erosional uncon. on W. Its strat. position is capable of 2 interpretations: (1) That it is basal memb. of Waits River ls. formed upon the rapidly subsiding sea floor when the sea transgressed upon pre-Camb. schists; (2) that it is basal memb. of a younger series of rocks lying in narrow belt btw. Montpelier sl. on E. and pre-Camb. schists on W. Named for Irasburg, Orleans Co., where it is best represented.

C. H. Richardson, 1912 (8th Rept. Vt. State Geol., p. 171). *Irasburg cgl.* assigned to Ord. All its boulders are pre-Ord. Underlies Waits River ls.

C. H. Richardson and E. F. Conway, 1912 (8th Rept. Vt. State Geol., p. 151). *Irasburg cgl.*—Lowest memb. of Ord. in east Vt. Is a ls. cgl. discovered and named in 1904. Pebbles are all pre-Ord. in a ls. matrix. Rests uncon. on pre-Ord (Camb. ?) schists.

C. H. Richardson et al., 1914 (9th Rept. Vt. State Geol., p. 309). In *Irasburg cgl.* at type loc. are boulders 1 to 3 ft. diam.

C. H. Richardson, 1916 (10th Rept. Vt. State Geol., p. 125). *Irasburg cgl.* is true basal cgl. Is uncon. on Camb. schists. Has been traversed approx. 100 mi., northward into Canada and southward through Irasburg and into Northfield. In entire distance the pebbles are of Camb. materials and the matrix Ord.

C. H. Richardson, 1919 (11th Rept. Vt. State Geol., pp. 46, 106, 128). *Irasburg cgl.* as it exists in Irasburg is wanting in Roxbury, Vt., but its geological equiv. as discovered in Northfield last summer extends into Roxbury. If Northfield were not preoccupied I would call this basal cgl. in Northfield the *Northfield cgl.*

C. H. Richardson, 1929 (16th Rept. Vt. State Geol., pp. 107–110). When discovered the *Irasburg cgl.* was supposed to be a more or less local phase of Waits River ls., but it is not. It carries a few plates of muscovite and biotite which are characteristic of Waits River ls. series. It has been followed into Canada for 200 mi. and S. through Vt. for 100+ mi. Discovery site is in bed of Lords Creek just outside S. limit of village of Irasburg. The area exposed in Irasburg Twp is 4 mi. long and ½ mi. wide. This cgl. or its time equiv. can be divided into 5 more or less distinct phases: *Irasburg phase, Albany phase, Northfield phase, Coventry phase, Magog, Quebec, phase.* The *Irasburg phase* is characterized by boulders more than 2 ft. diam., by porphyritic andesites, and by granite boulders. Fossils prove the cgl. began as early as Beekmantown. [For descriptions of the other "phases" see under each name.]

C. H. Richardson and J. E. Maynard, 1933 (18th Rept. Vt. State Geol., p. 346). The *Irasburg, Albany,* and *Northfield cgls.* form base of Ord. in eastern Vt.

Irasburg granite.

Devonian: Northeastern Vermont (Orleans County).

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), listed this name in Dev. of "central Vt.," but without definition. Probably named for Irasburg Twp or Irasburg village, in Orleans Co.

Ireland sandstone.

Pennsylvanian: Central Kansas (Woodson County).

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 93, 96, 113). [See under *Douglas fm.,* Moore, 1932.]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 146, 157, etc.). *Ireland ss. memb. of Lawrence sh.*—Massive or irregularly cross-bedded buff or brownish ss., some tens of ft. thick, prominent in Lawrence sh. at some places. Occurs partly in form of large sheets of varying horizontal extent and thickness, and partly as channel fillings associated locally with deposits of ls. cgl. up to 8 or 9 ft. thick in bottom of channel depressions. In Douglas and Leavenworth Counties the channel ss. is in contact with lower part of Lawrence sh., Haskell ls., Stranger fm., and probably in places with Iatan ls. and Weston sh. In type region top of Ireland ss. is only few ft. below top of Lawrence sh. Type loc., on Ireland Creek and farm of W. E. Ireland, 5 mi. SW. of Yates Center, Woodson Co.

Irene conglomerate.

Pre-Cambrian(?): Southeastern British Columbia and northwestern Idaho.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, maps 6 and 7, 116°30′ to 117°30′). *Irene cgl.*—Massive, greatly sheared; thin ls. lenses.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, pp. 141, 178, 194). *Irene cgl. fm.*—Coarse cgl. with some lenses of metamorphosed sss. and pelites a few inches to several ft. thick, metamorphosed to phyllitic schists. Thickness 5,000+ ft. Grades into overlying Irene volcanics. Basal fm. of Summit series. Assigned to Belt series. Rests uncon. on pre-Camb. Priest River terrane. Outcrops on summit and slopes of Irene Mtn, B. C.

C. W. Drysdale, 1917 (Canada Geol. Surv. Summ. Rept. 1916, p. 61). assigned this fm. to Camb.

Irene volcanic formation.

Pre-Cambrian(?): Southeastern British Columbia and northwestern Idaho.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, maps 6 and 7, 116°30′ to 117°30′). *Irene volcanic fm.*—Thick flows of pyroxene andesites, with some pyroclastics and a massive interbed of mag. ls.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, pp. 144, 178, 194). *Irene volcanic fm.*—Effusive greenstone, with few subordinate layers of basic tuff, a thick band of cgl. breccia, and a strong bed of dol. intercalated. Thickness 6,000 ft. Outcrops along W. slope of Irene Mtn, B. C. [just E. of 117th mer. and just N. of 49th par.]. Conformably underlies Monk fm. and grades into underlying Irene cgl. All included in Summit series, Beltian.

Irish sand.

A subsurface sand in eastern Okla., which is said to correlate with Tyner fm. (Ord.), also with the subsurface Wilcox sand. Named for the green shales with which it is associated. Also called "Green series."

Irondale limestone. (In Conemaugh formation.)

Pennsylvanian: Northern West Virginia, western Maryland, and southern Pennsylvania.

I. C. White, 1891 (U. S. G. S. Bull. 65, p. 95). *Irondale ls. and ore.*—Buffish-gray ls. with iron immediately beneath. Thickness 0 to 2 ft. Lies 155 ft. above Upper Freeport coal and directly beneath Masontown [?] coal. Occurs at Irondale, Preston Co., W. Va., and adjoining regions. [See also I. C. White, 1903 (W. Va. Geol. Surv. vol. 2).]

According to C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, p. 58, pl. 6), the *Irondale ls.* at Wheeling, W. Va., underlies fire clay beneath Brush Creek coal and overlies Mahoning red bed. In places rests on Corinth ss.

Irondequoit limestone member (of Clinton formation).

Silurian: Central and western New York and Ontario.

J. M. Clarke, 1906 (N. Y. State Mus. 2d Rept. Dir. Sci. Div., 1905, p. 12). The Clinton group of deposits in Rochester and Ontario Beach quads (field work by C. A. Hartnagel), is now divided, in accordance with Mr. Hartnagel's determinations, into following units (descending): *Irondequoit ls.*, Williamson sh., Wolcott ls., Furnaceville iron ore, and Sodus sh. Will be described by Hartnagel in forthcoming rept.

C. A. Hartnagel, 1907 (N. Y. State Mus. Bull. 114, pp. 5–35). *Irondequoit ls.*—Layers of ls. separated by bands of sh., the sh. bands in lower part green and in upper part gray. Top memb. of Clinton fm. in Rochester and Ontario Beach quads. [Rochester sh. is now considered top memb. of Clinton fm.] Rests on Williamson sh. and underlies Rochester sh. Named for town just N. of Rochester. [A. W. Grabau (Jour. Geol., vol. 17, 1909) gave 17 ft. as thickness of Irondequoit ls. In Niagara quad. it is 10 to 15 ft. thick.]

G. H. Chadwick, 1908 (Sci., n. s., vol. 28, pp. 346–348). Fauna of *Irondequoit ls.* is very nearly that of Rochester sh., to which it should, therefore, be transferred. [Chadwick classified it as basal memb. of Rochester sh., which he treated as a distinct fm. overlying the Clinton. All other writers, however, continue to treat it as distinct from Rochester sh.]

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 49). East from Wayne Co. the *Irondequoit ls.*, while still recognizable, has increased so much in shaly content as to be no longer recognized as a ls. It has been traced to Niagara River, where it directly overlies Wolcott ls. Excluded from Rochester sh.

C. Schuchert, 1914 (Geol. Soc. Am. Bull., vol. 25, p. 314), identified 4 ft. 5 in. of *Irondequoit ls.* at Hamilton, also at other places in Ont., resting on 8 ft. 8 in. of Wolcott ls.

E. O. Ulrich, 1923 (Md. Geol. Surv. Sil. vol., pp. 191, 347, etc.), placed *Irondequoit ls.* below Rochester sh. and above Williamson sh., which is position assigned to it by W. Goldring, 1931 (N. Y. State Mus. Hdb. 10).

†Iron Mountain series.

Pre-Cambrian (Llano series): Central Texas.

T. B. Comstock and E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. lvii, 274). *Iron Mtn series.*—Metamorphosed rocks; in descending order, chloritic slates and shales, carbonaceous schists, ferruginous rocks, and qtzites. Middle div. of Fernandan system. Underlies Click series and overlies Valley Spring series.

Same as Valley Spring gneiss.

Named for Iron Mtn, NW. of Valley Spring, Llano Co.

Iron Mountain conglomerate.

Upper Cambrian: Southeastern Missouri.

A. Winslow, 1894 (Mo. Geol. Surv. vol. 6, pp. 331, 354). *Iron Mtn cgl.*—Cgl. underlying La Motte ss. and forming basal part of Ozark series in SE. Mo. Possibly of Camb. age.

A. Winslow, 1896 (U. S. G. S. Bull. 132). *Iron Mtn cgl.*, 0 to 100 ft. thick, underlies La Motte ss. and overlies Archean granites and porphyries.

C. R. Keyes, 1901 (Am. Geol., vol. 28, pp. 51–53). [See 1901 entry under *Lamotte ss.*]

H. F. Bain and E. O. Ulrich, 1905 (U. S. G. S. Bull. 267). [See 1905 entry under *Lamotte ss.*]

Subsequent Mo. repts treat Lamotte ss. as basal Camb. fm. in Mo., and mention a cgl. at base, but apparently some authors still consider Pilot Knob cgl. to be older than Lamotte and of pre-Camb. age.

Named for Iron Mtn, St. Francois Co.

Iron Mountain porphyry.

Pre-Cambrian: Southeastern Missouri.

C. R. Keyes, 1894 (Mo. Geol. Surv. vol. 4, p. 30), and 1895 (Mo. Geol. Surv. Sheet Rept. No. 4, vol. 9). *Iron Mountain porphyry.*—Quartz porphyry, 300 ft. thick, in bold rugged hills near E. limit of Ozark region, the best known of which are Pilot Knob and Iron Mtn. Assigned to Archean. Older than Pilot Knob cgl. and younger than Knob Lick granite.

On 1922 geol. map of Mo. this porphyry is assigned to Laurentian (?).

J. Bridge (personal communication) states this fm. is now considered to be pre-Camb., and it is so classified by U. S. Geol. Survey.

Named for Iron Mtn, St. Francois Co.

Iron Mountain intrusive.

Cretaceous (?): Western Texas.

C. Schuchert, 1927 (Am. Jour. Sci., 5th, vol. 14, p. 400), under heading "Iron Mtn intrusive," stated that the rocks (syenite porphyry) form a conspicuous intrusive stock N. of Marathon known as Iron Mtn.

Iron Ridge ore bed.

Silurian: Southeastern Wisconsin.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, p. 561). With possible exception of the Mayville, which may be late Clinton, and the *Iron Ridge ore bed*, which is probably of Brassfield age, the Clinton group is not represented in Wis. [The Brassfield is now regarded as pre-Clinton.]

Iron River iron-formation member (of Michigamme slate).

Pre-Cambrian (upper Huronian): Northeastern Wisconsin and northern peninsula of Michigan.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184). *Iron River iron-fm. memb.*—The iron-fm. separating upper slates of Michigamme sl. from the lower slates of that fm. in Iron River (Mich.), Crystal Falls (Mich.), and Florence (Wis.) districts.

Ironshore limestone.

Recent or Pleistocene: Cayman Islands, British West Indies.

C. A. Matley, 1924 (Pan-Am. Geol., vol. 42, pp. 313–315). *Ironshore ls.*—Consolidated coral sand, marl, and ls., representing latest accretion to the area of Cayman Islands, and forming a low rocky shore, known locally as "ironshore." Rises inland to a height of 12 to 15 ft. above the sea, where it is generally backed by raised marine cliffs of the older Bluff ls. Is of Recent, or possibly of Pleist., age.

Ironside beds.

Pliocene: Northeastern Oregon (north part of Malheur County).

J. C. Merriam, 1916 (Univ. Calif. Pub. Dept. Geol. Bull., vol. 10, No. 9, pp. 129, etc.), described a *late Tert. fm.* that contained fossil mammals near Ironside, and consisted of buff sandy shales and shales with but little sand, standing at varying angles up to 20° at least. "Good reason for believing that the sediments at Ironside are not younger than middle Plio. and not older than late Mio." Merriam seems to have studiously avoided naming the beds or using the term *Ironside beds.*

J. C. Merriam, 1919 (Univ. Calif. Pub., Dept. Geol. Bull., vol. 11, No. 5, p. 437e), mapped *Ironside Pliocene.*

W. D. Smith and E. L. Packard, 1919 (Univ. Oreg. Bull., vol. 16, No. 7, p. 99). Sed. beds at Ironside (J. C. Merriam, Calif. Univ. Dept. Geol., Bull. 10, p. 129) have recently been designated *Ironside fm.* They consist of buff-colored sandy shales and shales, possibly 200 ft. thick, now deformed, which yielded a small vertebrate fauna that Merriam considers to be younger than Rattlesnake Plio. [Called *Ironside beds* in table in this Bull.]

Ironside dolomite member (of Sultan limestone).

Devonian: Southeastern Nevada (Goodsprings region).

D. F. Hewett, 1931 (U. S. G. S. P. P. 162, pp. 10, 14, etc.). *Ironside dol. memb.*—Dark gray to black dol., in beds 2 to 5 ft. thick. Basal memb. of Sultan ls. Thickness 5 to 125 ft. Underlies Valentine ls. memb. of Sultan ls. and overlies Goodsprings dol. Exposed near Ironside mine, 1 mi. N. of Boss mine, on W. side of Spring Mtns Range. E. Kirk says fossils are late Middle Dev. or early Upper Dev.

Ironstone quartz diorite.

Devonian (?): Central and southern Massachusetts and northeastern Connecticut.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 168–170 and map). *Ironstone quartz diorite* is the rock that forms the dark hornblendic border zone of the Milford granite. Is a dull-black, massive rock, of fine to medium grain. Named for exposures in long railroad cut at Ironstone, in town of Blackstone, Mass.

Ironton slate.

Pre-Cambrian: Southeastern Missouri (Iron County).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, p. 252). *Ironton terrane.*—Slates, 200 ft. thick, overlying Pilot Knob cgl. and uncon. underlying La Motte ss. Assigned to Animikian.

Probably named for Ironton, Iron Co.

Ironton sandstone member (of Franconia sandstone).

Upper Cambrian: Southwestern Wisconsin.

F. T. Thwaites, 1923 (Jour. Geol., vol. 31, p. 550). *Ironton memb.*—A few ft. of hard calc. coarse-grained ss. forming basal memb. of Franconia fm. in SW. Wis.

E. O. Ulrich, 1924 (Trans. Wis. Acad. Sci., Arts, and Lett., vol. 21, pp. 83, 93–94). *Ironton ss. memb.*—Basal ss. of Franconia fm. in SW. Wis. Has been recognized and studied at many places in Sauk, Richland, Vernon, La Crosse, Monroe, Jackson, Adams, and Juneau Counties, where it varies in thickness from about 2 ft. to 12 or possibly 15 ft. At Ironton [Sauk Co.], the type loc., it varies from 5 to 10 ft. Top is even. The memb. is composed mainly of reworked washed and relatively coarse residual grains of Dresbach ss., the surface of which had previously been subjected to subaerial leaching and wear. It extends downward to lowest plane indicating reworking and redeposition of the weather-loosened top sands of underlying Dresbach fm. It commonly includes a few grains of glauconite and other material that is not present in undisturbed underlying beds of Dresbach ss. But to make sure of identification of Ironton memb. it is advisable to search for its characteristic fossils. In Dresbach proper no organic remains—except perhaps worm burrows—have so far been observed.

Additional details are given by W. H. Twenhofel, G. O. Raasch, and F. T. Thwaites in Geol. Soc. Am. Bull., vol. 46, No. 11, 1935, pp. 1698–1699, etc.

Ironwood iron-formation.

Pre-Cambrian (middle Huronian): Northwestern Michigan and northwestern Wisconsin (Penokee-Gogebic).

C. R. Van Hise, 1901 (U. S. G. S. 21st Ann. Rept., pt. 3, p. 338). *Ironwood fm.*—Cherty iron-bearing carbonates, ferruginous slates and cherts, jaspilites, ore bodies, and actinolite-magnetite schists. Thickness 850 ft. Underlies Tyler sl. and overlies Palms fm. City of Ironwood, Mich., is partly located on the fm.

Later repts give thickness 850 to 1,500 ft.

C. R. Van Hise and C. K. Leith in 1909 (U. S. G. S. Bull. 360) and 1911 (U. S. G. S. Mon. 52) assigned this fm. to upper Huronian.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184) changed name to *Ironwood iron-fm.*, and assigned the fm. to middle Huronian.

†Iroquois moraine.

Pleistocene (Wisconsin stage): Northwestern Indiana (Newton and Jasper Counties).

F. Leverett, 1899 (U. S. G. S. Mon. 38). A ridged belt and bowldery strip N. of Iroquois River, in Newton and Jasper Counties, Ind.

F. Leverett, 1915 (U. S. G. S. Mon. 53, p. 126). Further work has shown that Iroquois moraine is simply a continuation of Marseilles morainic system, produced entirely by Illinois lobe, and "Iroquois moraine" has been discarded.

Iroquois.

Name applied to a glacial lake, of Pleist. age, in Great Lakes region.

Iroquois stage.

Pleistocene.

W. Upham, 1895 (Am. Geol., vol. 16, p. 106). Included in Champlain epoch.

Iroquois clay.

Pleistocene: Ontario.

A. P. Coleman, 1909 (Ontario Bur. Mines Ann. Rept., vol. 18, pt. 1, p. 297).

Irvine formation.

Pliocene (?): Central Kentucky.

M. R. Campbell, 1898 (U. S. G. S. Richmond folio, No. 46, p. 3). *Irvine fm.*—Unconsolidated sand, gravel, and clay capping the river hills in Richmond quad. Rests uncon. on Carbf. Assigned to Neocene.

A. M. Miller, 1925 (Ky. Geol. Surv., 6th ser., vol. 21, p. 141). Fossils of *Irvine fm.* seem to indicate late Pliocene or early Pleist. age.

Named for Irvine, Estill Co.

Irvine sand.

A subsurface sand, of Dev. age, in eastern Ky.

Irvineton parvafacies.

Upper Devonian: Northwestern Pennsylvania.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 28). The parvafacies of the Chagrin magnafacies within the Venango stage is termed *Irvineton parvafacies*, from village of that name on Allegheny River 4 mi. W. of Warren, Pa. [On p. 35 he speaks of the *Conewango parvafacies* of the *Irvineton magnafacies*.]

Irving greenstone.

Pre-Cambrian: Southwestern Colorado.

E. Howe, 1904 (Jour. Geol., vol. 12, pp. 501–509). *Irving fm.*—Greenstone complex, including schists and massive basic rocks sometimes possessing a porphyritic structure, others partly mashed or brecciated, and a few distinctly granular, while no well-defined system of bedding or stratification could be made out. All rocks are of dull-greenish color and appear to have undergone extensive alteration. At two places massive qtzite was found, and at a number of localities extremely siliceous schists. Rarely light-gray gneiss and mashed qtzite occur. Overlain by

Algonkian cgls. and qtzites, from which they are separated by an erosion interval of unknown extent, the overlying Algonkian cgl. containing quantities of pebbles of Irving greenstone. At first the Irving was assumed to be a part of the great Archean complex of schists and gneisses known to occur near by in Animas Canyon, but it is now regarded as early Algonkian.

W. Cross and E. Howe, 1905 (U. S. G. S. Needle Mtns folio, No. 131). *Irving greenstone.*—A complicated series of greenstone, greenstone porphyry, and greenstone schist, with subordinate quartz-mica schist and granite gneiss, and a few bands of qtzite, often mashed and schistose. Prominently exposed in SE. part of quad. and composes Irving Peak. Distinguished from underlying Archean schists by distinctive character of certain of its more massive members and by presence of sed. rocks. Actual base nowhere seen. Thickness exposed appears to be at least 10,000 ft. Overlain uncon. by Vallecito cgl. Considered to be most probably of Algonkian age.

On 1935 geol. map of Colo. this fm. was assigned to Gunnison River series, which comprises the oldest exposed pre-Camb. rocks in Colo. The terms "Algonkian system" and "Archean system" having been discarded by U. S. Geol. Survey, the Irving greenstone is now classified as pre-Camb.

Isabel sandstone.

A name applied by H. R. Wanless (Ill. Geol. Surv. Bull. 60, 1931, pp. 179–193) to an undescribed ss., 7 to 50 ft. thick, near top of Pottsville fm. (Penn.) of central western Ill. Shown on p. 192 as uncon. overlain by a thin bed of sh. underlying coal No. 2, and as in places cutting out all beds down to near top of his Bernadotte ss. Derivation of name not stated.

Isabella stage.

Quaternary: Puerto Rico.

B. Hubbard, 1923 (N. Y. Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, vol. 2, pt. 1, p. 95).

Isabella granodiorite.

Late Jurassic (?): Southern California (Kernville quadrangle).

W. J. Miller, 1931 (Univ. Calif. Pub., Bull. Dept. Geol. Sci., vol. 20, No. 9, pp. 343–352). *Isabella granodiorite.*—A large, generally massive, rather variable intrusive body consisting mainly of granodiorite. Typical occurrence in vicinity of Isabella. Grades into granite, also through quartz diorite into diorite. Is distinctly younger than the gabbro diorite that cuts Kernville series. May be late Jurassic. It more or less intricately cuts Kernville series and the intrusive gabbro diorite.

Isanti moraine.

Pleistocene (Wisconsin stage): Eastern Minnesota (Isanti County).

F. Leverett, 1932 (U. S. G. S. P. P. 161, p. 80). Third moraine of Rush Lake morainic system. Named for occurrence at old Isanti village, 1½ mi. N. of present town of Isanti, Isanti Co.

†Ischua sandstone.

Upper Devonian: Western New York.

E. N. Horsford, 1840 (N. Y. Geol. Surv. 4th Ann. Rept., pp. 466, 469–470). The *Ischua sss.* are developed in Allegany Co. at a few localities. The Ischua stone quarries, lying almost wholly in town of Machias, contain stone with which there are none other in the country to be compared.

G. H. Chadwick, 1924 (N. Y. State Mus. Bull. 251, pp. 152–153). Horsford early appropriated the name *Ischua ss.* to Cuba ss. lentil of Chemung fm.

Ishawooa intrusives.

Miocene: Yellowstone National Park, Wyoming.

A. Hague et al., 1904 (U. S. G. S. Mon. 32, Atlas; Canyon, Lake Crandall, and Ishawooa sheets). *Ishawooa intrusives.*—Massive andesite, diorite, and granite porphyry bodies penetrating the late basic breccia in Ishawooa quad. Also occurs as dike rocks, varying from diorite to granite porphyry, breaking through the late basic breccia in Canyon, Lake, and Crandall quads., Yellowstone Park.

Named for development on W. side of Ishawooa Mesa, Yellowstone National Park, Wyo.

†Ishpeming formation.

Pre-Cambrian (upper Huronian): Northwestern Michigan (Upper Peninsula).

C. R. Van Hise and W. S. Bayley, 1895 (U. S. G. S. 15th Ann. Rept., p. 590). *Ishpeming fm.*—Cgl., qtzite, grünerite-magnetite schist, and associated rocks. Underlies Michigamme fm. and uncon. overlies Negaunee fm. Includes Bijiki schist and Goodrich qtzite. Surrounds and underlies Ishpeming.

Unnecessary name, the Bijiki and Goodrich both being recognized in the dist.

Isidro formation.

Tertiary: Mexico (Lower California).

A. Heim, 1922 (Geol. Mag., vol. 59, p. 539).

†Island series.

Upper Cretaceous: Southeastern New York (Staten Island) and southeastern Massachusetts (Marthas Vineyard).

L. F. Ward, 1895 (U. S. G. S. 15th Ann. Rept., pp. 335–336). *Island series.*—Ferruginous concretionary beds extending from Staten Island to Marthas Vineyard, and considered to be very latest phase of Potomac fm.

A. Hollick, 1906 (U. S. G. S. Mon. 50). The Raritan and Cliffwood [Magothy] fms. are="Island series" of Ward.

Island Creek shale.

Pennsylvanian: Eastern Kansas and southeastern Nebraska.

R. C. Moore, 1931 (Kans. Geol. Soc. 5th Ann. Field Conf. Guidebook, correlation chart). *Island Creek sh.*, new name; underlies Farley ls. and overlies Argentine ls.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 92, 97). [See under *Wyandotte ls.* Derivation of name not stated. On p. 46 *Island Creek sh.* is described as consisting of 1 to 14 ft. of gray argill. sh.]

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pp. 18, 60). *Island Creek sh. memb. of Wyandotte ls.*—Gray argill. or limy sh., 0 to 15 ft. thick. Overlies Argentine ls. memb. and underlies Farley ls. memb. Named for Island Creek, in N. part of Wyandotte Co., Kans. Type exposures W. and S. of Wolcott.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), stated that Newell is author of this name.

Island Hill formation.

Lower Devonian: Northeastern Mississippi (Tishomingo County).

W. C. Morse, 1928 (Jour. Geol., vol. 36, pp. 31–43). *Island Hill fm.* consists of a few layers of more or less cherty and siliceous fossiliferous ls. with a thin basal ls. cgl. Thickness 3 ft. Assigned to Oriskanian series. Uncon. underlies Whetstone Branch sh. and overlies New Scotland ls. Named for isolated hill on Yellow Creek about 3 mi. above its mouth. The fm. is largely confined to its type loc.

W. C. Morse, 1930 (Miss. Geol. Surv. Bull. 23), gave many details of this fm. Thickness 3 ft.

Island Lake series.

Pre-Cambrian: Manitoba.

J. F. Wright, 1928 (Canada Geol. Surv. Summ. Rept. 1927, pt. B, pp. 63, 71).

Island Mesa beds.

Upper Devonian: Northern central Arizona.

A. A. Stoyanow, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, p. 500). Twelve mi. NE. of Jerome, on Verde River, and SW. of Island Mesa, the increase of aren. matter in upper part of Dev. is appreciable. The little shells of *Camarotoechia eximia* and

O. saxatilis found in ls. at Jerome invariably occur in ss., here. Even more striking is faunal aspect of uppermost layers. The usual complex of Upper Dev. fauna of Jerome fm. is at hand, but within 125 ft. from base of overlying Redwall ls. (Miss.) there are 40 ft. of grayish-lavender thin-bedded shaly ls. and sh. overlain by 8 ft. of massive aren. purplish-gray ls. containing rich Dev. fauna. Above these beds are purplish aren. sh. (11 ft. thick) and ledge-forming aren. ls. and ss. of same color (64 ft. thick). This terminal part of Dev. of north-central Ariz., underlying the Redwall in the abrupt cliff of the plateau and attaining thickness of 122 ft., is not represented at Jerome. It is characterized by peculiar assemblage of Mollusca and is here designated *Island Mesa beds*.

Island Mine conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan (Isle Royale).

A. C. Lane, 1898 (Mich. Geol. Surv. vol. 6, pt. 1, pp. 99, 204, 206, 217, and pl. I). Belongs to Marvine's group C [=Eagle River group].

Named for occurrence in Island mine, Isle Royale.

Island Run sand.

A subsurface sand in Conemaugh fm. (Penn.) of W. Va., that lies at or near horizon of Morgantown ss. memb.

Isle La Motte marble.

Ordovician (Lower and Middle): Northeastern New York and northwestern Vermont (northern part of Lake Champlain).

E. Emmons, 1842 (Geol. N. Y., pt. 2, div. 4, geol. of 2d dist., p. 386). *Isle La Motte marble.*—Black ls. remarkably thick-bedded. Character connects it rather with Birdseye than with Trenton ls. Is 8 ft. thick at Watertown and 12 ft. thick at Isle La Motte. Is called *Seven-foot tier*. Underlies Trenton ls. and overlies Birdseye [Lowville] ls. [As thus defined applies to post-Lowville part of Black River group. Isle Lamotte is an island of 4,670 acres in Lake Champlain about opposite village of Chazy, N. Y., in Rouses Point quad., Grand Isle Co., Vt.]

W. W. Mather, 1843 (Geol. N. Y., div. 4, geol., pt. 1, p. 367). Black marble of Isle la Motte belongs to Black River ls.

E. Emmons, 1846 (N. Y. Nat. Hist. Agric., vol. 1, btw. pp. 113 and 206). *Isle Lamotte marble* consists of 7 to 30 ft. of black finely granular marble, underlying Trenton ls. and overlying Birdseye ls.

C. B. Adams, 1846 (2d Rept. Geol. Vt., p. 164). *Isle la Motte ls.* includes the several members known as Chazy and Birdseye ls., etc., since they are most fully exhibited on Isle La Motte.

E. Hitchcock, 1861 (Rept. Geol. Vt., vol. 1). Black River ls. or *Isle La Motte marble* consists of 20 ft. of black marble, underlying Trenton ls. and overlying Birdseye ls. The Isle La Motte ls. of 2d Ann. Rept. Vt. Geol., p. 164, included Black River, Birdseye, and Chazy lss.

H. Ries, 1899 (N. Y. State Geol. 17th Ann. Rept., pp. 357–370). In Champlain Valley the Black River ls. is locally known as *Isle Lamotte marble*. Overlies Birdseye ls.

G. H. Perkins, 1904 (4th Rept. Vt. State Geol., map opp. p. 113, pp. 121–143). Isle La Motte shows following exposed fms.: Glacial clay; Utica sh.; Trenton ls.; Black River ls.; Chazy (643 ft. thick and=major part of "Isle La Motte ls." of early Vt. geologists); and Beekmantown ls. The early Vt. geologists were so impressed by the mass of Chazy on the island that they called it "Isle La Motte ls." The name *Chazy ls.* was given to major part of Adams' Isle La Motte ls. by Hall and Emmons after the fine exposure of this rock at Chazy Village, N. Y. The only area of Black River ls. on the island was included by Adams in his Isle La Motte ls.

G. H. Perkins, 1916 (10th Rept. Vt. State Geol., pp. 200–212). Probably best exposure of Chazy in all its divisions is on Isle La Motte, for nowhere else in Champlain Valley are these so well displayed. [Map shows that Isle La Motte comprises glacial clay, Utica, Trenton, Black River, Chazy, and Beekmantown.]

Isle La Motte sandstone.

Lower Ordovician: Northwestern Vermont (northern part of Lake Champlain).

H. M. Seely, 1906 (5th Rept. Vt. State Geol., pp. 174–187). *Isle La Motte ss.* is usually the base of Chazy fm. in Champlain Valley, Vt. Named for Isle La Motte. Is 25 ft. thick at the Head, on Isle La Motte.

H. M. Seely, 1910 (7th Rept. Vt. State Geol., pp. 257–313), stated his *Isle La Motte ss.* is ferruginous ss., so named for large development on island.

Isle Royale amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

R. D. Irving, 1883 (U. S. G. S. Mon. 5, p. 195). *Isle Royale cupriferous amygdaloid* occurs 510 ft. above cgl. No. 8 in Portage Lake section.

Belongs to Central Mine group. The mineralized part is Isle Royale lode. Named for occurrence in Isle Royale mine, Houghton Co.

Isle Royale flow.

Includes Isle Royale amygdaloid and underlying trap.

Isle Royale trap.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name long in use locally. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. Is the trap bed underlying the Isle Royale amygdaloid, and forms basal part of Isle Royale flow.

Islesboro formation.

Cambrian (?): Central southern Maine.

G. O. Smith, E. S. Bastin, and C. W. Brown, 1907 (U. S. G. S. Penobscot Bay folio, No. 149, pp. 2–3). *Islesboro fm.*—A series of somewhat metamorphosed rocks, mainly of sed. origin, which occupy larger part of Islesboro and neighboring smaller islands. Lower memb. consists of slates, schists, calc. shales, impure qtzites, and small amounts of pyroclastics, but sl. is by far most abundant rock. Lower memb. is at least 300 to 400 ft. thick and probably considerably more. Upper memb. is Coombs ls., 7 to 100 ft. thick. The fm. underlies Battie qtzite. Assigned to Camb. (?). Named for development on Islesboro, Waldo Co.

On 1933 geol. map of Maine, by A. Keith, these rocks are included in Ord. and Camb. block.

†Itasca moraine.

Pleistocene (Wisconsin stage): Northern Minnesota.

Mapped by W. Upham, 1894 (Minn. Geol. and Nat. Hist. Surv. 22d Ann. Rept., pl. 1, p. 49). Extends eastward from Lake Itasca.

This name is no longer used, because detailed mapping by F. Leverett has shown that the morainal belt in region described follows a different course from that indicated by Upham.

Itascan till.

A term introduced by C. [R.] Keyes for a till sheet (of Keewatin lobe) that he considers to be pre-Kansan and younger than his Moingonan till sheet. (See Pan-Am. Geol., vol. 47, No. 5, 1927, p. 352.)

Ithaca shale member (of Portage formation).

Upper Devonian: New York.

James Hall, 1839 (N. Y. Geol. Surv. 3d Rept., pp. 318–325). *Ithaca group.*—Alternating slaty and compact sh. and argill. ss., but differs from underlying strata by fossils and in some particulars in lithologic character. Sometimes contains thin layers of impure ls. Underlies Chemung group and overlies more than 200 ft. of [unnamed] argill. sss. and shales which rest on Upper Black sh. [Genesee sh.] overlying the Tully ls. Named for occurrence at Ithaca.

L. Vanuxem, 1840 (N. Y. Geol. Surv. 4th Rept., p. 381). A series of thin ss. flags with fucoides resembling those below the Ithaca separates Chemung group from Ithaca group.

According to Vanuxem's 1942 rept the Chemung "group" overlies Ithaca "group" and the Ithaca overlies Portage or Nunda group.

E. Emmons, 1846 (Agric. N. Y., vol. 1, pp. 190–193). Ithaca group is included in Chemung group, because there is no necessity of separating the Ithaca from the Chemung group.

H. S. Williams, 1882 (Am. Ass. Adv. Sci. Proc., vol. 30, pp. 186–191). *Ithaca sh.* is proposed for a soft, fragile argill. sh., very similar to the lighter-colored masses of Marcellus sh., and found well represented at Ithaca, forming transition beds btw. Portage and Chemung rocks. Total thickness about 25 ft. Contains plant beds and a recurrent Hamilton fauna. Lower bdy not clearly defined, but where *Spirifer laevis* has been found in the Portage below, the top of this sh. is observed to lie 50 to 60 ft. above highest strata containing that fossil.

C. S. Prosser and H. S. Williams, 1888 (Am. Inst. Min. Engrs. Trans., vol. 16, pp. 945–946), gave following downward succession of strata: Chemung; Upper Portage sss. and shales of H. S. Williams, 600 ft.; Middle Portage (consisting of Upper Ithaca, 200 ft.; Typical Ithaca, 100 ft.; and Lower Ithaca, 150 ft.); Lower Portage sss. and shales, 250 ft.; Genesee shales.

C. S. Prosser, 1893 (Am. Jour. Sci., 3d, vol. 46, pp. 217–218). Ithaca group of Vanuxem or middle Portage of Prof. Williams is 450 ft. thick.

J. M. Clarke, 1894 (N. Y. State Mus. 47th Ann. Rept., p. 750). Downward succession: Chemung; Portage sss. of Naples section [typical Portage] = Upper Portage of Ithaca section; Ithaca or Middle Portage; Lower Portage; Genesee.

J. M. Clarke, 1897 (N. Y. State Geol. 15th Ann. Rept., pp. 33–62). Portage group is a series of aren. deposits representing the time which elapsed from close of Hamilton period (including Tully ls. and a portion of Genesee sl. where present [more inclusive than the Hamilton of modern nomenclature]) to opening of Chemung period. The historical Ithaca group is the sedimental equal of major part of entire Portage fm., and is younger than Sherburne sss. or lower Portage beds.

J. M. Clarke and D. D. Luther, 1904 (N. Y. State Mus. Bull. 63, with map). The Ithaca beds of Canandaigua and Naples quads are divided into ***West Hill flags and sh.*** above and *Grimes ss.* below. They overlie Hatch sh. and flags of Portage beds [restricted] and underlie High Point ss. of Chemung beds.

H. S. Williams, 1906 and 1907 (Jour. Geol., vol. 14, pp. 579–598, and vol. 15, pp. 93–112; Am. Ass. Adv. Sci. Proc., vol. 56, pp. 265–267). *Ithaca sh. memb.* of Nunda fm., which is strat. equiv. of Portage or Nunda group of Hall, is divided at Ithaca into Enfield sh. memb., 550 to 800 ft.; Ithaca sh. memb., 80 to 460 ft.; and Sherburne flagstone memb., 188 to 260 ft. The Ithaca contains a *Reticularia laevis* zone at top and Ithaca *Lingula* shales (black sh.) at base, and is the typical Ithaca group of Hall and later writers.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 74). In western N. Y. the Portage fm. consists of the beds carrying the Naples fauna; in central N. Y. of the Sherburne and Ithaca beds partially intercalated with the Naples fauna; in eastern N. Y. of the Sherburne and Ithaca beds (marine) overlain by Oneonta beds (brackish). The Enfield sh. memb. composes greater part of original "Ithaca group" of Hall, the restricted Ithaca being the lower part of Hall's "Ithaca group."

H. S. Williams, 1913 (U. S. G. S. P. P. 79). Portage fm. of western N. Y. is divided into Enfield sh. memb. (top), *Ithaca sh. memb.*, and Sherburne memb. (base). It underlies Cayuta memb. of Chemung fm. and overlies Genesee sh. The Oneonta ss. of Chenango Valley is time equiv. of upper part of Ithaca memb. and in part younger than the Ithaca.

G. H. Chadwick, 1922 (Geol. Soc. Am. Bull., vol. 34, pp. 68–69). The Ithaca beds of Chemung Co. underlie Enfield sh., uncon. overlie Sherburne ss., and are = Grimes ss. and Hatch sh. of Steuben and Allegany Counties.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369), defined *Ithaca sh.* as underlying *Enfield sh.* and overlying *Cashaqua sh.* (*Sherburne ss.*), and included them all in Portage group.

G. H. Chadwick, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, pp. 314–352). *Naples group* divided into Enfield or Attica memb. above (which includes Hatch and Rhinestreet) and *Ithaca or Sonyea memb.* below (which includes Cashaqua and Middlesex). Underlies Cayuta memb. of Chemung group and overlies Sherburne memb. of Genesee group.

The U. S. Geol. Survey at present treats Ithaca sh. as a memb. of Portage fm.

Ithaca facies sub-group.

Upper Devonian: Central southern New York (Ithaca region).

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, pt. 1, p. 202). *Ithaca facies sub-group* of Ithaca region divided into (descending) Triphammer sh. memb., Marathon ss. memb., Williams Brook coquinite memb., and Cascadilla sh. memb. Underlies Enfield facies sub-group and overlies Middlesex sh. of Genesee group.

Iuka formation.

Mississippian (early): Northeastern Mississippi (Tishomingo County).

W. C. Morse, 1928 (Jour. Geol., vol. 36, pp. 31–43). *Iuka fm.*—In Miss. is almost wholly chert and pulverulent silica. At one or two places in Miss. and at several places in Ala. it contains ls. as well as chert. Overlies Carmack ls., with great uncon., and is separated from overlying Alsobrook fm. by a large uncon.

W. C. Morse, 1930 (Miss. Geol. Surv. Bull. 23, passim), gave many details of *Iuka fm.* "Includes all beds from definite uncon. at top of Carmack ls. to base of Chester series." "Named for county seat of Tishomingo Co., Miss., around which it is more or less exposed."

Ivan limestone member (of Thrifty formation).

Pennsylvanian: Central northern Texas (Brazos River region).

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31). *Ivan ls.* lies 50 to 80 ft. below top of Thrifty fm., of Cisco group. Is separated from underlying Avis ss. and from overlying Blach Ranch ls. by shales with some ls. and ss.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, p. 24; Univ. Tex. Bull. 2132, pp. 154–158). *Ivan ls. memb. of Thrifty fm.*—Light-yellowish to brownish-gray massive, locally nodular unfossiliferous ls., 2 to 8 ft. thick. Lies 35 to 80 ft. above Avis ss. memb. of Thrifty and 30+ ft. below Blach Ranch ls. memb. Not traceable very far to NE. but has been mapped into Eastland Co., to S. In places SE. of Breckenridge a ls. occurs in the ss. and sh. interval btw. Avis ss. and Ivan ls., but it is distinguished from the Ivan by numerous fossil corals. The Ivan ls. is same as "Speck Mtn" ls. of Drake [1893] of Colorado River Valley.

Named for exposures in vicinity of Ivan, Stephens Co.

Ivan Creek limestone.

Same as Ivan ls., the original name.

Ivanhoe limestone member (of Shady dolomite).

Lower Cambrian: Southwestern Virginia (Wythe County region).

C. Butts, 1933 (Va. Geol. Surv. Bull. 42, p. 3 and columnar section on geol. map of Appalachian Valley of Va.). *Ivanhoe ls. memb. of Shady dol.* [See explanation under *Patterson ls. memb.* This name was adopted from an unpublished ms. by L. W. Currier.]

L. W. Currier, 1935 (Va. Geol. Surv. Bull. 43). *Ivanhoe ls. memb.*—Dense massive ls. with subordinate dol. beds and a few thin red shaly or sandy partings. Thickness 0 to 600± ft. Top memb. of Shady dol. in lead and zinc region of SW. Va., from Huddle to Bertha. In Austinville basin probably represented in part by series of fossiliferous ls. beds alternating with crystalline dolomites. Grades into underlying saccharoidal dol. memb. of Shady and underlies Rome fm. Named for exposures at and around Ivanhoe, Wythe Co.

Ivy Point member.

Middle Devonian: Central New York (Skaneateles quadrangle).

B. Smith, 1935 (N. Y. State Mus. Bull. 300, pp. 11, 47). *Ivy Point memb. of Ludlowville sh.*—Coarsely bedded and hard sh. in upper and lower parts, with softer sh. in middle. Coarse layers may be cross-bedded. Land plants associated with marine invertebrates. Thickness 50 ft., although some exposures show thicknesses in excess of this, and type section seems to be slightly less. Type section is in first ravine N. of Ivy (or Willow) Point on E. side of Skaneateles Lake, about ¾ mi N. and slightly W. of Spafford Landing. Base of the Ivy Point is here about 107 ft. above Staghorn Point submember of Otisco memb. of the Ludlowville. Lower 15 or 20 ft. show some cross-bedding.

Iwana green schist.

Post-Carboniferous (?): Eastern Alabama.

See description under *Hillabee green schist.* Is intrusive. Named for exposures about Iwana, Coosa Co.

†Izard limestone.

Middle and Lower Ordovician: Northern Arkansas.

R. A. F. Penrose, Jr., 1891 (Ark. Geol. Surv. Ann. Rept. 1890, vol. 1, pp. 102, 112–113, 121–124, 587–593). *Izard ls.* suggested by J. C. Branner for massive blue or grayish blue ls., 280 ft. thick, overlying saccharoidal ss. and underlying St. Clair ls. [broad and abandoned use of St. Clair]. Sometimes assumes finely granular semi-crystalline structure. Weathered surface frequently shows very irregular spots and lenticular seams of buff-colored earthy appearance, varying in thickness from 1/8 to 1/2 inch. Near top are frequently strata of cream-colored or dark watery blue ls. with smooth, even, compact structure and conchoidal fracture.

Is now differentiated into Plattin and Joachim lss. at its type loc.—Penters Bluff, SE. Izard Co. (See H. D. Miser, U. S. G. S. Bull. 715G, 1920.)

Jacalitos formation.

Pliocene (lower): Southern California (Coalinga region).

R. Arnold and R. Anderson, 1908 (U. S. G. S. Bull. 357). *Jacalitos fm.*—Sand, gravel, clay, and ss., 1,600 to 3,600 ft. thick, with characteristic fauna. Underlies, in places probably uncon., the major beds of blue sand that are characteristic of lower part of Etchegoin fm., but the Jacalitos also includes a great thickness of blue-sand beds at its summit in SE. part of Kreyenhagen Hills. Uncon. overlies Santa Margarita fm. Named for exposures both N. and S. of Jacalitos Creek, and in Jacalitos Hills, Fresno Co.

Some California geologists are applying this name in San Joaquin Valley to cover "Arnold's original type Jacalitos and about 1,000 ft. of strat. higher beds." (See H. W. Hoots and S. C. Herold, Geol. of nat. gas, A. A. P. G., 1935, pp. 127, 130.)

Jackass Mountain conglomerate group.

Lower Cretaceous: British Columbia.

A. R. C. Selwyn, 1872 (Canada Geol. Surv. Rept. 1871–72, p. 60).

Now referred to Kootenai fm.

Jackass Mountain group.

Lower Cretaceous: British Columbia.

G. M. Dawson, 1877 (Canada Geol. Surv. Rept. 1875–76, pp. 253–255). Exact syn. of Shasta group of Calif.

Jackfish Lake conglomerate.

Pre-Cambrian: Ontario.

J. E. Gill and J. E. Hawley, 1931 (Jour. Geol., vol. 39, p. 656).

Jackfork sandstone.

Pennsylvanian (early Pottsville): Southeastern and central southern Oklahoma and southwestern Arkansas.

J. A. Taff, 1902 (U. S. G. S. Atoka folio, No. 79). *Jackfork ss.*—Brown and drab ss., shaly ss., and thin ss., 3,800 ft. thick. Overlies Standley sh.

J. A. Taff, 1909 (U. S. G. S. Bull. 380, p. 289). *Jackfork ss.* of Ouachita Mtns is 5,000 ft. thick, overlies Standley sh., and underlies Caney sh. [not true Caney and now known as *Johns Valley sh.*].

C. W. Honess, 1924 (Okla. Bur. Geol. Circ. No. 3). My own observations show that *Jackfork ss.* of McCurtain Co., Okla., is 10,000 to 13,618 ft. thick, provided whole section of sss. above Stanley sh. be included in one fm., and indeed there is no means of dividing it on lithological grounds, for upper part is in no wise different from lower part, and there is no large body of sh. which might be taken for Caney or any fm. resembling Atoka. The Jackfork grades into underlying Stanley sh. The Upper Jackfork, 7,000 ft. thick, is apparently a sandy shoreward phase of Atoka fm., of Penn. age, and is separated from Lower Jackfork by Morrow beds equiv. to Wapanucka ls. of Arbuckle Mtns. The Lower Jackfork is 6,000 ft. thick and overlies Stanley sh.

C. N. Gould, 1925 (Okla. Geol. Surv. Bull. 35, pp. 36–37). There has been much controversy on age of *Jackfork fm.* A Morrow (lower Penn.) fauna has been found by Honess at base of his "Upper Jackfork" ss., which he correlates with Atoka fm. Miser therefore excludes "Upper Jackfork" of Honess from Jackfork fm. and maps it as Atoka on State map. The true Jackfork ss. is classified as of Miss. age by U. S. Geol. Survey.

H. D. Miser, 1925 (Okla. Geol. Surv. Bull. 35, p. 37, footnote). Honess and I went together in 1923 to his main fossil locality in his Jackfork ss. In his rept he correlates the fossil-bearing beds with Wapanucka and Morrow fms. The ss. that overlies the fossil-bearing horizon is called by him *Upper Jackfork* and the ss. below is called by him *Lower Jackfork*, because it looks like real Jackfork and not like Atoka. If we, in applying fm. names, are to follow time equivalency instead of lithologic character, the Upper Jackfork of Honess should, in my opinion, be called *Atoka*. I have so called it and shown it on State map. Taff says he believes Honess' Jackfork fauna is not from real Jackfork but from Atoka.

H. D. Miser and C. W. Honess, 1927 (Okla. Geol. Surv. Bull. 44, pp. 11–12). Caney sh. in its type loc. (Johns Valley, formerly called Caney Basin or Cove, in upper Cane Creek Valley, 6 mi. N. of Eubanks, Pushmataha Co., Okla.) rests on Jackfork ss. This relation holds in a fairly large part of Ouachita Mtns of Okla., but Caney seems to overlap progressively both Jackfork and Stanley toward NW., in northern Atoka and southern Pittsburg Counties. If Caney does not overlap Stanley and Jackfork, it is possible, as suggested by Honess, that Stanley and Jackfork are=parts of Caney sh. In this latter case the Stanley and Jackfork wedge into the Caney laterally, and typical Caney sh. that rests upon Jackfork ss. may be one of southward-thinning beds of sh. The true relations of Caney, Jackfork, and Stanley will probably be discovered in time.

The Penn. rocks of the area S. and E. of Ti Valley-Choctaw belt of Ouachita Mtns of SE. Okla. and western Ark. are now divided by U. S. Geol. Survey into (descending): Atoka fm., 6,000 ft.; Johns Valley sh., 0 to 1,000 ft. (formerly included in Caney sh.); Jackfork ss., 5,000 to 6,600 ft.; Stanley sh., 6,000 to 10,000 ft.; and (in Hot Springs quad., Ark.) Hot Springs ss., 0 to 200 ft. In the Ti Valley-Choctaw belt of Ouachita Mtns, Okla., the downward succession is Atoka fm., Wapanucka ls., Springer fm., and *Caney sh.* (now restricted to Miss. part of rocks formerly called *Caney sh.*). In Arkansas Valley of Ark. the Atoka overlies Jackfork ss. (See H. D. Miser, 1934, A. A. P. G. Bull., vol. 18, No. 8.)

Named for Jackfork Mtn, Pittsburg and Pushmataha Counties, Okla.

†Jacksboro formation. (In Cisco group.)

Pennsylvanian: Central northern Texas (Jack and Young Counties).

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, pp. 133–145). *Jacksboro fm.*—Approx. 60 ft. of lss. and ss. with a little sh. Contains the fossiliferous *Campophyllum* bed that is everywhere recognized. Top memb. is *Jacksboro ls.*, which plays out in the ss. hills SW. of Jacksboro [Jack Co.] and appears again in section N. of Finis, on Mineral Wells-Graham road. Is present only in Jack Co. and E. part of Young Co. Basal fm. of Cisco div. Underlies Bunger fm. and overlies Eastland fm., of Canyon div.

According to F. B. Plummer and R. C. Moore, 1922 (Tex. Univ. Bull. 2132, p. 138 and table 2), Jacksboro ls. memb. of Graham fm. is characterized by *Campophyllum torquium*, but Campophyllum bed of Drake is the much younger Gunsight ls. memb. of Graham fm.

Jacksboro limestone member (of Graham formation).

Pennsylvanian: Central northern Texas (Brazos River region).

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, pp. 133–145). *Jacksboro ls.*, top memb. of Jacksboro fm. [See 1919 entry under †*Jacksboro fm.*]

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31; Univ. Tex. Bull. 2132, pp. 127–143). *Jacksboro ls. lentil.*—A ls. near base of Graham fm. (of Cisco group) in Brazos River Valley. In vicinity of Jacksboro it consists of 2 ls. beds separated by 12 ft. of sandy sh. and ss. Total thickness of memb. 25± ft. Overlies Finis sh. and underlies Gonzales Creek sh. and ss., all members of Graham fm. The lower ls. bed is dark gray (weathering rusty yellow), hard, crystalline, 1 to 4 ft. thick, and filled with *Campophyllum torquium*. The upper ls. is poorly bedded, massive, shaly, 6 to 18 ft. thick, in places very fossiliferous, and 5 or 6 mi. to SW. changes to calc. ss., and to NE, of Jacksboro grades into shales.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 104), transferred Jacksboro ls. and Finis sh. to Caddo Creek fm., and stated (p. 112) that Home Creek ls. memb. includes Jacksboro ls.

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, pp. 62+), included Finis sh. and Gonzales Creek sh. in Graham fm. The U. S. Geol. Survey draws base of Graham fm. at top of Home Creek ls. This is where base was put by F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501).

Named for exposures in vicinity of Jacksboro, Jack Co.

Jacksina formation.

Pre-Permian: Southeastern Alaska (headwater region of Copper and Tanana Rivers).

W. C. Mendenhall, 1905 (U. S. G. S. P. P. 41, p. 26, in column of table credited to "Schrader, geologic reconn. of headwater region of Copper and Tanana Rivers, Alaska: Prof. Paper, in preparation"), showed *Jacksina fm.* opp. Sil. This rept. by Schrader appears never to have been published, as his subsequent duties called him to the States. Above is only known use of *Jacksina fm.*

Jackson formation.

Eocene (upper): Gulf Coastal Plain (southwestern Alabama to southern Texas).

T. A. Conrad, 1856 (Phila. Acad. Nat. Sci. Proc., vol. 7, pp. 257–258). [See 1856 entry under *Vicksburg group.*]

E. W. Hilgard, 1860 (Rept. Geol. and Agric. Miss., pp. 128–135). *Jackson group.*—Marls and soft lss., the marls white and blue, often indurate. [Fossils listed.] *Zeuglodon* common. Thickness 80 ft. Underlies Red Bluff group, which seems to be intermediate, in position and fossils, btw. Vicksburg group above and Jackson group below.

E. W. Hilgard, 1867 (Am. Jour. Sci., 2d, vol. 43, pp. 29–41). *Jackson group* is present at Red Bluff, where it underlies Red Bluff group.

Most early repts excluded the Red Bluff clay ("group") from the Jackson, and either treated it as distinct from the Vicksburg or included it in the Vicksburg. The Forest Hill (†Madison) sand has also been both included in and excluded from the Jackson, but it is now generally agreed that it is probably approx. contemp. with Red Bluff clay and more properly belongs in Vicksburg group. (See under *Red Bluff clay.*)

C. W. Cooke, 1918 (Wash. Acad. Sci. Jour., vol. 8, No. 7, pp. 187–190). Typical *Jackson fm.* of Miss. is composed chiefly of more or less calc. clay and less prominent sand and marl beds, divided into Yazoo clay memb. above [70 to 600 ft. thick] and Moodys calc. marl memb. below [35 to 90 ft. thick]. It underlies Vicksburg group (Olig.), the basal fm. of which is Red Bluff clay (marine) and the contemp. Forest Hill sand (shallow water), and it overlies Claiborne group (middle Eocene). Contains a large marine fauna. [Cooke also stated (Ala. Geol. Surv. Spec. Rept. No. 14, p. 274, 1926) that at its type loc. (Jackson, Miss.) the fm. consists chiefly of massive, plastic, gray clay with a sandy shell bed at base.]

The Jackson fm. is now recognized by U. S. Geol. Survey from southern Tex. to Tombigbee River in SW. Ala. East of Tombigbee River in Ala. and in western Ga. the deposits of Jackson age are represented by Ocala ls.; farther E. in Ga. and in western S. C. they are represented by Barnwell fm.; in eastern S. C. they are represented by Cooper marl (above) and Santee ls. (below). The Fayette ss. of eastern Tex. is also of Jackson age.

Named for exposures at Jackson, Miss., along Pearl River and Moodys Branch.

See also *Fayette ss.*

†Jackson formation.

Pennsylvanian: Michigan (Lower Peninsula).

A. C. Lane, as reported by M. E. Wadsworth, 1893 (Mich. Geol. Surv. Rept. 1891 and 1892, p. 66). *Jackson coal group.*—Underlies Woodville ss. and overlies Parma ss. Thickness 47+ ft.

A. C. Lane, 1899 (U. S. G. S. W. S. P. 30). *Jackson Coal Measures.*—Black shales, fire clays, black band iron ore, coals, and sss., the sss. generally white. Thickness 400 to 600 ft. Uncon. underlies Woodville ss. and overlies Parma ss.

A. C. Lane, 1901 (Mich. Miner, vol. 3, No. 1, p. 9). We are considering replacing *Jackson* (preoccupied) by Saginaw.

A. C. Lane, 1902 (Mich. Geol. Surv. vol. 8, pt. 2, map at end), used *Saginaw fm.* for the beds overlying Grand Rapids group, thus abandoning "Jackson."

Named for exposures at Jackson.

Jackson limestone. (In Greene formation.)

Permian: Southwestern Pennsylvania (Greene County).

J. J. Stevenson, 1907 (Geol. Soc. Am. Bull., vol. 18, pp. 97, 110, 112). *Jackson ls.*—Tough, impure, rock, containing some crystalline sphalerite, and associated with plant-bearing shales in Jackson Twp. near White Cottage, Greene Co. Exposed in Center and Jackson Twps. Seems to be persistent for at least 30 mi. Lies about 275 ft. above Nineveh coal and about 30 ft. below Gilmore ss.

†Jackson rocks.

A name locally applied to Marietta ss. in Roane Co., W. Va., because it weathers into fantastic shapes on land of Mr. Munson Jackson.

Jackson sand.

A subsurface sand, of Miss. age, in western Ky. and Hart Co., Ill., that has been identified as Cypress ss., of Chester group. (See A. A. P. G. Bull., vol. 16, No. 3, p. 244, 1932.)

Jackson sand.

A subsurface sand, of Paleozoic age, in Healdton field, Carter Co., southern Okla., lying lower than Healdton sand and higher than Simpson sand.

Jacksonboro limestone.

Miocene (lower): Eastern Georgia (Screven County).

W. H. Dall, 1892 (U. S. G. S. Bull. 84, pp. 83–84). *Jacksonboro ls.*—A stratum of ls. containing very numerous casts of shells and occasionally a silicified specimen, on the whole not unlike Tampa ls. This stone was formerly burned for lime. [Lists fossils.] The section here [near confluence of Brier Creek and Beaver Dam Creek, which together form a tributary of the Savannah River, 3 mi. below Jacksonboro, Screven Co., Ga.] showed 5 ft. of ferruginous sand and over 12 ft. of compact marly rock with fossils. At present the presumption is obviously in favor of early Mio. age of this deposit.

W. H. Dall, 1903 (Trans. Wagner Free Inst. Sci. Phila., vol. 3, pt. 6, p. 1573). No reasonable doubt the horizon of Jacksonboro white ls. is practically that of Tampa ls.

Later studies of T. W. Vaughan and C. W. Cooke showed this ls. to be a bed in Tampa ls.

Jacksonburg limestone.

Middle Ordovician: Northern New Jersey.

H. B. Kümmel, 1908 (U. S. G. S. Franklin Furnace folio, No. 161). *Jacksonburg ls.*—The lss. hitherto called Trenton ls. in N. J. repts, but which contain fossils of Lowville [now included in Black River], Black River, and lower Trenton age. Thickness 135 to 150 ft. Includes (descending): (1) Calc. shales; (2) dark blue or black fossiliferous lss., 30 to 40 ft.; (3) shaly beds, 30± ft.; (4) dark blue or black fossiliferous lss., 30 to 40 ft.; (5) basal cgl., few inches to 50 ft. At Jacksonburg, Warren Co., shales and thin-bedded shaly lss. 19 or 20 ft. thick occur at base of section, overlain by 102 ft. of ls., and top of section is not seen. Underlies Martinsburg sh. and uncon. overlies Kittatinny ls.

Jacksonian.

Time term used by some geologists to cover the epoch during which the Eocene Jackson fm. and contemp. beds were deposited in the Coastal Plain.

Jackson Park shale. (In Kanwaka shale.)

Pennsylvanian: Eastern Kansas and southeastern Nebraska.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 94, 96). *Jackson Park sh.* is applied to basal memb. of Kanwaka sh. in eastern Kans. Underlies Clay Creek ls. [Derivation of name not stated. On p. 52 Jackson Park sh. is stated to be 52 ft. thick.]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 170). *Jackson Park sh. memb.*—Basal memb. of Kanwaka sh. Chiefly bluish-gray and yellowish-brown sandy sh., 50+ ft. thick along Kansas River; thins to less than 1 ft. in Nebr. Underlies Clay Creek ls. memb. Type loc. Jackson Park, SE. part of Atchison, Kans.

†Jacksonville formation.

Miocene (upper): Northeastern Florida.

W. H. Dall, 1892 (U. S. G. S. Bull. 84, pp. 124–125, 157, 158, 327). *Jacksonville ls.*—A porous, slightly phosphatic yellowish rock, derived from calc. sand, and containing numerous molds of fossil shells belonging to newer Mio. fauna. The borings at Jacksonville passed through what appears to have been this rock for nearly 300 ft. Considered to be younger than Alum Bluff fm. and older than Grand Gulf group.

G. C. Matson and F. G. Clapp, 1909 (Fla. Geol. Surv. 2d Ann. Rept.). *Jacksonville fm.* consists of light-gray to white ls. weathering yellow, and light-gray to yellow clay and gray sand, with some chert beds. Is contemp. with Choctawhatchee marl and younger than Alum Bluff fm. [group].

G. C. Matson, 1913 (Carnegie Inst., vol. 4, pp. 126–131). [Same definition as above. Thickness given as 400 to 500 ft.]

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept.). Dall's "Jacksonville ls." and "Manatee River marl," which it has been found impracticable to map separately, are here included in Hawthorn fm. (of Alum Bluff group), although their faunas seem to be younger than typical Hawthorn. [The fauna of †Jacksonville fm. was reported by T. W. Vaughan in 1921 and Julia Gardner in 1924 to be *upper* Mio. and younger than Alum Bluff group, which is lower and middle Mio. The Hawthorn fm. is lower Mio.]

Named for exposures in excavation made for city waterworks at Jacksonville.

Jacob sand.

Pleistocene: Southeastern New York (Long and Fishers Islands) and islands of southern New England (Block, Nantucket, Marthas Vineyard, No Mans Land, and probably Cape Cod).

M. L. Fuller, 1905 (Geol. Soc. Am. Bull., vol. 16, pp. 367–390). *Jacob sand* (interglacial), fine gray sands or the equivalents, 40+ ft. thick, conformably overlying Gardiner[s] clay on Long Island and eastward to New England islands and Cape Cod. Conformably underlies Herod gravel. Correlated with Yarmouth stage of Mississippi Valley.

M. L. Fuller, 1914 (U. S. G. S. P. P. 82). *Jacob sand* of Long Island and islands to E. is transitional from Gardiners interglacial stage to Herod glacial substage, and seems to mark the first influx of new material on the advance of the ice sheet, bringing to a close the interglacial stage characterized by Gardiners clay. Time of deposition called *Jacob stage*. Thickness on Long Island 0 to 50 ft. Named for exposures near Jacob Hill, 8 mi. NE. of Riverhead, L. I.

J. B. Woodworth and E. Wigglesworth, 1934 (Harvard Coll. Mus. Comp. Zool. Mem., vol. 52). *Jacob sand* (transitional btw. Gardiners clay and Herod gravel memb. of Manhasset fm.) occurs on Block, Nantucket, Marthas Vineyard, No Mans Land, and probably Cape Cod. Correlated with upper part of Yarmouth stage of Mississippi Valley. Time of deposition called *Jacob stage.*

Jacob stage.

The time covered by deposition of *Jacob sand* (Pleistocene).

Jacob sand.

A subsurface sand in lower part of Jackson fm. (upper Eocene), in Driscoll pool, Duval Co., SE. Tex. See I. R. Sheldon, 1933 (A. A. P. G. Bull., vol. 17, No. 7, p. 819).

Jacobsville sandstone.

Upper Cambrian: Northern Michigan.

A. C. Lane and A. E. Seaman, 1907 (Jour. Geol., vol. 15, pp. 680, 692). Red and brown ss. striped with streaks of red clay sh., conglomeratic where it laps upon older fms. Thickness 0 to 1,500+ (4,000?) ft. In view of uncertainty of relation of the three parts of the Lake Superior sss. as used by Houghton, separate names seem to us likely to be useful, and we propose not only the term *Freda ss.* for that W. of the Copper Range, but the term *Jacobsville* (from Jacobsville, where the famous quarries of Portage redstone occur) *ss.* for that E. of the Copper Range, and we suppose this term may apply to all the Lake Superior ss. skirting the coast at intervals to Grand Island, while the term *Munising ss.* is to apply to upper 250 ft. of Lake Superior ss. which crosses the bluffs back of Munising, dips southerly, and is white or light colored. Relations to Freda ss. undet., and may be same fm

Named for exposures at Jacobsville, Houghton Co.

Jacque Mountain limestone member (of Maroon formation).

Permian: Western central Colorado (Tenmile district).

S. F. Emmons, 1898 (U. S. G. S. Tenmile Special folio, No. 48). *Jacque Mtn ls.*—Light bluish gray ls., characterized by an oolitic structure in certain layers. Top memb. of Maroon fm. Conformably overlain by Wyoming fm. [Map shows upper part of Maroon fm. exposed on lower slopes of Jacque Mtn and Jacque Ridge, and that upper part of Jacque Gulch is cut in upper part of the Maroon.]

The present approved definition of Maroon fm. is for the beds above the †Weber grits and below Morrison fm., including the beds called "Wyoming fm." by Emmons at the time he defined Jacque Mtn ls. The Jacque Mtn ls. is not, therefore, the top memb. of Maroon fm., but occurs near the middle of the Maroon as now recognized.

Jacumba volcanics.

Early Quaternary or late Tertiary: Southern California (San Diego and Imperial Counties).

W. J. Miller, 1935 (Calif. Jour. Mines and Geol., vol. 31, No. 2, pp. 138–140, map). *Jacumba volcanics.*—Extrusive rocks well exposed in several areas N. to E. of Jacumba, in southern Peninsular Range. Under microscope are olivine basalts. Extensively eroded. Thickness several hundred ft. Rest on Table Mtn fm. Are late Tert. or early Quat.

Jagger Bend limestone. (In Belle Plains formation.)

Permian: Central Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 421, 426). *Jagger Bend bed.*—To S. mostly alternating flaggy, smooth ls., carbonaceous shaly ls., and carbonaceous clay, 25 to 75 ft. thick. Fossiliferous. To N. carbonaceous nature not so apparent. Memb. of Albany div. Underlies Valera bed and overlies bed No. 8 (50 to 75 ft. of clay).

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, p. 195). *Jagger Bend ls.* is a memb. of Belle Plains fm. (middle fm. of Wichita group). Underlies Valera sh. memb. and overlies "bed No. 8" sh. of Drake.

Named for Jagger Bend of Colorado River, central Texas.

Jameco gravel (also **formation**).

Pleistocene: Southeastern New York (Long and Fishers Islands) and islands of southern New England (Block Island, Marthas Vineyard, and probably Cape Cod and Nantucket Island).

A. C. Veatch, 1903 (Jour. Geol., vol. 11, pp. 766–776). *Jameco gravels* (glacial), 100 ft. thick. Underlie Sankaty beds and uncon. overlie glacial gravels 35 to

325 ft. thick, which are believed to represent Pensauken of N. J. Named for Jameco pumping station of Brooklyn water works, a few mi. S. of Jamaica, N. Y., where borings first revealed the beds. Correlated with Kansan glacial stage of Mississippi Valley.

M. L. Fuller, 1905 (Geol. Soc. Am. Bull., vol. 16, pp. 367-390). *Jameco gravel.*—Stratified glacial gravels, 40 to 100 ft. thick. Conformably underlie Gardiner clay and uncon. overlie Mannetto gravel. Correlated with Kansan.

A. C. Veatch, 1906 (U. S. G. S. P. P. 44). *Jameco gravel* of Long Island consists of dark-colored sands and gravels that vary considerably in coarseness and are distinguished by small percentage of contained quartz. Underlies Sankaty fm. and overlies Mannetto gravel.

M. L. Fuller, 1906 (Sci., n. s., vol. 24, pp. 467-469). *Jameco gravels,* 100 ft. thick, granitic, often sandy. Regarded as outwash from second, probably Kansan, glacier. Writer in 1904 recognized this fm. in cliffs of Block Island, Marthas Vineyard, and Cape Cod. Underlies Gardiner clay and uncon. overlies Mannetto of Veatch.

M. L. Fuller, 1914 (U. S. G. S. P. P. 82). *Jameco gravel,* glacial gravel, 50 to 100 ft. thick on Long Island. *Jameco stage* applied to time during which the deposit was laid down, which is tentatively correlated with Kansan stage of Mississippi Valley. Underlies Gardiners clay and uncon. overlies Mannetto gravel.

J. B. Woodworth and E. Wigglesworth, 1934 (Harvard Coll. Mus. Comp. Zool. Mem., vol. 52). *Jameco gravel* on Block Island and probably on Nantucket Island and Cape Cod. *Jameco fm.* on Marthas Vineyard, where it is divided into (descending): Moshup till member, 0 to 10 ft.; coarse gravel; ferruginous boulder bed. Underlies Gardiners clay and overlies Mannetto fm. Time covered by its deposition is called *Jameco stage* and correlated with Kansan stage of Mississippi Valley.

Jameco stage.

The time covered by deposition of *Jameco gravel.*

†Jamesburg formation.

Pleistocene: New Jersey.

R. D. Salisbury, 1894 (N. J. Geol. Surv. Ann. Rept. 1893, pp. 60-72). *Jamesburg fm.*—The third yellow gravel fm. Consists of gravel, sand, and loam, loam perhaps most abundant. Includes pebbles from Beacon Hill gravel and from Pensauken. Not distinctly stratified. Thickness 8 to 12 ft. Uncon. overlain by fourth yellow gravel fm., and uncon. underlain by Pensauken fm., the second yellow gravel fm. Well exposed in upper part of railway excavation near Jamesburg.

Practically a synonym of Cape May fm., and its use has been discontinued.

†James River series.

Lower Cretaceous: Eastern Virginia.

L. F. Ward, 1895 (U. S. G. S. 15th Ann. Rept., p. 318). *James River series or Basal Clays of Potomac fm.*—As seen on James River it consists of very coarse gray sand, not distinguishable from and perhaps same as that of Rappahannock series. Contains great number of clay lenses and clay balls. I am, however, disposed to refer the coarse sands of James and Appomattox Rivers to Rappahannock series and to confine James River series to the underlying clay deposits; but as these clays are often actually embedded in the sands, this would require assumption they have all been transported and redeposited. For the smaller clay pellets, clay balls, and clay lenses this assumption is abundantly sustained, but some of the clay lenses form strata sometimes 100 ft. in length and a few ft. thick. The series is well developed on James River from Richmond to Dutch Gap Canal, on Appomattox from below Petersburg to near its mouth, and and on W. bank of Potomac btw. Mount Vernon and Aquia Creek.

W. B. Clark and B. L. Miller, 1912 (Va. Geol. Surv. Bull. 4). James River series and part of Rappahannock and Aquia series of Ward are included in Patuxent fm.

James River shale.

Devonian (?): Southwestern Missouri.

E. M. Shepard, 1905 (Bradley Geol. Field Sta. Drury Coll. Bull., vol. 1, pt. 2, pp. 56, 67). *James River shales.*—Bluish-black, slightly carbonaceous soft and frequently fossiliferous shales, thin-bedded and often accompanied by pyrites. Underlie Kings [King] ls. and overlie Maquoketa shales. Same as Eureka sh.

The 1922 geol. map of Mo. shows that the fms. along and near James River consist of Jefferson City dol. overlain by undiff. Mississippian fms., in which are included all beds above Craghead Creek sh.

James River formation.

Ordovician: Nova Scotia.

M. Y. Williams, 1911 (Canada Geol. Surv. Summ. Rept. 1910, p. 241).

Jamestown conglomerate.

Upper Devonian: Western New York.

G. D. Harris, 1891 (Am. Geol., vol. 7, pp. 164–174). [In text he refers to the cgl. forming top memb. of Chemung group at Jamestown, N. Y., as *Jamestown cgl.* and *Jamestown well cgl.*, and says it lies 662 ft. lower than horizon of Panama cgl.]

Only record of name. See also †*Chemung cgl.*

Jamestown limestone member (of McLeansboro formation).

Pennsylvanian: Southwestern Illinois (Perry County).

A. H. Bell, C. Ball, and L. McCabe, 1931 (Ill. Geol. Surv. Press Bull. No. 19). *Jamestown ls. memb.*—Dark-blue ls., 2½ ft. thick, containing *Productus* sp. Top lies 4½ to 7 ft. below Bankston Fork ls. memb. and base lies 18± ft. above Herrin (No. 6) coal in vicinity of Pinckneyville and Jamestown, Perry Co. Typically exposed in vicinity of Jamestown.

Jamesville limestone.

Silurian: Central New York (Onondaga County).

B. Smith, 1929 (N. Y. State Mus. Bull. 281, pp. 26, 27, 30–31). *Jamesville ls.*—Rather dark-blue ls. replete with stromatoporoids and corals. Thickness 0 to 20 ft. Best seen in E. part of Onondaga Co. In W. part of county thickness is reduced by erosion. Included in Manlius group. Conformably underlies Pools Brook ls. and overlies, with sharp contact, Clark Reservation ls. Included in Manlius in Vanuxem's 1842 rept. p. 115. Has been classed as Helderbergian, or probably Helderbergian, by some authors. Named for Jamesville, town of De Witt, Onondaga Co. Type section is at "Green Lake" State Park (Clark Reservation), W. of Jamesville.

B. Smith, 1935 (N. Y. State Mus. Bull. 300, p. 18). [See 1935 entry under *Manlius ls.*]

Jane Lew sandstone. (In Conemaugh formation.)

Pennsylvanian: Northern West Virginia.

D. B. Reger, 1916 (W. Va. Geol. Surv. Rept. Lewis and Gilmer Counties, p. 153). Jane Lew ss.—Massive, greenish gray, weathering to dark brown, fine grained, micaceous, and somewhat shaly ss., 10 to 15 ft. thick. Overlain by 30 to 60 ft. of Pittsburgh red sh. and underlain by 42 ft. of Pittsburgh red sh. Exposed on Hackers Creek, just E. of Jane Lew, Lewis Co.

Jasper conglomerate.

Pre-Cambrian: Northwestern Iowa and southwestern Minnesota.

C. [R.] Keyes, 1914 (Iowa Acad. Sci. Proc., vol. 21, p. 187; Sci., n. s., vol. 40, p. 144). *Jasper cgl.*—Cgls., 30 ft. thick, comprising basal fm. of Animikean series. Older than Sioux qtzite.

Probably named for Jasper, Pipestone Co., Minn.

Jasper limestone.

Lower Ordovician (Chazy or older): Northern Arkansas (Eureka Springs, Harrison, and Yellville quadrangles).

A. H. Purdue and H. D. Miser, 1916 (U. S. G. S. Eureka Springs-Harrison folio, No. 202). *Jasper ls.*—Consists of ls. interbedded with considerable ss. The ls. is even-bedded, grayish blue, noncrystalline, in layers few inches to 4 ft.; conchoidal fracture; numerous minute cavities filled with colorless calcite crystals. Some of sss. are 5 ft. thick; are most abundant and thickest near base. Basal bed of fm. is white, friable ss. 8 to 20 ft. thick. Total thickness of fm. 0 to 50 ft. Uncon. underlies Fernvale ls. and uncon. overlies [so-called] Joachim ls. Named for Jasper, Newton Co.

E. T. McKnight, 1935 (U. S. G. S. Bull. 853). The so-called Joachim ls. of Eureka Springs-Harrison folio is a part of Everton ls. The *Jasper ls.* uncon. underlies true St. Peter ss. and overlies Everton fm. Writer believes more work may prove that it properly belongs to Everton fm., with which it is closely associated.

Jasper series.

Pre-Cambrian: Alberta.

J. A. Allan, P. S. Warren, and R. L. Rutherford, 1932 (Roy. Soc. Canada Trans., 3d ser., vol. 26, sec. 4, p. 231).

Jasper Creek shale. (In Graford formation.)

Pennsylvanian: Central northern Texas (Wise County).

G. Scott and J. M. Armstrong, 1932 (Univ. Tex. Bull. 3224, p. 33). *Jasper Creek shales.*—Shales with 4 sss., each 10 to 15 ft. thick. The shales are light-colored, with yellow and brown beds; are often sandy or carry thin beds of ripple-marked ss. flags. The sss. pinch out to NE. and the shales change to ls. on N. side of Trinity River. Thickness 300+ ft. Lie in valley of Jasper Creek and on the slopes of escarpment to W. Are exact strat. equiv. of Chico Ridge ls. to N. of Trinity River. Contain characteristic Graford fossils and belong in that fm.

Jasper Knob zone. (In Negaunee formation.)

Pre-Cambrian (middle Huronian): Northern Michigan (Marquette County).

J. L. Adler, 1935 (Jour. Geol., vol. 43, No. 2, pp. 113–132). *Jasper Knob zone of Negaunee fm.*—Typically thin *straight-bedded* (characteristic feature) layers of jasper btw. which are intercalated usually thinner layers of specularite; the non-specular iron oxide is chiefly martite and magnetite. Outcrops examined show that a few lenses of very subordinate extent contain white or gray chert and blue hematite, more of which may exist in lower part of this zone around Negaunee. At base a few soft ore bodies rest on the dolerite sill. Not unlikely that in places Jasper Knob zone rests on Corning Creek zone of the Negaunee. Type loc., SE. part of Ishpeming, N. slope of Jasper Knob.

Jay granite.

A name casually applied by F. W. Topham (Geol. of Maine, Dept. of Geol. Union Coll. Schenectady, p. 66, 1932—a mimeographed thesis) to middle Sil. granite quarried at North Jay quarries.

Jefferson limestone. (Also **Jefferson dolomite.**)

Middle Devonian: Montana (widespread), western Wyoming, southeastern and south-central Idaho, northern Idaho, northern Utah.

A. C. Peale, 1893 (U. S. G. S. Bull. 110). *Jefferson lss.*—Brown and black crystalline lss., 640 ft. thick. Underlie Three Forks shales and conformably overlie Gallatin fm. Well exposed in hills on both sides of Missouri River just below junction of the Three Forks of the Missouri, and on both sides of the Jefferson a few mi. above its mouth, in Three Forks quad., SW. Mont.

Jefferson gas sand.

A subsurface sand, of Miss. age, in central Okla., which lies 15 ft. below Lyons-Quinn sand and above Ingraham sand.

†Jefferson dolomite.

An abbreviated form of Jefferson City dol., employed by C. [R.] Keyes.

Jefferson City dolomite.

Lower Ordovician (Beekmantown): Missouri and northern Arkansas.

A. Winslow, 1894 (Mo. Geol. Surv. vol. 6, pp. 331, 373, 375). *Jefferson City ls.*—Mag. lss., 175 ft. thick, underlying Roubidoux or Saccharoidal ss. [not Roubidoux, but St. Peter ss.] and overlying Moreau ss. [Roubidoux fm.] in central Mo. Forms top part of Gasconade ls. [an early broad usage of Gasconade].

Until 1911 the name *Jefferson City ls.* was applied to all rocks in Mo. underlying "Saccharoidal ss." and overlying Roubidoux fm., and it has been thus applied in some later repts. In 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27) E. O. Ulrich defined Jefferson City ls. as indicated by following succession (downward): St. Peter ss.; Everton; uncon.; Yellville ls.; uncon.; Jefferson City; Roubidoux. According to A. H. Purdue and H. D. Miser, 1916 (U. S. G. S. Eureka Springs-Harrison folio, No. 202, p. 5), the Jefferson City ls. of Ulrich's 1911 rept cited above included Cotter dol. and Jefferson City dol. of present nomenclature; and in 1912 Ulrich determined that his Cotter dol. is younger than Jefferson City dol. at its type loc., and restricted Jefferson City to the beds beneath the Cotter. This is present commonly accepted definition. (See also under †*Jefferson City group.*)

Named for exposures at Jefferson City, Cole Co., Mo.

†Jefferson City group.

Lower Ordovician (Beekmantown): Missouri.

C. L. Dake, 1921 (Univ. Mo. School Mines and Met. vol. 6, No. 1). In published Mo. repts Jefferson City is made to include everything from Roubidoux below to Everton ls. above. As a result of recent work this fm. is now split up into Jefferson City restricted at base, followed by Cotter and Powell. While it is still impossible over most of Ozark region to draw boundaries btw. these units, it is thought best to call attention to known presence of each, since it allows a more thorough comparison with adjacent regions. The term *Jefferson City group* will be used to indicate all three.

Jeffersonian stage.

Pleistocene: Central northern Oregon.

E. T. Hodge, 1930 (Monthly Weather Rev., vol. 58, pp. 405–411). *Jeffersonian stage (Pleistocene).*—The younger epoch of glaciation and great precipitation in Oreg. Possibly correlates with Vashon, the youngest glacial epoch of Wash., and with Wisconsin stage of No. Am. Not as extensive as Cascadian stage. Nearly one-third of Mount Jefferson was cut away from its E. side by great Pleist. glaciers.

Jeffersonville limestone.

Middle Devonian: Indiana and north-central Kentucky.

E. M. Kindle, 1899 (Bulls. Am. Pal., vol. 3, No. 12, pp. 8, 23, 110). *Jeffersonville ls.*—Ls., about 20 ft. thick, underlying Sellersburg ls. and overlying Niagara ls.

Contains Onondaga fossils. Regarded as probably=Columbus ls. of Ohio.

Named for Jeffersonville, Clark Co., Ind.

Jellico formation.

Pennsylvanian: Northern Tennessee coal field.

L. C. Glenn, 1925 (Tenn. Geol. Surv. Bull. 33B, pp. 14, 18–21). *Jellico fm.*—Applied to 500 or 600 ft. of rocks overlying Briceville sh. and underlying Scott sh. in northern Tenn. coal field. The rocks occupying this position have previously been called *Wartburg ss.*, but that name is a misnomer and has been so misapplied that it is discarded. The ss. at Wartburg occupies strat. position in lower part of Briceville sh., 30 or 40 ft. beneath Poplar Creek or Oliver Springs coal. More than three fourths of the Jellico is sh., but sss. are more prominent in it than in either underlying Briceville or overlying Scott fm. The Pioneer ss. is top memb. of fm. and Smith coal (=Blue Gem coal) is basal memb. Named for occurrence of Jellico coal within the fm. as its most prominent economic feature.

Jelm formation.

Upper Triassic: Eastern and central Wyoming.

S. H. Knight, 1917 (Geol. Soc. Am. Bull., vol. 28, No. 1, p. 168). *Jelm fm.*—New name proposed for upper 250 ft. of Chugwater fm. in SE. Wyo., consisting of a pebble cgl. composed of small ls. pellets, wood fragments, and fragmentary remains of Triassic vertebrates. Is=Dolores fm. [Upper Tr. and Jurassic (?)] of SW. Colo. This peculiar cgl. is identical in lithologic and strat. habit with type Dolores cgl. and contains similar fragmentary remains. It rests discon. on Permocarbonic part of Chugwater fm., to which name *Chugwater* should be restricted. Named for good exposures of characteristic bone-bearing cgl. near E. base of Jelm Mtn [near S. line of Albany Co., Wyo.].

The U. S. Geol. Survey in 1923 adopted *Jelm fm.* for the reported Upper Triassic vertebrate-bearing beds previously included in top of Chugwater fm. in some areas in Wyo., and said to be same as *Popo Agie beds* of Williston, the type loc. of which is near E. end of Wind River Mtns. Although *Popo Agie* has priority, it was discarded because of objectionable pronunciation and inadequate definition. The U. S. Geol. Survey at present classifies this fm. as Upper Triassic, as have E. B. Branson (Jour. Geol., vol. 35, 1927, p. 610, and Jour. Geol. vol. 37, No. 1, 1929) and other writers. The Jelm, however, has been considered by most geologists to be=Popo Agie beds of Knight, which Branson in 1927 classified as Upper Triassic but as older than Jelm fm. Von Huene, also C. L. Camp, 1930 (Univ. Calif. Mem., vol. 10, p. 5, quarto), assign Popo Agie beds of Knight to Middle Triassic. There is therefore a possibility that Jelm fm. may be older than Upper Triassic, although the evidence now at hand does not seem to justify transferring it to Middle Triassic.

Jemez marl.

Tertiary: Central northern New Mexico.

A. B. Reagan, 1903 [See 1903 entry under *Albuquerque marl.*]

C. [R.] Keyes, 1932 (Pan-Am. Geol., vol. 58, No. 4, p. 289), substituted ***Jemez clays,*** 500 ft. thick, for Puerco fm. of current terminology, and applied ***Pueroan*** to the Torrejon and his Jemez.

Jemison chert.

Lower Devonian (Oriskany): Eastern Alabama.

C. Butts, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14, map, pp. 57, 145–147). ***Jemison chert.***—A calc. bed, ls. or dol., known only by much chert along its outcrop. The chert is generally light gray or iron-stained, of dense texture, greatly sheared, jagged, and rough in its contours. Thickness 20 to at least 500 ft. In places rests on Butting Ram ss. memb. of Talladega sl., and in other places lies a short distance above that memb. Is overlain by Yellow Leaf quartz schist. Contains Oriskany fossils. Mapped as Knox dol. on early geol. map of Ala.

Named for exposures at and near Jemison, Chilton Co.

Jenkins clay. (In Cimarron group.)

Permian: Central southern Kansas and western Oklahoma.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, pp. 27–28). ***Jenkins clay.***—Red clay sh., 7 to 10 ft. thick, separating Shimer gyp. above from Medicine Lodge gyp. below. Middle memb. of Cave Creek fm. [In 1897 (Am. Geol., vol. 19) Cragin gave thickness of this sh. as 30 to 45 ft. in Okla.]

C. N. Gould, 1902 (Okla. Geol. Surv. 2d Bien. Rept., pp. 47+). [See under ***Blaine gyp.***]

Named for former post office of Jenkins, Comanche Co., Kans.

Jennings formation.

Upper Devonian: Eastern West Virginia and northern Virginia and Maryland.

N. H. Darton, 1892 (Am. Geol., vol. 10, pp. 13, 17, 18). ***Jennings fm.***—Middle series of Dev. sediments in central Appalachian Va., consisting of light-colored shales (prevailingly olive, gray, and buff) with interbedded light-colored sss. Local sequence variable, but medial portion consists largely of aren. members. Contains Chemung and Portage fossils in middle beds, and also probably contains beds of Hamilton age. Thickness, 2,800 to 3,200 ft. Overlies Romney shales and underlies Hampshire fm.

According to G. W. Stose, 1909 (U. S. G. S. Mercersburg-Chambersburg, Pa., folio, No. 170), E. O. Ulrich, 1911 (G. S. A. Bull., vol. 22), E. M. Kindle, 1912 (U S. G. S. Bull. 508), G. W. Stose, 1912 (Pawpaw-Hancock, Md., folio, No. 179), C. S. Prosser, 1915 (Jour. Geol., vol. 23), G. P. Grimsley, 1916 (W. Va. Geol. Surv., Rept. Jefferson, Berkeley, and Morgan Counties), G. W. Stose, 1922 (Va. Geol. Surv. Bull. 23), and W. F. Prouty, 1927 (W. Va. Geol. Surv. Rept. on Hampshire and Hardy Counties) the Jennings fm. included Chemung, Portage, and Genesee fms. as later differentiated and mapped by W. Va. Geol. Surv., and the Romney sh. included the Hamilton, Marcellus, and Onondaga. In 1932 (Va. Geol. Surv. Bull. 34, pp. 63, 64) and 1933 (map of Valley of Va. and accompanying text) C. Butts did not recognize the presence of any beds of unquestioned Genesee age, and divided the beds of Portage age into two parts, to the upper of which he applied the central Pa. name *Brallier sh.*, and the lower of which he included in a map unit (which he stated consisted "mainly of black sh.") which he designated *Romney sh.*

Named for exposures at Jennings Gap and on Jennings Branch, Augusta Co., Va.

Jennings sand.

A subsurface sand in Cook Mtn fm. (middle Eo.) of Duval Co., Tex.

Jerome formation.

Devonian (Upper): Central Arizona (Jerome region).

A. A. Stoyanow, 1930 (Pan-Am. Geol., vol. 53, No. 4, pp. 316–317). In Devonic time the NW. and SE. areas of deposition were separated by a land barrier toward which lss. grade into aren. sediments containing *Arthrodiran* fishes. The sequence in NW. area is altogether different from that of SE. Ariz., and *Jerome fm.* is proposed for former.

A. A. Stoyanow, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 495–500), gave very detailed section of his Jerome fm. at Jerome, aggregating 505 ft., and stated that it is uncon. overlain by Redwall ls. (Miss.) and underlain by Tapeats ss. (Camb.). The section is almost wholly ls. A 4-ft. bed of ss. lying 146 ft. above base at Jerome is called *Arthrodiran ss.*, and said to be a valuable marker. "The name '*Sycamore Creek fm.*' was suggested for this ss. in 1925. As its thickness varies considerably and it gradually thins out to W. of Mazatzal land, it may be more appropriately termed *Sycamore ss. memb. of Jerome fm.*" Stoyanow states that in headwaters of East Verde River the *Arthrodiran ss.* is made up of a pink, compact, basal ss., succeeded upward by white, pink, and mottled aren. ls., brick-red ss., and pink and red hard qtzites, with thickness ranging from 50 to 75 ft. Also that the upper aren. part of Jerome fm. contains Upper Dev. fauna that correlates it with Martin ls.

Jerseyan stage of glaciation, also **Jerseyan drift** (Pleistocene).

Jerseyan drift is name applied to an old drift of Laurentide ice sheet in eastern part of United States; *Jerseyan stage* being applied to time during which this drift was deposited. The drift was named for its development in New Jersey. The name was originally proposed by T. C. Chamberlin and R. D. Salisbury (Geol., vol. 3, pp. 383–387, 1906).

†Jerseyian fauna.

Eocene: New Jersey.

S. Weller, 1907 (N. J. Geol. Surv., Pal., vol. 4, pp. 179, 184), applied *Jerseyian* to fauna of Rancocas group and Manasquan marl, and assigned it to late Upper Cret. This fauna was transferred to Eocene by C. W. Cooke and L. W. Stephenson in 1928 (Jour. Geol., vol. 36, pp. 139–148).

Jerusalem.

Cretaceous: Jamaica.

R. T. Hill, 1889 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 34, p. 42).

Jessamine series.

Middle Ordovician: Central northern Kentucky.

A. F. Foerste, 1906 (Ky. Geol. Surv. Bull. 7, p. 10). *Jessamine (Mohawkian) series.*—Approx.=Mohawkian of N. Y. Includes Lexington and Highbridge lss. Underlies Greendale bed of Cynthiana fm., and extends to base of Campnelson bed. [Type loc. not stated, but probably Jessamine, Jessamine Creek, or Jessamine Co.]

Jessamine limestone.

Middle Ordovician (Trenton): Central northern Kentucky.

A. M. Miller, 1919 (Dept. Geol. and Forestry Ky., ser. 5, Bull. 2, p. 25). *Jessamine substage* (of Lexington stage).—Rather thin-bedded grayish ls. with occasional thin shaly layers intercalated. Thickness 80± ft. Characterized by *Prasopora simulatrix* and *Dalmanella bassleri*. This is same bed named Wilmore by writer in 1905, but that name is preoccupied. Underlies Benson bed and overlies Hermitage substage. Named for Jessamine Creek, Jessamine Co.

R. S. Bassler, 1932 (Tenn. Dept. Ed., Div. Geol. Bull. 38, p. 80), placed this ls. btw. Bigby ls. and Hermitage and assigned it to Trenton epoch.

Jesse sandstone member (of Catron formation).

Pennsylvanian: Southeastern Kentucky and northeastern Tennessee.

G. H. Ashley and L. C. Glenn, 1906 (U. S. G. S. P. P. 49, pp. 31, 33, 41). *Jesse ss. memb.*—Coarse-grained ss., 20 to 70 ft. thick; in places cliff-making. Top memb. of Catron fm.

Named for Jesse Creek, Bell Co., Ky.

Jester dolomite. (In Blaine formation.)

Permian: Southwestern Oklahoma (Greer and Beckham Counties).

G. G. Suffel, 1930 (Okla. Geol. Surv. Bull. 49, pp. 29, 55–57, 63). North of Elm Fork a probable third dol. memb. of Blaine fm., the *Jester dol.*, was located at a number of places about midway btw. Haystack and Cedartop gypsums. This may eventually prove to be=Creta dol. S. of Elm Fork, or it may be older. It is a slightly platy medium- to fine-grained gray to brownish-gray dol. 9 to 24 in. thick. Exposed where road from Jester, Greer Co., crosses the heavy gypsums at SE. cor. sec. 25, T. 7 N., R. 24 W. [Mapped.]

Jester sand.

A subsurface sand in central western Okla. which has been correlated with part of Chickasha fm. (Perm.). But C. M. Becker, 1930 (A. A. P. G. Bull., vol. 14, No. 1, p. 56), placed it as older than Chickasha, as= lowest bed of Duncan ss. and as resting on Hennessey sh.

Jetmore chalk member (of Greenhorn limestone).

Upper Cretaceous: North central Kansas.

W. W. Rubey and N. W. Bass, 1925 (Kans. Geol. Surv. Bull. 10, pp. 16, 46, 51). *Jetmore chalk memb. of Greenhorn ls.*—Alternating thin beds of chalk and chalky sh., 20 ft. thick, lying 20 ft. below top of Greenhorn ls. and 28 to 40 ft. above Lincoln ls. memb. of Greenhorn ls. in Russell Co., Kans. Named for prominent exposures S. and E. of Jetmore, along S. side of Buckner Creek, Hodgeman Co. [The beds separating Jetmore chalk from Lincoln ls. are now known as *Hartland sh. memb.*]

Jett sand.

A subsurface sand, of Miss. age, in western Ky. and Hart Co., Ill., that has been identified as Tar Springs ss., of Chester group. (See A. A. P. G. Bull., vol. 16, No. 3, p. 244, 1932.)

Jewell phyllite. (In Casco Bay group.)

Carboniferous (Pennsylvanian?): Southwestern Maine.

F. J. Katz, 1917 (Wash. Acad. Sci. Jour., vol. 7, p. 198), mentioned *Jewell phyllite* as a fm. of Casco Bay group, but did not define it.

F. J. Katz, 1917 (U. S. G. S. P. P. 108, p. 171). *Jewell phyllite.*—An assemblage of alternating gray and bluish to black fine-grained sericite phyllites in thin beds (a few inches to a few ft. thick), containing also interbedded gray siliceous sl. and very thin layers of qtzite. In places is dominantly light-colored; in other places is dark, resembling the black phase of Scarboro phyllite, and heavily impregnated with small grains and crystals of pyrite. Estimated thickness 500 ft., but may be less. Belongs to Casco Bay group. Conformably overlies Spurwink ls. Probably underlies Mackworth sl. conformably. Named for development on Jewell Island, in Casco Bay. Assigned to Penn. (?).

Jewett sand and silt.

Name that has been applied to beds encountered in wells and loosely assigned to Temblor fm. (Mio.) on E. side of San Joaquin Valley, Calif. Immediately overlies Vedder sand. (See H. A. Godde, 1928, Calif. Oil Fields, Div. Mines and Min., vol. 14, No. 1, 1928, pp. 5–10.)

G. M. Cunningham and W. F. Barbat, 1932 (A. A. P. G. Bull., vol. 16, No. 4, p. 420). Unpublished ms. of A. R. May and J. D. Gilboe states that *Jewett sand and silt* of E. side of San Joaquin Valley underlies beds=Carneros ss. memb. of Temblor fm.

Jewett silt member.

Miocene: Southern California (Kern County).

A. Diepenbrock, 1933 (Calif. Oil Fields, Div. Oil and Gas, vol. 19, No. 2, pp. 16, 22, pl. 2). *Jewett silt memb.*—The sand facies of the micaceous silt memb. of the Lower Temblor [expanded use of *Temblor fm.*] first proved productive in Round Mtn oil field and was called *Jewett zone* (H. A. Godde, Calif. Oil Fields, vol. 14, No. 1, 1928, p. 9), from Shell Oil Co. well No. "Jewett" 1, sec. 29, T. 28 S., R. 29 E. Operators of Mount Poso field borrowed the name "Jewett" and applied it to the top of the oil shows in the micaceous siltstone memb. In some wells the oil shows occur practically at top of this memb.; therefore "Jewett" can be used to designate the entire thickness of the micaceous siltstone memb., which is separated from underlying Vedder sand memb. of the Lower Temblor by a bed of grit, and which includes the basal sand locally known as *Rench sand.*

A. Diepenbrock, 1934 (Calif. Oil Fields, vol. 19, No. 4, p. 7), divided his Lower Temblor of Round Mtn field (11 mi. NE. of Bakersfield) into (descending): (1) Ashy silt memb., 550 ft.; (2) *Jewett micaceous silt memb.*, 650 ft. of "brown, micaceous siltstone, containing sandy lenses and with a fine silty sand and pebble bed," resting on; (3) Vedder sand memb.

Jim Creek limestone. (In Wabaunsee group.)

Pennsylvanian: Eastern Kansas and southeastern Nebraska.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 94, 96). [See under *Dover ls.*, Moore, 1932.]

R. C. Moore and G. E. Condra, 1932 (Oct. 1932 revised classification chart of Penn. rocks of Nebr. and Kans.), replaced *Jim Creek ls.* with *Nebraska City ls.*

R. C. Moore, May 1, 1935 (Kans. Geol. Surv. Bull. 20, table opp. p. 14). *Jim Creek ls.* underlies French Creek sh. and overlies Friedrich sh.

G. E. Condra, late in 1935 (Nebr. Geol. Surv. Paper No. 8, pp. 9–10), gave following downward sequence of members of his *Pony Creek sh. fm.*: Sh., 5½ ft.; Greyhorse ls., 1 ft.; Caneyville sh., 17 ft.; Nebraska City ls., 2± ft.; French Creek sh., 16 ft.; *Jim Creek ls.*, 6 in. to 1 ft.; and Friedrich-Dry sh., 17± ft. Latter shown as overlying Dover ls. fm., which rested on Table Creek sh., top memb. of McKissick sh. fm.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 49, 239). *Jim Creek ls.* is here applied to thin but persistent ls. that underlies French Creek sh., overlies Friedrich sh., and has been traced across Kans. and into Okla. and Nebr., although it is nowhere more than 2 ft. thick. It is fine-grained, hard, and bluish gray or bluish; weathers brown and gray. Type loc. on Jim Creek, sec. 29, T. 7 S., R. 11 E., Pottawatomie Co., Kans.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Joachim dolomite.

Lower Ordovician (Chazy): Eastern Missouri, southwestern Illinois, and northern Arkansas.

A. Winslow, 1894 (Mo. Geol. Surv. vol. 6, pp. 331, 352). *Joachim ls.*—Dark earthy mag. shaly brecciated ls., 100 ft. thick; upper layers hard and dense, no chert. Overlies Crystal City [St. Peter] ss. and underlies Trenton ls. in SE. Mo.

E. R. Buckley and H. A. Buehler, 1904 (Mo. Bur. Geol. and Mines vol. 2, 2d ser.). *Joachim fm.* or First Mag. ls. overlies Pacific or First ss. and underlies Trenton ls.

H. F. Bain and E. O. Ulrich, 1905 (U. S. G. S. Bulls. 260, 267). *Joachim ls.*—Yellow and buff to light-gray thin-bedded mag. ls. alternating with beds of compact, brittle ls., and with locally thin beds of ss. Thickness 0 to 150 ft. Overlies St. Peter ss. Is=First Mag. ls. and=Folley ls.

The overlying ls. has for many years been called ***Plattin ls.***

Named for exposures along Joachim Creek, Jefferson Co., Mo.

Joana limestone.

Mississippian: Eastern Nevada (Ely region).

A. C. Spencer, 1917 (U. S. G. S. P. P. 96, pp. 24, 26, map, etc.). *Joana ls.*—Massive, uniformly bluish gray beds, which in a few places contain nodules of chert. Thickness 100 to 400± ft.; latter thickness on Pilot Knob Ridge. Underlies Chainman sh. and overlies Pilot sh. Named for Joana mine, on S. side of Robinson Canyon, 2 mi. above Ely.

†Joes Rock granite.

Devonian (?): Southeastern Massachusetts.

C. H. Warren and S. Powers, 1914 (Geol. Soc. Am. Bull., vol. 25, p. 456 and map). *Joes Rock granite.*—Pinkish to purplish granites, aplitic and felsitic, including quartz porphyry, feldspar porphyry, fine granite, and felsite. [Mapped over large area, including Joes Rock, W. of Sheldonville, Mass.]

B. K. Emerson, 1917 (U. S. G. S. Bull. 597), mapped this granite as Dedham granodiorite.

Joggins formation.

Carboniferous: Nova Scotia.

W. A. Bell, 1913 (12th Int. Geol. Cong. Guidebook 1, p. 334).

Johannesburg gneiss.

Pre-Cambrian: Southern California (Randsburg quadrangle, Kern and San Bernardino Counties).

C. D. Hulin, 1925 (Calif. State Min. Bur. Bull. 95, pp. 21–23, 28, map). *Johannesburg gneiss.*—Consists of a variety of rock types, the majority of them gneisses. In no case do they show true schistose cleavage. The most characteristic type represented may be termed hornblende-plagioclase gneiss; it shows a fine parallel banding of light and dark constituents. Another type, consisting entirely of coarsely crystalline black hornblende, may be termed hornblende gneiss. Interbedded with these varying types of gneisses there occur rather important quantities of massive and quite coarsely crystalline white marble in beds 1 to 20 ft. thick. In places thin layers of light-colored gneiss are intercalated with the ls. A subordinate amount of qtzite, which may be massive or coarsely banded, is interbedded with the marble and the gneisses. The fm. is predominantly if not entirely of sed. origin, and probably marine. The hornblende gneisses, however, may be derived from igneous rocks. A thickness of approx. 2,500 ft. outcrops, but neither top nor bottom was seen. Believed to uncon. underlie Rand schist. *Assigned to Archean. Named for exposures 2 mi. N. of Johannesburg, Kern Co.*

Johannian.

Upper Cambrian: New Brunswick and Nova Scotia.

G. F. Matthew, 1891 (Illustrations of fauna of St. John group No. 5, Trans. Roy. Soc. Canada, vol. 8, p. 129).

C. D. Walcott, 1891 (U. S. G. S. Bull. 81, p. 249). *Johannian* was proposed by G. F. Matthew [reference cited above] for a local series of strata in St. John Basin of New Brunswick that occur btw. *Paradoxides* zone, or Div. No. 1, and Upper Camb. zone, or Div. No. 3, which he calls *Bretonian.*

Johannian series.

Upper Cambrian: Newfoundland.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4), applied *Johannian series* to all of Upper Camb. of Newfoundland, represented by one fm., named *Elliott Cove fm.*

John Day formation.

Miocene (lower) and upper and middle Oligocene: Central northern Oregon (John Day country).

O. C. Marsh, 1875 (Am. Jour. Sci., 3d, vol. 9, p. 52). *John Day lake basin.*—Mio. lake, of which the Blue Mtns formed E. and S. shores, but its other limits are difficult to ascertain, as this whole country has since been deeply buried by successive outflows of volcanic rocks. It is only where latter have been washed away that the lake deposits can be examined. The typical localities of this Mio. basin are along John Day River, and this name may very properly be used to designate the lake basin. The strata of the basin are more or less inclined and of great thickness. One section near John Day River seems to indicate thickness of not less than 5,000 ft. The upper beds alone of this series correspond to deposits of White River Basin. The lower part also is clearly Mio., as shown by its vertebrate fauna, which differs in many respects from that above. Overlain by Plio. beds in a few places and underlain by Eocene beds, which are more highly inclined than the Mio. beds.

E. D. Cope, 1888 (Am. Geol., vol. 2, pp. 290–292). *Johnday fm.* is 4,000 to 5,000 ft. thick according to Marsh. It occupies a considerable tract on upper part of course of John Day River in Oreg.

J. C. Merriam, 1901 (Geol. Soc. Am. Bull., vol. 12, pp. 496–497, and Jour. Geol., vol. 9, pp. 71–72). *John Day fm.*, of John Day Basin, is uncon. overlain by Columbia [River] lava and rests (probably uncon.) on Clarno fm. The upper or buff beds correspond to *Meryoochoerus* beds of Wortman, but as *Merycochoerus* does not occur in the John Day, the upper beds will be called *Paracotylops* beds. They overlap the middle div. of the John Day and older fms. The middle John Day consists of blue-green beds, very fossiliferous, and corresponds to *Diceratherium* beds of Wortman. The lower John Day beds are usually of deep-red color, considerably contorted in places, and rarely contain fossils.

J. C. Merriam, 1901 (Univ. Calif. Pub., Bull. Dept. Geol., vol. 2, No. 9, pp. 278–314), gave thickness of upper div. of *John Day series* as 300 to 400 ft., of middle div. as 500 to 1,000 ft., and of lower div. as 250–300+ ft., and described it as uncon. overlain by Columbia [River] lava and underlain, probably uncon., by Clarno fm. [Merriam included the beds at Bridge Creek in Clarno fm. and assigned them to upper Eocene.]

F. C. Calkins, 1902 (Univ. Calif. Pub., Bull. Dept. Geol., vol. 3, No. 5, pp. 111–172). The principal material in all 3 divisions of *John Day series* is fine-grained tuff. A few thin flows of lava are intercalated in various sections, and water-worn gravels and sands occur near upper limit of the series.

J. C. Merriam and W. J. Sinclair, 1907 (Univ. Calif. Pub., Bull. Dept. Geol., vol. 5, No. 11, p. 173). *Upper John Day* is mainly buff-tinted tuffs, with sands and gravels near top. *Middle John Day* is drab and bluish green tuffs. *Lower John Day* is red, white, and green tuffaceous sh. Rests uncon. on Clarno fm. and is uncon. overlain by Columbia [River] lava. [Their table shows upper part of upper John Day is Mio. and rest of fm. Olig.]

H. F. Osborn, 1909 (U. S. G. S. Bull. 361, p. 65), and 1919 (Am. Mus. Nat. Hist. Mem., n. s., vol. 2, pt. 1, pp. 8, 9, 12), assigned John Day fm. to lowermost Mio., upper Olig., and uppermost middle Olig. Some later repts, by other authors, assign it all to Mio. and others all to Olig. The U. S. Geol. Survey classifies it as lower Mio. and upper and middle Olig.

Johnnie formation.

Lower Cambrian: Southeastern Nevada (Spring Mountains region).

T. B. Nolan, 1928 (Am. Jour. Sci., 5th, vol. 17, pp. 461–472). *Johnnie fm.*—Lower 3,500 ft. chiefly fine-grained qtzites, of characteristically greenish or grayish-green color, with a few sh. zones, as much as 250 ft. thick, but containing a rather large amount of sand; locally cross-bedded. Upper 1,000 ft. distinguished by much larger proportion of sh. and by presence of 2 or 3 beds of dol., each about 10 ft. thick; many of shales are green, but beds of brown and gray sh. also occur. Is more than 3,500 ft. thick at head of Johnnie Wash, N. of Johnnie mine. Underlies, apparently conformably, Stirling qtzite, and is basal fm. in Spring Mtns section, Clark Co. No fossils found.

Johnsburg limestone.

Pre-Cambrian: Northeastern New York (Adirondacks).

H. L. Alling, 1918 (N. Y. State Mus. Bull. 199). *Johnsburg ls.* is included in Grenville series. Thickness 30+ ft. Rests on Sacandaga qtzite and underlies Dresden amphibolite. Type loc., Johnsburg, Warren Co.

Johnson gravels.

Miocene: Northern California (Taylorsville region).

J. S. Diller, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 371–394). *Johnson gravels.*—Auriferous gravels of fluviatile origin, containing Mio. plants. Lie at altitude of 5,000 to 5,600 ft. Turner has traced these gravels S. of 40th parallel, through Cascade mine to vicinity of Haskell Peak, where they have elev. of 7,000 ft. The southerly inclination of the pebbles, the northerly slope of the deposits, and the distribution of pebbles containing Jurassic fossils afford strong evidence that the stream by which the gravels were laid down flowed from vicinity of Haskell Peak northwardly across Genesee Valley and northern arm of Indian Valley to Mountain Meadows. Lie uncon. on upturned edges of massive Jurassic and Triassic fms., and although not in contact with the valley alluvium (Pleist.) their uncon., due to erosion, is well marked. [Derivation of name not stated.]

In subsequent publications Diller did not use this name, but described the gravels simply as *auriferous gravels*.

Johnson shale.

Pennsylvanian: Southeastern Nebraska and northeastern Kansas.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 84, 86, 88). *Johnson sh.*—Bluish argill. sh. modified by thin grayish sandy layers, calc. plates, some gypsiferous material and geodes. Thickness 16 to 25 ft. in Nebr. and 16 to 20 ft. in NE. Kans. Underlies Glenrock ls. and overlies Long Creek ls. Named for exposures 1½ mi. N. of Johnson, Johnson Co., Nebr.

G. E. Condra and R. C. Moore included these beds in Elmdale sh. in their 1932 classification, but Condra in 1935 (Nebr. Geol. Surv. Paper No. 8) discarded Elmdale and used *Johnson sh. fm.*

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), transferred this unit to Perm. This change in Perm.-Penn. bdy has not been considered by U. S. Geol. Survey for its publications.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Johnson granite porphyry.

Probably Cretaceous: Yosemite National Park, California.

F. C. Calkins, 1930 (U. S. G. S. P. P. 160, pp. 127–128, map). The most centrally located, most siliceous, and youngest rock of Tuolumne intrusive series. Is next younger than Cathedral Peak granite. Its major part resembles an aplite, but it is distinguished by widely scattered phenocrysts of microcline. Part of mass has texture of more typical granite porphyry.

Named for fact it forms Johnson Peak.

Johnson oil and gas sands.

Subsurface sands in midst of Penn. section in Graham field, NW. part of Carter Co., southern Okla., 250 to 500 ft. below Kirk gas sand and 75 to 244± ft. above Atlantic oil sand. Thickness 55 to 300± ft.

Johnson sand.

A subsurface sand, of Ord. age, in Oklahoma City oil field, NE. Okla., that has been correlated with basal part of Simpson fm. Named for a farm. See under *Kinter sand*.

Johnsonburg sandstone.

Mississippian: Northwestern Pennsylvania.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, pp. 139–140). In face of the 2d tier of lower cuttings of Yingling-Martin sh. quarry at Johnsonburg a thick flaggy to massive yellow ss. charged with plant material is believed to be on the horizon of Shenango ss. Until it can be checked it is suggested that it be known as

Johnsonburg ss. [On p. 110 he gives a detailed section at southern suburb of Johnsonburg, Pa., which shows *Johnsonburg fm.* as 24 ft. thick, and as lying 281 ft. below Johnson Run ss. and 111 ft. above Knapp fm.]

†Johnson Creek conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. C. Lane, 1911 (Mich. Geol. and Biol. Surv. Pub. 6, geol. ser. 4, pp. 527, 546, 554, 555). The *Johnson Creek cgl.* is that at the Shawmut, on Elm River property. Is same as Shawmut cgl. Younger than No. 8 cgl. [Bohemia cgl.].

Belongs in Central Mine group.

Probably named for exposures on Johnson Creek, Houghton Co.

Johnson Gulch porphyry.

Eocene: Leadville district, Colorado.

S. F. Emmons, J. D. Irving, and G. F. Loughlin, 1927 (U. S. G. S. P. P. 148). A gray porphyry very similar to Lincoln porphyry, but lacking the large phenocrysts of orthoclase and quartz. Is the "main mass" of Gray porphyry of Leadville monograph. Named for development in Johnson Gulch, Leadville dist.

Johnson River sandstone.

Misprint (on p. 211 of U. S. G. S. Bull. 191) for *Johnson Run ss.*, the name used by Ashburner in publication cited.

†Johnson Run sandstone. (In Pottsville formation.)

Pennsylvanian: Central northern Pennsylvania.

C. A. Ashburner, 1879 (2d Pa. Geol. Surv. geol. map of McKean Co.). The bottom of the Lower Productive Coal Measures is marked by the Twin Creek coal bed, which lies btw. Kinzua Creek and Johnson Run sss.

C. A. Ashburner, 1880 (2d Pa. Geol. Surv. Rept. R). The Johnson Run ss., 30 to 75 ft. thick, is without doubt=Homewood ss. The boldest outcrop of the rock is to be found in Johnson run coal basin, E. of Wilcox, Elk Co., Pa.

Replaced by Homewood ss. memb. of Pottsville fm.

Johnson Run sand.

A subsurface sand, of Penn. age, in SW. Pa. that is believed to lie at or near horizon of Homewood ss. (top memb. of Pottsville fm.).

Johnstown limestone member (of Allegheny formation).

Pennsylvanian: Western Pennsylvania.

H. M. Chance, 1880 (2d Pa. Geol. Surv. Rept. V_2). *Johnstown cement ls.*—Separated from overlying Kittanning Upper coal by 0 to 4 ft. of fire clay and sh. and from underlying Kittanning Middle coal by 40 to 50 ft. of shaly beds. Named for occurrence at Johnstown, Cambria Co.

†Johnstown cement bed.

Name applied in early Pa. and W. Va. repts to *Johnstown ls. memb.* of Allegheny fm.

Johnstown iron ore. (In Conemaugh formation.)

A name that has been applied to a bed occurring in strat. interval btw. Philson ls. above and Brush Creek coal below. (See J. D. Sisler, Pa. Geol. Surv., 4th ser., Bull. M_7, 1925, p. 268.)

Johnstown moraine.

Pleistocene (Wisconsin stage): Southern Wisconsin. Shown on moraine map (pl. 23) of U. S. G. S. P. P. 106. Named for Johnstown and Johnstown Center, Rock Co.

Johns Valley shale.

Pennsylvanian: Southeastern Oklahoma (Ouachita region) and central western Arkansas (Scott County).

E. O. Ulrich, 1927 (Okla. Geol. Surv. Bull. 45, pp. 6, 21–23, 30, 36–37). *Johns Valley sh.* proposed for the boulder-bearing black Penn. sh. of Ouachita Mtns, which is typically exposed in center of Tuskahoma syncline, particularly in N. half of T. 1 S., R. 16 E., where it rests on Jackfork ss. and is overlain by sandy shales and sss. referred to Atoka fm. Its lower part contains abundance of large and smaller, often fossiliferous, erratics of ls. and other sed. rocks that were originally parts of older fms., found in place beyond northern and western limits of Ouachita area. It is, so far as known, confined to Ouachita area, and is not known to contain a fauna or flora of its own, but the boulders in this sh. contain fossils from Canadian, Ord., Sil., Dev., Miss. (Caney sh.), and early Penn. fms. of Arbuckle Mtns, and I regard them as transported from that area, while Miser believes that the Miss. Caney fauna that occurs in my Johns Valley sh. lived, died, and was buried where it is now found. The Johns Valley sh. also contains erratics of Wapanucka ls. of Arbuckle Mtns, which is of Penn. age, and it is therefore unquestionably of Penn. age and younger than Wapanucka. It has heretofore been included in Caney sh., but *Caney* is here restricted to the non-boulder-bearing black sh. which contains a Miss. (middle Meramec) fauna and is confined to N. and W. of Ouachita area. Named for settlement (on Cane Creek, in NW. part of Pushmataha Co., about 6 mi. N. of Eubanks) which is now called Johns Valley, but which, at time Taff named the Caney sh., was locally known as Caney, and which Taff in 1925 stated was type loc. of his Caney sh.

The introduction of this name into the literature, for the Penn. part of Caney sh. of previous repts, and restriction of Caney to the Miss. part of that fm., aroused considerable discussion among geologists, and resulted in several field trips to ascertain validity of the unit and its relations to neighboring fms. In 1934 the following sequence of fms. was adopted by U. S. Geol. Survey for the Penn. rocks of the area S. and E. of Ti Valley-Choctaw belt of Ouachita Mtns of Okla. and Ark. (descending order): Atoka fm., 6,000 ft.; Johns Valley sh. (boulder-bearing black sh., 0 to 1,000 ft.; Jackfork ss., 5,000 to 6,600 ft.; Stanley sh., 6,000 to 10,000 ft.; and (in western Ark. only) Hot Springs ss., 0 to 200 ft.; and Caney sh. was restricted to Miss. part of the strata formerly included under that name. (See H. D. Miser, 1934, A. A. P. G. Bull., vol. 18, No. 8.) According to Miser, Johns Valley is 10 mi. N. of Kosoma, Okla.

Joie. See *Madame Joie fm.*

Joins formation.

Lower Ordovician (Chazy): Central southern Oklahoma (Arbuckle Mountains).

E. O. Ulrich. See *Joins Ranch fm.*

C. E. Decker, 1930 (A. A. P. G. Bull., vol. 14, No. 12, pp. 1498–1505). *Joins fm.*—Chiefly ls., but some ss. and sh. Underlies Oil Creek fm. [Overlies Beekmantown (?) cgl., according to table on p. 1498, but in sections on pp. 1500 and 1501 this cgl. is included in Joins fm.] Occurs only in W., SW., and central parts of Arbuckle Mtns. Is of early Chazy age. Thickness 30 to 300± ft.

C. E. Decker and C. A. Merritt, 1931 (Okla. Geol. Surv. Bull. 55, pp. 11+). The *Simpson* is here raised to a *group*, divided into 5 fms. (ascending): *Joins*, Oil Creek, McLish, Tulip Creek, and Bromide. Fossils believed to be very basal Chazy.

See also 1933 entries under *Simpson fm.*

Named for exposures on Joins ranch, in Carter Co., T. 2 S., R. 1 W., N. and NW. of Woodford.

Joins Ranch formation.

Lower Ordovician (Chazy): Central southern Oklahoma (Arbuckle and Wichita Mountains).

Name used by E. O. Ulrich in ms. chart shown at N. Y. meeting of Geol. Soc. Am. in 1928, which he discarded (before publication) in favor of *Joins fm.* The part of Ulrich's chart containing this name was, however, published by C. E. Decker in Dec. 1930 (A. A. P. G. Bull., vol. 14, No. 12, p. 1495). Ulrich later called the beds *Joins fm.* (See U. S. Nat. Mus. Proc., vol. 76, 1930, art. 21, pp. 73, 77; and Geol. Soc. Am. Bull., vol. 44, pt. 1, p. 105, 1933.)

Joliet limestone.

Silurian (Niagaran): Northeastern and western Illinois.

G. A. Shufeldt, Jr., 1865 (Am. Jour. Sci., 2d, vol. 40, p. 389). *Joliet marble.*—Yellowish-white stone, very compact, 200 ft. thick, with no signs of oil. Overlain by 40 ft. of porous and much decomposed oil-bearing rock, and underlain by 200 ft. of gray oil-bearing lss. All included in Upper Sil.

T. E. Savage, 1926 (Geol. Soc. Am. Bull., vol. 37, pp. 515, 522, 530, 533). *Joliet ls.* is proposed to include all strata that occur above the weathered and pitted surface occurring 1 to 3 ft. above *Stricklandinia pyriformis* zone up to near top of quarry of Nat. Stone Co. at Joliet. At this quarry it consists of (1) 48 ft. of yellowish-gray dol., in rather thick layers that weather into layers 3 to 8 inches thick and contain several discontinuous bands of chert in middle part; underlain by (2) 32 ft. of gray to pink dol., somewhat granular, in rather thick layers, with greenish sh. partings and, in upper part, a few thin bands of chert. As here defined it includes strata lower than any exposed in vicinity of Waukesha, Wis. Overlies (probably uncon.) Kankakee (Brassfield) ls. and underlies, in Joliet region, a cherty ls. that is believed to correspond to Waukesha ls. of Waukesha, Wis. In Jersey and Calhoun Counties [SW. Ill.] it consists of 45 ft. of yellowish gray dolomitic ls., in layers 1 to 40 inches thick; overlies Kankakee (Brassfield) ls. and is overlain by Dev. In NW. Ill. it consists of 30 to 38 ft. of yellowish brown dol. overlying Kankakee (Brassfield) ls. and underlying Waukesha ls. Fossils. Correlated with Lockport dol.

A. C. Trowbridge et al., 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., fig. 1), classified *Joliet* as of Lockport and Clinton age. On p. 27 is statement: It is now considered likely that the Joliet may prove to be time equiv. of the Clinton (oral communications from T. E. Savage and A. Foerste to A. C. T.). On p. 46 is statement that Clinton is absent or possibly represented by the Joliet, and that if Clinton is absent an important uncon. should separate the Joliet and the Kankakee.

Joliet conglomerate.

Pleistocene: Northeastern Illinois (Des Plaines Valley).

J. W. Goldthwait, 1909 (Ill. Geol. Surv. Bull. 11, p. 42). *Joliet cgl.*—Gravel firmly cemented by carbonate of lime into cgl. Thickness more than 18 ft. Uncon. overlain by Wisconsin till. Regarded as at least as old as Illinoian drift.

Named for Joliet.

Jolliff limestone member (of Dornick Hills formation).

Pennsylvanian: Central southern Oklahoma (Carter County).

J. A. Waters, 1927 (Jour. Pal., vol. 1, p. 129). [See 1st entry under *Dornick Hills fm.*]

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z, p. 14). At base of Dornick Hills fm. is *Jolliff memb.*, a tan fossiliferous ls., 4 to 15 ft. thick, locally associated with a little cgl.

C. W. Tomlinson, 1929 (Okla. Geol. Surv. Bull. 46, p. 29). *Jolliff memb.* is only about 4 ft. thick at type loc., but it is tentatively correlated with beds N. of Ardmore that attain thickness of 10 to 15 ft. Named for excellent outcrops in Jolliff Prairie, on allotment of Norman Criner Jolliff, in sec. 24, T. 5 S., R. 1 E., a trifle E. of axis of Overbrook anticline. Lies 300 to 1,000 ft. below Otterville memb. Was mapped by Goldston as Otterville ls.

Jolly limestone. (In McLeansboro formation.)

Pennsylvanian: Western Kentucky.

F. M. Hutchinson, 1912 (Ky. Geol. Surv. Bull. 19, pp. 30–125). *Jolly ls.*—Hard gray or grayish-blue ls., 3 to 6½ ft. thick, with abundance of crinoidal stems and brachiopod shells. Included in Lower Coal Measures of Central City quad., btw. coals Nos. 11 and 12.

L. C. Robinson (1931) replaced Jolly ls. of Hutchinson with *Providence ls.*, without giving his reasons. *Jolly* has priority, and *Providence* is preoccupied.

Probably named for Jolly, Webster Co.

Jolly limestone member (of Savanna sandstone).

Pennsylvanian: Central southern Oklahoma (Pontotoc County).

G. D. Morgan, 1924 (Bur. Geol. [Okla.] Bull. 2, pp. 74–75). *Jolly ls. memb.*—A thin ls. bed near bottom of Savanna ss., which is important in that it shows clearly the overlapping nature of itself and the strata above it, across the basal beds of the fm. This bed is very well exposed in road in front of J. S. Jolly's house, 300 yds. E. of NW. corner of sec. 8, T. 1 N., R. 7 E. [Pontotoc Co.]. It carries an abundant gastropod fauna, the most prominent species of which is *Bellerophon crassus* var. *wewokanus*. At point just mentioned the ls. is less than 100 ft. above top of McAlester fm. [on which Savanna ss. rests]. When followed SE. to W. side of sec. 10 of same twp and range, it is found to swing toward a more easterly direction, while the strike of underlying strata continues southeastward. In this way a greater and greater section is exposed btw. the diverging outcrops, until in area near E. edge of the outcrop the ls. is approx. 200 ft. above top of McAlester fm.

Jollytown limestone member (of Washington formation).

Permian: Southwestern Pennsylvania, western Maryland, and northern West Virginia.

I. C. White, 1891 (U. S. G. S. Bull. 65, pp. 22, 23, 24, 29, 34). *Jollytown ls.*—Lies from 5 to 35 ft. above Jollytown coal, and 25 to 30 ft. below Dunkard coal, all of which are younger than Upper Washington ls. Ranges in thickness from 1½ to 10 ft. Included in Dunkard Creek series [Dunkard group]. Named for exposures in vicinity of Jollytown, Greene Co., Pa.

According to subsequent folios and repts of U. S. Geol. Survey and Pa. Geol. Survey the Jollytown ls. and Jollytown coal are older than Upper Washington ls.

Jollytown sandstone. (In Washington formation.)

Permian: Southwestern Pennsylvania (Washington County).

E. V. d'Invilliers, 1895 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 3, pt. 2, p. 2573). *Jollytown ss.*, massive ss., of irregular structure, weathering into fantastic forms. Overlies Middle Washington ls. and at Lantz's, ⅜ mi. below mouth of Hoover Run, on Dunkard Creek, it lies 70 ft. below Jollytown coal.

Jones sand.

Name applied to subsurface sands in different parts of country. (1) To two sands (Upper and Lower Jones) in Lee fm. of Pottsville group (Penn.) of Knox Co., SE. Ky.; (2) to a sand lying 325 ft. below top of Marble Falls ls. (Penn.) in central Tex., which was first found in Jones well at Ranger, Eastland Co.; (3) to two sands in Strawn fm. (Penn.) of Bryson oil field, Jack Co., Tex.; (4) to a sand, 75± ft. thick, in central northern Okla. that is in lower part of Coffeyville fm. (Penn.); (5) to a Miss. oil sand in western Ky. and Hart Co., Ill., that has been identified as Hardinsburg ss., of Chester group (see A. A. P. G. Bull., vol. 16, No. 3, p. 244, 1932), and as a part of underlying Golconda fm., of Chester group (see Ky. Geol. Surv. ser. 6, vol. 41, p. 221, 1931); and (6) to a Plio. sand in Townsite area of Huntington Beach oil field, Calif., that is probably=Upper Ashton sand (A. A. P. G. Bull., vol. 18, No. 3, pp. 330, 336, 1934).

Jonesboro limestone.

Mississippian: Southwestern Illinois (Union County).

H. Engelmann, 1868 (Ill. Geol. Surv., vol. 3, p. 43). Massive light-gray or nearly white subcrystalline or earthy ls. that breaks regularly into rectangular blocks and forms a good building stone. Comprises lowest portion of St. Louis group as here delimited. Thickness more than 30 ft. Well exposed ½ mi. W. of Jonesboro, Union Co., and is known in that region as *Jonesboro ls.* No well-defined fossils but is assigned to St. Louis group on strat. position and lithology.

†Jonesboro limestone.

Upper Cambrian: Northeastern Tennessee and southwestern Virginia.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pp. 564, 637, 671–674, pl. 27). Thin to moderately thick-bedded, usually fine-grained and in part mag. ls. of Canadian age is found rather generally in eastern or Athens trough S. of Lexington, Va. In SW. Va. and in E. Tenn. as far S. at least as Greenville, this ls. rests on Upper

Camb. Nolichucky sh. and hitherto has always been described as a sparingly cherty representative of Knox dol. It is a great valley maker in this region and very thick. I have measured it at only one place, namely, Jonesboro, Tenn., where the fm. though incomplete above, reaches thickness of 1,850± ft. Total thickness in this vicinity is probably 400 ft. more, or in all 2,250± ft. As a rule the early Stones River Mosheim ls. succeeds it. Gastropods allied to *Maclurea oceana* and *M. affinis* and to *Seelya*—types so far wholly unknown in typical Knox or, indeed, in any Ozarkian fm.—occur at intervals in Jonesboro section to within 400 ft. of top of underlying Nolichucky. The upper 400 ft. of the ls. very commonly contains *Ceratopea keithi* and less frequently other gastropods and cephalopods. Mr. Arthur Keith found this same fauna E. of Knoxville in beds referred by him to upper Knox. As this fm. is a strat. and lithologic unit, and distinct from all others now recognized by name in Appalachian Valley, the term *Jonesboro ls.* is here proposed for it. [Pages 672–673.] According to these data it appears that Jonesboro ls. represents only lower half of Canadian system [Beekmantown group] as now constituted. [Page 674.] [Pl. 27 shows it uncon. below Mosheim ls. and uncon. above Lower Knox (?), and as correlated with Stonehenge ls., Nittany dol., and lower part of Axemann ls. of Beekmantown group of central Pa.]

E. O. Ulrich, 1924 (Tenn. Dept. Ed., Div. Geol., Bull. 28, p. 34). *Jonesboro ls.* of E. side of Athens trough is Upper Canadian and = Cotter dol. of central Tenn.

C. Butts, 1928 (Wash. Acad. Sci. Jour., vol. 18, No. 13, pp. 357–380). As defined by Ulrich the Jonesboro ls. was made to include beds corresponding to Nittany dol. and still higher beds to base of Mosheim ls. But it is now agreed that the Nittany is a distinct and easily separable unit in SW. Va., and *Jonesboro ls.* is here redefined and restricted to the ls. which near Jonesboro, Washington Co., Tenn., underlies Nittany dol. and rests on Nolichucky sh. Thickness 2,000± ft. Upper 500 ft. contains Beekmantown fossils. No fossils in lower 1,000 ft. Lower two-thirds of fm. may be a ls. facies of Copper Ridge dol. [which belongs to Ulrich's Ozarkian system].

Replaced by Conococheague ls. (an older name) in Dec. 1931, the ls. having been traced northward by C. Butts to typical areas of the Conococheague. (See C. Butts, 16th Int. Geol. Cong. Guidebooks of Va.)

Jonesburg sandstone member (of Nelagoney formation).

Pennsylvanian: Central northern Oklahoma (Osage County) and southern Kansas (Chautauqua County).

M. I. Goldman, 1920 (U. S. G. S. Bull. 686W, pp. 329–330). *Jonesburg ss.*—A persistent bed which forms rim of many minor ridges and plateaus in NW. part of T. 29 N., Rs. 11 and 12 E., Okla. Named for conspicuous exposure on top of ridge W. of Jonesburg, Chautauqua Co., Kans., a short distance N. of T. 29 N., R. 11 E. Probably is lowest bed of "Chautauqua ss." of Adams (1908). Physical appearance not sufficiently characteristic to distinguish it from other sss. of these twps, but it can be recognized by its relation to a thin ss. 12± ft. above it, which generally exhibits fossil imprints, mainly pelecypods and gastropods. Very rarely the fossils of this overlying ss. appear in the Jonesburg itself. In places the top of the Jonesburg shows a heavy stain of red to yellow ocher, and the tops of main beds display beautifully preserved ripple marks and current marks. Thickness 5 to 75 ft. Lies 125± ft. above Cheshewalla ss.

In Kans. is a memb. of Lawrence sh.; in Okla. a memb. of Nelagoney fm. and probably=basal part of Fourmile ss. memb. Some geologists have suggested it is=Bowhan ss.

Jones Point shale. (In Calhoun shale.)

Pennsylvanian: Southeastern Nebraska, eastern Kansas, and southwestern Iowa.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 40, 43, 51). *Jones Point sh.*—Bluish-gray argill. to calc. sh., with some carbonaceous material. Thickness 8 to 10 ft. Is basal bed of Calhoun sh. Overlies Ervine Creek ls. and underlies Meadow ls. Named for Jones Point, a spur in Missouri River bluffs E. of Union.

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, 2d ser., p. 47), stated that true Meadow ls. belongs in Stanton ls., and he applied *Sheldon ls.* to the ls. underlying Iowa Point sh. and overlying Jones Point sh.

R. C. Moore and G. E. Condra, 1932 (Oct. 1932 revised classification chart of Penn. rocks of Kans. and Nebr.), restricted Calhoun sh. to beds above Sheldon ls. and included Jones Point sh. and Sheldon ls. in Deer Creek ls. (redefined). Calhoun sh. restricted thus occupies interval previously named Iowa Point sh.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 11), divided *Calhoun sh. fm.* into (descending) Iowa Point sh., Sheldon ls., and Jones Point sh. This classification was adopted by R. C. Moore, Aug. 31, 1936 (Kans. Geol. Surv. Bull. 22, p. 48), but on pp. 187–194 he proposed to redefine Ervine Creek ls., Jones Point sh., and Sheldon ls. on a cyclothem basis. (See 1936 entry under *Sheldon ls.*)

R. C. Moore, Sept. 4 to 7, 1936 (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 41). Topeka ls. divided into (descending): Coal Creek ls., 16 ft.; Holt sh., 15 ft.; Du Bois ls., 14 ft.; Turner Creek sh., 36 ft.; Hartford ls., 40 ft.; *Jones Point sh.*, 5 ft. and *Dashner ls.*, 4 ft. Rests on Calhoun sh. [In above section *Jones Point sh.* is placed in Topeka ls. (instead of basal memb. of Calhoun sh.) and Dashner ls. is a new name for basal part of his Hartford ls. of p. 11 and pp. 194 and 195 of his Kans. Geol. Surv. Bull. 22, 1936.]

For Condra's latest interpretation of strat. position of this sh. see 1937 entry under *Topeka ls.*

Jordan sandstone.

Upper Cambrian: Southern Minnesota and Wisconsin, Iowa, and northern Illinois.

A. Winchell, 1872 (Rept of geol. survey vicinity of Belle Plaine, Scott Co., Minn., 16 pp.). A sandrock fm., exposed in beer vaults at Jordan and along Sand Creek, consisting of (descending): (F), Sandrock, buffish, quite ferruginous, thick-bedded, seen at mill 6 ft.; (E), sandrock, ferruginous, thin and irregularly bedded, friable and disintegrating, with many ferruginous seams, crusts and concretions, in the quarry 3 ft.; (D), sandrock, irregularly whitish or ferruginous, heavy-bedded, obliquely and beautifully banded with iron streaks and laminae, in quarry 12 ft.; (C), sandrock, buffish, similar to D, but thinner-bedded, in quarry 8 ft.; (B), sandrock, hard and ferruginous above, soft, friable, and buffish red below, Falls of Sand Creek 10 ft.; and (A), sandrock, whitish, compact, in the beer vaults 12 ft. seen. Overlain by Lower Mag. ls. of Owen. Occurs at considerable elevation above the mag. ls. at St. Lawrence. Regarded as Potsdam ss. [In two places is called *Jordan ss.*]

N. H. Winchell, 1874 (Minn. Geol. Nat. Hist. Surv. 2d Ann. Rept., pp. 127–156), gave (p. 149), as typical outcrop of Jordan ss., a section on Sand Creek, about ½ mi. above village of Jordan, Scott Co., Minn., which is same section as that given by A. Winchell in 1872, to which latter section reference is made, and credit for name *Jordan ss.* is also given to A. Winchell, 1872 rept cited above. In 1874 rept cited N. H. Winchell divided the rocks of Minnesota Valley into (descending) Trenton ls. and shales, St. Peter ss., Shakopee ls., Jordan ss., St. Lawrence ls., St. Croix ss., and Potsdam ss. Thickness of Jordan ss. (p. 147) 50 ft.

In subsequent early repts the fm. overlying Jordan ss. was called *Shakopee ls.*, *Lower Mag. ls.*, *Main body of Lower Mag. ls.*, and, since 1891, *Oneota dol.* In early repts the Jordan ss. was also confused with the younger New Richmond ss., which has been described as a fm. btw. Oneota dol. and Shakopee dol., and also as a memb. of the Shakopee.

In 1924 (Wis. Acad. Sci., Arts, and Lett., vol. 21, pp. 72–84) E. O. Ulrich restricted *Jordan ss.* to the wholly unfossiliferous ss., such as is found at Jordan type loc., and applied *Norwalk ss.* (which he treated as top memb. of his Trempealeau fm.) to the underlying fossiliferous ss. that had previously been assigned to the Jordan. He also defined Jordan ss. of eastern Wis. as overlain by a recently discovered fm., to which he applied the name *Devils Lake ss.*, and stated that in western Wis. the still younger Madison ss. intervenes btw. Jordan ss. and overlying Oneota dol. The U. S. Geol. Survey in 1927 adopted Norwalk ss. as a memb. of Jordan ss., since, according to C. R. Stauffer (Jour. Geol., vol. 33, pp. 699–713, 1925) and other geologists, it is the only part of the Jordan that outcrops at type loc. and it has always been included in the Jordan. (See A. C. Trowbridge and G. I. Atwater, Geol. Soc. Am. Bull., vol. 45, p. 60, 1934. Also see 1917 and 1925 entries under *Kasota stone.*)

J. M. Wanenmacher, W. H. Twenhofel, and G. O. Raasch, 1934 (Am. Jour. Sci., 5th, vol. 28, pp. 1–25) included Jordan ss. in their Trempealeau fm.

A. C. Trowbridge and G. I. Atwater, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 21–79). *Jordan ss.* is=Madison ss. and=Norwalk ss. The Norwalk is all of Jordan present at Jordan type loc. Jordan ss. should continue to be used for the beds overlying Lodi sh. memb. of St. Lawrence fm. and underlying Oneota dol. It seems best to leave the Jordan undivided at present.

A. C. Trowbridge stated (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., 1935, p. 61) that stratigraphers of Minn. and Iowa classify Madison ss. of Wis. merely as upper beds of Jordan ss. (For explanation see 1935 entries under *Madison ss.*) In this rept. Norwalk ss. was discarded by Trowbridge, Twenhofel, Raasch, and Thwaites, and the beds were restored to Jordan ss., of which they comprise the lower and major part.

E. O. Ulrich, 1936 (Geol. Soc. Am. Proc. 1935, p. 113). There are 3 sss. in Wis. that previously have been regarded as constituting an indivisible strat. unit. The Norwalk ss. is top memb. of Trempealeau fm., the Jordan is a separate final deposit of the Camb. of upper Miss. Valley, and the Madison is first deposit of Ozarkian of the region.

U. S. Geol. Survey at present follows the earlier and established definitions: Treats Jordan ss. as a distinct fm. from underlying St. Lawrence fm. and overlying Madison ss.; includes in it, at base, Norwalk ss. memb. of Ulrich; and has not adopted Trempealeau fm.

Named for exposures in Sand Creek at Jordan, Scott Co., Minn.

Jordan limestone member (of Bingham quartzite).

Pennsylvanian: Central northern Utah (Bingham district).

A. Keith, 1905 (U. S. G. S. P. P. 38, pp. 38+, map, sections). *Jordan ls. memb. of Bingham qtzite.*—Calc. strata more or less altered by mineralizing agents and intrusive masses of monzonite. Most common unaltered rock is a pure fine-grained ls. of light to dark or even black color; light-gray and dove-colored beds also present. On slopes of West Mtn a ls. cgl. about 20 ft. thick is interbedded in the ls. 75± ft. above its base, but this cannot be traced far. Also contains small layers of qtzite, and considerable chert in nodules, layers, and masses. Thickness 20 to 300 ft. May possibly be same as Highland Boy ls. Named for occurrence in Old Jordan mine. [Sections show Jordan ls. as lying much lower than Commercial ls. and much higher than Lenox ls.]

Jornadan series.

A term introduced by C. [R.] Keyes to designate 25 ft. of Quat. adobe in N. Mex. In his Conspectus of geol. fms. of N. Mex., 1915, p. 8, he defined it as "Principal intermont plains soils and surface deposits."

Josephine formation.

Paleozoic: British Columbia.

S. J. Schofield, 1919 (Canada Geol. Surv. Summ. Rept. 1918, pt. B, p. 60).

Jualin diorite.

Early Cretaceous (?): Southeastern Alaska (Berners Bay region).

A. Knopf, 1911 (U. S. G. S. Bull. 446, pp. 24–25, map). *Jualin diorite.*—Intrudes Berners fm. (Jurassic or Lower Cret.). Exposed at Jualin and in Jualin mine. Assigned to early Cret. (?).

Juana Diaz shales.

Juana Diaz marls.

Tertiary: Puerto Rico.

C. P. Berkey, 1915 (N. Y. Acad. Sci. Annals, vol. 26, pp. 10, 17). Included in Arecibo fm.

Juan Ascencio chert beds.

Cretaceous (?): Puerto Rico.

D. R. Semmes, 1919 (N. Y. Acad. Sci., Scientific survey of Porto Rico and Virgin Islands, vol. 1, p. 65).

Juan Ascencio member (of Fajardo shale).

Cretaceous: Puerto Rico.

H. A. Meyerhoff, 1931 (N. Y. Acad. Sci., Scientific survey of Porto Rico and Virgin Islands, vol. 2, pt. 3, p. 288).

Jubilee limestone.

Cambrian: British Columbia.

C. S. Evans, 1933 (Canada Geol. Surv. Summ. Rept. 1932, pt. A2, p. 124).

Judique series.

Mississippian: Nova Scotia (Cape Breton Island).

P. D. Trask and K. F. Mather, 1927 (Wash. Acad. Sci. Jour., vol. 17, p. 323).

†Judith group.

See under *Judith River fm.*

†Judithian series.

A term applied by C. [R.] Keyes to Judith River fm. of other geologists.

Judith River formation. (Of Montana group.)

Upper Cretaceous: Central, northern, southeastern and southern Montana.

F. B. Meek and F. V. Hayden (Phila. Acad. Nat. Sci. Proc., vol. 8, p. 267, 1856; vol. 9, p. 123, 1858; vol. 13, p. 417, 1862; Am. Phil. Soc. Trans., n. s., vol. 12, 1862) described but did not name the fresh-water and brackish-water deposits near mouth of Judith River, Mont. They did, however, casually allude to them as *Judith deposit, Judith beds,* and *Judith River beds.*

F. V. Hayden, 1869 (U. S. Geol. and Geog. Surv. Terr. 3d Ann. Rept., pp. 89–92). To these groups (Fort Union, Wind River, White River, and Loup Fork) might be added the *Judith River beds,* a small basin in Missouri River, near foot of the mtns, about 15 to 20 mi. in width and 40 mi. in length. This group is probably of lower tertiary age, but I think it was always separated from the great lignite group.

F. V. Hayden, 1871 (U. S. Geol. and Geog. Surv. Terr. 4th Ann. Rept., p. 97). There is one other basin near sources of Missouri River which has already yielded many fossils of great interest but which seems to be isolated from the others. This is what I have called the Judith Basin, and inasmuch as it seems to be one of the ancient lake deposits, and characterized by a peculiar group of organic remains, I will designate the strata as *Judith group.* The sediments do not differ materially from those of Fort Union group, and they contain impure beds of lignite, fresh-water Mollusca, and a few leaves of deciduous trees. But the most remarkable feature of this group is the number and variety of the curious reptilian remains, of which we have only yet caught a glimpse.

F. B. Meek, 1873 (U. S. Geol. and Geog. Surv. Terr. 6th Ann. Rept., pp. 459, 460). We have always considered the *Judith River beds* to be Lower Tert., but there are some reasons for suspecting they may be Upper Cret.

E. D. Cope, 1874 (U. S. Geol. and Geog. Surv. Terr. 7th Ann. Rept., p. 434). From standpoint of writer the *Judith River beds* would be at top of Cret. and more or less related to Fort Union epoch.

F. B. Meek, 1876 (U. S. Geol. and Geog. Surv. Terr. Mon. 9), gave a section (p. xlviii) of *Judith River group* at mouth of Judith River, listed its fossils, and stated that it rested conformably on Fox Hills group, was overlain by Fort Union group, and was probably of Cret. age. Subsequent writers designated these beds as *Cretaceous No. 6 or Judith River group,* and called the underlying deposits *Cretaceous No. 5 or Fox Hills group.* In 1883 C. A. White included the Judith River deposits in Laramie "group."

J. B. Hatcher, 1896 (Am. Nat., vol. 30, pp. 112–120), showed *Judith River beds* to be older than Ceratops beds of Converse Co., Wyo. In 1902 (Sci., n. s., vol. 16, pp. 831–832) he stated that they are overlain by 300 to 400 ft. of sh. similar to Pierre sh. and which he had little doubt really represented the Pierre.

J. B. Hatcher and T. W. Stanton, 1903 (Sci., n. s., vol. 18, pp. 211–212), divided the Montana group of Mont. and adjoining parts of Canada (all of which they suggested was probably of Pierre age) into (descending): (1) Bearpaw sh. (600 ft. of dark clay sh. with many calc. concretions); (2) *Judith River beds* (500 to 600 ft. of light-colored, mostly nonmarine beds); (3) Claggett fm. (400 ft. of marine sh. and sss.); and (4) Eagle fm. (250 to 300 ft. of coarse, light-colored sss. with beds of clay sh. and lignite).

T. W. Stanton and J. B. Hatcher, 1905 (U. S. G. S. Bull. 257). *Judith River beds.*—Mostly fresh water, but occasionally contain intercalated brackish water layers, the most persistent of which is near top of fm. More rarely there are local marine deposits in upper part. The beds are prevailingly light-colored and tend to weather into "badlands" forms. Little more than 500 ft. thick near Judith. The Judith River beds in original area consist of light ash-colored sss. alternating with usually darker colored and more friable shales and clays mingled with frequent seams of lignite. The early use of Judith River by Meek and Hayden was in a general untechnical sense to include all the fms. occurring near mouth of Judith River. The Judith River beds as here defined underlie Bearpaw sh. and grade into underlying Claggett fm., which is well exposed in neighborhood of Judith, where it is 400 ft. thick. At many places in Bearpaw Mtns and at other favored localities the Bearpaw sh. is seen resting conformably on Judith River beds. It is not yet determined whether Bearpaw includes equiv. of Fox Hills. [This is present generally accepted definition of Judith River fm.]

T. W. Stanton, 1919 (U. S. G. S. P. P. 120, p. 167), correlated overlying Bearpaw sh. with upper part of Pierre sh. and lower part of Fox Hills ss.

Judith River sand.

Name locally applied to the first gas sand (subsurface) in Pierre sh. of Cedar Creek anticline, SE. Mont., which appears to lie at approx. horizon of Judith River fm.

Julian schist.

Triassic or older: Southern California (San Diego County).

F. J. H. Merrill, 1914 (Geol. and Min. Res. San Diego and Imperial Counties: Calif. State Min. Bur., pp. 11–12). *Julian group.*—Metamorphic fms. of mica schists, slates, qtzites, and ls., the first being especially well exposed near Julian and the latter occurring in small areas at several points. Age uncertain. May be Triassic, Carbf., or older.

F. S. Hudson, 1922 (Univ. Calif. Pub., Bull. Dept. Geol. Sci., vol. 13, No. 6, pp. 181, 182–190, map). *Julian schist.*—In Cuyamaca region consists of quartz-mica schists, quartz two-mica schists, quartz-muscovite schists, and some thin-bedded qtzites. The metamorphosed product of shales, fine clayey sss., and nearly pure quartz sss., with subordinate layers of basic volcanic rock. Thickness more than 6,600 ft. Named for village of Julian, San Deigo Co., which occurs in midst of the mass. Of Triassic age, or late Paleozoic, or both.

W. J. Miller, 1935 (Calif. Jour. Mines and Geol., vol. 31, No. 2, pp. 120–121). *Julian schist* of Southern Peninsular Range is same as Julian group of Merrill and *Julian schist of Hudson.* No fossils found. May include rocks of Triassic, late Paleozoic, or even older ages. Evidence obtained strongly suggests it is largely or wholly metamorphosed Triassic sediments.

Julian group.

See under *Julian schist*, 1914 entry.

†Julian limestone.

Name proposed by C. [R.] Keyes (Pan-Am. Geol., vol. 37, pp. 252–255, 1922) to replace the well-established name *Galena dol.*, which he does not consider well founded. Named for Julian Twp, Iowa.

†Julian series.

Name proposed by C. [R.] Keyes (Pan-Am. Geol., vol. 47, pp. 146–148, 1927) as a designation for the Middle Ord. sequence of Dubuque region, Iowa, extending from top of Galena dol. down to base of Glenwood sh.

Juliand member.

Upper Devonian: Southeastern New York (Greene County).

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60, pp. 99, 285). East of Ithaca both Enfield and Ithaca become divisible, the latter separating into Otselic sh. below and Cincinnatus flags above; the Enfield into Kattel sh. below, a middle memb. I have been calling the *Juliand*, from exposures in Juliand Hill, just E. of village of Greene, N. Y., and at top Van Etten sh. ("First *Tropidoleptus* zone").

G. H. Chadwick, 1935 (Am. Mid. Nat., vol. 16, No. 6, pp. 858, 862). Eastward from Canandaigua Lake the Enfield splits into (descending): Van Etten ("First *Tropidoleptus*") zone, *Juliand zone,* and Kattel (*"Leiorhynchus globuliforme"*) zone.

Jumbo volcanics.

Mesozoic or late Paleozoic: Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 95, map). *Jumbo volcanics.*—Greatly altered and metamorphosed lavas and intrusive igneous rocks of apparent andesitic composition. Lie on S. border of Rossland volcanics. As a rule much more altered than lavas of Rossland volcanic group, but possibly are in part correlative with Rossland. Appear to rest uncon. on Mission argillite and Northport ls. On NE. appear to pass beneath lower members of Rossland volcanic group, but contact may be fault contact. Occur at headwaters of Fifteen Mile Creek, at E. end of Jumbo Mtn, and occupy 11± sq. mi. Assigned to Tert. [The Rossland volcanic group is now assigned to Carbf. (?), Triassic (?), Jurassic (?).]

Jumbo dolomite member (of Talladega slate).

Probably Paleozoic: Eastern Alabama.

C. Butts, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14, map, p. 53). *Jumbo dol. memb. of Talladega sl.*—Apparently lies several thousand ft. above the ferruginous ss. memb. of the Talladega, and several thousand ft. below top of the Talladega, being both underlain and overlain by ordinary phyllite of Talladega type. In at least one place this memb. consists of an upper dol. bed 60 ft. thick and a lower dol. bed 20 ft. thick, the two separated by a 40-foot bed of phyllite. Thickness at least 120 ft. Extends from NE¼ sec. 4, T. 23 N., R. 16 E., S. and W. to half a mile W. of old Jumbo post office.

Named for exposures and quarries at and near Jumbo, Chilton Co.

Juncos gabbro.

Age (?): Puerto Rico.

C. R. Fettke, 1924 (N. Y. Acad. Sci., Scientific survey of Porto Rico and Virgin Islands, vol. 2, pt. 2, p. 153, and Am. Inst. Min. and Met. Engrs. Trans., vol. 70, pp. 1026–1042).

Junction limestone.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, pp. 36, 301). *Junction fm.*—Lss., 200 ft. thick, underlying Brush sh., overlying Bishop sss., and composing a middle fm. of Flaming Gorge series in Utah. Assigned to late Jurassic. [But Keyes also stated that it may correspond to Minnewaste ls., which is Lower Cret. Derivation of name not stated.]

According to A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1936 (U. S. G. S. P. P. 183, chart opp. p. 40), these lss. are Curtis fm. (Upper Jurassic).

Junction City quartzite.

Pre-Cambrian (middle Huronian): Central northern Wisconsin (Portage County).

S. Weidman, 1907 (Wis. Geol. Nat. Hist. Surv. Bull. 16, p. 91). *Junction City qtzite.*—Several separated areas of qtzite and qtzite schist exposed in vicinity of Junction City, Portage Co. The fm. varies rapidly from qtzite to sh. Approx. 200 to 500, possibly 1,000 ft. thick. Base not exposed. May be same as Rudolph qtzite. Assigned to lower Huronian (?).

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, chart opp. p. 598), assigned the qtzites and slates of north-central Wis. to middle Huronian.

June Bell rhyolite.

Tertiary: Central northern Nevada (western part of Elko County).

E. H. Rott, Jr., 1931 (Univ. Nev. Bull., vol. 25, No. 5). *June Bell rhyolite* (Tert.) on surface is limited to small area on June Bell claim in Gold Circle or Midas mining dist. but underground it is more extensive. If extrusive it is older than Elko Prince rhyolite; if intrusive it is younger.

Juniata coal measures.

F. Platt, 1877 (2d Pa. Geol. Surv. Rept. H_2, pp. xxiii-xxx), applied this name to the rocks in SW. Pa. underlying the Genesee black sh. and overlying his Marcellus black sh.

Juniata formation.

Upper Ordovician (Richmond): Central southern and eastern Pennsylvania, western Maryland, western Virginia, and eastern West Virginia.

N. H. Darton, 1896 (U. S. G. S. Piedmont folio, W. Va.-Md., No. 28, and Franklin folio, W. Va.-Va., No. 32). *Juniata fm.*—Brownish-red sss. alternating with red shales. Thickness 685 to 1,125 ft. Underlies Tuscarora qtzite and overlies Martinsburg sh. Is basal part of Medina of early repts on this region. Assigned to Sil. [Derivation of name not stated.]

W. B. Clark, 1897 (Md. Geol. Surv. vol. 1, pp. 172–188). *Juniata fm. (red Medina ss.)* of western Md. is best developed in Wills Mtn, NW. of Cumberland, where it is 550 ft. thick. Consists of alternating shales and sss. of deep red color. Named for typical occurrence on Juniata River in Pa. Assigned to Sil.

This fm. continued to be universally assigned to Sil. (as was Medina group of N. Y.) until 1908, when R. S. Bassler (Econ. Geol., vol. 3, p. 510) classified the fm. in Va. as Ord. and of Lorraine age. In 1909 (Sci., n. s., vol. 29, pp. 353, 355, 415) A. W. Grabau correlated Juniata with Queenston sh. of western N. Y. ("of late Lorraine and Richmond age"), and assigned both of those fms. to Upper Ord. The Tuscarora, however, he placed in Sil. Although no fossils were obtained from the rocks, the Juniata fm. of U. S. G. S. Mercersburg-Chambersburg folio, No. 170, 1909, was classified as Upper Ord.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27), assigned the Juniata to Upper Ord. and the Richmond to Sil.; and, although no fossils were obtained, this classification of the Juniata was followed by G. W. Stose in U. S. G. S. Pawpaw-Hancock folio, No. 179, 1912.

In 1913 (12th Int. Geol. Cong., pp. 593–666) E. O. Ulrich assigned Juniata fm. (=Queenston sh.) to Richmond epoch and assigned the Richmond to Sil. Grabau, however, the same year (Geol. Soc. Am. Bull., vol. 24, pp. 408-410) assigned Juniata (=Queenston and=Richmond) to Upper Ord. Ulrich still classifies the Richmond group (and equiv. fms. in other parts of the country) as Sil. In this he is followed by R. S. Bassler, R. Ruedemann, and the present N. Y. State and Pa. State Surveys. The U. S. Geol. Survey and geologists and paleontologists in general assign the Richmond group and its equivalents to Upper Ord. Although the Juniata is nonfossiliferous, its correlation with Richmond group appears now to be accepted by all writers.

Juniata moraine.

Pleistocene (Wisconsin stage): Eastern Michigan (The Thumb). Shown on moraine map (pl. 32) in U. S. G. S. Mon. 53. Named for Juniata, Tuscola Co.

Juniata River series.

Name proposed by F. Platt (2d Pa. Geol. Surv. Rept. H, pp. 6, 8, 1875) for the Dev. coal beds of No. VIII, which he included in his Hamilton series.

J. P. Lesley, 1877 (2d Pa. Geol. Surv. Rept. H_3, p. xxiii), applied *Juniata River coal group* to part if not all of his *Hamilton sss.*, which occupied interval btw. Genesee black shales above and Marcellus black shales below.

Juniper andesites.

Age(?): Northern California (Lassen National Park).

H. Williams, 1932 (Calif. Univ. Pub., Bull. Dept. Geol. Sci., vol. 21, No. 8, pp. 214–376, map). *Juniper andesites.*—Pale-gray and dark bluish-gray platy and slabby pyroxene andesites. Surround Juniper Lake on all but S. side and extend W. a distance of 4 mi. Overlie Willow Lake basalts.

Juniper Hill formation.

Upper Devonian: Central northern Iowa.

A. O. Thomas, 1925 (Iowa Geol. Surv. vol. 30, p. 116, footnote). *Juniper Hill fm.* introduced to replace *Sheffield fm.* of Fenton, 1919, Sheffield being a misnomer for the rocks to which Fenton applied it, because the shales at Sheffield are much younger than the Upper Dev. beds which Fenton named *Sheffield fm.*

Named for fact that Juniper Hill, about 1 mi. NW. of Rockford Brick and Tile Plant, Floyd Co., is in midst of numerous good exposures of the fm.

See also under *Sheffield fm.*

Jupiter formation.

Silurian: Quebec (Anticosti Island).

W. H. Twenhofel, 1928 (Canada Geol. Surv. Mem. 154, p. 26).

Jupiter River formation.

Silurian: Quebec (Anticosti Island).

C. Schuchert and W. H. Twenhofel, 1910 (Geol. Soc. Am. Bull., vol. 21, p. 713).

Jura.

Same as *Jurassic.* Chiefly employed by Europeans.

Jurassic period (or **system**).

The time (and the rocks) of the middle period of the Mesozoic era, succeeding Triassic and preceding Cretaceous. For definition see U. S. G. S. Bull. 769, pp. 62–64.

Jurasside revolution.

A. Knopf, 1924 (U. S. G. S. Bull. 762, p. 11). As has long been recognized and generally accepted, the folding of the Triassic and Jurassic rocks of Star Peak Range, Nev., took place in post-Jurassic time, most probably at end of Jurassic, contemporaneously with the revolution that affected Sierra Nevada region at this time—the great crustal disturbance that will here be termed *Jurasside revolution.*

†Juratrias.

A term employed in early geologic repts to include rocks of Jurassic and Triassic age.

Jurupa series.

Paleozoic(?): Southern California (Riverside County).

J. W. Daly, 1935 (Am. Min., vol. 20, No. 9, pp. 638–647, map). *Jurupa series.*—Oldest rocks of Jurupa Mtns. A thick series of recrystallized sedimentaries, divided into (descending): Sky Blue Quarry ls., 500+ ft.; Chino Quarry qtzite, 75+ ft.; Chino Quarry ls., 470+ ft.; and an undiff. complex consisting of 3,700+ ft. of qtzites, schists, and gneisses with small ls. lenses. Age undet.; tentatively assigned to *Paleozoic(?)*.

Jutten volcanics.

Pre-Cambrian: Ontario (Savant Lake area).

G. Rittenhouse, 1936 (Jour. Geol., vol. 44, No. 4, p. 456).

Kaaterskill formation.

Upper Devonian: New York.

B. Willard, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 3, p. 498), suggested the use of *Kaaterskill* to replace Chadwick's restricted Catskill, for the red beds underlying the Catawissa and overlying the Oneonta, and advocated the continued use of Catskill in the broad sense, which "is synonymous with Dev. red beds, continental."

G. H. Chadwick, 1933 (Am. Jour. Sci., 5th, vol. 26, pp. 480–484). [See this entry under *Catskill fm.*]

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 26). [See this entry under *Catskill fm.*]

B. Willard, Jan. 1936 (N. Y. State Mus. Bull. 307, p. 74, letter to G. H. Chadwick, dated Mar. 4, 1935). *Kaaterskill* is proposed for red sss. and shales now thought to be of Tully age, which make up a part of original Catskill group of Mather in Catskill Mtns, N. Y. Their type is the principal reddish and olive-gray ss. ledges and associated red shales overlooking the Kaaterskill clove on N. and making the falls of the Kaaterskill. Further field work may be necessary precisely to determine the strat. boundaries of this memb., which is a conspicuous element in the succession. [Chadwick, on p. 99, shows *Kaaterskill* as underlying Onteora, as overlying Kiskatom, and as=Tully.]

Kaau volcanics.

Pleistocene (late): Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Kaau volcanics.*—Tuff and basalt erupted from Kaau Crater. Included in lower part of Honolulu volcanic series [q. v.].

Kachess rhyolite.

Eocene: Central Washington (Snoqualmie quadrangle).

G. O. Smith and F. C. Calkins, 1906 (U. S. G. S. Snoqualmie folio, No. 139). *Kachess rhyolite.*—Thick flows of white or yellow rhyolite aggregating 0 to 4,000 ft. Well exposed on NE. side of Kachess Lake. Is in part younger than Naches fm. and in part contemp. with the Naches, so that a heavy flow of Kachess is interbedded with the Naches ss. and basalt.

Kaegel fanglomerate.

See *Kagel fangl.*

Kagawong beds.

Upper Ordovician: Ontario (Manitoulin Island).

A. F. Foerste, 1912 (Ohio Nat., vol. 13, p. 46), divided Richmond strata on Manitoulin Island into Waynesville beds or Lower Richmond and *Kagawong beds or Upper Richmond*, the former being correlated with Waynesville of Ohio and northern Ky., the Kagawong faunas being distinctly younger than Waynesville of Ohio. The fossil zones are described. Total thickness of this upper part of Richmond, from Stromatocerium reef to base of Clinton, varies apparently from 45 to 60 ft. on Manitoulin. Exposed at Kagawong, Maintoulin Island.

In 1924 (Canada Geol. Surv. Mem. 138) Foerste correlated his Kagawong memb. of Richmond fm. with Whitewater and Saluda of SW. Ohio.

†Kagawong member (of Cataract formation).

Silurian (early): Ontario (Georgian Bay region).

M. Y. Williams, 1913 (Ottawa Nat., vol. 27, pp. 37–38). *Kagawong member.*—Red clay sh., which forms upper memb. of Cataract fm. in Georgian Bay region. Well exposed along road btw. villages of Kagawong and West Bay, at a locality NE. of Kagawong Lake, on Manitoulin Island. Is overlain by about 6 ft. of green sh., which appears to grade upward into the argill. dol. of Lockport fm. At Cabot Head probably 16 ft. of firm red shales underlie soft red clay sh. similar to that on Manitoulin Island. Firm red sh. containing Bryozoa overlie Manitoulin dol. along S. side of Georgian Bay. According to interpretation of writer, all the red shales are to be included in Kagawong memb. The age and complete strat. relations of a considerable thickness of gray to green shales, occurring above the red shales at Cabot Head, are not yet definitely determined, although they may, in part at least, represent a later phase of Kagawong sedimentation. They are overlain by about 6 ft. of green sh. beneath argill. dol. of Lockport age, as is the case with the Kagawong sh. on Manitoulin Island.

In 1914 (Canada Geol. Surv. Summ. Rept. for 1913, pp. 179-188) M. Y. Williams used Grabau's name *Cabot Head sh.* to replace *Kagawong*, "preoccupied by Foerste's use of the name for an upper Richmond member."

Kagel fanglomerate.

Quaternary: Southern California (San Gabriel Mountains).

M. L. Hill, 1930 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 19, No. 6, pp. 141, 144). *Kagel fm.*—The younger and topographically lower Quat. fangl., in which Kagel Canyon is being dissected. Composed of subangular and poorly sorted fragments of gneiss and granitic rocks up to 2 ft. diam. Is not so brown in color as the older Lopez fangl. Overlies Saugus fm. with angular uncon.

Kagey sand.

A subsurface sand, of Penn. (?) age, in Stephens Co., southern Okla., lying at 2,300 ft. depth in Empire pool, the Blaydes sand lying at 2,200 ft. and the Maloney at 2,600 ft.

Kaibab limestone. (Of Aubrey group.)

Permian: Northern Arizona, southern Utah, and southeastern Nevada.

N. H. Darton, 1910 (U. S. G. S. Bull. 435, pp. 21, 28, 32). *Kaibab ls.*—Top fm. of Aubrey group. Heretofore called "Aubrey" ls. Overlies Coconino ss. and underlies "Moencopie fm." of Ward. Caps Kaibab Plateau, on N. side of Grand Canyon. According to Walcott (G. S. A. Bull., vol. 1, 1890, p. 50) the ls. is 805 ft. thick on E. side of Kaibab Plateau, and according to Gilbert (Rept. U. S. Geog. Surv. W. 100th Mer., vol. 3, Geol., 1875, p. 177) it reaches its max. of 820 ft. on lower part of Kanab Creek, where it contains much chert, which locally in upper beds amounts to half of the rock. At Grand Canyon Station it is nearly 675 ft. thick; at other places 100 to 410 ft.

L. F. Noble, 1928 (U. S. G. S. P. P. 150, p. 41). Complete section of Kaibab ls. is exposed in Kaibab Gulch (a deep canyon cut entirely across N. part of Kaibab Plateau), 8± mi. SW. of abandoned settlement of Paria, Utah, about 6 mi. N. of Ariz. line. Here the Kaibab beds can be seen resting on Hermit sh. and overlain by Moenkopi fm. The section in Kaibab Gulch is therefore proposed as the type section, because it is only section of Kaibab ls. in type area that is known to be complete. [This is now recognized by U. S. G. S. as type section.]

Kailua volcanic series.

Tertiary and possibly early Pleistocene: Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Kailua volcanic series.*—Composed of amygdaloidal basalt and its feeding dikes or dike complex. The basalt flows are of pahoehoe and aa basalt up to 60 ft. thick. The clinker beds in the aa flows have been cemented into hard breccia. Quartz geodes are not uncommon and numerous semiprecious gems have been cut from its minerals. The rocks are distinctly metamorphosed; and the vesicles filled with secondary minerals. The source of the flow is a little NE. of the rift that supplied the Koolau volcanic series, which overlies Kailua series without any apparent uncon. The Kailua series is never in contact with Waianae volcanic series, but it is correlated with lower basalt memb. of Waianae series. It forms the low hills surrounding Kailua btw. Kaneohe and Waimanalo.

Kaimuki volcanics.

Pleistocene (late): Hawaii (Oahu Island).

C. K. Wentworth, 1926 (Bernice P. Bishop Mus. Bull. 30, pp. 40, 42, 44). *Kaimuki basalt.*—Varies from a dense rock nearly free from vesicles to very scoriaceous material with abundant cavities 2 centimeters in diam. Extruded from small crater that occupies center of Kaimuki spur and no part of flow extended more than 1¼ mi. from rent. Seems to be younger than Diamond Head tuff.

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Kaimuki volcanics.*—Chiefly basalt; some cinders and spatter. Overlies Diamond Head tuff. Included in middle part of Honolulu volcanic series [q. v.]. Forms Kaimuki Hill. Assigned to late Pleist.

†Kainozoic. See *Cenozoic*, the modern name.

Kaiparowits formation.

Upper Cretaceous: Central southern Utah (Kaiparowits Plateau region).

H. E. Gregory and R. C. Moore, 1931 (U. S. G. S. P. P. 164). *Kaiparowits fm.*—Chiefly fine-grained drab arkose ss., composed of quartz, orthoclase, albite and biotite cemented by lime. Within and btw. the ss. beds lie thin, flat lenses and stub-ended lenses of slightly more firmly cemented sand grains, commonly of lighter color, some of them buff or yellow. The fm. also contains lenses, pancakes, flattened balls, and irregular beds, some traceable 100 ft., of brown, gray-green, and white sandy ls.; some thin lenses of nearly pure ls.; also lenses of ls. cgl. of concretionary balls and irregular chunks of ls. mingled with sand. Thickness 2,000± ft. Uncon. underlies Wasatch fm. (Eocene) and overlies Wahweap ss. on Kaiparowits Peak and Table Cliff.

Kakabeka formation.

Pre-Cambrian: Ontario.

T. L. Tanton, 1931 (Canada Geol. Surv. Mem. 167, p. 25).

Kalama volcanics.

Latest Pleistocene or Recent: Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Kalama volcanics.*—Basalt (aa lava, petrographically an olivine basanite) and pyroexplosion deposits erupted from Kalama Crater. Included in upper part of Honolulu volcanic series [q. v.].

Kalamazoo morainic system.

Pleistocene (Wisconsin stage): Southern Michigan, northern Indiana, and possibly northern Illinois. Shown on moraine map (pl. 32) in U. S. G. S. Mon. 53 and on moraine map in P. P. 106. Named for Kalamazoo, Mich. In some earlier repts called *Kalamazoo moraine.*

Kalihi volcanics.

Pleistocene (late): Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Kalihi volcanics.*—Chiefly basalt. Included in lower part of Honolulu volcanic series [q. v.]. Occurs near head of Kalihi Valley.

Kalkberg limestone.

Lower Devonian: Eastern and east-central New York.

G. H. Chadwick, 1908 (Sci., n. s., vol. 28, pp. 346–348). *Kalkberg ls.* is proposed to cover certain layers heretofore included variously by writers with the beds above (New Scotland) or below (Coeymans), and carrying a mixed fauna, highly developed and excellently silicified on Catskill Creek [Greene Co.], where the beds show numerous thin parallel seams of black flint nodules. The name *Kalkberg* (lime hill) is local Dutch designation for the Helderbergian ridge, and is pronounced Collak-barrakh. [Thickness not stated.]

The commonly accepted classification of Helderberg group in N. Y. is (descending) Becraft, New Scotland, Kalkberg, and Coeymans lss.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 373), gives thickness of this ls. at type loc. as 25 to 40± ft., and as 20 ft. in Helderberg area.

Kalorama member.

Pleistocene: Southern California (Ventura County).

E. D. Pressler, 1929 (Univ. Calif. Pub. Bull. Dept. Geol. Sci., vol. 18, No. 13, pp. 325–345). *Kalorama memb.* (also *Kalorama horizon*).—Lower part of Las Posas fm. Contains a marine Pleist. fauna, but of cooler water than overlying Long Canyon memb. Correlated with Saugus fm. Is of approx. same age as or slightly older than Lower San Pedro Pleist.

[Derivation of name not stated.]

T. L. Bailey, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 3, p. 492). Pressler's *Kalorama memb. of Las Posas fm.* contains a typical Santa Barbara fauna, and is here included in Santa Barbara fm., which is now tentatively classified as Lower Pleist. and Upper Plio.

Kaltag formation.

Upper Cretaceous: Southwestern Alaska (Nulato-Norton Bay district, Lower Yukon River region).

G. C. Martin, 1926 (U. S. G. S. Bull. 776, pp. 395–412, chart opp. p. 474). Upper Cret. of lower Yukon region divided into 4 conformable fms. (descending), *Kaltag fm.*, Nulato fm., Melozi fm., and Ungalik cgl. The Kaltag consists of 800+ ft. of coal-bearing rocks (fresh-water ss., sh., and coal beds with possibly some thin marine members) containing fossil plants, fresh-water invertebrates, and perhaps a few marine invertebrates. Named for exposures on NW. bank of the Yukon btw. Kaltag and the Williams mine.

See under *Skaktolik group*. Also see U. S. G. S. P. P. 159, 1930.

Kamanaiki basalt.

Pleistocene (late): Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Kamanaiki basalt.*—Fresh, dark-gray, slightly vesicular basalt. Forms a V-shaped fill in Kamanaiki Valley SE. of Kamanaiki triangulation station at altitude of 750 ft., and occurs in patches at other localities in this and adjacent valleys. Included in middle part of Honolulu volcanic series [q. v.].

Kamehame basalt.

Recent and late Pleistocene (?): Hawaii (Mauna Loa and Kilauea).

H. T. Stearns, 1926 (Geol. Soc. Am. Bull., vol. 37, p. 151) and 1930 (U. S. G. S. W. S. P. 616, p. 69). *Kamehame basalt* assigned to Recent and late Pleistocene (?).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Kamehame basalt.*—Comprises all lava flows and ash deposits from Mauna Loa and Kilauea which lie above the ash memb. at top of Pahala basalt. Thickness 5 to 800 ft. The lower part was deposited in prehistoric times, the upper part in historic times. The ash beds vary in thickness from a few inches to several ft. The lavas consist of approx. equal amounts of aa and pahoehoe. Named for Kamehame Hill, 3½ mi. S. of village of Pahala, where a prehistoric lava flow entered the sea.

Kamiah volcanics.

Tertiary (probably Miocene or Oligocene): Northern Idaho (Orofino region).

A. L. Anderson, 1930 (Idaho Bur. Mines and Geol. Pam. 34). *Kamiah volcanics.*—A thick series of andesitic and latitic lava which heretofore had not been recognized in this part of Idaho, although rocks of apparently similar character are widely distributed over south-central part of state. In other localities these rocks have been assigned to Mio., with lower part probably Olig., but their age in this region cannot be accurately fixed. They rest on eroded surface of quartz diorite, of probable late Jurassic age, and were much eroded before Columbia River basalt (upper Mio.) welled up about them. They are represented in outline and area by Kamiah Buttes, about 12 mi. S. of town of Kamiah. The Buttes cover about 22 sq. mi. and rise to max. height of 1,000 ft. above plateau surface. The rocks are essentially horizontal. Most of flows of Kamiah Buttes have composition of andesite with at least one of quartz latite. Most of the andesites are grayish and vesicular, but some are reddish.

Kaminis granite.

Pre-Cambrian: Manitoba.

E. L. Bruce, 1918 (Canada Geol. Surv. Summ. Rept. 1917, pt. D, p. 6).

Kaministikwia group.

Pre-Cambrian: Canada (Rainy River district).

T. L. Tanton, 1927 (Geol. Soc. Am. Bull., vol. 38, p. 114, abstract). The *Kaministikwia group* (Upper Copper-bearing series of Logan), a granite intrusive, is divisible into following 3 series (descending) *Osler series, Sibley series,* and *Animikie series.* Rests with great uncon. on Basement Complex. [All of definition. Type localities not stated.]

See also *Kaministiquia fm.*

T. L. Tanton, 1927 (Geol. Soc. Am. Bull., vol. 38, p. 739), and 1931 (Canada Geol. Surv. Mem. 167, p. 57), gave additional information.

Kaministiquia formation.

Age (?) : Western Ontario.

Cambrian according to Chapman (Canada Inst., n. s., vol. 8, pp. 186–190, 1863) ; Algonkian (Huronian) according to Walcott (Geol. Soc. Am. Bull., vol. 10, p. 222, 1899) ; same as Keweenawan according to W. G. Miller and C. W. Knight (Ontario Bur. Mines Rept., vol. 22, pt. 2, chart opp p. 126, 1914).

See also *Kaministikwia group.*

Kamishak chert.

Upper Triassic: Central southern Alaska (Cook Inlet region).

G. C. Martin and F. J. Katz, 1912 (U. S. G. S. Bull. 485, p. 47, table opp. p. 80, map, etc.). *Kamishak chert.*—Thin-bedded chert, black calc. sh., and impure ls.; the chert and ls. generally black, green, or dark red when fresh, but weather to lighter shades. Complexly crumpled and faulted, cut by small calcite veins, and intruded by quartz diorite. Typically exposed on W. shore of Kamishak Bay, especially in vicinity of Bruin Bay. Total thickness unknown; at Ursus Cove it probably exceeds 2,000 ft. and may be much greater. Contains Upper Triassic invertebrates.

Kamloops volcanic group.

Miocene or Oligocene: British Columbia.

R. A. Daly, 1913 (12th Int. Geol. Cong. Guidebook 8, p. 118), and C. W. Drysdale (p. 241 of book cited).

Kamouraska formation.

Cambrian (?): Quebec.

J. A. Dresser, 1912 (Canada Geol. Surv. Mem. 35, p. 14). [Assigned to Camb., but later repts by others question the age.]

†Kanab sandstone.

Jurassic (?) and Upper Triassic: Southwestern Utah (Kane County).

E. Huntington and J. W. Goldthwait, 1903 (Jour. Geol., vol. 11, pp. 46–63), divided the rocks btw. Colob [Navajo] ss. above and Shinarump cgl. below into *Upper Kanab* (red ss.) and *Lower Kanab* (red sss. and sh), and also designated the Upper Kanab as *Kanab ss.* In 1904 (Harvard Coll. Mus. Comp. Zool. Bull., geol. ser., vol. 6, p. 203, pl. 7) they restricted *Kanab ss.* to their *Upper Kanab* (which they described as consisting of 1,750 ft. of hard red ss., often cross-bedded, with a thin series of weak beds at base) and named their Lower Kanab (Upper Triassic) the *Painted Desert shales.*

A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1936 (U. S. G. S. P. P. 183, chart opp. p. 33), show Kanab ss. of Huntington and Goldthwait's 1904 rept. is=lower part of Navajo ss. and upper part of Chinle fm.

Kanab limestone.

Name proposed by C. [R.] Keyes (Pan-Am. Geol., vol. 66, 1936, p. 216) to replace *Kaibab ls.*, which was introduced in 1910 to replace "Aubrey ls.," the term *Aubrey* being adopted in the broader sense in which it had been used for many years. Derivation of name not stated.

Kanaka formation.

Mississippian: Northern California (Colfax region).

H. G. Ferguson, 1929 (Am. Inst. Min. and Met. Engrs. Pub. 211, p. 4). *Kanaka fm.*—Chiefly interbedded dark-colored slates and chloritic greenstones (the latter largely andesitic tuffs and breccias), with a cherty memb. [200 to 300 ft. thick] toward middle of fm., and a basal conglomeratic memb. [200 to 350 ft. thick]. Contains some beds that are interpreted as flows, and possibly in part intrusive sheets, of andesite and dacite. Thickness of fm. probably nearly 2,000 ft. Conformably underlies Relief qtzite and overlies, probably uncon., Tightner fm. Named for exposures in valley of Kanaka Creek, Sierra Co. Extends from Oregon Creek to South Yuba.

Kanawha black flint. (In Kanawha formation.)

Pennsylvanian: Northern West Virginia.

I. C. White, 1891 (U. S. G. S. Bull. 65, p. 98). *Kanawha black flint.*—Beneath Mahoning ss., and forming basal beds of Elk River series, are shales, 0 to 50 ft. thick, containing (along Great Kanawha River, on Elk River, and at other places) a peculiar deposit known locally as "Black Flint." It is usually of dark or bluish color, but in places is light-colored; is 5 to 15 ft. thick, and contains marine fossils.

This bed is in upper part of Kanawha fm., lying 80 to 150± ft. below Homewood ss. memb.

Kanawha formation. (In Pottsville group.)

Pennsylvanian: West Virginia and adjacent parts of Virginia and Kentucky.

M. R. Campbell and W. C. Mendenhall, 1896 (U. S. G. S. 17th Ann. Rept., pt. 2). *Kanawha fm.*—Great mass of coals, shales, and sss., 1,150 to 1,200 ft. thick, underlying Charleston ss. and overlying Fayette ss. Includes [Kanawha] black flint at top. Complete section exposed in hills N. of Kanawha Falls, W. Va.

M. R. Campbell, 1901 (U. S. G. S. Charleston folio, No. 72). *Kanawha fm.* underlies Charleston ss. and overlies Sewell fm.

M. R. Campbell, 1902 (U. S. G. S. Raleigh folio, No. 77). *Kanawha fm.* is overlain by Charleston ss. and underlain by Nuttall ss. lentil of Sewell fm.

I. C. White, 1908 (W. Va. Geol. Surv. vol. 2A). *Kanawha series or Upper Pottsville.*—Includes all beds btw. top of Roaring Creek (Homewood) ss. and top of Nuttall ss. [This is definition of Kanawha "group" that is still followed by W. Va. Geol. Survey.]

†Kanawha series.

†Kanawha River series.

†Kanawha River Coal Series.

†Kenawha Coal Measures.

†Kenawha River system.

In some early repts the name "Kenawha River system" was applied to rocks in W. Va. and Pa. that included Pottsville group, Mauch Chunk sh., and Greenbrier (†Mountain) ls. of present repts; the name "Kanawha series" was applied to Allegheny fm. and most of Pottsville group of present terminology; and the names "Kanawha River series," "Kenawha Coal Measures," and "Kanawha River Coal Series" were applied to middle part of Pottsville group as now recognized in W. Va., or to approx. the New River "group" of the present W. Va. Survey classification. These usages of *Kanawha* were, however, long ago abandoned.

†Kanawha Falls rock.

A name that has been applied locally to Homewood ss. memb. in southern W. Va., because it forms the Kanawha Falls in Kanawha River.

Kandik formation.

Lower Cretaceous: Northeastern Alaska (Eagle-Circle district).

J. B. Mertie, Jr., 1930 (U. S. G. S. Bull. 816, p. 136). *Kandik fm.*—Name applied (by E. Blackwelder in unpublished notes) to the Lower Cret. rocks of the upper Yukon, which are typically exposed in valley of Kandik River from the Yukon NE. probably to the bdy. Mainly a monotonous sequence of black argill. sl. and thin sss. No calc. sh., ls., chert, or silicious sl. seen. Lies everywhere uncon. on pre-Jurassic rocks, the Jurassic being absent. Believed to underlie uncon. the Upper Cret. rocks. Name is intended to include all Lower Cret. sed. rocks of the region, but it seems highly probable only ss., sl., and cgl. are represented. Thickness 2,400+ ft. Lower Cret. fossils.

Kane limestone. (In Allegheny formation.)

Pennsylvanian: Central northern Pennsylvania (Elk County).

C. A. Ashburner, 1885 (2d Pa. Geol. Surv. Rept. R_2, pp. 72, 73). *Kane ls.,* also *Kane Quarry (Ferriferous) ls.*—Rotten greenish-gray ls., 3 ft. thick, forming upper bench of Ferriferous. Quarried at Gen. Kane's quarry, W. of road leading from Catholic Church to J. Pistner's, Elk Co. Separated from bottom bench of Ferriferous ls. by 8 ft. of gray sh. and 1 ft. of iron ore.

Kane sand.

A subsurface sand of Upper Dev. age in western Pa. Is older than Bradford sand group, and has been placed below Elk sand in some repts, but Pa. Geol. Surv., 4th ser., Bull. M19, 1933, plates, places 1st Kane, 2d Kane, and 3d Kane sands of McKean Co., Pa., higher than 1st Elk, 2d Elk, and 3d Elk. J. D. Sisler stated (p. 28 of Bull. M19) "the Kane of Bradford dist. does not correlate with Kane sand of Kane dist." [McKean Co.]. In W. Va. the name has been applied to sand said to be of Portage age.

Kanektok silts and gravels.

Pleistocene: Central southern Alaska.

J. E. Spurr, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, p. 177). *Kanektok silts and gravels,* Pleist., extend along lower course of Kanektok River to Oklune Mtns and farther up Kanektok River.

Kaneohe volcanics.

Pleistocene (late): Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Kaneohe volcanics.*—Chiefly basalt. Included in lower part of Honolulu volcanic series [q. v.]. Type loc. on main highway 2 mi. S. of village of Kaneohe.

Kangaroo formation.

Permian and Pennsylvanian (?): Central Colorado (Monarch-Tomichi region).

R. D. Crawford, 1913 (Colo. Geol. Surv. Bull. 4, p. 70). *Kangaroo fm.*—Qtzites, cgls., and metamorphosed shales; generally gray, often with brown, blue, or light-green tones; cgl. at base. Thickness 3,000 ft. Includes all sed. rocks in dist. above Garfield fm., upon which it lies with uncon. Named for Kangaroo Gulch, Monarch dist.

Kankakee limestone.

Silurian (early): Northeastern, central, and western Illinois, and eastern Missouri (north of St. Louis).

T. E. Savage, 1916 (Geol. Soc. Am. Bull., vol. 27, pp. 305–324). *Kankakee ls.,* new name for 20 to 39 ft. of hard gray to brown ls., of Brassfield age, in NE. Ill., western Ill., and eastern Mo. N. of St. Louis. Contemp. with Sexton Creek ls. of SW. Ill. and eastern Mo., but deposited in separate basin. Uncon. overlies Edgewood ls., which includes *Platymerella manniensis* zone at top. Well developed and clearly exposed along Kankakee River about 5 mi. S. of Richey [Macon Co., *central* Ill.].

T. E. Savage and M. L. Nebel, 1923 (Ill. Geol. Surv. Bull. 43, pp. 22–72). *Kankakee ls.,* relatively pure nonmag. ls. 0 to 50 ft. thick, was deposited at about same time as Sexton Creek ls. of SW. Ill. but in a sea that invaded from E. or NE. and extended as far as Calhoun and Jersey Counties, Ill.

D. J. Fisher, 1925 (Ill. Geol. Surv. Bull. 51). *Kankakee fm.,* 20 to 70 ft. thick in Joliet quad., NE. Ill., includes all rocks lying above *base* of *Platymerella manniensis* zone and below Niagaran dol. Rests uncon. on Edgewood fm. Is top fm. of Alexandrian series. [This definition placed *Platymerella manniensis* zone in Kankakee. It had previously been included in Edgewood ls.]

T. E. Savage, 1926 (Geol. Soc. Am. Bull., vol. 37, pp. 517–526, 533). *Kankakee (Brassfield) ls.* of NE. Ill. includes *Platymerella manniensis* zone, rests uncon.

on Edgewood ls. and is overlain uncon. by Joliet ls. (of early Lockport age), Clinton being absent. Is same as "Waucoma ls." [*which has priority over Kankakee*, and is an Iowa name].

T. E. Savage, 1926 (Ill. State Acad. Sci. Trans., vol. 19, pp. 286–287). *Sexton Creek* (*Brassfield*) *ls.* extends as far N. as Belvidere, near N. border of State [in McHenry Co.].

A. C. Trowbridge et al., 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 48). Savage determined his Waucoma to be same as Kankakee, the earlier name, and Kankakee is now applied in NW. Ill. [Waucoma has priority, but is an Iowa name, while Kankakee is an Ill. name.]

A. H. Sutton, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 270–274). *Kankakee fm.*, top fm. of Alexandrian series in NE. and NW. Ill. Consists of 20 to 70 ft. of purplish-gray, white, buff, brownish, or yellowish-brown ls. and dol. in layers 3 to 36 in. thick. Commonly cherty in NW. Ill. and Iowa. Includes *Platymerella manniensis* zone at base. Overlies Edgewood ls. and underlies Joliet ls. Is correlated with *Waucoma* (*Kankakee*) of Iowa, the Byron of Wis., the Brassfield of Ind., Ohio, Ky., and Tenn., and the Sexton Creek of southern Ill.

See also under *Sexton Creek ls.*

Kankakee torrential deposits.

Pleistocene: Illinois. See L. F. Athy, 1928 (Ill. Geol. Surv. Bull. 55, p. 66).

Kano quartz diorite.

Jurassic (?): British Columbia.

J. D. MacKenzie, 1916 (Canada Geol. Surv. Mem. 88, p. 51).

Kanouse sandstone.

Middle Devonian: Northern New Jersey and southeastern New York.

H. B. Kümmel, 1908 (U. S. G. S. Franklin Furnace folio, No. 161). *Kanouse ss.* introduced to replace [objectionable] name "New Foundland grit." Thick-bedded fine-grained cgl. below and greenish ss. above. Thickness 215 ft. Underlies Pequanac [Cornwall] sh. and rests on Decker ls. Carries Onondaga fauna. Exposed in valley W. of Kanouse Mtn [Passaic Co.], N. J.

Kansan stage of glaciation, also **Kansan drift** (Pleistocene).

Kansan drift is name applied to second drift of eastern, as well as western, part of area covered by Laurentide ice sheet; the name *Kansan stage* being applied to the time during which this drift was deposited. The drift was named for its development in Kansas. The name *Kansan* was originally applied by T. C. Chamberlin (Geikie's Great ice age, 3d ed., 1894, pp. 724–775, and Jour. Geol., vol. 3, pp. 270–277, 1895) to *oldest* drift of western or Keewatin part of Laurentide ice sheet, the name "*East Iowan*" being applied to the second drift; but in 1896 (Jour. Geol., vol. 4, pp. 872–876) Chamberlin, as the result of further studies, shifted the name *Kansan* to the *second* drift (which is the drift that covers NE. Kansas), and shifted the name Iowan to a younger drift. The Kansan drift overlies Aftonian soil and interglacial deposits and underlies Yarmouth interglacial deposits.

Kansan period.

Pennsylvanian: Kansas.

L. C. Wooster, 1906 (Kans. Acad. Sci. Trans., vol. 20, pt. 1, pp. 75–82), divided Carbf. of Kans. into (descending) Permian period, *Coal Measures or Kansan period*, and Mississippian period; and divided his *Kansan period* into Upper Coal Measure or *Upper Kansan epoch* (from top of Elmdale fm. to top of Iola ls.) and Lower Coal Measure or *Lower Kansan epoch* (from top of Iola ls. to base of Cherokee sh.).

†Kansas onyx.

Popular name for Medicine Lodge gyp. where quarried in Barber Co., Kans.

†Kansas City oolite.

Pennsylvanian: Northwestern Missouri.

G. C. Broadhead, 1886 (St. Louis Acad. Sci. Trans., vol. 4, p. 483). The oolitic ls. in Coal Measures of Miami and Franklin Counties, Kans., very much resembles *Kansas City oolite*, but is probably a different stratum, higher in the series.

Is upper part of Drum ls. memb. of Kansas City fm. and same as Kansas City ls. of Gallaher, according to H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines, vol. 13), but is older than Drum ls., according to N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pp. 35, 40), and is upper part of Westerville ls., the lower (nonoolitic) part being called "Bull ledge" at Kansas City.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 95, 100, 252). †Kansas City oolite of Broadhead refers to beds now classed as Westerville ls. and is abandoned.

†Kansas City limestone.

Pennsylvanian: Northwestern Missouri.

J. A. Gallaher, 1898 (Mo. Geol. Surv. Bien. Rept., p. 51), and 1900 (Mo. Geol. Surv. vol. 13, p. 206), used *Kansas City ls.* for a bed of ls. in Upper Coal Measures of Mo. btw. coals Nos. 5 and 6, which is same as †Kansas City oolite of repts, and composes upper part of Drum ls. memb. of Kansas City fm. of Hinds and Greene, 1915 (Mo. Bur. Geol. and Mines vol. 13), who divided Drum ls. into two beds separated by thin sh., the upper bed being the "oolitic ledge" and the lower bed the "Bull ledge" of repts. According to R. C. Moore (1936), however, the Drum of Hinds and Greene is Westerville ls., and true Drum is younger. See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Kansas City group. (In Kansas.)

Kansas City formation. (In Missouri and Iowa.)

Pennsylvanian: Northwestern Missouri, eastern Kansas, southeastern Nebraska, and southwestern Iowa.

H. Hinds, 1912 (Mo. Bur. Geol. and Mines vol. 11, p. 7). *Kansas City ls.*—Basal fm. of Missouri group, extending from top of Iola ls. memb. down to base of Hertha ls. memb. Underlies Lansing fm. and overlies Pleasanton fm., of Des Moines group. Thickness 225 ft. at Kansas City, 200 ft. in Harrison Co. and at Leavenworth, and 165 ft. near St. Joseph. Very thick lss. interbedded with sh. [See also Hinds and Greene, Mo. Bur. Geol. and Mines vol. 13, 1915.]

The foregoing was commonly accepted definition of Kansas City group until 1932.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3, pp. 91, 97). In reclassification of Penn. system of Kans. the term *Kansas City group* is tentatively proposed to apply in a *restricted* sense to the mainly sh. unit which occurs btw. top of Winterset ls. and base of Wyandotte ls. It includes (descending) Lane sh. [restricted], Iola ls., Chanute sh., Drum ls., and Cherryvale sh. [This definition excluded from lower part the Winterset ls., Galesburg sh., Bethany Falls ls., Ladore sh., and Hertha ls.]

R. C. Moore and G. E. Condra, Oct. 1932 (Revised classification chart of Penn. rocks of Kans. and Nebr.), again redefined *Kansas City group*, by drawing its top at base of Plattsburg ls. and its base at top of Winterset ls., the Winterset and underlying beds formerly included in the Kansas City being included in their Bronson group. This restricted definition of Kansas City was followed by Moore in his 1935 and 1936 classifications. According to Moore the so-called Iola ls. of Hinds and Greene is not true Iola but is Argentine ls.; according to Newell (1935) it is = Frisbie and Argentine lss.

For Moore and Condra's modified definitions see Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936. The U. S. Geol. Survey has not yet considered, for its publications, these modified definitions.

The 1933 (57th) Bien. Rept. of Mo. State Geol. continued to draw top of Kansas City fm. at top of Iola ls. and base at base of Hertha ls.

Named for Kansas City, Mo., at and near where its full thickness of 225 ft. is exposed, in the bluffs on which the city is located.

Kanuti group.

Paleozoic: Northern central Alaska (Kanuti River region).

W. C. Mendenhall, 1902 (U. S. G. S. P. P. 10, p. 37, pl. 5). *Kanuti series.*—Youngest rocks of series are basalts, basaltic tuffs, and diabases, in some instances intrusive into the serpentines of the series. Oldest members are greenstones of doubtful origin and hornstones, which are succeeded by massive gabbroic rocks, and serpentines derived from them, which are regarded as intrusive into the greenstone members. Kanuti River flows for 30 mi. through canyon cut in these Paleozoic rocks. May belong to same period as Spurr's Rampart series.

P. S. Smith, 1936 (U. S. G. S. Bull. in process of publication). Kanuti series of Mendenhall probably includes rocks of diverse ages. The bulk of them appear to be Dev. or Carbf., but H. M. Eakin suggests that some he studied may be as old as Ord.

Kanuyak formation.

Pre-Cambrian: Arctic Canada.

J. J. O'Neill, 1924 (Canadian Arctic Expedition 1913–18, Rept., vol. 11, pt. A, p. 22).

Kanwaka shale (in Shawnee group), in Kansas.

Kanwaka shale member (of Shawnee formation), in Missouri.

Pennsylvanian: Eastern Kansas, southeastern Nebraska, northwestern Missouri, and southwestern Iowa.

J. W. Beede, 1902 (Kans. Univ. Sci. Bull., vol. 1, p. 163). *Kanwaka shales* proposed by G. I. Adams, in unpublished ms., for sh., at least 97 ft. thick, divided into 65 ft. of clay sh. at base, overlain by 16 ft. of aren. sh. succeeded by 5 ft, of sandrock, with 11 ft. of sandy buff sh. at top. Overlies Oread ls. and underlies Lecompton ls.

Was for years treated as basal memb. of Shawnee fm. (In Kans. the Shawnee is treated as a group and the Kanwaka sh. as a fm.) Since 1931, however, R. C. Moore has drawn base of Shawnee group at base of Oread ls., instead of at base of Kanwaka sh. When Condra introduced *Kereford ls.* in 1927 he included it and an underlying sh. in Kanwaka sh., and treated Plattsmouth ls. as top memb. of Oread ls. But in 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 89–97) R. C. Moore transferred Kereford ls. and underlying sh. (Heumader sh.) to Oread ls.; and Condra's 1935 and Moore's 1936 classifications followed latter definitions of Kanwaka sh. and Oread ls.; but Moore stated (p. 169) that where Kereford ls. is absent Kanwaka sh. extends down to top of Plattsmouth ls. The U. S. Geol. Survey has not considered, for its publications, these modified definitions.

Named for fact it forms a large part of surface of Kanwaka Twp, Douglas Co., Kans. R. C. Moore stated (Kans. Geol. Surv. Bull. 22, 1936, p. 169) type loc. is exposures E. of Stull, 9± mi. due W. of Lawrence. Also that it is well exposed near SE. cor. sec. 26, T. 12 S., R. 18 E.

Kaohikaipu volcanics.

Latest Pleistocene or Recent: Hawaii (Kaohikaipu Island).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Kaohikaipu volcanics.*—Basalt (black pahoehoe) and pyro-explosion deposits (bedded red cinders, spatter, and bombs cut by irregular dikes) composing Kaohikaipu Island. Included in upper part of Honolulu volcanic series [q. v.].

†Kappa subdivision.

A Greek name applied by F. W. Cragin (U. S. G. S. Bull. 266, 1905) to upper 40 ft. of Malone fm. of Malone Mtn, El Paso Co., Tex.

Karmutsen volcanics.

Triassic: Vancouver Island.

H. C. Gunning, 1933 (Canada Geol. Surv. Summ. Rept., pt. A2, p. 33).

†Karquines series.

†Karquinez series.

See *Carquinez*, the spelling adopted by U. S. Geog. Board.

Kasaan greenstone.

Probably Lower Cretaceous: Southeastern Alaska (Ketchikan region).

A. H. Brooks, 1902 (U. S. G. S. P. P. 1, pp. 40–52, map). *Kasaan greenstone.*—Largely effusive rock, of general character of andesite, but shows great local variations and probably includes some intrusive rocks. Occurs in peninsula lying btw. Clarence Strait and Kasaan Bay. The peculiar copper deposits of Kasaan Peninsula are associated with this rock.

Kashong member. (In Moscow shale.)

Middle Devonian: Central New York.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 218, 231, etc.). *Kashong memb. of Moscow fm.*—Soft sh. characterized by *Adolfia marcyi* and great abundance of unusually large and well preserved specimens of *Tropidoleptus carinatus*, capped by 3 to 5 ft. of sh. containing grotesquely shaped calc. concretions. This concretionary bed is succeeded by 4 ft. of hard sandy rock, at base of which *Leptostrophia junia* occurs in great abundance. The sandy rock is top bed of Kashong memb. Thickness 39 ft. W. of Canandaigua Lake and 80 to 85 ft. in Genesee Valley. Thins to W. and disappears W. of Spring Brook. Writer believes the Kashong correlates with *Orthonota* zone of Cleland in Cayuga Lake region and that it thins eastward by nondeposition. In W. part of State it is overlapped by Windom sh. The Kashong sh. of Genesee Valley and westward is partial equiv. of Portland Point memb. Type section is on Kashong Creek, Seneca Lake, where it is 24 ft. thick.

Kaskapau member.

Cretaceous: Alberta.

F. H. McLearn, 1926 (Canada Geol. Surv. Bull. 42, p. 119).

†Kaskaskia limestone.

†Kaskaskia formation.

†Kaskaskia group.

Mississippian: Western Illinois, eastern Missouri, and western Kentucky.

J. Hall, 1857 (Am. Ass. Adv. Sci. Proc., vol. 10, pp. 55–56). *Kaskaskia ls. or Upper Archimedes ls.*—Extensive and important ls. fm., constituting the lss. of Kaskaskia and Chester, Ill., and those below Ste. Genevieve, Mo. Consists of beds of ls., of greater or less thickness, alternating with thin seams of marl or sh., and in some parts heavy-bedded ls. of considerable thickness, without shaly partings or with very thin ones. Also embraces one or more heavy ss. beds and mass of green sh. or marl, more than 50 ft. thick in places. Overlain by Coal-measures and underlain by Ferruginous [Aux Vases] ss.

Replaced by more widely established term *Chester group*, used by A. H. Worthen (who first correctly interpreted the true relations of the rocks) in manuscripts as early as 1853. The type loc. of Chester group is Chester, Randolph Co., Ill., at mouth of Kaskaskia River.

Named for Kaskaskia, Ill., near mouth of Kaskaskia River.

Kaskaskian series.

A term used by C. R. Keyes to cover same rocks as Chester group. (See his broadside sheet of geol. fms. of Ill., 1923.)

Kaslo volcanics.

Carboniferous: British Columbia.

M. F. Bancroft, 1918 (Canada Geol. Surv. Summ. Rept. 1917, pt. B, pp. 29, 36).

Kaslo schists.

Jurassic: British Columbia.

M. F. Bancroft, 1920 (Canada Geol. Surv. Summ. Rept. 1919, pt. B, p. 43).

Kaslo series.

Triassic: British Columbia.

C. E. Cairnes, 1929 (Canada Geol. Surv. Summ. Rept. 1928, pt. A, p. 98), and J. F. Walker, p. 127 of same rept. Also J. F. Walker and M. F. Bancroft, 1929 (Canada Geol. Surv. Mem. 161, p. 14).

Kasota sandstone.

Lower Ordovician: Southeastern Minnesota (Lesueur County).

L. H. Powell, 1935 (St. Paul Inst. Sci. Mus., Sci. Bull. 1, pp. 2–16). The fauna of the sand bed (6½ ft. thick) btw. Jordan ss. and Oneota dol. is unique, and on basis of fauna the bed is here described as *Kasota ss. fm.* and tentatively correlated with Eminence dol. of Mo. The fauna is believed to be Ord. [This ss. and the overlying "siltstone" were included in Oneota dol. by Stauffer, 1925, 1934.] Named for characteristic exposure in bluff of Minn. River at Kasota, Minn. Consists of white, medium- to coarse-grained sand, grains well rounded, bedding somewhat irregular. Can only be separated from underlying Jordan ss. by its fauna, which is known to occur at St. Peter in bank of Minn. River beneath W. end of highway bridge, at Kasota in upper sand beds in a sandpit in bluff of Minn. River, and at Rapidan, Blue Earth Co. The bed is apparently reworked Jordan ss., reworked at a later age, and contains a fauna of that age. It is overlain, seemingly conformably, by Blue Earth siltstone bed. [Fossils described and discussed. On p. 17 he said: From Ottawa to Mankato, along Minn. River, the Kasota ss. seems to be everywhere overlain by a thin bed of white to greenish (sometimes red) laminated siltstone (the Blue Earth siltstone), which seems to spread beyond the limits of Kasota ss. and in places to rest directly on Jordan ss. On p. 21 he said Kasota ss. and Blue Earth siltstone intervene btw. Oneota dol. and Jordan ss. only in limited region from Ottawa, Minn., to Mankato.]

A. C. Trowbridge. 1917 (Proc. Iowa Acad. Sci., vol. 24, pp. 177+), stated that Oneota dol. of Upper Miss. Valley rests conformably on Jordan ss. through 20 ft. or more of transition beds.

C. R. Stauffer, 1925 (Jour. Geol., vol. 33, pp. 706–707), published a section of Oneota dol. and Jordan ss. in Minn. River Bluff and at adjacent quarries at Kasota, Minn., in which he stated that floor of the quarry lies 10 ft. above top of Jordan ss.; this 10-foot interval consisting of (descending): (1) ls., dolomitic, gray to buff, mottled, thin-bedded, base very uneven, 3 ft.; (2) clay or clay sh., gray to greenish, 6 in.; (3) ss., white, medium- to coarse-grained, with numerous specimens of *Raphistoma minnesotensis* together with several species of same genus, several species of *Ophileta*, and a trilobite, bedding somewhat irregular, 6½ ft. He stated (p. 706) that this basal 6½ ft. had always been included in Jordan ss., but that it was probably reworked after deposition and should be included with the Oneota (p. 713), where its fauna seemed to belong (p. 712).

The Kasota ss. of L. H. Powell is an older rock than the Kasota stone of the trade, lying 3½ to 6 ft. lower in the section.

A. C. Trowbridge et al., 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., fig. 1), show *Blue Earth and Kasota, local fms. in Minn.*, as equiv. to basal part of Oneota dol.

The U. S. Geol. Survey at present recognizes Oneota dol. as resting on Jordan ss.

Kasota stone.

A trade name applied to a stone quarried from Oneota dol. at Kasota, Lesueur Co., Minn., according to O. Bowles (U. S. G. S. Bull. 663, 1918).

Katahdin granite.

Carboniferous (?): Western Maine (eastern part of Piscataquis County).

C. H. Hitchcock, 1861 (Maine Bd. Agric. 6th Ann. Rept., p. 259), mentioned *Katahdin granite.*

F. W. Toppan, 1932 (Geol. of Maine, Contr. Dept. Geol. Union Coll., Schenectady, pp. 68–69). *Katahdin granite.*—Lying on E. bdy of Piscataquis Co. and extending into Penobscot Co. is a great mass of granite that represents a denuded batholith of which Mount Katahdin, 5,267 ft. A. T., is most conspicuous feature.

In hand specimen it is medium-coarse, even-grained granite tinted slightly pink by the orthoclase feldspar. Intrudes Ripogenous series (Sil.).

On the 1933 geol. map of Maine, by A. Keith, this granite is assigned to Carbf.

Katalla formation.

Tertiary (Miocene ?): Southeastern Alaska (Katalla district, Controller Bay region).

G. C. Martin, 1905 (U. S. G. S. Bull. 250, p. 13). *Katalla fm.*—Series of dark, argill. and carbonaceous shales, with occasional bands of ss., ls., cgl., and volcanic ash. Petroliferous. Typically exposed in region NE. of Katalla, along banks of Katalla River, and in range of hills to SE., whence it extends eastward, occupying whole of peninsula btw. Bering Lake and Controller Bay and cropping out in most of hills S. and E. of Bering River. Good exposures on W. shore of Bering Lake. The few fossils indicate Tert. age, probably Eo. Is probably overlain by Kushtaka fm., of probable Olig. age. Thickness undet.

G. C. Martin, 1908 (U. S. G. S. Bull. 335, pp. 24, 27), gave thickness of the 5 members of Katalla fm. in Controller Bay region, which aggregate 6,500 ft., and stated that "position of the fm. with reference to the other Tert. fms. is not definitely established," but in columnar section he placed a new fm., named *Stillwater*, btw. the Katalla and the Kushtaka fm. The Katalla fm. occurs to S. of Bering Lake, the Stillwater, Kushtaka, and Token to N. of Bering Lake.

N. L. Taliaferro, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 3, pp. 771–782). *Writer has divided the marine Katalla fm. of Martin into 2 fms.*, largely on basis of lithology. There is no strat. break btw. the 2 fms., but a decided change in lithology. The *lower*, 3,600+ ft. thick, is here called *Katalla fm.*; the upper, 5,100± ft. thick, is here named *Redwood fm.* The Katalla is further divided into Burls Creek sh. memb. above and Split Creek sh. and ss. below. It occupies fully 85 percent of Katalla dist.; the Redwood is restricted to a broad, steeply plunging syncline btw. Redwood and Burls Creeks and to ridge btw. Cave and Hey Points. Fossils rare and as a rule poorly preserved, but the sediments are similar lithologically to the fossiliferous beds of Yakataga dist., which are pronounced by B. L. Clark to be upper Olig., and they are therefore here assigned to upper Olig. The Katalla and Redwood fms. are also well developed in Nichawak dist.

The U. S. Geol. Survey classifies typical Katalla fm. as Mio. (?).

†Katemcy series.

Upper Cambrian: Central Texas.

T. B. Comstock and E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. lxi, 289–293). *Katemcy (Potsdam) series.*—Consists of (descending): (1) Cgl. and ls. called Potsdam ls; (2) greenish shales and sandy lss. called Potsdam flags; (3) greensand 20 ft, white ss. 10 to 20 ft., and red ss. 50 to 100 ft., together known as Potsdam ss. or Lingula grits. Uncon. overlies Riley series and underlies Leon series.

Includes most if not all of Camb. (Upper Camb.) of central Tex.

Named for Katemcy Creek, Mason Co.

Katherine granite.

Pre-Cambrian: Northwestern Arizona (Katherine district, Mohave County).

C. Lausen, 1931 (Ariz. Bur. Mines Bull. 131, map (pl. 2) and pp. 22–27). *Katherine granite.*—The prevailing rock in Katherine dist. A coarse-grained, somewhat porphyritic granite; weathers brownish, due to decomposition of ferromagnesian constituents.

†Katmai series.

Term applied by W. C. Mendenhall (U. S. G. S. 20th Ann. Rept., pt. 7, 1900, table on p. 317) to Jurassic rocks described by Spurr. In essentially the same table published by Spurr on p. 187 of book cited the name *Naknek series* appears instead of *Katmai series*, and on p. 169 Spurr described the rocks at Katmai, Katmai Point, and on Katmai River as *Naknek series*. Spurr appears to have changed his ms. name *Katmai series* without informing Mendenhall of the change.

Katsberg red beds.

Upper Devonian: Eastern New York (Catskill Mountains).

G. H. Chadwick, 1933 (Am. Jour. Sci., 5th, vol. 26, pp. 480, 482–483, 484). *Katsberg red beds.*—Upper or Enfield part of Catskill fm., as I proposed (16th Int. Geol. Cong. Guidebook 9A, p. 4, 1933) to restrict that name, but proposed restriction now seems questionable. I therefore now propose the old Dutch name for these mtns miscalled "Catskills" by the English (kill is creek), namely *Katsberg* (pronounced cots-barrakh). Grades down into red beds, of Tully to Oneonta age, here named *Onteora red beds.* Type section of *Katsberg fm.* will be taken in steep slopes of highest peak, Slide Mtn, exclusive of the capping Slide Mtn cgl. (possibly of Chautauquan age).

K. E. Caster, 1934. (See 1934 entry under *Catskill fm.*)

G. H. Chadwick, 1935 (Am. Mid. Nat., vol. 16, No. 6, pp. 858, 862). *Katsberg red-beds fm.*, of Enfield age, includes (descending) Van Etten, Julland, and Kattel.

Kattel shale.

Upper Devonian: Southeastern New York (Otsego County).

G. H. Chadwick, 1932 (Eastern States Oil and Gas Weekly, vol. 1, No. 17, p. 7). The lower Enfield (*Kattel*) extends E. to Delhi as the "Chemung" of N. Y. map before reddening. Overlies Oneonta.

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60, pp. 191, 192). *Kattel sh.*—Marine sh. of lower Enfield age. Underlies Katsberg beds (partly red) and overlies Oneonta red beds.

G. H. Chadwick, 1935 (Am. Mid. Nat., vol. 16, No. 6, pp. 858, 862). The Enfield splits into (ascending): *Kattel* ("*Leiorhynchus globuliforme*") zone and the Julland and Van Etten ("First *Tropidoleptus*") zones. The Kattel persists as a marine deposit (600 ft. thick) far E. btw. Oneonta reds below and Enfield beds above, and forms a recognizable band of grey flagstones clear through the continental mass of Catskill Mtns. The continental Kattel and later beds, of Enfield age, constitute Katsberg red-beds fm. or upper half of restricted Catskill.

G. H. Chadwick, 1936 (letter dated Jan. 2). Type loc. of Kattel is Kattel Hill, especially the long Lackawanna railway cut around its E. base, btw. Chenango Bridge and Chenango Forks.

Kaupo basalt.

Latest Pleistocene or Recent: Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Kaupo basalt.*—Pahoehoe basalt, on which the abandoned village of Kaupo is located. Included in upper part of Honolulu volcanic series [q. v.].

†Kawishiwin agglomerate.

†Kawishiwin greenstones.

†Kawishiwin series.

Pre-Cambrian (Keewatin): Northeastern Minnesota (Vermilion district).

N. H. Winchell, 1889 (Minn. Geol. Surv. 17th Ann. Rept., for 1888, pp. 41–42, 45–46, 68, 70). *Kawishiwin.*—Name proposed for the greenstone stage of the Keewatin, because Kawishiwi River and some of its tributaries run for many mi. over rock belonging to this epoch of the Keewatin.

N. H. Winchell, 1892 (Am. Geol., vol. 9, pp. 359–368). *Kawishiwin aggl.* (also *Kawishiwin greenstones*).—The youngest memb. of the Keewatin, the pronounced "greenstone" stage in which occur the iron ores of Vermilion iron range in Minn.

N. H. Winchell, 1899 (Minn. Geol. Nat. Hist. Surv. Final Rept., vol. 4, p. 546). It is now known that the greenstone terrane or *Kawishiwin* contains the oldest known rocks in Minn. It is proposed to continue the use of this term and to include in it both massive and fragmental portions of the greenstones of the Lower Keewatin.

N. H. Winchell, 1900 (Minn. Geol. Surv. Final Rept., vol. 5). Lower Keewatin or *Kawishiwin series* consists of massive and fragmental greenstones uncon. underlying Upper Keewatin.

J. M. Clements, 1903 (U. S. G. S. Mon. 45, p. 131). "Kawishiwin" was proposed by Minn. Geol. Surv. to comprise Ely greenstone and Soudan fm. of this vol.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52). Winchell's "Kawishiwin greenstones" is same as Ely greenstone, and his "Kawishiwin aggl." is an ellipsoidal phase of the Ely greenstone.

Kayenta formation. (In Glen Canyon group.)

Jurassic(?): Southeastern and southern Utah, northeastern Arizona, and southwestern Colorado.

A. A. Baker, C. H. Dane, and E. T. McKnight, June 1931 (U. S. G. S. prel. map showing geol. structure of parts of Grand and San Juan Counties, Utah). *Kayenta fm.*—Irregularly bedded gray to red ss. with subordinate sh. Thickness 200 to 320 ft. Name adopted to replace *Todilto (?)*, field studies by A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., having shown that Todilto ls. at its type loc. is much younger than Kayenta fm. Type loc. for Kayenta fm. is 1 mi. N. of Kayenta, Ariz. Underlies Navajo ss. and overlies Wingate ss.

This fm. is more fully described and mapped by A. A. Baker, 1933 (U. S. G. S. Bull. 841), and by A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1936 (U. S. G. S. P. P. 183).

Kearsarge conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. R. Marvine, 1873 (Mich. Geol. Surv. vol. 1, pt. 2, p. 114 and chart). Is cgl. No. 11 of Keweenaw Co.

Belongs to Central Mine group.

Named for occurrence in old Kearsarge mine, Houghton Co.

Kearsarge andalusite group.

Paleozoic (?): Central southern New Hampshire (Mount Kearsarge quadrangle, Merrimack County).

C. H. Hitchcock, 1877 (Geol. N. H., pt. 2, pp. 585–588, 674, pl. 24). *Kearsarge andalusite group.*—A mass of strata similar to Monadnock area of andalusite rocks. Occurs upon Mounts Kearsarge and Ragged, constituting a band 12 mi. long and from 3 to 4 mi. wide in towns of Warner, Sutton, Andover, and Salisbury. The strata display large contortions, while the gneisses below do not seem to have been greatly disturbed. Clearly these schists are granitic masses, approx. similar to those so common in the Rockingham country. The crystals are smaller than on Monadnock or E. side of Mt. Washington, but are well defined in certain localities, sufficiently so to render probable the reference of all the elongated prisms to the mineral andalusite, rather than fibrolite. The Kearsarge area is more sandy than the Monadnock, or especially the Mount Washington, which carries a great deal of argill. matter. All these areas are believed to be of same age. Thickness of Kearsarge andalusite group is 1,300 ft. Of Paleozoic (?) age. Older than Coos group and Calciferous mica schist, and younger than Lyman, Lisbon, and Swift Water groups. [On map placed above his Merrimack group.]

C. H. Hitchcock, 1879 (Macfarlane's Geol. Ry Guide, p. 56), included his *andalusite schists* in Camb.

C. H. Hitchcock, 1884 (Bull. Am. Mus. Nat. Hist., vol. 1, pl. 17), placed *Kearsarge group* below his Coos group and above his Huronian. On other pages he placed it higher than his Merrimack group and higher than his Rockingham mica schists.

C. H. Hitchcock, 1896 (Jour. Geol., vol. 4, pp. 44–62), placed *Kearsarge group* below his Merrimack group and above his Rockingham mica schists, and assigned all to Huronian [pre-Camb.].

F. J. Katz, 1917 (U. S. G. S. P. P. 108 I). The Kearsarge group of Hitchcock as mapped by him in this part (the coast dist.) of SE. N. H. and SW. Maine is approx. = Rindgemere fm. (Penn.?) of this rept.

M. Billings, 1928 (Am. Acad. Arts and Sci. Proc., vol. 63, No. 3). In North Conway quad., N. H., Hitchcock mapped certain clay slates as "Kearsarge andalusite group." In opinion of writer the clay slates of this quad. do not belong to Hitchcock's "Kearsarge andalusite group," and for this reason they are here mapped as a new fm., named *Intervale clay slates*, of Sil. (?) age.

On 1932 geol. map of U. S. these rocks are mapped as pre-Camb.

M. Billings, 1935 (letter dated Aug. 27). I am unfamiliar with Kearsarge andalusite group in type loc., but on Mount Monadnock it is very similar to our katazonal Littleton (Dev.).

Kearsarge amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

L. L. Hubbard, 1895 (Mich. Geol. Surv. vol. 5, pt. 1, p. 117, footnote). Kearsarge amygdaloid lies 1,250 ft. below Kearsarge cgl. at the Kearsarge location [Houghton Co.]. [The amygdaloid is described by C. Rominger on pp. 117–118 of book cited, but he did not call it Kearsarge amygdaloid. The mineralized part is the Kearsarge lode.]

Belongs to Central Mine group.

Kearsarge flow.

Includes Kearsarge amygdaloid and underlying trap.

Kearsarge trap.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name applied to the trap bed beneath Kearsarge amygdaloid. Forms basal part of Kearsarge flow.

Kearsarge West amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name locally in use many years. The fm. is younger than Kearsarge amygdaloid. Belongs in Central Mine group. The mineralized part is the Kearsarge West lode. Named for fact that it lies W. of Kearsarge amygdaloid.

Kearsarge West flow.

Includes Kearsarge West amygdaloid and the underlying trap.

Keasey shale.

Eocene: Northwestern Oregon (Columbia County).

H. G. Schenck, 1927 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 16, No. 12, pp. 457, 459). *Keasey sh.*—In Columbia Co., underlying the ss. at Pittsburg Bluff, are sandy shales that contain, among other fossils, *Turcicula columbiana* Dall, a new species of *Conus*, numerous diminutive (dwarfed?) naticas, and a few acilas. The fauna of this sh., which is typically exposed on railroad at Keasey station, Rock Creek drainage, suggests it should be regarded as lower Olig. [Thickness not mentioned.]

H. G. Schenck, 1928 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 18, No. 1, pp. 35–39). *Keasey sh.*—Sandy, tuffaceous, bluish and black, fossiliferous sh. that outcrops on banks of Rock Creek near Keasey. Best exposures in railroad cuts btw. Tara and Keasey stations. Assigned to lower Olig.

H. G. Schenck, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 217). Recent investigation shows clearly that *Keasey sh.* rests on Cowlitz Eocene beds and underlies Pittsburg Bluff fm. [Thickness not stated.]

H. G. Schenck and R. M. Kleinpell, 1935 (Pan-Am. Geol., vol. 64, No. 1, p. 76). Microfossils and strat. relations suggest Keasey sh. is late Eo.

†Keddie formation.

Pennsylvanian: Northern California (Lassen Peak and Taylorsville regions).

Name used in prel. proof-sheet edition of U. S. G. S. Lassen Peak folio, 1892, for rocks forming "a narrow belt upon NE. slope of Keddie-Dyer Ridge," in Plumas Co. In published Lassen Peak folio (No. 15), by J. S. Diller, 1895, the rocks are mapped as *Robinson fm.*

Keechelus andesitic series.

Miocene and post-Miocene (?): Central Washington (Snoqualmie quadrangle).

G. O. Smith and F. C. Calkins, 1906 (U. S. G. S. Snoqualmie folio, No. 139). *Keechelus andesitic series.*—Extensive lava flows and tuffs of andesite, with some basalt and rhyolite. Thickness 0 to 4,000 ft. Exposed on both sides of Keechelus Lake. Mainly Mio. but contains some material that is almost certainly post-Mio. Is later than Guye fm. (Mio.).

Keechi Creek shale and sandstone. (In Mineral Wells formation.)

Pennsylvanian: Central northern Texas (Palo Pinto County).

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 25, 31; Univ. Tex. Bull. 2132, p. 78). *Keechi Creek ss. and sh.*—A series of light-gray cross-bedded calc. sss. and light-gray sandy shales underlying Palo Pinto ls. Top memb. of Mineral Wells fm. of Strawn group. Thickness 100 to 150 ft. Typically exposed along Keechi Creek W. of Mineral Wells [Palo Pinto Co.].

Above is definition still in use. (See F. B. Plummer and J. Hornberger, Jr., Univ. Tex. Bull. 3534, 1936.)

Keefer sandstone member (of Clinton formation).

Silurian: Central Pennsylvania to northeastern West Virginia, and western Maryland.

See under *McKenzie fm.*

Keene limestone.

Middle Devonian and Upper Cambrian: Western central Montana (Elkhorn region).

W. H. Weed, 1901 (U. S. G. S. 22d Ann. Rept., pt. 2, map, pp. 434, 438, 505). *Keene ls.*—In part argill.; is slightly aren., and though devoid of fossils is believed to include Yogo ls. (Camb.) and Jefferson ls. (Dev.). Lower part is bluish-gray ls., usually altered to fine-grained marble; upper part is more thickly bedded and of lighter color. Thickness 500 ft. in Elkhorn min. dist. Underlies Union sh. and overlies Elkhorn sh. The Keene mine, which lies about 1,000 ft. N. of Elkhorn mine, occurs along the bedding plane btw. an underlying ls. (the Keene ls.) and an overlying argill. bed.

Keene gneiss.

Pre-Cambrian: Northern New York (Essex County).

W. J. Miller, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 400–462 and map). *Keene gneiss.*—True transition rocks. Probably little more than 1,000 ft. thick. One of most interesting rock types of Adirondack region. Locally developed as belts or irregular bodies along portions of borders btw. the anorthosite and the syenite-granite series. Both Marcy and Whiteface types of anorthosite show such border rocks. Very strong evidence this is really a transition rock btw. anorthosite and syenite or granite due to actual digestion or assimilation of anorthosite by the invading syenite-granite magma along portions of its borders. It is here proposed to call this rock *Keene gneiss,* because fine exposure of typical fresh rock occurs by side of the State road just N. of village of Keene, in Lake Placid quad. [Essex Co.].

H. L. Alling, 1924 (Am. Jour. Sci., 5th, vol. 8, pp. 27–29). *"Keene" gneiss* is composed of two intrusives of slightly different ages—an unfortunate procedure.

Keener sand.

Subsurface sand in western Pa., SE. Ohio, and northern W. Va.; believed to lie in upper part of Burgoon ss. memb. of Pocono fm. (Miss.). Named for discovery well on Keener farm, near Sistersville, Tyler Co., W. Va.

Keepalloo iron formation.

Pre-Cambrian: Canada (Belcher Islands).

E. S. Moore, 1918 (Jour. Geol., vol. 26, p. 429).

Keeseville sandstone.

Upper Cambrian (?): Northern New York.

E. Emmons, 1841 (N. Y. Geol. Surv. 5th Rept., pp. 130, 131). The *Potsdam and Keeseville ss.* is lowest of Transition series. Extends from Keeseville to Hopkinton, embracing and extending around the primary in a somewhat circular manner.

In 1842 (Geol. N. Y., pt. 2) Emmons treated *Keeseville ss.* as a variety of Potsdam ss. (See 1842 quotation under *Potsdam ss.*) The same year L. Vanuxem (Geol. N. Y., pt. 3) also treated *Keeseville ss.* as a variety of Potsdam ss. In 1915 (Geol. Soc. Am. Bull., vol. 26, pp. 289–291) G. H.

Chadwick doubtfully identified the "*Upper Potsdam white ss.*" of St. Lawrence Valley as *Keeseville* (*?*), and stated that the underlying typical *Potsdam sss.* are mostly red. In 1919 (N. Y. State Mus. Bull. 207, 208) H. I. Alling stated that the "*white Potsdam ss.*" is Keeseville ss. of many geologists, but recent work indicates it is not same as Potsdam. In 1920 (N. Y. State Mus. Bull. 217, 218) G. H. Chadwick again doubtfully identified "White Potsdam ss." (mostly white) of Canton quad., N. Y., as *Keeseville* (*?*) *ss.*, and stated that the underlying *typical red Potsdam ss. and cgls.* are possibly separated from it by an uncon.

Keeseville granite.

See under *Ausable granite.*

Keewatin series (or **epoch**).

As used for many years this term applied to the oldest provincial series of the "Archean system" in Great Lakes region and the time covered by its formation. (For definition see U. S. G. S. Bull. 769, pp. 128–132.) The U. S. Geol. Survey, however, no longer uses "Archean system," and the Keewatin is therefore now classified as the oldest pre-Camb. series of rocks in Lake Superior region.

Keewatin till.

Keewatin drift.

Names that have been applied to the gray drift of Keewatin ice sheet (Wisconsin stage of Pleist.) in Lake Superior region.

†Keg Creek sand.

Eocene (upper): Coastal Plain of eastern Georgia.

S. W. McCallie, 1919 (Jour. Geol., vol. 27, p. 176). [Name used, in table only, for beds underlying Vicksburg fm., including, at base, Twiggs clay memb., and assigned to Eocene Jackson group. As thus defined it is a synonym of Barnwell sand.]

Named for exposures on Keg Creek, Washington Co.

Kekekabic granite.

Pre-Cambrian (lower Huronian): Northeastern Minnesota (Vermilion district).

N. H. Winchell, 1900 (Minn. Geol. Surv. Final Rept., vol. 5, pt. 1, p. 32). *Kekequabic granite.*—A small isolated area of reddish-gray gneissoid granite rising domelike in midst of the Keewatin along S. side of Kekequabic Lake.

The spelling of this lake adopted by U. S. Geog. Bd. is *Kekekabic.* It has also been spelled *Cacaquabic* and *Kekequabic.*

Kekequabic.

See *Kekekabic.*

Keld beds.

Cretaceous: Manitoba.

S. R. Kirk, 1930 (Canada Geol. Surv. Summ. Rept. 1929, pt. B, p. 118).

Kelligrew Brook formation.

Cambrian: Newfoundland.

B. F. Howell, 1925 (Bulls. Am. Pal., vol. 11, No. 43, p. 59).

Kelly limestone.

Mississippian: Central New Mexico (Magdalena district).

C. L. Herrick, 1904 (Am. Geol., vol. 13, pp. 310–312). [See under †*Graphic-Kelly ls.*]

C. H. Gordon, 1907 (Jour. Geol., vol. 15, p. 807, and Am. Jour. Sci., 4th, vol. 24, pp. 62–63). *Kelly ls.*, of Magdalena Mtns, consists of 125 ft. of subcrystalline ls. with compact 5-foot layer near middle called "Silver Pipe ls." by miners. Most important ore bodies are just beneath "Silver-Pipe ls." It underlies Sandia fm.

and overlies pre-Camb. rocks. Is same as Herrick's Graphic-Kelly ls. So far as known is confined to Magdalena dist. Cannot yet be correlated with Lake Valley ls.

Named for Kelly, Magdalena dist.

Kelly Hill facies.

Name applied by P. B. Stockdale (Ind. Dept. Cons., Div. Geol. Pub. 98, pp. 77, 186, etc., 1931) to a lithologic development of his Carwood fm. in a part of southern Ind.

Kelly Island formation.

Lower Ordovician: Newfoundland.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4). *Kelly Island fm.*—Sss. and shales carrying *Lingula howleyi*, and forming basal beds of Bell Island series. Overlain by Little Bell Island fm. and discon. underlain by Riders Brook fm. [Derivation of name not stated.]

Kelso sand.

A subsurface sand, of Penn. age, in Cleveland pool, Pawnee Co., Okla., which lies at 500 ft. depth, the Layton sand lying at 1,300 ft. depth.

Kelvin conglomerate.

Upper Cretaceous: Central northern Utah (central Wasatch Mountains).

A. A. L. Mathews, 1931 (Oberlin Coll. Lab. Bull., n. s., No. 1, Feb.). *Kelvin cgl.*—A basal cgl. of very coarse, well-rounded, well-polished boulders cemented with a rather resistant cement; the boulders from a few in. to 2 ft. diam., averaging 6 to 8 in.; somewhat variable in color, being locally red, reddish gray, and, in places, pure gray; roughly stratified, indicating still-water origin. Crosses Emigration Creek at Kelvins Grove, a rather prominent and well-established locality in Emigration Canyon. Thickness variable. Age early Upper Cret. Appears to occupy position of Dakota sss. farther S. and E. Underlies marine sss. of Colorado age and uncon. overlies Morrison fm.

Kemp clay. (In Navarro group.)

Upper Cretaceous (Gulf series): Northeastern Texas.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, pp. 342–344). *Kemp clay beds.*—Yellow clay, containing nodules carrying supposedly Cret. fossils. Extends from Trinity River N. of Chatfield to W. of Stranger, Falls Co. Uppermost part of Navarro fm. Overlies Corsicana beds. Cannot be defined with accuracy, nor can Cret. age be asserted with positiveness.

W. S. Adkins and L. W. Stephenson, 1933 (Univ. Tex. Bull. 3232, pp. 239, 270, 488, 495, 516). *Kemp fm.* here restricted to upper clay memb. of Hill's Kemp beds, the name *Corsicana fm.* (restricted) being applied to the underlying chalky marl memb., which rests on Nacatoch sand. The presumable type loc. of Kemp beds of Hill is the faulted inlier near Kemp [Kaufman Co.]. The Kemp fm. has been in part correlated by many writers with Arkadelphia clays of Ark.

The Navarro group is now divided by U. S. Geol. Survey into (descending) *Kemp clay (restricted)*, Corsicana marl (restricted), Nacatoch sand, and Neylandville marl.

Kenai formation.

Eocene (upper): Central southern Alaska (Kenai Peninsula).

W. H. Dall and G. D. Harris, 1892 (U. S. G. S. Bull. 84, p. 234). *Kenai group* (*Mio.*).—Consists of (1) Unga cgl., resting conformably on (2) coal-bearing beds. Thickness 2,000 to 3,000 ft. Laid down in lakes or marshes. Is early Mio. or latest Eo. [Also called it *Kenai series*, and on map (pl. 3) applied the name in all parts of Alaska.]

W. H. Dall, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, p. 345), assigned the Kenai to Eo., and stated that it is most fully displayed on NW. slope of Kenai Peninsula, Cook Inlet, but that it extends along coast and in interior, from Norton Sound on N. to B. C. and perhaps Oreg. on S.

In subsequent repts the name *Kenai fm.* was, for many years, applied generally to the Tert. coal-bearing rocks of Alaska, but that practice was later discontinued, and the name has for several years been restricted to the Eo. coal-bearing rocks of Kenai Peninsula.

Kenawha.

See *Kanawha.*

Kendall tuff.

Tertiary: Southwestern Nevada (Goldfield district).

F. L. Ransome, 1909 (U. S. G. S. P. P. 66, pp. 28, 41, etc.). ***Kendall tuff.***—Of uniform character and as a rule easily distinguished from the much younger tuffaceous beds of Siebert [Esmeralda] fm. [upper Mio.] with which it is in places in contact. Is rather dark gray, has andesitic appearance, and is flecked with irregular spots of pale green (usually less than ½ in. diam.), of a soft waxy material that sometimes contains small scales of biotite. Microscope shows it to be everywhere more or less altered and to consist of fragments of glassy rhyolite and of latite or andesite. Closely associated with Sandstorm rhyolite, with which it is regarded as practically contemp. Greater part of the tuff is near or at base of the rhyolite. One body of this tuff is enclosed in Sandstorm rhyolite in Kendall mine. Thickness of 200+ ft. of the tuff was found beneath Sandstorm rhyolite in 2 mines. Is much older than Siebert [Esmeralda] fm. [which is upper Mio.].

Kendall moraine.

Pleistocene (Wisconsin stage): Southwestern Michigan. Shown on moraine map (pl. 32) of U. S. G. S. Mon. 53. Belongs to Kalamazoo morainic system. Named for Kendall, Van Buren Co.

Kendall Green slate.

Pre-Cambrian: Eastern Massachusetts (Boston Basin).

W. E. Hobbs, 1899 (Am. Geol., vol. 23, pp. 109–115). *Kendall Green sl.*—In the main a schistose sl. (using term *sl.* in widest sense), consisting of hornblende, quartz, and many other constituents. Thickness probably 5,000 ft. Grades into underlying Stonybrook qtzite, and is overlain by Lincoln sl.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597), mapped the rocks of Kendall Green area, Middlesex Co., as Marlboro fm. The Marlboro includes considerable sl.

Kendrick shale. (In Pottsville group.)

Pennsylvanian: Southeastern Kentucky (Floyd County).

W. R. Jillson, 1919 (Ky. Dept. Geol. and Forestry, ser. 5, vol. 1, pp. 96–104). *Kendrick sh.*—Fossiliferous limy sh., generally soft blue-gray calc. sh. carrying many calc. and magnesium nodules. [Thickness not stated.] Fossils (listed by C. Schuchert) are new and unmatched as a collection either in or outside of Ky. Fauna is clearly Pottsville. Local strat. suggests the Kendrick should be placed in lower part of Wise fm. or Upper Pottsville, with Norton fm. just below it. Lies about 170 ft. above Prestonburg, Miller's Creek, or Van Lear coal. Type fossiliferous outcrop is 150 yds. above Kendricks homestead, on headwaters of Cow Creek, Floyd Co. Rests on blue sandy calc. sh. and is overlain by 15 to 20 ft. of massive, somewhat cross-bedded ss.

W. C. Morse, 1931 (Ky. Geol. Surv., ser. 6, vol. 36, p. 298). ***Kendrick shales*** named by Jillson from exposures at Dr. Kendrick homestead. [Gives detailed section at type loc., where they are 19⅓ ft. thick.] They form roof shales of Thacker coal and lie 221 ft. below "Taylor" or Copeland coal.

†Kennedy gravels.

Pleistocene (pre-Wisconsin): Northwestern Montana (northwestern part of Teton County).

B. Willis, 1902 (Geol. Soc. Am. Bull., vol. 13, pp. 315, 328–330). *Kennedy gravels.*—Well-rounded or subangular high-level gravel of local origin; rarely boulders 2 ft. across occur; those 6 to 12 inches diam. are common. Finer gravel and gravelly soil make up the mass. Obscurely stratified; glacial striae absent. Thickness 100+ ft.; base not seen. Believed to be a remnant of an alluvial cone of Kennedy Creek. Type loc. a gravel mesa, 5,800 ft. high, 5 mi. E. of Chief Mtn, N. of Kennedy Creek and 900 ft. above it. Rest on Benton sh. Description largely compiled from notes by G. I. Finlay.

W. C. Alden (personal communication June 1932), who found glaciated material in typical †Kennedy gravels on Kennedy Ridge, regards the deposit as of glacial origin, and includes it in his pre-Wisconsin glacial drift. (See also W. C. Alden, U. S. G. S. P. P. 173, 1932.)

Kennetcook limestone.

Mississippian: Nova Scotia.

W. A. Bell, 1921 (Am. Jour. Sci., 5th, vol. 1, p. 166).

Kenneth limestone.

Silurian (Cayugan): Northern central Indiana (Cass County).

E. R. Cumings and R. R. Shrock, 1927 (Ind. Acad. Sci. Proc., vol. 36, pp. 76–77). *Kenneth ls.*—Very cherty ls., from 1 to 20 ft. thick in outcrops, resting on Kokomo ls. of Foerste with possible uncon. Top of fm. not known. Exposed in quarries at Kenneth Station and vicinity, Cass Co.

E. R. Cumings and R. R. Shrock, 1928 (Ind. Cons. Comm., Div. Geol. Pub. 75, pp. 117–135), explain that their *Kenneth ls.* is upper part (brachiopod-bearing beds) of Kokomo ls. of Foerste (1904). (See under *Kokomo ls.*) Thickness few ft. at Kokomo to over 35 ft. near type section. Fossils listed. Fauna has Cayugan affinities, but much work is needed to establish its correlation.

M. A. Harrell, 1935 (Ind. Dept. Cons. Pub. 133, mimeographed thesis, pp. 89–90). *Kenneth ls.* is found only in structural sag btw. Peru and Logansport. Cumings (Ind. Acad. Sci., Proc., vol. 39, 1929, p. 208, 1930) has expressed opinion fauna of Kenneth ls. of northern Ind. is comparable with early Dev. faunas (Keyser) of Md., Pa., and N. J. The Kenneth is therefore probably Lower Dev.

Kennett rock.

Pre-Cambrian: Southeastern Pennsylvania (Chester County).

P. Frazer, 1883 (2d Pa. Geol. Surv. Rept. C_4, pp. 307–308). *Kennett rock,* upper memb. of Potsdam ss. A thin-bedded rock composed of fragments of white limpid qtzite, generally coarse-grained. Named for borough of Kennett Square. The lower memb. of Potsdam ss. is Toughkenamon rock.

The qtzite at and around Kennett Square is mapped as Setters qtzite (pre-Camb.) in U. S. G. S. West Chester-Coatesville folio, No. 223, 1932.

Kennett formation.

Middle Devonian: Northern California (Redding region).

J. P. Smith, 1894 (Jour. Geol., vol. 2, pp. 591–593, 598). *Kennett lss. and shales.*—A thick series of dark contorted siliceous shales, with occasional masses of ls. that contain Dev. fossils, probably Middle Dev. Exposed btw. Squaw and Backbone Creeks, about 4 mi. W. of Kennett, on Sacramento River. Compose Sacramento fm. (H. W. Fairbanks ms.). We do not know age of the rocks immediately underlying the Baird shales, but the siliceous shales of Sacramento River lie some distance below them, and are probably in part of Carbf. age.

According to J. S. Diller (U. S. G. S. Redding folio, No. 138, 1906) the Baird sh. is underlain by Bragdon fm. (Miss.), which rests uncon. on Kennett fm.

Kennett limestone.

Pre-Cambrian: Southeastern Pennsylvania.

T. D. Rand, 1900 (Phila. Acad. Nat. Sci. Proc. 1900, pt. 1, pp. 235–242). *Kennett ls.,* Camb. according to Mr. Walcott. [Seems to be named for Kennett Square Station, Chester Co.]

The ls. at and around Kennett Square Station is mapped as Cockeysville marble (pre-Camb.) in U. S. G. S. West Chester-Coatesville folio, No. 223, 1932.

Kennicott formation.

Lower Cretaceous: Alaska (Copper River region).

O. Rohn, 1900 (U. S. G. S. 21st Ann. Rept., pt. 2, pp. 424–440, pl. 52). *Kennicott series.*—Light-colored arkoses, shales, and lss. occurring on Bear and Fourth of July Creeks btw. Fohlin Creek and Kennicott Glacier. Of late Jurassic or early Cret. age. Uncon. (?) overlies McCarthy Creek shales (Triassic).

F. H. Moffit and S. R. Capps, 1911 (U. S. G. S. Bull. 448, pp. 31–43), applied *Kennicott fm.* to all the supposedly Jurassic sed. rocks of Nizina dist. and several areas of ss. N. of upper Chitina River which are now considered to be Cret.

G. C. Martin, 1926 (U. S. G. S. Bull. 776), restricted *Kennicott fm.* to the Lower Cret., that being the age of the rocks in type region.

F. H. Moffit (rept on Chitina Valley and adjacent area, in process of publication). The rocks of type loc. of Rohn's Kennicott fm., in Fourth of July Pass, are now considered to be Lower Cret., and consist of (descending): (1) Black sh. or sl., intruded by many light-colored porphyry dikes, 3,000± ft.; (2) crumbly gray sh. with concretions, 50 (?) ft.; (3) massive brown ss., 100 to 200 ft.; (4) cgl. with angular and subangular fragments, few ft. They rest uncon. on Upper Triassic sh.

Kenogami River formation.

Silurian: Ontario.

W. S. Dyer, 1930 (Ontario Dept. Mines 38th Ann. Rept., pt. 4, p. 54).

Kenosha shale. (In Tecumseh shale.)

Pennsylvanian: Southeastern Nebraska and northeastern Kansas.

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, 2d ser., pp. 47, 52). *Kenosha sh.* is proposed in this rept. for the 6 or 7 ft. of sh. at base of Tecumseh sh. memb., and underlying Ost ls. Type loc. in Missouri River bluff near Kenosha landing at mouth of second small valley S. of King Hill, Cass Co., Nebr.

Kent bed.

Lower Cretaceous (Comanche series): Southern Kansas.

F. W. Cragin, 1895 (Am. Geol., vol. 16, p. 383). *Kent bed* proposed for an *Ostrea quadruplicata* zone which occurs below Fort Worth zone, to distinguish it from *Ostrea quadruplicata* zone above the Fort Worth. Occupies position near that of Duck Creek chalk of NE. Tex. and above that of Tucumcari zone.

Derivation of name not known. Above is only record of this name.

Kent formation.

Upper Jurassic: Southwestern British Columbia (Harrison Lake region).

C. H. Crickmay, 1927 (Stanford Univ. Abstracts of Dissert. 1924–26, vol. 1, p. 132).

C. H. Crickmay, 1930 (Geol. Mag., vol. 67, map, p. 487). *Kent fm.*—Cgl., 3,000 ft. thick, of Upper Jurassic age. Underlies Agassiz Prairie fm. (Upper J.) and uncon. overlies Billhook fm. (Upper J.).

Kentucky shale.

Mississippian: Eastern Kentucky.

N. S. Shaler, 1877 (Ky. Geol. Surv., n. s., vol. 3, pp. 183–186, bottom pagination). In eastern Ky. the amount of sh. in the Carbf. rocks succeeding the Sub-carbf. ls. is much greater than in western Ky. As this period is set apart by physical and vital conditions from anything that came before or afterward, it deserves a special designation. I shall therefore give it the name *Kentucky sh.*, which is especially fitting, inasmuch as in region about headwaters of Ky. River we have best exemplification of the Sub-cgl. coal series which has yet been examined. Is uncon. overlain by Millstone Grit.

†Kentucky marble.

†Kentucky River marble.

†Kentucky River limestones.

Names that have been loosely applied to many Ord. lss. of Ky.

Kentville formation.

Silurian: Nova Scotia.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 203).

Kenwood beds.

Middle Devonian: Eastern Iowa.

W. H. Norton, 1894 (Iowa Acad. Sci. Proc., vol. 1, pt. 4, p. 23). *Kenwood beds.*—Massive argill. and ferruginous shales, buff and reddish-brown lss., irregularly bedded, passing horizontally and vertically beneath into buff thinly laminated or shaly ls. weathering into marly clay. Thickness 40 ft. Underlie Lower Davenport beds and overlie 5 ft. of bluish or greenish sh. believed to represent Independence shales, but latter term may readily be extended to include all the ls. and sh. of

Kenwood beds, a term which is therefore used only as a local synonym for Independence shales. [Discarded by U. S. G. S. in 1911, *Independence sh. memb. of Wapsipinicon ls.* being adopted instead.]

Rept. 9th Ann. Field Conf. Kans. Geol. Soc., 1935, fig. 1, shows Independence sh. as much younger than *Kenwood.* (See 1935 entry under *Wapsipinicon ls.*)

Named for Kenwood, Linn Co. According to M. A. Stainbrook (p. 251 of 1935 rept cited above) this unit is typically developed in right bank of Indian Creek, back of the country club at Kenwood Park, a suburb of Cedar Rapids. He redefined Kenwood by removing from its top 20 ft. of beds which he named *Spring Grove memb. of Wapsipinicon fm.*

Kenwood sandstone. (In Osage group.)

Mississippian: Western and northern Kentucky and southern Indiana.

C. Butts, 1915 (Ky. Geol. Surv., 4th ser., vol. 3, pt. 2, p. 148). *Kenwood ss.*—Thin sss. alternating with sh. Thickness 40 ft. Contains Keokuk fossils. Underlies Rosewood sh. and overlies New Providence sh.; all belonging to Osage group.

C. Butts, 1922 (Ky. Geol. Surv., ser. 6, vol. 7, p. 29). *Kenwood ss.* extends southward perhaps only to Lebanon Junction, Bullitt Co., Ky.

E. R. Cumings, 1922 (Hdb. Ind. Geol., pt. 4, Sep. Pub. 21, p. 491). *Kenwood ss.* does not persist very far into Ind.

P. B. Stockdale, 1931 (Ind. Dept. Cons., Div. Geol. Pub. 98, pp. 52, 54, 92, 93, 94, 111, etc.). At top of New Providence sh. in Floyd Co., southern Ind., usually within an interval of 20 ft. or less, are occasional resistant ss. beds up to 2 ft. thick. These ss. layers are Indiana's sole representative of what in Jefferson Co., Ky., has been named "Kenwood ss." by Butts. Uppermost limit of New Providence fm. is nicely marked in east-central and south Floyd Co., Ind., and in Jefferson Co., Ky., because of presence of abrupt ss. layers (Kenwood ss. of Butts); but northward as far as Brown and Bartholomew Counties the upper limit is conjectural in most places as a consequence of a remarkably gradual transition into overlying rocks. [On pp. 93–94 he proposes to modify definition of *New Providence fm.* so as to include Kenwood ss. as a memb., and he names the overlying beds *Locust Point fm.* On p. 93 he says Kenwood ss. is "generally 40 ft. thick, 30 ft. of which appear on Kenwood Hill." On p. 94 he says: "In this rept. the ss. layers will be referred to as the *Kenwood beds of the New Providence fm.*"] [See also under *New Providence fm.*]

Named for Kenwood Hill, near Louisville, Ky.

Keokuk limestone. (Of Osage group.)

Mississippian: Iowa, Illinois, eastern Missouri, and western Kentucky.

D. D. Owen, 1852 (Rept. Geol. Surv. Wis., Iowa and Minn., pp. 91, 92). *Keokuck cherty lss.*—Gray cherty lss., forming wall of rock washed by the Mississippi below Keokuck Landing, Iowa. Overlain by Shell beds and underlain by Hannibal beds (brown Encrinital lss. alternating with bands of chert), which rest on Burlington beds (the Encrinital group of Burlington). [According to later Iowa repts the Keokuck cherty lss. of Owen are the "cherty beds of passage" separating the Keokuk and Burlington lss. of Hall.]

J. Hall, 1857 (Am. Ass. Adv. Sci. Proc., vol. 10, pt. 2, pp. 53–56). *Keokuk or lower Archimedes ls.*—Highly fossiliferous ls., separated from overlying Warsaw or Second Archimedes ls. by "Geode bed" (a mass of shales or marls with impure lss. containing geodes), overlain, locally, near Warsaw, Ills., Appanoose, Iowa, and other places, by 10 ft. of mag. ls. Separated from underlying Burlington ls. by 60 to 100 ft. of beds of passage, consisting of cherty layers with intercalated beds of light-gray ls.

The "cherty beds of passage" were treated as a distinct unit and excluded from both Keokuk and Burlington by Hall in 1858, 1859, 1864; by Worthen in 1858; by C. R. Keyes in 1894; by J. A. Udden in 1901; by H. Hinds in 1909; and by C. R. Keyes in 1914. They were included in the Burlington by C. A. White; by Wachsmith; by C. H. Gordon (1892 and 1895); by

C. R. Keyes in 1895 (under the name "Montrose chert"); by W. H. Norton and H. E. Simpson in 1912; and by F. M. Van Tuyl in 1912. They were included in Keokuk by A. W. Vodges in 1888 and by F. M. Van Tuyl in 1925 (Iowa Geol. Surv. vol. 30, pp. 47, 146), who stated that in them appear for first time several Keokuk types of brachiopods. The "geode bed" referred to by Hall has in subsequent repts been both included in and excluded from Keokuk ls.

The present accepted definition of Keokuk ls. excludes the "geode bed" (which is now included in the overlying Warsaw, because its fauna and lithology are said to be more closely allied to that of the Warsaw ls.) and includes the cherty beds at base. The U. S. Geol. Survey treats the Keokuk as top fm. of Osage group.

Named for exposures at Keokuk, Iowa, especially good exposures occurring along Soap Creek and in a quarry in Miss. River bluff near mouth of the creek.

†Keokuk group.

A term applied in some early Miss. Valley repts to rocks now called *Osage group.*

Keosauqua sandstone.

Mississippian: Southeastern Iowa.

C. H. Gordon, 1895 (Jour. Geol., vol. 3, pp. 304–305). ***Keosauqua ss.***—Coarse brown ss., few ft. to 25 ft. thick, near top of St. Louis group in SE. Iowa. Underlies compact granular lss. forming top memb. of St. Louis group and overlies brecciated ls. of the St. Louis.

According to F. M. Van Tuyl (Iowa Geol. Surv. vol. 30, p. 259, etc., 1925) this ss. is of basal Ste. Genevieve age, is overlain by ls. of Ste. Genevieve age, *underlain* by true St. Louis ls., and was included in Verdi beds by Gordon, but belongs in Pella beds.

Named for exposures in S. bank of Des Moines River about 2½ mi. below Keosauqua, Van Buren Co.

Keota sandstone member (of Savanna sandstone).

Pennsylvanian: Eastern Oklahoma (Muskogee, Haskell, and McIntosh Counties).

C. W. Wilson, Jr., 1935 (A. A. P. G. Bull., vol. 19, No. 4, pp. 503–520). ***Keota ss. memb. of Savanna ss.***—Gray to brown ss., regularly bedded, blocky, ripple marked. Thickness in Muskogee-Porum area 10 ft. Lies 70± ft. above Tamaha ss. memb. and 50± ft. below Spiro ss. memb. Named for exposures at Keota, Haskell Co.

Keowee zone.

Pre-Cambrian: Northwestern South Carolina.

E. Sloan, 1907 (Summary of mineral resources of S. C., p. 12). [In table on page cited this name is placed opposite Tyger zone, but there is no definition. Probably named for Keowee River, bdy btw. Oconee and Pickens Counties.]

Keppel dolomite.

Silurian (early): Ontario.

A. W. Grabau, 1913 (Geol. Soc. Am. Bull., vol. 24, pp. 438, 460). ***Keppel dolomites.***—Marine lss. and dolomites, 0 to 36 ft. thick. Underlie Cabot Head beds and overlie, probably discon., Queenston sh. Named for their nearly continuous exposure along lake front in Keppel Twp, from Owen Sound to Cape Commodore.

These beds appear to be same as Manitoulin memb. of Williams, 1914, and Manitoulin ls. memb. of Schuchert, 1914, a name that has had considerable usage, while above-cited rept is only record of Keppel.

Kerber formation.

Pennsylvanian: Southern Colorado (Bonanza district, Saguache County).

W. S. Burbank, 1932 (U. S. G. S. P. P. 169). *Kerber fm.*—Series of coarse-grained sss. or grits and black carbonaceous shales which overlie, with possibly a strat. break, the Leadville ls. and extend up to base of lowest red-colored micaceous sediments or sandy shales of Maroon fm. Thickness 200± ft. Basal memb. is a ss. 70 to 75 ft. thick. Named for exposures along Kerber Creek.

Kereford limestone. (In Oread limestone.)

Pennsylvanian: Eastern Kansas, southeastern Nebraska, and northwestern Missouri.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., p. 45). Near Lecompton and Atchison, Kans., and at Amazonia, Mo., the lower part of Kanwaka sh. memb. contains one or more lensing lss. for which name *Kereford ls.* is proposed. Heretofore this ls. has been known as *"Waverly Flagging,"* a nongeographic name, and has been loosely correlated as top part of Oread memb. It is not persistent enough to serve as a horizon marker. The stone is dense, somewhat aren., in part oolitic, and fossiliferous. In writer's opinion this bed belongs in Kanwaka sh. memb. and not in Oread ls., where Hinds and Greene placed it.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 94, 96). Writer has modified Condra's classification slightly by including *Kereford ls.* as top div. of Oread fm. (instead of basal div. of Kanwaka sh.). The *Kereford* exhibits characteristics of the "super" divisions of the cycle. The thin underlying sh. is termed *Heumader sh.* [The Oct. 1932 revised classification of Penn. rocks of Kans. and Nebr. by Moore and Condra placed *Kereford ls.* as top memb. of Oread ls., and Condra in 1935 (Nebr. Geol. Surv. Paper No. 8, p. 12) followed this classification, also R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22).]

Type loc., Kereford quarry at S. edge of Atchison, Kans.

Kerens member (of Wills Point formation).

Eocene (lower): Northeastern Texas (Brazos River to Trinity River region).

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 535, 559, 562). *Kerens memb.*—Forms upper two-thirds of Wills Point fm. Dark gray silty or sandy clay; 300 ft. thick in Brazos River Valley; 450 or possibly 500 ft. thick in Trinity River Valley. [On p. 535 thickness of Kerens memb. is given as 225 ft.] Overlies Wortham aragonite lentil of Wills Point and underlies Seguin fm. Type loc. comprises the exposures along Trinity River N. of St. Louis & Southwestern R. R., E. of Kerens, Navarro Co.

The U. S. Geol. Survey includes in Kerens memb. the 8- to 10-inch bed called *Wortham aragonite lentil* by Plummer. The Kerens as thus defined rests on Mexia memb.

Kern River group.

Kern River formation.

Kern River series.

Pliocene and later (?): Southern California (Kern River region).

F. M. Anderson, 1905 (Calif. Acad. Sci. Proc., 3d ser., vol. 2, pp. 187–188, 191). *Kern River beds.*—Mainly sands and sandy clays, dipping gently to W. The locality is on Kern River, 2 to 6 mi. E. of Oil City, Kern Co. Entire thickness of strata exposed along the river aggregates about 3,000 ft., of which lower two-thirds belongs to Mio. Toward base they become very fossiliferous. [Lists many fossils.] Most complete and most typical fauna of Lower Mio. of Calif. interior is that of Kern River beds on SE. border of San Joaquin Valley.

F. M. Anderson, 1911 (Calif. Acad. Sci. Proc., 4th ser., vol. 3, pp. 95, 111). *Kern River group.*—Green and brown beds, gravels, sands, and clays, almost without fossils, but includes Kern oil measures. Well exposed 1 or 2 mi. E. of Kern River oil field and elsewhere. Beds of gravel and cgl. and frequently large boulders are characteristic of the group. Is a terrigenous rather than an organic deposit. Called *Kern River group* because the productive oil measures of Kern River dist. are confined to it. The oil measures make up about half of volume of the beds. Uncon. overlies Temblor group. Assigned to Neocene.

J. B. Stevens, 1924 (A. A. P. G. Bull., vol. 8, No. 1, p. 33). *Kern River series.*—Gravel, sand, and clay, 2,000 ft. thick. Is uncon. overlain by alluvium and terrace deposits and uncon. underlain by Monterey group (Mio.). Probably includes at base equiv. of Santa Margarita Miocene. Rest of fm. assigned to Plio.

L. S. Fox, 1929 (A. A. P. G. Bull., vol. 13, No. 2, p. 103). *Kern River series.*—Unconsolidated sands and clays of fresh-water origin, and, in its more basinward phase, of interstratified marine Etchegoin sediments. At numerous places along E. fringe of the valley these beds are lacking, but farther W. they increase in thickness to several thousand ft. within a short distance. These Kern River beds represent entire series of deposits from early Plio. to Recent time.

A. Diepenbrock, 1933 (Calif. Oil Fields, Div. Oil and Gas, vol. 19, No. 2, pp. 12–29). *Kern River series* has been used for all beds (*Plio. and Pleist.*) in Bakersfield area that are younger than Mio. For convenience the group has been divided into 3 members, which have been popularly named (descending) *"Kern River fm."* (50 to 850 ft. thick), "Etchegoin fm.," and Chanac fm.

Kernville series.

Jurassic or older: Southern California (Kernville quadrangle).

W. J. Miller, 1931 (Univ. Calif. Pub., Bull. Dept. Geol. Sci., vol. 20, No. 9, pp. 335–343). *Kernville series.*—Oldest rocks in this part of Calif. Constitute a meta-sedimentary series. Largely composed of three kinds of rocks—phyllite, qtzite, and crystalline ls. Phyllite is most abundant; varies locally to mica schist, particularly close to its contacts with the granite; is highly foliated and generally of greenish-gray color. Thin-bedded, generally light-gray to dark bluish-gray qtzites are usually interbedded with the phyllite, the qtzite in some places making up about half of the combination. A number of lenses of crystalline ls. are interbedded with the phyllite-qtzite series. Thickness 12,000 ft. Named for many excellent exposures in vicinity of Kernville. All these metamorphosed strata are presumed to belong to a single series. They are lithologically similar and no strat. break was found. But careful search failed to yield fossils and the areas are widely scattered, so that it must be admitted the Kernville series may represent more than one fm. It is evident the scattered areas of Kernville series represent merely remnants of once very widespread strata with a conservatively estimated thickness of at least 3 mi. Actual age unknown, but it is Jurassic or older. It may be Miss. It is cut by gabbro-diorite and its facies.

Kerrick morainic system.

Pleistocene (Wisconsin stage): Northeastern Minnesota and northwestern Wisconsin.

F. Leverett, 1928 (U. S. G. S. P. P. 154). Includes Cromwell and Wright moraines. Named for Kerrick, Pine Co., Minn.

Kessler limestone member (of Bloyd shale).

Pennsylvanian (Pottsville): Northwestern Arkansas.

F. W. Simonds, 1891 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 4, pp. 26, 103–105). *Kessler ls.*—Thin-bedded shaly ls., gray to reddish brown, with occasional light streaks. Thickness 10 to 15 ft. Uppermost bed of Lower Carbf. or Miss. Underlies Coal Measures and overlies the coal-bearing sh. in Washington Co.

G. I. Adams and E. O. Ulrich, 1904 (U. S. G. S. P. P. 24), included this ls. in Morrow fm., of Penn. age. Later the Morrow was made a group, divided into Bloyd sh. above and Hale fm. below, and this ls. is now treated as a memb. of Bloyd sh. It lies 0 to 190 ft. below top of the Bloyd.

Named for Kessler Mtn, Washington Co.

†Ketchikan series.

Upper Triassic and Carboniferous: Southeastern Alaska (Ketchikan region).

A. H. Brooks, 1902 (U. S. G. S. P. P. 1, pp. 40–52, map). *Ketchikan series.*—Argill. and aren. schists, argillites, and some lss. and aren. beds. Occurs along E. margin of Gravina Island and along W. margin of Revillagigedo Island, and in vicinity of Ketchikan, on both sides of Tongass Narrows, on Cleveland Peninsula, along George Inlet, on E. arm of Behm Canal. Believed to be in part Mesozoic (Triassic?) and in part Upper Paleozoic.

T. Chapin, 1919 (U. S. G. S. P. P. 120, p. 88). Brooks' "Ketchikan series" included Upper Triassic and Carbf. rocks, as suggested by him.

Ketchum Bluff conglomerate.

Pennsylvanian: Central southern Oklahoma (Jefferson County).

See under *Oscar ss.*

Ketona dolomite.

Cambrian (Upper): Northern central Alabama.

C. Butts, 1910 (U. S. G. S. Bull. 400, p. 14; U. S. G. S. Birmingham folio, No. 175, p. 3). *Ketona dol. memb. of Knox dol.*—Nearly pure dol., with but little chert. Is thick-bedded, of crystalline texture, and light-gray color. Basal memb. of Knox dol. Thickness 600 ft.

Later work by E. O. Ulrich resulted in discovery of beds in Knox dol. of Ala. older than Ketona dol. (to which older beds he applied the name *Brierfield dol.*), also to subdivision of post-Ketona beds of Knox into (ascending) Bibb dol., Copper Ridge dol., and Chepultepec dol. The Ketona dol. is therefore now treated as a fm., underlain by Brierfield dol. and overlain by Bibb dol. (See C. Butts, Ala. Geol. Surv. Spec. Rept. No. 14, 1926.)

Named for exposures at Ketona, Jefferson Co.

Kettle meta-andesite.

Pennsylvanian: Northern California (Taylorsville region).

J. S. Diller, 1908 (U. S. G. S. Bull. 353). *Kettle meta-andesite.*—An extended series of lava flows and products of volcanic explosions. The principal rock is decidedly porphyritic, with many small phenocrysts of feldspar, some of hornblende, and, rarely, round grains of quartz, all embedded in a reddish-brown or gray partially crystalline groundmass containing small grains of plagioclase and quartz. Also includes considerable pale greenish-gray generally nonporphyritic rock. Both types are intimately associated with fragmental rocks, mainly tuffaceous, but locally passing into fine cgl. and ss. Appears to have been erupted about the time Robinson fm. was deposited, but to be older than Reeve meta-andesite.

Named for development around Kettle Rock, NE. of Taylorsville.

Kettle interlobate moraine.

Pleistocene (Wisconsin stage): Southeastern Wisconsin. See T. C. Chamberlin, Wis. Acad. Sci. Trans., vol. 4, pp. 201–234, map, 1878. Also shown on moraine map (pl. 23) of U. S. G. S. P. P. 106. Named for Potash Kettle Range, a term applied in early Wisconsin repts to the region occupied by the moraine, as explained in U. S. G. S. P. P. 106, p. 13.

Kettleman lake bed.

Probably Pliocene: Southern California (Tulare Lake region).

J. G. Cooper, 1894 (Calif. Acad. Sci. Proc., 2d ser., vol. 4, p. 167). *Kettleman lake bed.*—A fossiliferous fresh-water deposit about 10 mi. W. of Tulare Lake, on edge of what was probably a Plio. lake about 20 mi. long and 5 mi. wide, or half as large as Tulare Lake is now, and S. of W. from it, in W. corner of Tulare Co. Lies 600 ft. above sea level. [Type loc. not stated, but the beds are probably the fresh-water deposit mentioned as occurring on W. border of Kettleman Plains.]

†Kettle River sandstone.

Name locally applied in some early Minn. repts to Hinckley ss., from exposures on Kettle River.

Kettle River formation.

Tertiary (Oligocene?): Southern British Columbia and northeastern Washington.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, maps 10, 11, 118° 30′ to 119°30′). *Kettle River fm.*—Olig. ss., cgl., sh., arkose. Underlies Midway volcanic group. [Mapped along Kettle River, B. C., N. of 49th par.]

C. W. Drysdale, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 135); and O. E. LeRoy, 1912 (Canada Geol. Surv. Mem. 21, pp. 20, 27, 42). [LeRoy called it Olig. (?).]

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 394). *Kettle River fm.*, Olig., Wash. and B. C., 0 to 2,100+ ft. of ss., cgl., sh., traces of lignite. Patches. Fossil plants identified by Penhallow as Olig. Uncon. overlies Rock Creek granodiorite (Jurassic), also Anarchist series (Carbf. ?).

C. W. Drysdale, 1915 (Canada Geol. Surv. Mem. 56, p. 62). *Kettle River fm.*, Eocene or Olig., B. C.

Keuka flagstone.

Upper Devonian: Western central New York (Keuka-Seneca Lake region).

I. W. Fox, 1932 (A. A. P. G. Bull., vol. 16, No. 7, pp. 677, 683, 687). *Keuka flagstone.*—Hard dark-gray flag, 2 to 4 inches thick, lying 85 to 90 ft. below top of Standish fm. in Keuka-Seneca Lake region. Is easily recognized by its position btw. dense black shales or a thin layer of light-gray sh. intervening btw. it and the black stratum beneath. Named for excellent exposures on all shores of Keuka Lake.

†Keweenaw group.

†Keweenaw series.

Same as Keweenawan series.

Keweenawan series (or **epoch**).

As used for many years the term applied to the upper provincial series of Algonkian rocks of Great Lakes region and the time covered by their formation. (For definition see U. S. G. S. Bull. 769, pp. 104–105.) But the U. S. Geol. Survey no longer uses "Algonkian system." The Keweenawan is therefore now classified as the youngest series of pre-Camb. rocks in Lake Superior region, and as separated from the overlying Upper Camb. sss. by a great structural and erosional uncon. The Keweenawan, however, is regarded by A. C. Lane as partly Camb. and partly pre-Camb.

†Keweenawian.

†Keweenian.

†Kewenaw series.

†Kewenawic.

†Kewenian.

Variants of *Keweenawan.*

Kewstoke conglomerate.

Mississippian (?): Nova Scotia (Cape Breton Island).

P. D. Trask and K. F. Mather, 1927 (Wash. Acad. Sci. Jour., vol. 17, p. 324).

†Key sandstone.

Lower Ordovician: Northern Arkansas.

G. I. Adams and E. O. Ulrich, 1904 (U. S. G. S. P. P. 24, pp. 20, 95–97). *Key ss.*—Ss. locally known as "sand ledge" or "sand cap." Also called "saccharoidal ss.," because when struck with hammer it crumbles into fine white sand very similar in appearance to granulated sugar. Outer surface usually brownish as result of iron oxide coating. Occasionally, when unweathered, small masses of pyrite occur in it and it has a water-green color. When weathered the green color disappears and the pyrite is oxidized and transferred to the surface, forming a ferruginous coating. Thickness of strata varies from few inches to several ft. and bedding changes materially in short distance. Frequently exhibits ripple marks and false-bedding. Weathered surfaces have peculiar rounded appearance. Ledges are beveled so that layers have fluted edges. Appears to have been deposited under shallow-water conditions, in which quartz sand was worn into more or less rounded grains. Thickness few ft. to over 100 ft. Same as St. Peter ss., "First Saccharoidal," Crystal City ss., and Cap au Gres ss. Underlies Izard ls. and overlies Yellville fm.

G. I. Adams and E. O. Ulrich, 1905 (U. S. G. S. Fayetteville folio, No. 119). Sylamore ss. memb. of Chattanooga sh. is the ss. present at type loc. of "Key" ss., but the ss. to which *Key* was applied in the section is St. Peter ss.; so Key will have to be abandoned.

Later work in northern Ark. has shown that several sss. (Kings River ss., Newton ss., and Sylamore ss.) have been mistaken for true St. Peter ss.

Named for Key, near Rogers, Benton Co.

Key Largo limestone.

Pleistocene: Southern Florida.

S. Sanford, 1909 (Fla. Geol. Surv. 2d Ann. Rept., table opp. p. 50 and pp. 209, 214–218). *Key Largo ls.*—Marine ls., extremely variable in appearance and structure, being solid ls. of coral origin, in some parts a coral cgl., over much larger areas a fine white ls. It is often free from any proofs of an organic origin. It breaks with a conchoidal fracture, a splintery surface, and rings under the hammer. Other portions are made of standing corals with the intervals filled in by reef debris and the whole cemented solid. In places the rock is a typical breccia composed of angular and cherty fragments in a limy cement, the cement and many of the fragments being bright red. Thickness, judged from well records, 69 to 130 ft. This ls. represents only known fossil coral reef in southern Fla. In places the Key West oolite apparently rests on Key Largo ls.; the relations to Miami oolite and Lostmans River ls. are less certain.

C. W. Cooke aud S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept., p. 208). *Key Largo ls.* believed to be contemp. with Miami oolite.

Named for exposures in cuts and borrow pits on Key Largo, at frequent intervals from S. shore of Lake Surprise to W. end of the island at Tavernier Creek, a distance of 15 mi.

Keys sand.

A subsurface sand, of Penn. age and 15 to 20 ft. thick, in Cotton Co., Okla. Lies 95 to 100 ft. below top of Priddy sand and higher than Zypsie sand.

Keyser limestone member (of Helderberg limestone).

Lower Devonian: Pennsylvania, western Maryland, northern West Virginia, and western Virginia.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pp. 563, 590, 591, pl. 28). *Keyser ls.*—Basal fm. of Helderberg of N. Y., Pa., Md., Va., and W. Va. Underlies Coeymans ls. and uncon. overlies upper Cayugan deposits (including (?) Manlius of N. Y.).

C. K. Swartz et al., 1913 (Md. Geol. Surv. Lower Dev. vol., pp. 82, 85). *Keyser memb. of Helderberg fm.*—Ls., massive and very nodular in lower part, more shaly and thin-bedded above. Thickness 270 to 290 ft. Rich coral and brachiopod fauna. Basal memb. of Helderberg fm. Underlies Coeymans memb., probably uncon., and overlies Tonoloway fm. Is clearly transitional btw. Sil. and Dev. Accepting the principle that the age of the fm. is that of its youngest fauna, the Keyser is here referred to the Helderberg, although the majority of its species are distinctly Sil. The Helderberg fauna thus appears to have invaded Md. before its advent in N. Y. in Coeymans time. Fauna of Keyser memb. as a whole shows pronounced relations to Helderberg, to which it is referred.

Named for exposures at Keyser, W. Va.

Keystone sandstone. (In Pottsville group.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, p. 237). *Keystone ss.*—Massive, medium grained, micaceous buff; 0 to 25 ft. thick. Underlies Landgraff coal and overlies Keystone coal. Exposed at Keystone, McDowell Co.

Lies near base of Pottsville group.

†Key West oolite.

Pleistocene: Southern Florida.

S. Sanford, 1909 (Fla. Geol. Surv. 2d Ann. Rept., table opp. p. 50, and pp. 209, 218–221). All oolite outcropping on keys S. of Florida Bay is here designated *Key West oolite.* Typically it is a soft white or light-colored fossiliferous oolitic ls., the ovules being scattered through amorphous carbonate of lime or surrounded by crystalline cement that develops most freely along bedding planes. Is less sandy than Miami oolite, but resembles latter in general appearance and physical qualities, there being little difference btw. hand specimens of the two. Is of marine origin. Apparently overlies Key Largo ls. Relations to nonoolitic Lostmans River ls. not determined. Is overlain by recent marls and calc. sands and in places along shores of the Keys may have a thin veneer of beach rock. Thickness probably less than 50 ft. Covers the islands W. of Bahia Honda Channel to Key West. Outcrops on shores of Harbor Key and Content Key and on most of keys to S. and SW. Underlies Bay of Florida for at least 3 mi. SE. of Big Bahia Honda Key, and forms surface of Boca Grande, 10 mi. W. of Key West.

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept.). Same as Miami oolite, and name "Key West" abandoned. Only difference btw. Miami oolite and "Key West" oolite is that the Miami contains a little more sand than the "Key West."

Kialagvik formation.

Jurassic (Middle?): Southwestern Alaska (Cold Bay district, Shelikof Strait).

S. R. Capps, 1923 (U. S. G. S. Bull. 739, pp. 90, 91, 94, map). *Kialagvik fm.*—A few hundred ft. (500+) of ss., sandy sh., and cgl. that form bluffs along beach of NW. shore of Kialagvik Bay from near mouth of Pass Creek to SW. end of bay and extend short distance inland. Underlies Shelikof fm. (Upper Jurassic), uncon. Very fossiliferous. Fauna is Middle Jurassic. [The fauna is now considered either early Middle Jurassic or late Lower Jurassic.]

Kiamichi formation. (In Washita group.)

Lower Cretaceous (Comanche series): Northeastern Texas and central southern and southeastern Oklahoma.

R. T. Hill, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 504, 515). *Kiamitia clays or Schloenbachia beds.*—Marly clays, often stiff and black before oxidation, alternating with firm, hard, thin dimension layers of yellow lime. Basal fm. of Washita div. Underlies Duck Creek chalk and overlies Goodland ls. of Fredericksburg div.

In southern Okla. overlies Goodland ls. and underlies Caddo ls. C. N. Gould, 1925 (Okla. Geol. Surv. Bull. 35, p. 98), stated that thickness in Okla. is variable up to 150 ft. Some authors now include this fm. in Fredericksburg group. For history of name, see under *Fredericksburg group*.

Named for historic plains of Kiamitia (correctly spelled Kiamichi) River near Fort Towson, Choctaw Co., Okla.

†Kiamitia clay.

Lower Cretaceous (Comanche series): Northeastern Texas and southeastern Oklahoma.

See *Kiamichi fm.*, approved spelling.

Kiask series.

Pre-Cambrian: Ontario.

H. C. Cooke, 1919 (Canada Geol. Surv. Mem. 115, p. 19).

Kibbey sandstone member (of Quadrant formation).

Mississippian (upper): Central northern Montana (Great Falls-Fort Benton region).

W. H. Weed, 1899 (U. S. G. S. Fort Benton folio, No. 55). Lowest beds of Quadrant fm. in this quad. are reddish and yellow clayey sss., often holding interbedded layers of gyp. and constituting *Kibbey ss.*, which is 153 ft. thick near Riceville. These are overlain by Otter shales, holding interbedded lss., and forming upper memb. of Quadrant in this quad. The Kibbey ss. rests on Madison ls. [Quadrant fm. mapped over large area at and around Kibbey, which is on Little Otter Creek, in SW. corner of quad.]

The U. S. Geol. Survey adopted *Kibbey ss. memb. of Quadrant fm.* in 1907. See under *Big Snowy group* of Scott (1935), who treats this as basal fm. of his Big Snowy.

†Kickapoo marl.

Upper Cretaceous (Gulf series): Northeastern Texas.

R. T. Hill, 1894 (Geol. Soc. Am. Bull., vol. 5, p. 308). Glauconitic marls, called *Brownstown marls* in Ark. and *Kickapoo marls* in Tex., which bear a growth of hardwood, including Bois d'Arc. Overlie White Cliffs or Anona chalk and underlie the Glauconitic sands. [Derivation of name not stated.]

J. A. Udden, C. L. Baker, and E. Böse, 1916 (Univ. Tex. Bull. 1916, No. 44, p. 74). In NE. Tex. the Taylor is probably represented by Marlbrook marls, which have also been called *Kickapoo marls.*

†Kickapoo limestone.

Pennsylvanian: Eastern Kansas.

E. Haworth and J. Bennett, 1908 (Kans. Acad. Sci. Trans., vol. 21, pt. 1, p. 81). *Kickapoo ls.*—Thin ls., extending entirely across Kans., from State line in Chautauqua Co. to Doniphan Co. Underlies Lawrence shales and overlies LeRoy shales.

H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines, vol. 13). "Kickapoo ls." discarded; is same as Iatan ls.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 139, 140). Kickapoo ls. of Haworth and Bennett (1908) included Iatan ls. and Haskell ls.

Named for Kickapoo, Leavenworth Co., 5 mi. S. of Iatan.

Kickapoo beds.

Pleistocene (Wisconsin stage): Central western Illinois.

C. O. Sauer, 1916 (Ill. Geol. Surv. Bull. 27). *Kickapoo beds.*—Gravels, sand, and silt, 20 to 70 ft. thick, well developed about mouth of North Kickapoo Creek, Illinois Valley, Ill. Belongs to Wisconsin glacial deposits.

Kickapoo sand.

A subsurface sand in McLeansboro fm. (Penn.) of Clark Co., Ill. (See Ill. Geol. Surv. Bull. 54, index.)

Kickapoo Falls limestone. (In Millsap Lake formation.)

Pennsylvanian: Central northern Texas (Brazos River region).

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, p. 138). *Kickapoo Falls ls.*—Top memb. of Millsap div. Outcrops in Parker Co. Best exposures of the Millsap are at Kickapoo Falls, 10 mi. S. of Weatherford, Parker Co.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 106, 107), replaced *Millsap fm.* with *Millsap Lake fm.*, and described Kickapoo Falls ls. as next to basal memb. of the fm. (See 1933 entry under *Millsap Lake fm.*)

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, pp. 15, 16). *Kickapoo Falls ls.* was named by Plummer and Moore from prominent exposures at Kickapoo Falls on Kickapoo Creek, in N. edge of Hood Co. It is treated as basal bed of Lazy Bend memb. of Millsap Lake fm.

Kiddville limestone.

Middle Devonian: East-central Kentucky.

A. F. Foerste, 1906 (Ky. Geol. Surv. Bull. 7, pp. 92, 93). *Kiddville bed or layer.*—Dense light-gray ls., blue argill. gritty ls., and reddish-brown ls. Thickness 0 to 3 ft. Characterized by fish remains. Bottom layer of Boyle ls. (Dev.). Underlain by Crab Orchard fm. (Sil.).

Named for small hamlet 1 mi. N. of Indian Fields, Clark Co.

Kiefer sandstone.

See *Keefer ss. memb.*

Kiester moraine.

Pleistocene (Wisconsin stage): Western Minnesota and North Dakota.

W. Upham, 1888 (Minn. Geol. and Nat. Hist. Surv., vol. 2, pp. 415, 625). The 4th or *Kiester moraine.* Named for occurrence in vicinity of Kiester, Faribault Co., Minn.

Kiewitz shale. (In Stanton limestone.)

Pennsylvanian: Southeastern Nebraska.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 42, 55). Howard ls. memb. of Shawnee fm. in Nebr. consists of 2 lss. separated by a sh. bed of variable thickness here named *Kiewitz sh.*, from Kiewitz quarry, W. of Meadow, Nebr. This sh. is bluish to gray, argill. to quite calc., fossiliferous, and 2 or more ft. thick. The upper ls. of Howard memb. was named "Louisville ls." by Condra and Bengston, from Louisville, Nebr., and that name, although preoccupied, is in use for this unit in Nebr. The lower ls. of Howard memb. is here named *Church ls.*

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, 2d ser., pp. 11, 27, 31). The units called Louisville ls., Kiewitz sh., Du Bois ls., Severy sh., Topeka ls., and Meadow ls. in Bull. 1 are parts of Stanton ls. The name *Louisville ls.* is preoccupied hence *Stoner ls.* is proposed for this unit, to include also *Kiewitz sh.* and so-called Du Bois ls.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 134). †*Kiewitz sh.*, a part of Stoner ls., is abandoned.

Kiger division. (In Cimarron group.)

Permian: Central southern Kansas and northwestern Oklahoma.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, pp. 3, 39). *Kiger div.*—All rocks [250 ft. thick] of so-called "red beds" that lie above Medicine Lodge gyp. on central plains N. of Ouachita Mtns. In southern Kans. it is divided into (descending) Big Basin ss., Hackberry shales, Day Creek dol., Red Bluff sss., and Dog Creek shales. Upper div. of Cimarron series. Overlies Salt Fork div., from which it is chiefly characterized by bright-red color of its major fm. (Red Bluff sss., 175 to 200 ft. thick). [In 1897 (Am. Geol., vol. 19, pp. 351–363) Cragin excluded Dog Creek sh. from his Kiger div. and included it in top of his Salt Fork div.]

E. Haworth and J. Bennett, 1908 (Univ. Geol. Surv. Kans., vol. 9, p. 77). *Kiger stage* includes (descending) Taloga fm., Day Creek dol., and Red Bluff fm. Overlies Dog Creek fm. of Salt Fork stage.

This name is not used in subsequent repts.

Named for Kiger Creek, Clark Co., Kans.

Kigluaik group.

Early Paleozoic or older: Northwestern Alaska (Seward Peninsula).

A. H. Brooks, G. B. Richardson, and A. J. Collier, 1901 (Reconn. in Cape Nome and Norton Bay regions, Alaska, in 1900: U. S. G. S. Spec. Pub., p. 27, map). *Kigluaik series.*—Highly crystalline lss., interbedded with gray mica schists, also some amphibole schists. The ls. usually massive, pure, generally white but sometimes bluish. Intruded by granites. More metamorphosed than overlying Kuzitrin series. First found in heart of Kigluaik Mtns, and later identified at other places.

F. H. Moffit, 1913 (U. S. G. S. Bull. 533, pp. 20–23, maps). *Kigluaik group* divided as follows (descending): Tigaraha schist, several thousand ft.; coarsely crystalline ls., 800 to 1,000 ft.; biotite gneiss. All except upper siliceous part of Tigaraha schist were included in Kigluaik series as originally defined and heretofore used. Assigned to Paleozoic, possibly in part pre-Paleozoic.

Kilbuck conglomerate lentil.

See *Killbuck cgl. lentil*, the approved spelling.

Killarney granite.

Pre-Cambrian (post-Keweenawan): Western Ontario (north shore of Lake Huron).

W. G. Miller and C. W. Knight, 1914 (Ontario Bur. Mines Rept., vol. 22, pt. 2, p. 125). Assigned to Algoman interval. Intrusive.

See also A. C. Lawson, 1929 (Geol. Soc. Am. Bull., vol. 40, pp. 361–383); also C. K. Leith, 1933 (16th Int. Geol. Cong. Guidebook 27, pp. 1–10), who placed it in Huronian, tentatively, but stated it may be as late as Keweenawan.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), classified Killarney granite as post-Keweenawan pre-Camb., but stated that there is some doubt as to its position.

Killarney revolution.

A period of granitic intrusion believed by some geologists to have immediately followed the formation of the Keweenawan rocks and to constitute the closing episode of pre-Camb. time. Other geologists have assigned the Killarney granite to lower part of Huronian epoch. For definition see U. S. G. S. Bull. 769, pp. 121–123. See also *Killarney granite.*

Killbuck conglomerate lentil (of Cattaraugus formation).

Devonian or Carboniferous: Southwestern New York (Cattaraugus County).

L. C. Glenn, 1903 (N. Y. State Mus. Bull. 69, p. 977) and 1904 (Geol. Soc. Am. Bull., vol. 14, pp. 522–531). *Kilbuck cgl. lentil.*—Massive flat-pebble cgl. that weathers into large flat blocks. Thickness 10 to 15 ft. Best developed NE. and E. of Kilbuck, Cattaraugus Co. [The village and post office are now spelled *Kill Buck.*] Occurs in upper part of Cattaraugus beds, being separated from underlying Salamanca cgl. lentil by 50 to 70 ft. of sh. and overlain by soft sh. forming top memb. of Cattaraugus.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 426). *Kilbuck cgl.* lies 50 to 70 ft. above Salamanca cgl.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 91). *Killbuck lens* of Glenn is same as "Tuna" or Tunangwant cgl.

Killians limestone.

Middle Devonian: Northeastern Michigan (Thunder Bay region).

A. S. Warthin, Jr., and G. A. Cooper, 1935 (Wash. Acad. Sci. Jour., vol. 25, No. 12, pp. 524–526). *Killians ls.*—Dark gray to black ls. with black sh. layers. Overlain by gray and brown granular beds of Alpena ls. and underlain by gray shales and lss. of Genshaw fm. Is the "black Alpena" zone of Ver Wiebe's Alpena ls. Greatest measured thickness, 23 ft. Is top fm. of Long Lake stage [as here redefined]. Type loc., exposures along French road, ½ mi. S. of Killians resort, Long Lake, Alpena Co.

Kiln shale.

Upper Devonian: Alberta (Jasper Park).

P. E. Raymond, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 294, 296, 300). *Kiln sh.*—Black fissile sh.; large concretions; 200 ft. thick. Best exposed at the old limekilns S. of Disaster Point. Overlies Fiddle ls. and underlies Bedson ls. (Miss.).

Kimball sand.

Drillers' name for an oil, water, and gas-bearing ss., 50 ft. thick, in upper part of Mowry sh. in Basin oil field, Bighorn Co., Wyo. Lies 45 ft. above Octh Louie sand. (See U. S. G. S. Bull. 621, Jan. 21, 1916, pp. 167, 169, etc.)

†Kimball or †Madder dirt.

Name applied by drillers to a bed of sh., 10 to 20 ft. thick, underlying Raytown ls. bed and overlying Cement City ls. bed of Chanute sh. memb. of Kansas City fm. of Mo.

Kimberling shale.

Upper Devonian: Southwestern Virginia and southeastern West Virginia.

M. R. Campbell, 1894 (Geol. Soc. Am. Bull., vol. 5, pp. 171, 177, Pl. 4). *Kimberling sh.*—Includes all shales above Walker black sh. and beneath Carbf. Price ss. Its base is the transition series [at top of Walker black sh.]; these pass upward into green, argill. shales, which grow more sandy as we ascend, until in upper portion it carries many thinly bedded sss. and some cgls.

On some early maps the top and base of Kimberling sh. were drawn at different places. In some areas beds as high as lower part of Maccrady fm. and as old as Portage appear to have been included.

Named for Kimberling Creek, Bland Co., Va.

Kimberly moraine.

Pleistocene (Wisconsin stage): Eastern Minnesota.

F. Leverett, 1932 (U. S. G. S. P. P. 161, p. 51). Named for occurrence at Kimberly, Aitken Co.

Kimbrel bed.

Eocene (upper): Northwestern Louisiana (Grant County).

T. L. Casey, 1902 (Sci., n. s., vol. 15, p. 716). *Kimbrel bed.*—Greenish black and brick red clays, not so rich in species as Montgomery bed and more limited horizontally. Outcrops on estate of T. W. Kimbrel. Is well above Moody's Branch beds. Is characterized by same fossils as Young's Bluff beds, and in addition immense numbers of extremely minute *Lucina*, which is characteristic fossil of Kimbrel horizon. Is older than Youngs Bluff bed and younger than Montgomery bed. Belongs to horizon noticeably distinct from Montgomery outcrop. Impossible at present to state number of ft. of strata separating Kimbrel horizon from Montgomery bed, but there are several changes in fossils that indicate considerable lapse of time. Included in Jackson stage. Named for outcrops on estate of T. W. Kimbrel, S. of Montgomery, Grant Co.

Kimmswick limestone.

Middle Ordovician (Trenton and Black River?): Eastern Missouri, southwestern Illinois, and northern Arkansas.

E. O. Ulrich, 1904 (Mo. Bur. Geol. and Mines vol. 2, 2d ser., p. 111). *Kimmswick ls.*—More or less crystalline ls. quarried at Graysboro, Cape Girardeau, Glen Park, Kimmswick, and other localities in SE. Mo. The thin bed, 2 to 5 ft. thick, generally found at top, which holds the Fernvale Richmond fauna, is not included. Overlies Plattin ls.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27), defined *Kimmswick ls.* as consisting wholly of beds of late Black River age, uncon. overlain, in eastern Mo., by what he called "Upper Prosser," which in turn was overlain, in places uncon., by McCune dol., of Trenton age. This definition of Kimmswick ls. was repeated by R. S. Bassler in 1915.

A. F. Foerste, 1920 (Denison Univ. Bull. Jour. Sci. Lab., vol. 19, pp. 175+). *Kimmswick ls.* (broad sense) is = McCune ls. of Keyes (1898). [This same statement was made by Keyes, 1923 (Pan-Am. Geol., vol. 39, pp. 67–70).]

J. H. Bradley, Jr., 1925 (Jour. Geol., vol. 33, pp. 53–54, 65, 69). Beds that have been included in Kimmswick ls. are McCune or *Fusispira* zone at top; *Comarocystites* or *Echinosphaerites* zone (which forms top bed of Kimmswick at Cape Girardeau) 30 ft.; *Receptaculites oweni* zone, 68 to 80 ft.; and basal beds, 50 ft. It seems likely Kimmswick ls. in its type exposures does not rise above *base* of *Fusispira* or McCune zone, which is here only provisionally included in Kimmswick. The Kimmswick of Ralls Co. is probably 100 to 125 ft. thick; total thickness of fm. probably approaches 200 ft. The presence of certain [listed] species of fossils is strong evidence that Kimmswick is at least as young as Lower Trenton of type section.

S. Weller and S. St. Clair, 1928 (Mo. Bur. Geol. and Mines vol. 22, 2d ser., pp. 104–110), restricted Plattin ls. by removing the shaly beds at top, which they designated as *Decorah sh.* The Kimmswick ls. of Mo., SW. and central western Ill. has, therefore, for several years been defined as resting on Decorah sh. (See under *Decorah sh.*, last entry.)

The Kimmswick ls. is now classified by U. S. Geol. Survey as of Trenton age, but possibly including at base some beds of Black River age.

Named for exposures at Kimmswick, Jefferson Co., Mo.

Kincaid formation. (In Midway group.)

Eocene (lower): Eastern Texas.

Julia Gardner, 1933 (A. A. P. G. Bull., vol. 17, No. 6, p. 744). *Kincaid fm.*—Probably 100± ft. thick in Frio River section. Lower fm. of Midway group. Includes beds 7 to 5 of Vaughan's section of "Myrick fm." on Frio River, about ½ mi. above Myrick's lower apiary (now Bob Evans apiary), as given in U. S. G. S. Uvalde folio, No. 64, 1900. The Kincaid fm. in that section consists of (descending): (7) Rather soft yellowish ss., 22 ft. 6 in.; (6) soft yellow sandy clay with bluish streaks, some pebbles in lower part, 2 ft. 6 in.; (5) nodules of glauconitic ss. containing considerable number of small pebbles, 6 in. Underlies Wills Point fm. [restricted] and uncon. overlies Escondido fm. (Upper Cret.). Type exposures are on old Kincaid ranch (Lewis ranch) ¾ mi. above Bob Evans' apiary to ¼ mi. below it.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 532, 535, etc.), divided Kincaid fm. into Pisgah memb. above and Littig memb. below, and included Tehuacana ls. in Pisgah memb. He stated: Some geologists place the upper glauconite of Midway group in Kincaid fm. and draw dividing line btw. Wills Point and Kincaid at top of this glauconite. The upper glauconite is now placed in base of Wills Point fm. because: (1) Glauconitic sands containing phosphatic nodules and pebbles mark commonly basal layers of divisions; (2) the uncon. appears to be at *base* of the glauconite; (3) although the glauconite layer has large fossils which occur both in fms. above and below, it has certain significant ones, like *Venericardia bulla* Dall, that appear for first time; (4) a large percentage of the foraminifera in the glauconite are similar to species in upper or Wills Point clay.

Kinchloe limestone.

Pennsylvanian: Western Kentucky.

F. M. Hutchinson, 1912 (Ky. Geol. Surv. Bull. 19, fig. 28, loose sheet in back of book). *Kinchloe ls.*, 4 ft. thick, shown in section of rocks at Madisonville, Hopkins Co. [May be=Upper Madisonville ls. of pp. 13 and 94 (a ls. 4½ ft. thick lying 38 ft. above Madisonville ls.), but fig. 28 does not show Madisonville ls. nor Upper Madisonville ls., and does not give numbers of coals. Fig. 13 shows Kinchloe coal (seems to be No. 14 or 14A) underlain by 1½ ft. of ls. which may be the Kinchloe ls. of fig. 28.]

Derivation of name not stated, but there is a Kinchloes Bluff in adjoining Muhlenberg Co.

Kinderhook group.

Mississippian: Illinois, Iowa, Missouri, and western Kentucky.

F. B. Meek and A. H. Worthen, 1861 (Am. Jour. Sci., 2d, vol. 32, p. 288). *"Kinderhook group"* is now proposed to include the beds lying btw. Black sl., below, and Burlington ls. above, which have heretofore been considered equivalents of Chemung group of N. Y. This designation will be used in Ill. repts.

A. H. Worthen, 1866 (Ill. Geol. Surv., vol. 1). *Kinderhook group.*—Consists of 100 to 150 ft. of gritstones, sandy and argill. shales, and thin beds of fine-grained and oolitic lss., overlying Dev. Black sl. and underlying Burlington ls. Includes Chouteau ls., Lithographic [Louisiana] ls., Vermicular ss. and shales [Hannibal sh.] of Mo. Rept., the so-called Chemung of Iowa Rept., the Goniatite ls. of Rockford, Ind., and that part of Waverly ss. of Ohio that overlies the Black sl.

R. C. Moore, 1928 (Mo. Bur. Geol. and Mines vol. 21, 2d ser., p. 282), divided *Kinderhookian* group of Jersey and Calhoun Counties, Ill., into (descending) Chouteau ls., Hannibal fm., Glen Park ls., Louisiana ls., and Saverton and Grassy Creek shales; and showed the type Kinderhook (of Pike Co., Ill.) as consisting of (descending): (1) McKerney ls., ss., and sh. memb. of Hannibal fm. resting uncon. on (2) Louisiana ls., uncon. on (3) Saverton and Grassy Creek shales, with Chouteau ls. (top fm.) and Glen Park fm. (btw. Hannibal and Louisiana ls.) absent.

A. H. Bell, 1932 (Ill. Geol. Surv. Press Bull. No. 24), and R. C. Moore, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc.) included in Kinderhook group Saverton sh., Grassy Creek sh., and Sweetland Creek sh. of Iowa, Mo., and Ill.

For the fms. now included in this group, see Ill. and Mo. correlation charts. The Fern Glen ls., formerly treated as top fm., was several years ago transferred to overlying Osage group, being now treated as basal fm. of the Osage, the next overlying fm. being Burlington ls.

Named for exposures at Kinderhook, Pike Co., Ill.

Kinderhookian.

A time term employed by some geologists to cover the epoch during which the Kinderhook group was deposited.

Kineo rhyolite.

Devonian: Western Maine (Moosehead Lake quadrangle, Piscataquis County).

E. H. Perkins, 1925 (Am. Jour. Sci., 5th, vol. 10, p. 371). *Kineo rhyolite.*—An intrusion of rhyolite locally known as "*Kineo flint.*" Forms a line of hills from Blue Ridge on SW. through Mount Kineo [Moosehead Lake quad.], Shaw Mtn, and Little Kineo to Table Mtn.

E. S. C. Smith, 1925 (Am. Jour. Sci., 5th, vol. 10, pp. 440–444). *Kineo rhyolite,* of post-Oriskany age, cuts Moose River ss., of Oriskany age. Splendid outcrops near Mount Kineo hotel.

F. W. Toppan, 1932 (Geol. of Maine, Contr. Dept. Geol. Union Coll., Schenectady, pp. 70, 71). Beginning some 6 or 7 mi. SW. of Lobster group of mtns is a series of low rhyolite hills which extend in exact alignment a distance of about 15 mi. Running NE. to SW. these hills are Norcross Mtn, Table Mtn, Little Kineo, Shaw Mtn, Mount Kineo, and Blue Ridge. While the lava comprising each of these hills is identical it has been named *Kineo rhyolite* by E. S. C. Smith (Am. Jour. Sci., 5th, vol. 10, Nov. 1925), from Mount Kineo, which, because of its steep glaciated cliffs and commanding position on shore of Moosehead Lake, is most striking eminence of the group of mtns. Intrudes Moose River ss., of Oriskany Dev. age.

On 1933 geol. map of Maine, by A. Keith, this rhyolite is assigned to Dev.

King limestone.

Lower Ordovician (Beekmantown): Southwestern Missouri.

E. M. Shepard, 1898 (Mo. Geol. Surv. vol. 12, pt. 1, pp. 49, 71–74). *King ls.*—Soft fine-grained, compact light ashy-gray ls. ("cotton rock" of miners), 1 to 15 ft. thick. No fossils found. Overlies [?] Black or Eureka sh. and underlies Sac ls. All included in Hamilton stage of Dev.

Later repts by S. Weller (1901) and other geologists assigned this fm. to Kinderhook group.

R. C. Moore, 1928 (Mo. Bur. Geol. and Mines vol. 21, 2d ser., pp. 113–114). Sac ls. uncon. underlies "Phelps" (Sylamore) ss. and overlies King ls. Both Sac and King are lacking in organic remains, are highly mag., and resemble underlying "Mag. series" of the Ord. so closely that in many cases they may be confused with very similar beds of First and Second Mag. lss.

The King ls. appears to belong to lower part of Powell ls. or to Cotter dol. (which uncon. underlies Powell ls. in SW. Mo., and contains the "cotton rock" of the miners), and the overlying Sac ls. appears to belong to upper part of Powell ls., which uncon. underlies Sylamore ss. in SW. Mo. (See Mo. correlation chart.)

Named for outcrops on King Branch and King Mound, Greene Co.

Kingak shale.

Jurassic (Lower?): Northern Alaska (Canning River region).

E. D. Leffingwell, 1919 (U. S. G. S. P. P. 109, pp. 103, 119, map). *Kingak sh.*—About 4,000 ft. of black sh., overlying Shublik fm. (Upper Triassic), and probably underlying Ignek fm. (Jurassic?). The fm. name is confined to the shales containing the Lower Jurassic fauna here listed. The fm. has been identified at only 1 loc., Kingak Cliff, near camp 263, at SE. end of Sadlerochit Mtns.

King Ferry shale member. (In Ludlowville shale.)

Middle Devonian: Central New York.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 219, 228, etc.). *King Ferry shale memb. of Ludlowville fm.*—Mostly dark aren. sh. occupying interval btw. Ledyard sh. below and Portland Point ls. memb. of Moscow fm. above. Is = Wanakah and Deep Run members, which could not be differentiated btw. Seneca and Owasco Lakes. Is upper memb. of Ludlowville fm. in Cayuga Lake region. Thickness 120 to 130 ft. Type loc., at Clearview, King Ferry, Cayuga Lake.

†Kingfisher formation. (In Cimarron group.)

Permian: Central Oklahoma and southern Kansas.

F. W. Cragin, 1897 (Am. Geol., vol. 19, pp. 352–355). *Kingfisher fm.*—Includes Salt Plain measures and saliferous Harper sss., which are in places difficult to separate. Included in Salt Fork div.

Named for Kingfisher Creek and town in Kingfisher Co., Okla.

King Hill shale. (In Lecompton limestone.)

Pennsylvanian: Southeastern Nebraska, northeastern Kansas, southwestern Iowa, and northwestern Missouri.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 44, 45, 47). *King Hill sh.*—Bluish-green and reddish argill. sh., about 7 ft. thick at type loc. (in King Hill, SE. of Rock Bluff, Nebr.). Is 4 ft. thick in Mo. and 6 to 7 ft. in Kans. Underlies Avoca ls. and overlies Cullom ls. [later named *Beil ls.* and still later *Cullom* was abandoned]. All included in Lecompton ls.

Kings limestone.

Devonian: Missouri.

E. M. Shepard, 1904 (Drury Coll., Bradley Geol. Field Sta. Bull., vol. 1, p. 41), listed, in table of geol. fms. of Mo., *Kings ls.* as underlying Sac ls. and overlying Eureka sh., all included in Hamilton epoch of Dev.

Kings Branch limestone.

Age (?): Southwestern Missouri (Greene County).

E. M. Shepard, 1905 (Drury Coll., Bradley Geol. Field Sta. Bull., vol. 1, in description of the mag. lss. of Greene Co., Mo.). *Kings Branch ls.*—Soft, very fine-grained, compact white to ashy-gray "cotton" rock, in thin alternating layers of softer and harder material, weathering in thin ridges and grooves, representing successive bedding planes. [All of definition.]

Only record of name.

Kingsbridge marble.

Pre-Cambrian: Southeastern New York (Manhattan Island).

L. D. Gale, 1839 (N. Y. Geol. Surv. 3d Ann. Rept., p. 183). At N. part of this valley [on New York Island, as he called it] and on E. slope of ridge, the ls. generally called *Kingsbridge marble* commences and continues to Kingsbridge, a distance of nearly 1¼ mi. Is mostly granular ls. Has been chiefly wrought for burning into lime. Belongs to the gneiss fm., as is evident from the commingling of the two in many places throughout the course of the ls.

R. P. Stevens, 1867 (N. Y. Lyc. Nat. Hist. Annals, vol. 8, pp. 116–120). [On his "Section across New York [Manhattan] Island along southern shore of Spuyten-Duyvel Creek and Harlem River" *King's Bridge ls.* is shown upturned btw. High Bridge gneiss on one side and Fort Washington gneiss on the other side.]

J. D. Dana, 1881 (Am. Jour. Sci., 3d, vol. 21, pp. 435, 441). [Referred to ls. S. of King's Bridge as *King's Bridge ls.*]

J. F. Kemp, 1887 (N. Y. Acad. Sci., Trans., vol. 7, pp. 49–64). The ls. called *Kingsbridge marble* composes NE. corner of Manhattan Island. It is interbedded with the gneiss.

In U. S. G. S. New York City folio (No. 83) the ls. at and around Kings Bridge was mapped as Stockbridge dol. (of Camb. and Ord. age), but it is now considered by geologists generally to be pre-Camb., and is universally called *Inwood ls.* The gneiss with which it is associated is Fordham gneiss.

Kingsbury conglomerate member (of Wasatch formation).

Eocene: Northern Wyoming (Bighorn Mountains region).

N. H. Darton, Nov. 17, 1906 (U. S. G. S. P. P. 51, pp. 13, 60, etc.). *Kingsbury cgl.*—Appears on S. side of Beaver Creek, developing either out of lower part of top beds of underlying Piney fm. or lower beds of overlying De Smet fm. Thickness 0 to 2,500 ft. Consists of pebbles and bowlders, mostly of Carbf. lss. and darker colored chert and the very distinctive flat-pebble cgl. of Deadwood fm. of mtns to W. Occurs mostly in layers 6 to 12 ft. thick, interbedded with dark greenish to light-yellow clays. The name *Kingsbury*, here used for first time, is from Kingsbury Ridge, [6 mi.] SW. of Buffalo.

In 1910 the U. S. Geol. Survey decided to replace *De Smet fm.* with *Fort Union fm.*, the older name; and adopted *Kingsbury cgl. memb. of Fort Union fm.* for Darton's Kingsbury cgl. Later work, however, proved that Kingsbury cgl. grades laterally into basal part of Wasatch fm., and the Kingsbury is therefore now treated as basal memb. of Wasatch fm., being thus mapped on 1924 geol. map of Wyo.

†Kings Creek silex.

†Kings Creek phase.

Oligocene and upper Eocene: Western South Carolina (Barnwell County) and southeastern Georgia.

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies, published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 12, 18, name only, not defined); 1908 (S. C. Geol. Surv. ser. 4, Bull. 2, pp. 435, 464–465). *Kings Creek silex or silicified marls;* also *Kings Creek phase.*—Comprises ledges of highly siliceous rock inclosing many spicules of sponges and other forms now silicified. The surface of high ground btw. Johnson's Landing, near mouth of Lower 3 Runs, Barnwell Co., S. C., to point immediately S. of King's Creek and about 1 mi. W. of river road is in places strewn with small masses of chalcedony of many hues of white, red, and blue; at the King's Creek locality a moderately prominent knoll is well shingled with this material, specimens of which exhibit silicified corals and other fossil forms studded with minute crystals of silica. This fm. passes under the Brier Creek marls. Its probable equiv. is exhibited capping the high hill immediately S. of McBean Creek near McBean Station. Assigned to Olig.

C. W. Cooke, 1936 (U. S. G. S. Bull. 867). Kings Creek phase of Sloan includes Glendon fm. and upper part of Eocene, and is abandoned.

Kingsdown marl.

Pleistocene: Southwestern Kansas.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, pp. 53, 54). *Kingsdown marls.*—Yellowish brown lacustrine or slack-water marls, with concretions of carbonate and silicate of lime; 100 to 200 ft. thick. Overlies Pearlette ash and uncon. underlies Quat. Supposed to be of late Plio. age and to belong to Tule div. of Cummins (*Equus* beds of Cope). Named for Kingsdown, Ford Co.

Kingsley red shale member (of New Milford formation).

Upper Devonian: Northeastern Pennsylvania (Susquehanna County).

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 571–589). *Kingsley red shale memb.*—Basal memb. of New Milford fm. Recognized but not named by I. C. White. Well exposed in R. R. cut at Kingsley, Susquehanna Co. Occurs at several places in the region, where it is convenient datum for measuring interval up to Damascus red beds, which overlie the New Milford. This interval is occupied by Lanesboro memb. of New Milford fm.

Kings Mill sandstone.

Upper Devonian: Central Pennsylvania (Perry County).

E. W. Claypole, 1885 (2d Pa. Geol. Surv. Rept. F_2, pp. 73–77). *King's Mill ss.*—White ss.; some lenticular layers are merely masses of stone honeycombed by cavities left by solution of shells. Fossils indicate transition from Chemung to Catskill, but some may prefer to include them in Catskill. Exposed near King's Mill, 2 mi. NW. of Duncannon, Perry Co.

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, p. 585). As Shohola fm. is largely Chemung in age, it is approx. = the 500 ft. of red beds below Kings Mill ss.

Kings Mill shales.

Upper Devonian: Central Pennsylvania (Perry County).

E. W. Claypole, 1885 (2d Pa. Geol. Surv. Rept. F_2, p. 77). *King's Mill shales.*—A series of red sss. and shales, green shales and thin lss., some of latter crowded with poorly preserved fossils. Near middle lies the upper fish bed. Thickness

500 ft. Underlie Dellville ss. and overlie Kings Mill ss. Belong to transition btw. Chemung and Catskill, but some may prefer to include them in Catskill.

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 582, 585). The 500 ft. of red beds beneath Kings Mill ss. are approx.=Shohola fm., and the Dellville ss. of Claypole, which overlies Kings Mill shales of Claypole, is possibly=Honesdale ss. [This would correlate latter shales with Damascus red sh. of Willard.]

†King's Mountain group.

†King's Mountain series.

†King's Mountain slates.

Cambrian and pre-Cambrian: Northwestern South Carolina and western North Carolina.

O. M. Lieber, 1858 (Rept. of survey of S. C. for 1856, pp. 23, 30). [On p. 23 the name *King's Mtn series* is used for the rocks mapped and described as *talcose slate*, and on p. 30 the same rocks are called *King's Mtn group*.]

E. Sloan, 1908 (Repts and resolutions of General Assembly of S. C., regular session commencing Jan. 14, 1908, vol. 1, pp. 648–651; also S. C. Geol. Surv., ser. 4, Bull. 2, pp. 414–417, 1908). *King's Mtn slates* (*Archean*).—Comprise large bodies of quartz schist, quartz-mica schist, qtzite, mica schist, sericites, monzonite schists, gneissoids, and some argillites with highly developed slaty cleavage, and intermediate forms of rocks of sedimentary origin, all of which have been more or less foliated, greatly folded and otherwise disturbed by a vast series of igneous intrusions of enormous volumes. Largely confined to Abbeville-York zone, but outlying patches extend to Anderson-Spartanburg zone. Some igneous phases of this fm. find their apparent equivalence in some rocks of Edgefield-Chesterfield zone. The Vaucluse zone also comprises certain highly altered sed. rocks of probable equivalence of King's Mtn slates.

Divisible into several fms., of which Kings Mtn qtzite is one.

Named for development on Kings Mtn, in Cleveland and Gaston Counties, N. C.

Kings Mountain quartzite.

Cambrian (probably Lower): Southern North Carolina and northwestern South Carolina.

A. Keith and D. B. Sterrett, 1931 (U. S. G. S. Gaffney-Kings Mtn folio, No. 222). *Kings Mtn qtzite*.—Includes 3 distinct kinds of qtzite with gradations btw. them in some places (white nearly pure qtzite, kyanitic qtzite, and chloritic-sericitic qtzite grading into schist; the white qtzite normally at top), with Draytonville cgl. memb. at base; apparent gradations or replacements of the cgl. by the qtzite occur in places. Thickness of fm. 5 to 500 ft. Underlies Blacksburg schist and rests uncon. on Battleground schist (Algonkian) and on Archean rocks.

Named for development on Kings Mtn, in Cleveland and Gaston Counties, N. C.

Kings River sandstone member (of Everton formation).

Lower Ordovician: Northwestern Arkansas (Eureka Springs-Harrison region).

A. H. Purdue and H. D. Miser, 1916 (U. S. G. S. Eureka Springs-Harrison folio, No. 202). *Kings River ss. memb. of Everton ls.*—Massive saccharoidal ss., with cgl. at base. Thickness 0 to 40 ft. Uncon. overlies Sneeds ls. lentil, the basal bed of Everton ls., and is overlain by the white, light-gray, and dove-colored nonmag. ls. forming major part of the Everton. Named for exposures along Kings River, Eureka Springs quad.

Kingston group.

Pre-Cambrian: New Brunswick.

L. W. Bailey and G. F. Matthew, 1872 (Canada Geol. Surv. Rept. 1870–71, pp. 122–138).

Kingston conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. R. Marvine, 1873 (Mich. Geol. Surv. vol. 1, pt. 2, p. 114 and chart). Is cgl. No. 10 of Keweenaw Co.

According to B. S. Butler (U. S. G. S. P. P. 144, 1929) is probably same as Kearsarge cgl. (No. 11).

Belongs to Central Mine group.

Named for occurrence on Kingston farm, on Keweenaw Point.

†Kingston beds.

Lower Devonian: Eastern New York.

J. M. Clarke and C. Schuchert, 1899 (Sci., n. s., vol. 10, pp. 874–878). ***Kingston beds***, the "upper shaly beds" of W. M. Davis, which are typically exposed and attain a thickness of 250 ft. in vicinity of Kingston. Underlie Oriskany beds and overlie Becraft ls. Top fm. of Helderbergian group.

The name "Kingston" being preoccupied, it was in 1903 replaced by *Port Ewen ls.*, which is now included in Oriskany group, having been transferred to that group by Schuchert in 1903 (Am. Geol.).

Kingston formation.

Pleistocene: Jamaica.

R. T. Hill, 1899 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 34, p. 88).

Kingston limestone.

Carboniferous: British Columbia.

C. Camsell, 1910 (Canada Geol. Surv. Mem. 2, pp. 47, 54).

†Kingstown series.

Carboniferous: Central southern Rhode Island.

A. F. Foerste, 1899 (U. S. G. S. Mon. 33, pp. 331–347, and map, pl. 31). ***Kingstown series.***—Irregularly alternating beds of coarse qtzitic ss. (almost an arkose), cgls., medium-grained and fine-grained sss., and dark blue shales. Basal part consists of 100 to 200 ft. of arkose and cgls. often associated with much coaly sh. Thickness 11,200 ft. Typically developed in South and North Kingstown. Underlies Aquidneck shales.

J. B. Woodworth, 1899 (U. S. G. S. Mon. 33, p. 134), showed Kingstown series of Foerste as including lower part of Rhode Island Coal Measures and all of Wamsutta fm., and as resting on beds equiv. to Pondville cgl.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, map), mapped all areas of Kingstown series of Foerste as Wamsutta fm. and Pondville cgl.

Kingwood sand.

A subsurface sand, of early Penn. (Cherokee) or late Miss. age, in central and eastern Okla., reported to lie considerably lower than Deaner sand, higher than Lyons sand, and to correlate with lower part of Dutcher sand series. According to Okla. Geol. Surv. Bull. 40Q, 1928, p. 180, the Deaner sand is Miss.

Kinishba beds. (In Supai formation.)

Permian: Southeastern Arizona (Fort Apache Indian Reservation).

A. A. Stoyanow, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 533–536). [See under *Fort Apache ls.*]

Kinkaid limestone. (Of Chester group.)

Mississippian: Southern and western Illinois and adjacent parts of Kentucky.

S. Weller, 1920 (Jour. Geol., vol. 28, No. 4, pp. 281–290, and No. 5, pp. 395–416; also Ill. Geol. Surv. Bull. 41). *Kinkaid ls.*—Ls. and sh., with possibly some thin beds of ss. The lss. are of variable character, but chiefly hard, dense, and compact, breaking with splintery or conchoidal fracture; they are of gray, yellowish, and black colors, the yellow layers being a conspicuous feature in many outcrops. Some ls. beds are siliceous; chert beds of greater or less extent are scattered through the fm.; one massive light-colored chert bed in lower part recognized over considerable area. The shales are also of variable character, some being almost pure clay, some calc., some siliceous, and some more or less sandy; and they vary in thickness from thin shaly partings btw. the lss. to beds 15 or more ft. thick. In color the shales are black, gray, olive green, and red. Thickness of fm. 100 to 150 or more ft. Top fm. of Chester group. Heretofore not recognized. Contains a Chester fauna. Rests on Degonia ss. with apparent conformity. Uncon. overlain by Pottsville fm. Included in Clore fm. as mapped in previous repts.

Named for good exposures along Kinkaid Creek and some of its tributaries in Jackson Co., Ill.

Kinney limestone. (In Chase group.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., p. 37). *Kinney ls.*—Middle memb. of Matfield fm. Thickness 12 ft. in Nebr. and 15 ft. or more in southern Kans. in vicinity of Burden. In Nebr. it consists of (descending): (1) Two mudstone lss. separated by sh., about 1 ft. 8 in.; (2) gray sh., 5 or 6 ft.; (3) gray ls., 5 ft. or more. In central and southern Kans. the lower ls. becomes prominent and massive and the upper zone becomes about 6 ft. of very thin fossiliferous ls. beds separated by sh. seams, with 2 or 3 ft. of limy sh. remaining as zone 2. Underlies Blue Springs sh. memb. and overlies Wymore sh. memb. Type loc. is Burlington R. R. cut just E. of Kinney, Nebr.

Kinnick formation.

Miocene (lower): Southern California (northeastern part of Kern County).

J. P. Buwalda, 1934 (Pan-Am. Geol., vol. 61, No. 4, p. 310). *Kinnick fm.*—Mainly basic volcanics, several hundred ft. thick, containing, in interbedded sediments, the Lower Mio. Phillips ranch mammalian fauna. Strongly deformed. Occurs NE. of Monolith [NE. part of Kern Co.]. Underlies (probably uncon.) Bopesta fm. and rests on Witnet fm. with strong angular uncon. [Derivation of name not stated.]

Kinnikinic quartzite.

Ordovician (Middle?): Southern central Idaho (Custer County).

C. P. Ross, 1932 (Idaho correlation chart compiled by M. G. Wilmarth). *Kinnikinic qtzite.*—Massive light-colored qtzite with local lenses of dol. and dolomitic sh. and some cgl. Thickness 3,500± ft. Underlies Saturday Mtn fm. and overlies Ramshorn sl. Named for creek which flows into Salmon River at Clayton, Custer Co.

C. P. Ross, 1934 (Geol. Soc. Am. Bull., vol. 45, p. 947, etc.). *Kinnikinic qtzite.*—Name here definitely applied only to the strata exposed at intervals from vicinity of Kinnikinic Creek NE. to Round Valley (near Challis) and the area on both sides of that valley. The Ord. strata along Morgan Creek and at N. end of Lost River Range, S. of Ellis, are closely similar to and doubtless to be correlated with Kinnikinic qtzite. No lithologically similar strata exist in Hailey quad. with possible exception of parts of the qtzite members of the 2 supposed pre-Camb. fms. In Bayhorse quad. most of Kinnikinic qtzite is well-bedded, nearly pure qtzite in which shaly partings and subordinate amounts of shaly beds (partly calc.) are common. Thickness 3,500± ft. Fossils discussed.

Kinross moraine.

Pleistocene (Wisconsin stage): Northern Michigan (Chippewa County). See F. Leverett, U. S. G. S. P. P. 154A, 1929. Named for Kinross Station.

Kinsman granodiorite.

Late Devonian or late Carboniferous: Northwestern New Hampshire (Ammonoosuc River region, Franconia and Moosilauke quadrangles).

C. R. Williams, 1934 (Appalachia, vol. 20, No. 4, pp. 69–78). *Kinsman granodiorite* (*Carbf. ?*), exposed around Kinsman Mtn [Franconia quad.].

M. P. Billings and C. R. Williams, 1935 (Geology of Franconia quad., N. H., pp. 9, 20, map). *Kinsman quartz monzonite*, named for Kinsman Notch, in Moosilauke quad., occupies much of W. and N. parts of Franconia quad. and extends N. in Rumney and Plymouth quads. Is white to gray, coarse- to medium-grained; in places contains large white crystals of potash feldspar 1 to 2 inches long. Is younger than Littleton fm., and either late Dev. or late Carbf. Assigned to New Hampshire magma series.

See also M. P. Billings, Geology of Littleton and Moosilauke quads., N. H., 1935.

Kinter sand.

Ordovician: Northeastern Oklahoma (Oklahoma City oil field).

D. A. McGee and W. W. Clawson, Jr., 1930 (A. A. P. G. Bull., vol. 16, pp. 966, 974+). *Kinter ss.*—An oil and gas horizon, 20 to 80 ft. thick, in Ord. rocks of Oklahoma oil field, NE. Okla. Base lies about 110 ft. above Arbuckle ls. Variously known as "Olds," "Johnson," "Lowery," and "Hoopes." Overlies "Stamper" zone and lies 150± ft. below "Hammer-Haindl" ss.

This sand has been correlated, in earlier repts, with basal part of Simpson fm. Named for a farm.

Kintla argillite.

Pre-Cambrian (Belt series): Northwestern Montana (Glacier National Park) and southern British Columbia.

B. Willis, 1902 (Geol. Soc. Am. Bull., vol. 13, pp. 316, 324). *Kintla argillite.*—Argillite and qtzite, thin-bedded, maroon red, ripple-marked, sun-cracked, containing casts of salt crystals, also occasional beds of white qtzite and some calc. beds. Thickness 800+ ft. No upper limit seen. Is top fm. of Algonkian. Younger than Sheppard qtzite. Closely resembles Grinnell argillite. Named for occurrence in mtns on 49th par. NE. of Upper Kintla Lake, Mont.

Kinzers formation.

Lower Cambrian: Southeastern Pennsylvania.

G. W. Stose and A. L Jonas, 1922 (Wash. Acad. Sci. Jour., vol. 12, pp. 359, 362–363). *Kinzers fm.*—Siliceous banded dark-blue dol., resting on 50 ft. (in places) of blue hackly sh. (containing *Olenellus* fauna), and, at base, a few thin beds of impure dol. Thickness 150 ft.; S. of Welsh Mtn. only 25 ft. Underlies Ledger dol. and overlies Vintage dol., the 3 fms. being considered=Tomstown dol. Named for exposures in Pa. R. R. cut at Kinzers, Lancaster Co.

†Kinzua Creek sandstone. (In Pottsville formation.)

Pennsylvanian: Central northern Pennsylvania.

C. A. Ashburner, 1879. [See first entry under †*Johnson Run ss.*]

Correlated with Connoquenessing ss. by J. F. Carll in 1880 (2d Pa. Geol. Survey Rept. I_5, p. 82), also by Ashburner in 1880 (2d Pa. Geol. Survey Rept. R). Thickness 45 to 60 ft.

Named for exposures in Kinzua Creek Valley, McKean Co.

Replaced by Connoquenessing ss. memb. of Pottsville fm.

Kiowa shale.

Lower Cretaceous (Comanche series): Central southern Kansas.

F. W. Cragin, 1894 (Colo. Coll. Studies, 5th Ann. Pub., p. 49). *Kiowa sh.*—Inferiorly dark-colored and superiorly light-colored fossiliferous shales, a locally modified northern extension of part of Hill's Comanche series, cut off from main part by erosion. Eastern exposures rest on Cheyenne ss., middle and western exposures rest on "Red-beds." Overlain by brown sss. of middle Cret. age or by Tert. or Pleist. deposits.

F. W. Cragin, 1895 (Am. Geol., vol. 16, pp. 361, 368), redefined *Kiowa sh.* so as to exclude basal oyster bed, 1½ ft. thick, which he named *Champion shell bed.* In 1896 Cragin restored the oyster bed to Kiowa sh., and that classification has since been followed by all writers, and adopted by U. S. Geol. Survey, also by Kans. Geol. Survey (Bull. 9, 1924, by W. H. Twenhofel).

F. M. Bullard, 1928 (Okla. Geol. Surv. Bull. 47, p. 50). It may seem advisable to separate Champion shell bed from the Kiowa, especially if it represents any part of the Fredericksburg. Considering Kans. area alone, the Champion may well be included with the Kiowa, but for convenience of description it is here separated from Kiowa.

Named for Kiowa Co.

Kipp sandstone. (In Bearpaw shale.)

Upper Cretaceous: Southern Alberta (Lethbridge region).

T. A. Link and A. J. Childerhose, 1931 (A. A. P. G. Bull., vol. 15, No. 10, pp. 1232, 1236). *Kipp ss.*—Top lies 410 ft. above base of Bearpaw sh. and 150± ft. below Rye Grass ss. Base lies 100± ft. above McGrath ss. Thickness 40 ft. Named for outcrop on N. bank of Oldman River 1½ mi. SW. of Kipp Station. Of light greenish-blue color; coarse locally, and readily distinguished in diamond cores. A thin zone of glauconitic sand, 3± ft. thick, lies 30 ft. above its top. Many bentonite beds occur directly above upper ledge of this ss., but very few occur below it.

†Kirby clay.

Lower Cretaceous (Comanche series): Central southern Kansas.

C. N. Gould, 1898 (Am. Jour. Sci., 4th, vol. 5, pp. 170–174). *Kirby clays.*—Yellowish clays, aren. below, reddish above, containing several beds of light-yellow ss. Thickness 20 to 130 ft. Underlies Reeder ss. and overlies Greenleaf ss. Included in Medicine beds.

Named for Kirby, or C. W., or Fullington ranch, on upper Medicine River, 10 or 12 mi. W. of Belvidere, Kiowa Co.

The U. S. Geol. Survey discarded this name in 1921, the beds to which it was applied being regarded as Kiowa sh.

Kirby granite.

Age (?): Northeastern Vermont (Kirby Township, Caledonia County). See under *Knox Mtn granite*, 1906.

Kirk gas sand.

Occurs in upper part of section in Graham field, NW. part of Carter Co., Okla., 320 or 400 ft. below Moyer gas sands and 250 to 500 ft. above Johnson oil and gas zone. Thickness 30 to 125 ft. According to Okla. Geol. Surv. Bull. 40Q, 1928, p. 179, this sand is Perm.; according to C. W. Tomlinson and W. Storm (A. A. P. G. Bull., vol. 8, pp. 593–620, 1924, and Okla. Geol. Surv. Bull. 40Z, 1928) it is Penn.

Kirker tuff.

Oligocene: Western California (San Francisco Bay region).

B. L. Clark, 1918 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 11, pp. 54–111). *Kirker tuff.*—In Sobrante anticline, in Concord quad., the fm. consists of about 100 ft. of fairly indurated white tuff beds, which contain a few minor layers of tuffaceous ss., the fm. as a whole being very fine and homogeneous in texture, and discon. overlain by Concord fm. and underlain by San Ramon fm. At type loc. (on Kirker Creek, N. of Mount Diablo) the fm. consists of (descending): Tuffaceous ss., 50 ft.; rhyolitic white tuff beds with lentils of bluish tuffaceous ss., 350 ft.; and ss., tuffaceous toward top, 50 ft., resting discon. on Markley fm. and uncon. overlain by San Pablo fm. In latter region the beds were included in San Pablo by Turner (1898) and Weaver (1909).

Kirker's Pass beds.

Miocene: Western California (Mount Diablo region).

J. P. Smith, 1910 (Jour. Geol., vol. 18, table opp. p. 226). [*Kirker's Pass beds with Santa Margarita fauna* appears in column headed "Mount Diablo region." Assigned to middle Mio. and correlated with upper part of San Pablo.]

Kirkfield limestone group.

Ordovician: Ontario.

R. A. Johnston, 1911 (Canada Geol. Surv. Summ. Rept. 1910, p. 190).

Kirkland formation.

Name proposed by E. O. Ulrich in 1918 (Geol. Soc. Am. Bull., vol. 29, p. 82), for a part of Clinton fm. of N. Y., Pa., and Md., but practically abandoned by him in 1923. See explanation under *Clinton fm.*, 1918 and 1923 entries.

Kirkland limestone and iron ore.

Name proposed by G. H. Chadwick in 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 327–368), for a bed, 6 ft. thick, in the upper part of the pre-Rochester part of Clinton fm. See explanation under *Clinton fm.*, 1918 entry.

Kirkland Lake series.

Pre-Cambrian: Quebec.

M. E. Wilson, 1918 (Canada Geol. Surv. Mem. 103, p. 52).

Kirkwood formation.

Miocene (middle): New Jersey Coastal Plain.

G. N. Knapp, 1904 (N. J. Geol. Surv. Ann. Rept. State Geol. 1903, pp. 81–82). *Kirkwood fm.* (Mio.), underlies Cohansey fm. It carries water-bearing sands at several different strat. horizons.

H. B. Kümmel, 1909 (Jour. Geol., vol. 17, p. 373). *Kirkwood fm.*—Sand and clay, 100 ft. thick. Consists of fine clayey sand, 10 to 20 ft. thick (the Shiloh marl of many repts) underlain by 80 to 90 ft. of chocolate or drab-colored clay. Uncon. overlies Shark River marl and uncon. underlies Cohansey fm.

Named for exposures at Kirkwood, Camden Co.

Kirkwood sand.

A subsurface sand of Chester (Miss.) age in Ind. that has been correlated with Mooretown ss. of Cumings. Also a sand in Chester group of Ill. (See Ill. Geol. Surv. Bull. 54, index.)

Kirtland shale.

Upper Cretaceous (of Montana age): Southwestern Colorado and northwestern New Mexico.

C. M. Bauer, 1916 (U. S. G. S. P. P. 98P). *Kirtland sh.*—Predominantly clayey. Mostly gray sh. with some brown, bluish, greenish, and yellowish shales, easily weathering gray-white ss., and, in upper part, the brown resistant Farmington ss. memb. So far as known the fm. is of fresh-water origin, although possibly formed in deltas and lagoons. Thickness 836 to 1,180 ft., including Farmington ss. memb., which is 0 to 455 ft. thick, lies 40 to 110 ft. below top of the Kirtland and 271 to 830 ft. above its base. The Kirtland grades into underlying Fruitland fm. and is overlain, with apparent conformity, by Ojo Alamo ss. Was included in so-called Laramie of Holmes' 1877 rept. Named for exposures at Kirtland P. O., San Juan Co., N. Mex.

J. B. Reeside, Jr., 1924 (U. S. G. S. P. P. 134, pp. 22–25). *Kirtland sh.* (*restricted*).—Consists of three members (all of fluviatile origin): Upper sh. memb., 12 to 475 ft. thick; middle or Farmington ss. memb., 20–480 ft. thick; lower sh. memb., 271–1,031 ft. thick. Grades into underlying Fruitland fm. Except near Durango, Colo., the overlying McDermott fm. seems to be conformable with Kirtland, and the bdy btw. the two is arbitrary. In Durango region the McDermott appears to be uncon. with Kirtland. The McDermott fm. (150 to 200 ft. thick in San Juan Co., N. Mex.) was included in uppermost part of Kirtland sh. of Bauer (1916) and in part in Kirtland sh. of Bauer and Reeside (U. S. G. S. Bull. 716, 1921). [For his opinion as to age see 1924 entry under *Fruitland fm.*]

Kiser gypsum member (of Blaine gypsum).

Permian: Southwestern Oklahoma.

C. N. Gould, 1902 (Okla. Geol. Surv. 2d Bien. Rept., pp. 42, 55). *Kiser gyp.*—Soft bluish or greenish to drab or gray gyp., 1 to 3 ft. thick, occurring in shales which separate Chaney gyp. below from Haystack gyp. above. Included in Greer div. The Kiser is older than Haystack gyp., Cedartop gyp., Collingsworth gyp., and Mangum dol.

C. N. Gould, 1924 (A. A. P. G. Bull., vol. 8, No. 3). [See under *Chaney gyp. memb.*]

Named for Kiser salt plain, on Elm Fork, Greer Co.

Kishenehn formation.

Tertiary (Eocene?): Southern British Columbia.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 86). *Kishenehn fm.*—Fresh-water deposit (lake beds) of Tert. age, not known to have an exact strat. equiv. anywhere else in area covered by Commission. Thickness of 250 ft. is exposed in Flathead trough at Boundary line; total thickness in wells probably 700 ft. Tert. fossils (Eocene or later). Named for Kishenehn Creek. Dawson discovered same fm. near mouth of the Kishenehn in 1885, and Willis encountered it in 1901 on N. Fork of the Flathead. He regarded it probably Mio. or Plio. [According to Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, sheets 1 and 2) this fm. does not extend into Mont. but stops at Int. Bdy. Mackenzie, 1916 (Canada Geol. Surv. Mem. 87, p. 31), spelled this name *Kishinena*, and Rose, 1918 (Canada Geol. Surv. Summ. Rept. 1917, pt. C, p. 31), spelled it *Kishenena*.]

Kishwaukee moraine.

Pleistocene (Wisconsin stage): Northeastern Illinois. (See M. M. Leighton, 16th Int. Geol. Cong. Guidebook 26, 1933, p. 51.)

Kiskatom formation.

Middle Devonian: Southeastern New York (Greene, Albany, Ulster, and Schoharie Counties).

G. H. Chadwick, 1932 (Eastern States Oil and Gas Weekly, vol. 1, No. 17, p. 7). Under the supposed "Oneonta" reds (lower Ithaca or Otselic and older than true Oneonta), in Albany and Greene Counties, are reds once included in the Catskill that prove to be of upper Hamilton age. We shall call them *Kiskatom red beds*. They occur only in Hudson Valley.

G. H. Chadwick, 1933 (Sci., n. s., vol. 77, pp. 86–87). A. G. Cooper's field work this summer, with which he has kept me informed, has shown that top of Hamilton (middle Dev.) goes even higher in the red beds than I had supposed. Publication of his results will be awaited with greatest interest, but meantime it seems wise to extend term *Kiskatom*, following the original intention, up to top of middle Dev. reds, until such time as these may submit to subdivision. Overlies Ashokan.

G. H. Chadwick, 1933 (Am. Jour. Sci., 5th, vol. 26, p. 480), showed *Kiskatom red beds* as underlying Onteora red beds and overlying Ashokan flags.

G. H. Chadwick and G. M. Kay, 1933 (16th Int. Geol. Cong. Guidebook 9A, pp. 4–7). *Kiskatom red beds* include the continental red and gray shales and sss. that have been called *Oneonta*, though they are considerably older than typical Oneonta, which occurs farther W. They overlie Ashokan bluestone.

G. H. Chadwick, 1935 (Am. Mid. Nat., vol. 16, No. 6, p. 857). To the Hamilton red beds of Greene, Albany, Ulster, and Schoharie Counties, N. Y., the name *Kiskatom fm.* is now applied, pending time when this mass may be more accurately subdivided. The original Catskill fm. of Mather included all of Kiskatom (2,500± ft. thick, including the Tully) and perhaps a little of overlying beds of Genesee age, but since Catskill has later come to apply to Upper Dev. beds, it may be best to let that name continue to be used for post-Kiskatom strata. Westward the Kiskatom passes into the familiar marine beds, the Skaneateles, Ludlowville, and Moscow of Hamilton group.

Kiski volcanics.

Pre-Cambrian: Manitoba.

F. J. Alcock, 1920 (Canada Geol. Surv. Mem. 119, p. 16).

Kisner sand.

A subsurface sand, 10 ft. thick, in central northern Okla., correlated with part of Garrison sh. (Perm.). In Garber pool (Garfield Co.) it is reported to lie at 700 ft. depth. See under *Hoy sand*.

Kisseynew gneisses.

Pre-Cambrian: Saskatchewan.

E. L. Bruce, 1918 (Canada Geol. Surv. Mem. 105, p. 27).

Kissinger sand.

A subsurface sand, of Penn. age, in Kissinger and Moren fields, Young Co., north-central Tex., lying at 2,400 to 2,500 ft. depth.

Kitchener quartzite.

Pre-Cambrian: Southeastern British Columbia and northwestern Montana (Purcell Range).

R. A. Daly, 1905 (Canada Geol. Surv. Summ. Rept. 1904, pp. 96–100). *Kitchener qtzite.*—Hard sss. and argillites interbedded; contain high proportion of disseminated iron oxides; thin-bedded; ripple marks; sun cracks. Thickness 7,400 ft. in section along Int. Bdy btw. Port Hill, Idaho, and Gateway, Mont. Conformably underlies Moyie argillite and conformably overlies Creston qtzite. The intrusive Moyie sill of gabbro, 2,500 ft. thick, lies in middle of Kitchener qtzite.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, map 4, 115°30′ to 116°). *Kitchener qtzite.*—Thin- to thick-bedded greenish-gray qtzite and metargillite; somewhat dolomitic in places. Upper part is=Siyeh fm., and lower part is=Wigwam fm.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, pp. 128, 257). *Kitchener fm.* was named for station on Canadian Pacific Ry (in Kootenay Province of B. C.).

Kitchi schist.

Pre-Cambrian (Keewatin): Northwestern Michigan (Marquette district).

C. R. Van Hise and W. S. Bayley, 1895 (U. S. G. S. 15th Ann. Rept., pp. 490, 492, 496+). *Kitchi schists.*—Greenstone schists characterized by pebble and boulder-like bodies scattered through them, which are so well rounded that the rocks look like a sedimentary cgl. Indeed, so conglomeratic are their features that they have frequently been called *Deer Lake cgls.* [p. 496]. But they are plainly basic tuffs, which have preserved their tuffaceous character much more perfectly than the banded varieties of Mona schists. Differ from Mona schists in composition, but are of about same age as the Mona. Exposed on Kitchi Hills, in vicinity of Deer Lake.

Kitsalas formation.

Triassic (?): British Columbia.

R. G. McConnell, 1913 (12th Int. Geol. Cong. Guidebook 10, p. 17).

Kitsilano formation.

Tertiary: British Columbia.

W. A. Johnston, 1923 (Canada Geol. Surv. Mem. 135, p. 23).

Kittanning coal group. (In Allegheny formation.)

Pennsylvanian: Western Pennsylvania and Maryland.

J. P. Lesley and I. C. White, 1876 (2d Pa. Geol. Surv. map of southern Butler County). [The block beneath Darlington coal reads (descending): "*Kittanning group,* Kittanning coal." This map is in library of U. S. G. S.]

J. P. Lesley, 1877 (2d Pa. Geol. Surv. Rept. H_5, p. xxiii), divided Lower Productive Coal Measures [Allegheny fm.] into (descending) Freeport coal group, *Kittanning coal group,* and Clarion coal group.

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q). *Kittanning group* extends from top of Upper Kittanning coal to top of the Buhrstone iron ore overlying the Ferriferous (Vanport) ls.

G. H. Ashley, 1926 (Pa. Topog. and Geol. Atlas, No. 65, Punxsutawney quad., pl. 4, p. 28). *Kittanning fm.* includes beds from top of Upper Kittanning coal to top of Vanport ls. memb.

Kittanning coal group is treated by U. S. Geol. Survey as an economic memb. in middle of Allegheny fm. In Md. it includes Upper, Middle, and Lower Kittanning coals and, at base, Split-six coal.

Kittanning sandstone member (of Allegheny formation).

Pennsylvanian: Western Pennsylvania and eastern Ohio.

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q). *Kittanning (Industry) ss. and sh.*—In Beaver Co., Pa., is 42 to 50 ft. thick. At Industry, on Ohio River, it is 50 ft. thick and forms massive vertical cliff. Underlies Kittanning fire clay [Lower Kittanning clay] and lies 30 ft. above Vanport ls.

W. G. Platt, 1880 (2d Pa. Geol. Surv. Rept. H_6 p. 283). *Kittanning ss.*—Coarse-grained to pebbly ss. 25 to 40 ft. thick. Underlies Middle Kittanning coal and lies higher than Lower Kittanning coal. Exposed in small ravine btw. village of Worthington and Buffalo mills, and extends to W. edge of Worthington, which town is built on it. [As defined this is a younger ss. than Kittanning ss. memb. of generally accepted nomenclature, which is older than Lower Kittanning coal. On p. xxi of this rept. J. P. Lesley says this ss. "might receive the name of *Pine Creek ss.* east of the river, or of *Worthington ss.* west of the river, because of the fine exhibitions which it makes in those localities." On p. 319 Lesley says this ss. "may be called *Pine Creek ss.* where it is a cgl. It usually comes under Kittanning Middle coal, but sometimes occupies interval between Kittanning Upper coal and Kittanning Lower coal. *Worthington ss.* would be a good name for it."]

I. C. White, 1891 (U. S. G. S. Bull. 65). *Kittanning ss.* is separated from overlying Lower Kittanning coal by Kittanning fire clay, 0 to 15 ft. thick. [This is definition of Kittanning ss. now in use.]

Kittanning shale. (In Allegheny formation.)

Pennsylvanian: Western Pennsylvania.

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q). *Kittanning (Ferriferous) sh. and ore.*—Dark sandy shales with nodular iron ore.. Thickness 35 to 40 ft. Overlies Lower Kittanning coal. May represent Johnstown cement bed.

I. C. White, 1879 (2d Pa. Geol. Surv. Rept. Q_2). *Kittanning sh.*—Sandy shales, 35 to 50 ft. thick. Overlie Middle Kittanning coal and underlie Darlington (Upper Kittanning) coal. Seldom exposed in Lawrence Co.

Kittanning fire clay. (In Allegheny formation.)

Pennsylvanian: Southwestern Pennsylvania.

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q). *Kittanning (New Brighton) fire clay.*—Underlies Lower Kittanning coal and overlies Kittanning ss.

Is same as *Lower Kittanning clay* of current nomenclature. Is an economic bed in Allegheny fm. Has been mined at Kittanning, Pa., and at New Brighton, Beaver Co., Pa.

Kittanning limestone. (In Allegheny formation.)

Pennsylvanian: Ohio.

E. Orton, Jr., and S. V. Peppel, 1904 (Ohio Geol. Surv. Bull. 3, p. 92), applied *Middle Kittanning ls.* and *Lower Kittanning ls.* to 2 lss. occurring lower in Ohio section than Freeport ls. and higher than Lower Kittanning (No. 5) coal.

Kittanning formation.

See under *Kittanning coal group*, G. H. Ashley, 1926. The name was first used by Ashley in a table in Eng. and Min. Jour.-Press, vol. 115, No. 25, 1923, pp. 1106–1108, but was not defined.

Kittatinny limestone.

Cambrian (Upper, Middle, and Lower?) and Lower Ordovician: Northern New Jersey.

H. D. Rogers, 1840 (N. J. Geol. Surv. 2d and Final Rept., p. 112), applied *Kittatinny ls.* to the ls. "described in preceding pages" as blue ls. or fm. No. 2 of northern N. J. Overlies white quartzose ss. and underlies 3,000 ft. of dark argill. sl. composing fm. No. 3. Thickness probably 2,000+ ft. [As thus defined included Jacksonburg ls. of present nomenclature.]

H. B. Kümmel and S. Weller, 1901 (Geol. Soc. Am. Bull., vol. 12, p. 151; N. J. Geol. Surv. Ann. Rept. 1900, pp. 4, 30–40). *Kittatinny ls.*—Mostly dolomitic and unfossiliferous, variable in texture, bedding and color; color usually blue or gray, sometimes nearly black; in places a pinkish tinge. Thickness 2,500 to 3,000 ft. Nearly all ls. of Kittatinny Valley and the allied highland valleys is included in this fm. Uncon. underlies Trenton ls. [Jacksonburg ls.] and conformably overlies Hardiston qtzite. Contains Beekmantown and Upper Camb. fossils. In previous repts called Mag. ls. and "blue" ls.

†Kittatinny sandstone.

A name casually applied by H. D. Rogers (N. J. Geol. Surv. 2d and Final Rept., p. 112, 1840) to the cgl. later named *Shawangunk cgl.* Conflicts with Kittatinny ls. of same area.

Kittery quartzite.

Carboniferous (Pennsylvanian?): Southwestern Maine and southeastern New Hampshire.

F. J. Katz, 1917 (Wash. Acad. Sci. Jour., vol. 7, p. 198). *Kittery qtzite.*—Thin-bedded qtzites and argillites, extending, in a belt about 10 mi. wide, along coast from Saco, Maine, to Portsmouth, N. H., and continuing thence inland in SW. direction to Merrimack River, where it forms [part of] the Merrimack qtzite of Mass. Is of Carbf. (Penn.?) age.

F. J. Katz, 1917 (U. S. G. S. P. P. 108, p. 168). *Kittery qtzite.*—Banded flinty and vitreous qtzites, subordinate argillitic and micaceous qtzites, some argillite, and very thin beds of micaceous sl. and schist; all fine grained and characteristically thin bedded. Most striking feature is a fine interbanding of various tones of dark gray, bluish, chocolate-brown, and black with a little light gray and white. Is only slightly metamorphosed. Estimated minimum thickness 1,500 ft.; maximum unknown. In SW. Maine overlain, conformably, by Casco Bay group and by the in part contemp. Eliot sl. Overlies Berwick gneiss, either uncon. or by fault contact. Assigned to Penn. (?). Named for exposures in Kittery, York Co., Maine.

†Kittitas system.

Eocene: Western central Washington (Puget Sound region).

I. C. Russell, 1893 (U. S. G. S. Bull. 108). *Kittitas system.*—Shales, sss., and valuable coal seams, including the coal at Roslyn. Well exposed in W. part of Kittitas Co. Future study may show it can be subdivided. Uncon. overlies crystalline rocks and underlies Columbia lava.

I. C. Russell, 1900 (U. S. G. S. 20th Ann. Rept., pt. 2, p. 118). "Kittitas system," provisional name, is divided into Swauk and Roslyn fms., and "Kittitas" abandoned.

Kitzault River formation.

Jurassic: British Columbia.

G. Hanson, 1922 (Canada Geol. Surv. Summ. Rept. 1921, pt. A, p. 11).

†Klamath schists.

†Klamath schist series.

Pre-Cambrian (?): Northern California (Klamath Mountains).

Terms used by O. H. Hershey (Am. Geol., vol. 27, pp. 225–245, 1901) to include Abrams mica schist (sedimentary) and Salmon hornblende schist (intrusive).

Klamath gravels.

Pleistocene: Northern California (Weaverville and Red Bluff quadrangles).

N. E. A. Hinds, 1933 (Calif. Jour. Mines and Geol., vol. 29, Nos. 1 and 2, pp. 120–121). At many places along various canyons of Weaverville quad. are deposits of boulders, pebbles, gravel, and sand similar in appearance to Red Bluff gravels of Redding quad. but generally coarser in texture. Considerably dissected. Present thickness 50 to 100+ ft. Apparently deposited during the Pleist., when the streams were supplied with an exceptional amount of coarse detritus. Rest uncon. on all other fms. Pleist. bones in Weaverville quad. These gravels are continuous with Red Bluff deposits of Redding and Red Bluff quads. Since they are so widespread through the canyons of Klamath Mtns, and since they are so much coarser-textured than the flood-plain phase at type loc. near Red Bluff, writer proposes for them the name *Klamath gravels.* The *Red Bluff* is an accumulation over a surface of low relief deposited by sluggish streams and should be designated *Red Bluff phase.* Upstream this phase grades into the coarser Klamath type near city of Redding. Part of Red Bluff as mapped by Diller is Tehama fm.

Klein sand.

A subsurface sand in Chester group (Miss.) of Marion Co., Ill. (See Ill. Geol. Surv. Bull. 54, index.)

Klondike series.

Pre-Cambrian (?): Canada (Klondike gold fields).

R. G. McConnell, 1900 (Canada Geol. Surv. Rept. on Klondike gold fields, pp. 8–9).

Klondike drift.

Tertiary: Canada.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 220).

Klondike member. (In Columbus limestone.)

Middle Devonian: Central Ohio (Delaware County).

L. G. Westgate, 1926 (Ohio Geol. Surv., 4th ser., Bull. 30, pp. 17, 22–25). *Klondike member.*—Blue-gray, massive, thick-bedded, fossiliferous ls., weathering thin bedded. Thickness 38 to 40 ft. Top memb. of Columbus ls. in Delaware Co. Overlies *Sp. macrothyris* zone. Was called Delhi beds by Winchell (Ohio Geol. Surv., vol. 2, p. 296, 1874), from old name of Radnor. Makes most of Venice and Marblehead members of Swartz. Best exposed at quarry of Scioto Lime & Stone Co., popularly known as Klondike quarry.

Klusha intrusives.

Tertiary or Pleistocene: Yukon Territory.

D. D. Cairnes, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 51).

Klutina group.

Carboniferous or older: Alaska (Copper River region).

F. C. Schrader, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 410, 413). The Valdes rocks, roughly speaking, extend N. to region of Lake Klutina. Here they form base of the mtns, are still exposed in lower reaches of gulches, but gradually give way to a different class of rocks, which appear above Lake Klutina in upper slopes of the mtns and extend into foothills at edge of Copper River Plateau. These rocks are provisionally called *Klutina series.* They form most of the mtns about the lake and seem to overlie Valdes rocks. They consist of mica schists, quartz schists, sometimes cherty or jaspery, and crystalline ls. or marble. Judging from lithologic resemblance they may belong to Fortymile series. If so, they are probably pre-Sil.

A. H. Brooks, 1906 (U. S. G. S. P. P. 45, p. 256). Valdez rocks rest, probably uncon., on *Klutina series.*

T. Chapin, 1918 (U. S. G. S. Bull. 668, p. 22), assigned *Klutina group* to Carbf. or pre-Carbf.

Knapp formation.

Devonian or Carboniferous: Southwestern New York and northern Pennsylvania.

L. C. Glenn, 1903 (N. Y. State Mus. Bull. 69, pp. 967–989). *Knapp beds.*—In Salamanca quad. there are beneath Olean cgl. two thin cgls. interbedded with shales lithologically very similar to Oswayo shales. These are doubtless in part at least equivalents of grits and shales just beneath the Olean at rock city and which are there included in the Oswayo, but which evidently thicken and coarsen westward till they are capable of differentiation as *Knapp fm.* Most eastern exposure is at Knapp's Creek Station (Cattaraugus Co., N. Y.), where there are two coarse beds separated by varying thickness of sh. Consist of (descending): Sh., 25 to 30 ft.; cgl., 10 to 15 ft.; sh., 30 to 40 ft.; and cgl., 10 to 20 ft. Overlie Oswayo beds and underlie Olean cgl., probably uncon. The last Devonic forms disappear at top. Assigned to Carbonic.

C. Butts, 1910 (U. S. G. S. Warren folio, No. 172). *Knapp fm.* was long known in Pa. repts as "*sub-Olean cgl.*" It lies 350 to 400 ft. lower than Shenango ss., with which it has heretofore been correlated.

The Knapp, Oswayo, and Cattaraugus fms. were assigned to Carbf. by J. M. Clarke (1903 Hdb.), by C. A. Hartnagel (1912 Hdb.), and by E. O. Ulrich (Geol. Soc. Am. Bull., vol. 22, 1911). They were classified as "Devono-Carboniferous" by C. Butts in 1910 (U. S. G. S. Warren folio, No. 172), and were assigned to Dev. by W. A. VerWiebe, 1917 (Am. Jour. Sci., 4th ser., vol. 44), by G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, pp. 68–69), 1924 (N. Y. State Mus. Bull. 251, p. 157), and 1925 (Geol. Soc. Am. Bull., vol. 36, pp. 455–464), and by C. Schuchert (1924 Textbook of geology). (See further explanation under †*Bradfordian*, which included all these fms.)

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, pp. 202–203). *Knapp fm.* (*revised Cussewago group*) of NW. Pa. is here divided into (descending): Hayfield sh. memb. (including Littles Corner ls.); *Glade ss. memb.* ("Sub-Olean"–Knapp cgl.); Ridgway sh. memb.; Ludlow cgl. memb. ("Lower Knapp cgl."); and

Smethport sh. memb. or lower upper "Riceville" sh. All are of Miss. age. [He did not explain relations of his Glade ss. to Cussewago ss., nor did he define the various members.]

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61, pp. 61, 103–104), replaced some of names given in his 1933 paper cited above, as follows: Glade ss. replaced by Cobham ss.; Ridgway sh. replaced by East Kane sh.; Ludlow cgl. replaced by Wetmore cgl.; Smethport sh. replaced by Kushequa sh.; and he divided his 1933 Hayfield sh. into (descending) Hayfield sh. [restricted] and Tidioute sh. memb., the latter present but only "meagerly developed" at Hayfield type loc. He assigned all of these beds to Miss., and included them in his Knapp monothem. On p. 41 he stated: "At base of *Knapp sh.* (Kushequa sh. of this rept.) there is a faunal and lithic break," and he drew Miss.-Dev. bdy at this point. (See also under his *Knapp formational suite* and his *Knapp monothem.*)

G. H. Chadwick, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, p. 332), assigned his Hayfield sh. and underlying fms. to Upper Dev. (See Chadwick, 1935 entry under *Conewango fm.*)

C. Butts, 1936 (personal communication). Typical Knapp fm. is only Cobham cgl. memb. of Caster, and contains true Kinderhook fossils. Caster's East Kane sh. and underlying beds are part of typical Conewango fm. of Warren folio.

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, p. 593). The Knapp persists far enough S. to tie in with lower part of basal memb. of the Pocono, the "Berea," if, indeed, it is not actually the attenuated equiv. of that entire memb. [p. 593.] In north-central Pa. the basal Pocono or Knapp rests directly upon the Elk Mtn, or Oswayo, depending upon whether the latter be continental or marine. [p. 600.]

In view of lack of agreement as to age of Knapp, Oswayo, and Cattaraugus fms. the U. S. Geol. Survey at present classifies them as *Dev. or Carbf.*

Knapp formational suite.

Devonian or Carboniferous: Southwestern New York and northwestern Pennsylvania.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 60, p. 111). [*Knapp formational suite* is shown as occurring in lower part of "Cussewago stage," as underlying Tidioute sh. memb. (new name for a sh. which he placed below Hayfield sh.) and overlying Kushequa sh. memb. (new name), and as divided into 3 newly named members, in descending order, Cobham cgl. memb., East Kane sh. memb., and Wetmore cgl. memb., and is assigned to Miss.]

Knapp monothem.

Devonian or Carboniferous: Southwestern New York and northwestern Pennsylvania.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, pp. 103–104). *Knapp monothem* (Miss.) as used in this rept is extended down to include the chocolate-colored aren. (Oswayo-like) sh. beneath lower cgl. memb. of Knapp fm. of Glenn. This sh., which is here named *Kushequa sh. memb.*, contains the very characteristic Knapp fauna. Above the upper Knapp cgl. memb. is also a sh. memb. which is part of the monothem. This upper sh., which is usually eliminated by the Olean nonconformity E. of Warren, Pa., is known as *Hayfield fm.* [As defined above Knapp monothem of Caster includes his Knapp formational suite and younger and older beds than he included under latter designation, and according to his table opp. p. 61 it is = his Cussewago monothem = his Cussewago stage.]

†Knife slates.

See under *Knife Lake sl.*

Knife Lake slate.

Pre-Cambrian (pre-Huronian ? and post-Laurentian): Northeastern Minnesota (Vermilion district).

C. R. Van Hise and J. M. Clements, 1901 (U. S. G. S. 21st Ann. Rept., pt. 3, pp. 401–409, map). *Knife slates.*—Named for Knife Lake, where specially developed. Uncon. underlie Gunflint fm. and overlie Lower Huronian iron-bearing fm. [Agawa].

J. M. Clements, 1903 (U. S. G. S. Mon. 45). *Knife Lake slates.*—Slates of varying characters, dark- and light-colored. Thickness 2,500+ ft. Conformably overlie Agawa fm. and underlie Gunflint fm.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), redefined *Knife Lake sl.*, by including in it *Agawa iron-fm. memb.* (as they designated it) and underlying *Ogishke cgl. memb.*; they also removed it tentatively from Huronian series and assigned it to *Knife Lake series*, of pre-Huronian and post-Laurentian age.

Knife Lake series.

Pre-Cambrian (pre-Huronian ? and post-Laurentian): Northeastern Minnesota (Mesabi and Vermilion districts and Rainy Lake region).

F. F. Grout, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 5, pp. 992–995). *Knife Lake series.*—Shows poorly assorted sediments, with no clear qtzites or lss. Uncon. underlies Animikie series and overlies Keewatin greenstone. Includes Knife Lake sl. and, at base, Ogishke cgl., which is erratic in occurrence and thickness but may locally be hundreds of ft. thick. The Knife Lake sl. is interfingered with or overlies Ogishke cgl. Recent (1929) work by J. W. Gruner indicates the series may be a complex with some unconformities and igneous activity, but in the areas mapped slates and graywackes of fairly constant nature largely predominate over cgl. and volcanic rocks. The slates are widely exposed at type loc., Knife Lake, and extend W. far along Vermilion dist. as synclines in the area of Keewatin greenstone. Has been considered Archean or Lower Huronian.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), redefined *Knife Lake sl.* (by including in it, as members, the Agawa iron-fm. and Ogishke cgl.), and on the map assigned it and contemp. deposits in Ontario to the newly recognized *Knife Lake series*, herein classified as of pre-Huronian and post-Laurentian age, but which may eventually prove to be Lower Huronian. In U. S. G. S. Mon. 52, 1911, these rocks were called "lower-middle Huronian." They rest with marked uncon. on Laurentian and Keewatin rocks and underlie, with conspicuous angular discordance, the Middle Huronian group. They are closely folded, metamorphosed, and intruded by granites of Algoman age.

Knight formation. (In Wasatch group.)

Eocene: Southwestern Wyoming.

A. C. Veatch, 1907 (Jour. Geol., vol. 15, pp. 547–549). *Knight or Coryphodon beds* is proposed for upper part of Wasatch of SW. Wyo. containing *Coryphodon* remains. Named for Knight Station [Uinta Co.], which is near place where fossils belonging to this genus were first found in No. Am., and where typical upper Wasatch is well developed. Rests uncon. on Fort Union.

A. C. Veatch, 1907 (U. S. G. S. P. P. 56). *Knight fm.*—Variegated yellow and red sandy clays, with irregularly bedded white and yellow sss. Contains *Coryphodon* and other animal remains. Thickness 500 to 1,500± ft. Top fm. of Wasatch group in SW. Wyo. Underlies Green River fm. and uncon. overlies Fowkes fm. (middle fm. of Wasatch group).

†Knob sandstone.

Mississippian: Indiana and western-central Kentucky.

D. D. Owen, 1856 (Ky. Geol. Surv. Rept., vol. 1, pp. 89 and 90). Sub-carbf. ss., called *"Knob fm."* because it weathers into conical hills. Greenish-gray argill. ss. and brown ss., with argill. shales in lower part, and locally earthy ls. beds. Thickness 200 to 400 ft. Overlain by sub-carbf. lss. and underlain by Dev. Black Lingula shales.

Same as †Knobstone fm. or group, but the nongeographic terms "Knob ss." and "Knob sh." have also been applied to separate fms. in this group of beds, which is now called *Osage group* and divided into several fms., named (descending) Holtsclaw ss., Rosewood sh., Kenwood ss., and New Providence sh.

†Knob shale.

A descriptive term applied in some early repts to New Providence sh. of Ind., and also to New Providence and Rosewood shales.

†Knob limestone.

A descriptive term applied in some early repts to the basal Miss. lss. of Ind.

Knob Creek facies.

Name applied by P. B. Stockdale (Ind. Dept. Cons., Div. Geol. Pub. 98, pp. 76, 163, etc., 1931) to a lithologic development of his Carwood fm. in a part of southern Ind.

Knob Hill group.

Pre-Carboniferous: British Columbia.

O. E. Le Roy, 1912 (Canada Geol. Surv. Mem. 21, pp. 19, 26, 30).

Knob Lick granite.

Pre-Cambrian: Southeastern Missouri.

C. R. Keyes, 1895 (Mo. Geol. Surv. Sheet Rept. No. 4 (vol. 9), pp. 18, 19, 24). ***Knob Lick granite.***—Rather coarse-grained, very compact granite, of reddish to bluish color, in texture approaching porphyritic. Thickness 400 ft. Underlies Iron Mtn porphyry in Mine La Motte dist. Assigned to Archean.

J. Bridge, 1930 (personal communication). Knob Lick granite is now considered by Mo. geologists to be probably Algonkian.

Named for Knob Lick, St. Francois Co.

†*Knob Noster group.*

Pennsylvanian: Central western Missouri.

G. C. Broadhead, 1873 (Mo. Geol. Surv. Prel. Rept. on Iron Ores, pt. 2, pp. 169, 176). *Knob Noster group.*—Shales, clays, and lss., 97 ft. thick, including beds 16 to 33 of detailed section of lower Coal Measures from Sedalia to Kansas City. Underlies Warrensburgh group and overlies bed 15 of detailed section.

Is a part of Cherokee sh.

Named for exposures at Knob Noster, Johnson Co.

Knobs-Cherokee coal group.

Name locally applied to Lance fm. of Rock Springs uplift, Sweetwater Co., SW. Wyo. (See U. S. G. S. Bull. 702, 1920.)

†Knobstone formation.

†Knobstone group.

Names applied in early repts on Ind. and western Ky. to the Miss. rocks of Osage age, the term being derived from tendency of the rocks to weather into conical hills called knobs. Cumings has proposed *Borden group* to replace this descriptive term.

†Knobstone sandstone.

A term applied in early Ind. repts to Holtsclaw ss. of SE. Ind.

Knobsville continental beds.

Middle Devonian: Central Pennsylvania (Fulton County).

B. Willard, 1935 (Geol. Soc. Am. vol. 46, Proc. Pal. Soc. Feb. 28, pp. 202, 214, 215, 221). In northern Fulton Co. are 800 to 1,000 ft. of fresh-water beds of Hamilton (Mahantango) age to which *Knobsville cgl. phase* may be applied. They are well developed btw. Knobsville and Hustontown and northward toward Fort Littleton, where they are exposed in highway cuts. Here Marcellus black sh. passes up into what are probably a few ft. of normal but barren Mahantango shaly beds, which are succeeded by barren red or green beds (the Knobsville continental beds), which continue upward into post-Hamilton members with no trace of Genesee. Grade laterally into marine Mahantango shales and sss. In places usurp most of the Mahantango. Contemp. in part with Montebello ss.

Knobtown sand.

A subsurface sand near top of Pleasanton fm. (Penn.) of west-central Mo. Lies higher than Wayside sand. Named for outcrop N. of Knobtown, Jackson Co., on U. S. Highway 50, sec. 22, T. 48 N., R. 32 W. (See Mo. Bur. Geol. and Mines 57th Bien. Rept., 1933, pp. 13, 19, App. 2, pl. 2.)

Knowlton amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name locally in use many years. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. The fm. belongs in lower part of Central Mine group. The mineralized part is the Knowlton lode. Named for occurrence in Knowlton mine, Ontonagon Co.

Knowlton flow.

Includes Knowlton amygdaloid and the underlying trap.

Knox dolomite.

Upper Cambrian and Lower Ordovician: Tennessee, western North Carolina, and northwestern Georgia.

J. M. Safford, 1869 (Geol. Tenn., pp. 151, 158–159, 204–226). *Knox dol.*—Heavy-bedded ridge-making dolomites and lss., chiefly dol., 4,000 ft. thick. Lowest strata blue, oolitic, and often fossiliferous; strata next above dark gray and granular; upper strata, light gray with chert layers. Top fm. of Knox or Knoxville group. Overlies Knox [Conasauga] sh. Underlies Trenton or Lebanon [Stones River] group.

In eastern Tenn. underlies Chickamauga ls., or Mosheim ls., where that ls. is present, and overlies Nolichucky sh. (=upper part of Conasauga sh. to S.). In NW. Ga. it rests on Conasauga sh.

Named for development in Knox Co., Tenn.

†Knox group.

Cambrian (Lower, Middle, and Upper) and Lower Ordovician: Eastern Tennessee, western North Carolina, northwestern Georgia, and northern Alabama.

J. M. Safford, 1869 (Geol. Tenn., pp. 151, 158–159, 203–226). *Knox or Knoxville group.*—Sss. and shales, dolomites and lss. forming by its outcrops greater part of surface of East Tenn. Valley. City of Knoxville is on ridge made of its lss. and dolomites, and this circumstance, together with fact that the threefold typical character of the series is well developed in Knox Co., has induced me to name it *Knoxville or Knox group.* Includes (descending) Knox dol. (4,000 ft.), Knox sh. (1,500 to 2,000 ft.), and Knox ss. (800 to 1,000 ft.). Underlies Trenton or Lebanon [Stones River] group and overlies Chilhowee ss.

Includes most of Camb. and part of Ord., and conflicts with Knox dol.

†Knox shale.

Upper and Middle Cambrian: Eastern Tennessee, western North Carolina, northwestern Georgia, and northern Alabama.

J. M. Safford, 1869 (Geol. Tenn., pp. 151, 158–159, 204–226). *Knox sh.*—Variegated shales, with occasional layers of blue oolitic dol. and ls.; fossiliferous in places. Thickness 1,500 to 2,000 ft. Middle fm. of Knox or Knoxville group. Underlies Knox dol. and overlies Knox ss. [Rome fm].

Conflicts with Knox dol. In Ala. and Ga. replaced by ***Conasauga sh.*** In eastern Tenn. divided into 4 fms. (descending): Nolichucky sh., Maryville ls., Rogersville sh., and Rutledge ls.

Named for Knox Co., Tenn.

†Knox sandstone.

Lower Cambrian: Eastern Tennessee, western North Carolina, northwestern Georgia, and northern Alabama.

J. M. Safford, 1869 (Geol. Tenn., pp. 151, 158–159, 203–226). *Knox ss.*—Hard shales and thin sss., interstratified with heavier sss., and intercalated with layers of dol. Heavier sss. often of coarse grain, sometimes quartzose. Thickness 800 to 1,000 ft. Strata often ripple marked and sometimes covered with fucoidal impressions and ledges. In NE. counties becomes more calc. Basal fm. of Knox or Knoxville group. Underlies Knox sh. and overlies Chilhowee ss.

Conflicts with Knox dol. Replaced by *Rome fm.*

Named for Knox Co., Tenn.

Knox sand.

A subsurface sand in Pottsville group (Penn.) of eastern Ky, also a subsurface sand in SW. Okla., correlated with part of Wellington fm. (Perm.).

Knox gneiss.

Pre-Cambrian: Central southern Maine (Waldo County).

E. H. Perkins and E. S. C. Smith, 1925 (Am. Jour. Sci., 5th, vol. 9, pp. 204–228). A series of igneous and sed. gneisses and schists which have been tentatively grouped under name *Knox gneiss*. The intruded material is a dark-bluish quartz gneiss, strongly foliated and even schistose in places. Biotite is common but varies greatly in amount. Bedding almost entirely destroyed; where shown is greatly contorted. Sedimentary origin indicated by garnets. A second type of gneiss is made up of bands of light and dark material a fraction of an inch thick; the dark layers contain garnets and are probably sedimentary; the light layers are feldspathic and represent igneous material. The third phase is a biotite gneiss which intrudes the sed. gneiss in dikes and irregular bodies. All gneisses are associated with basic dikes and injected pegmatites. Knox gneiss adjoins Hogback schist on E., and is bounded on E. by Penobscot fm., of which it may represent a highly intruded phase. Is probably pre-Camb. [Probably named for occurrence in town of Knox, Waldo Co.]

On 1933 geol. map of Maine, by A. Keith, the rocks of this area are mapped as pre-Camb.

Knox Mountain granite.

Age (?): Northeastern Vermont (Orange County).

C. H. Richardson, 1906 (5th Rept. Vt. State Geol.), mentioned *Knox Mtn granite* in Orange, NE. Vt. (coarser than Kirby granite); *Kirby granite* on Kirby Mtn [E. part of Kirby Twp, Caledonia Co.]; *Barre granite; Bethel granite;* and *Woodbury granite*. The latter 3 granites are now assigned to Dev.

†Knoxville group.

Cambrian (Lower, Middle, and Upper) and Lower Ordovician: Tennessee, North Carolina, Georgia, and Alabama.

See †*Knox group*, 1869 entry.

Knoxville formation.

Lower Cretaceous (Shasta series): California and Oregon.

C. A. White, 1885 (U. S. G. S. Bull. 15, pp. 19–32). The strata of Shasta group occupy only a few isolated areas in Calif., and are in every case either uncon. with rocks both above and below them, or so disturbed that their strat. relations are obscure. Judged by their fossils, two divisions of the strata are plainly indicated, and I shall designate the divisions as *Horsetown beds* and *Knoxville beds*, respectively. The Horsetown beds have been found mainly in Shasta Co. and the Knoxville beds mainly in Lake, Colusa, Contra Costa, and Santa Clara Counties. The Knoxville beds are characterized by *Aucella*, which is, so far as known, absent from the Horsetown. The Horsetown fossils appear to represent the Gault and the Knoxville fossils to represent the Lower Neocomian. There is probably a considerable hiatus btw. the Knoxville and Horsetown beds.

J. S. Diller and T. W. Stanton, 1894 (Geol. Soc. Am. Bull., vol. 5, pp. 435–464), reported that the Knoxville, Horsetown, and Chico fms. grade into one another and show that they are one continuous series of deposits. They described the Horsetown as consisting of 6,000± ft. of shales, sss., and cgls., and the Knoxville as consisting of an indivisible mass of beds, 20,000 ft. thick, chiefly sh., but containing many sss. and calc. layers, the sss. being especially prominent in lower part. The fm. was named for exposures at Knoxville, Napa Co., Calif. Upper part of the Knoxville characterized by *Aucella crassicollis* and lower part by *Aucella piochii*. [Detailed sections and faunal lists.]

Recent repts of some authors advocate restriction of *Knoxville fm.* to lower and larger part of the Knoxville of the literature, and application of *Paskenta fm.* to upper 4,000± ft. of the Knoxville of the literature, the Knoxville restricted being assigned by them to Upper Jurassic and the proposed Paskenta to Lower Cret. (See under *Paskenta fm.*) These proposed modifications have not been adopted by U. S. Geol. Survey.

†Knoxville marble.

Lower Ordovician (late Chazy): Eastern Tennessee.

J. M. Safford and J. B. Killebrew, 1900 (Elements of geol. of Tenn., pp. 105, 117, 121). *Knoxville marble.*—Red and gray marble, 380 ft. thick, worked at many points in East Tenn. Is a variegated sparry marble, to great extent made up of fragments of fossil crinoids and corals. The belt of it runs lengthwise through middle of Valley of East Tenn. Is found as high as Hawkins Co. and as far S. as McMinn and Bradley. Overlies Lenoir ls. and underlies Sevier sh.

Replaced by Holston marble lentil (of Chickamauga ls.).

Named for Knoxville, Tenn., near which it is exposed. Is not the dol. on which Knoxville is built.

Knoydart formation.

Devonian: Nova Scotia.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 207).

Knuckle Island granite.

Age (?): Ontario (Rainy Lake district).

A. C. Lawson, 1913 (Canada Geol. Surv. Mem. 40, p. 99).

Kodak white sandstone.

Silurian: Western New York (Rochester region).

G. H. Chadwick, 1935 (A. A. P. G. Bull., vol. 19, No. 5, p. 702). *Kodak white ss.* introduced to replace "gray band" in Genesee Gorge at Rochester, which was formerly called, by writer and others, *Thorold ss.*, but which is now known to be younger than true Thorold ss. of Niagara Gorge, and of Clinton age. Type exposure in lower Genesee Gorge from the lower falls to Kodak Park, Rochester.

J. T. Sanford, 1935 (A. A. P. G. Bull., vol. 19, No. 9, p. 1390). Chadwick's proposed new name *Kodak ss.* for "gray band" at Rochester is unnecessary, for the "gray band" there does contain *Arthrophycus*, although index value of this fossil is open to question.

Koipato formation.

Middle (?) Triassic: Northern Nevada.

C. King, 1876 (U. S. Geol. Expl. 40th Par. Atlas, map V) and 1878 (U. S. Geol. Expl. 40th Par. vol. 2, pp. 267–278). *Koipato group.*—Lower div. of Triassic in West Humboldt Range. Consists of qtzitic and argill. beds at head of Buena Vista Canyon. To N. it consists of argillites and siliceous beds interposed with siliceous argillites; no ls. beds. To this whole group of schists and porphyroids we have given the title Koipato group, from the Indian name of West Humboldt Range. No fossils except a few crushed and distorted *Nautilus* remains. Thickness 4,000 to 6,000 ft. Underlies Star Peak group and uncon. overlies Archean granite and schist.

†Koipatoan series.

Triassic (Middle?): Northern Nevada.

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 52, 59, 79). *Koipatoan series.*—Title adopted from King's Humboldt Range section of Mid Triassic sss., 2,000 ft. thick, underlying Staran series and younger than Inyoan series. Covers all Mid Triassic of Nev. The early title of *Koipatoan* [Koipato "series"] for entire Mid Triassic section of this region is probably too comprehensive; and if the section in this folded belt is actually so thick as formerly considered several units of serial rank are doubtless represented.

Same as Koipato fm., which was named for development in West Humboldt Range, Humboldt Co., the Indian name for which is *Koipato*.

Koko volcanics.

Latest Pleistocene or Recent: Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Koko volcanics.*—Tuff and olivine basalt; the tuff well bedded, lithic, gray to brown. Included in upper part of Honolulu volcanic series [q. v.]. Forms Koko Head.

Kokomo limestone.

Silurian (Cayugan): Central Indiana.

A. F. Foerste, 1904 (Ind. Dept. Geol. and Nat. Hist. 28th Ann. Rept., p. 33). *Kokomo ls.*—Geographic name applied to fm. which in previous Ind. repts has been called "Waterlime." Thickness 65 to 150 ft. Fossils suggest equivalence to Bertie or Lower Waterlime bed in lower part of Cayugan.

A. F. Foerste, 1909 (Cincinnati Soc. Nat. Hist. Jour., vol. 21, p. 6). The brachiopod horizon at Kokomo should probably be distinguished from underlying eurypterid horizon by a distinct name, and *Kokomo ls.* be restricted to eurypterid beds, but at present no suitable name is at hand. [Kokomo ls. continued to be used as originally defined until 1927.]

E. R. Cumings and R. R. Shrock, 1927 (Ind. Acad. Sci. Proc., vol. 36, pp. 71–84). *Kokomo ls. of Foerste* (1904), which is probably of Cayugan age, consists of 60 ft. of finely laminated impure ls., more argill. in lower part and more calc. in upper part; alternating beds of earthy material and purer ls. being characteristic. Rests uncon. on Mississinewa sh., and is overlain, possibly uncon., by Kenneth ls., a very cherty ls. 1 to 20 ft. thick, the base of which is exposed in Defenbaugh and Markland Ave. quarries in Kokomo.

E. R. Cumings and R. R. Shrock, 1928 (Ind. Cons. Comm., Div. Geol. Pub. 75, pp. 117–135). *In 1927 writers restricted name Kokomo ls.* to the thinly laminated ls. lying btw. Mississinewa sh. below and a cherty ls. above, containing the brachiopod horizon as exposed in Markland Ave. quarry at Kokomo. *The brachiopod horizon was included in overlying fm. called Kenneth ls.* As now defined Kokomo ls. includes 45 to 50 ft. of finely laminated argill. ls. uncon. overlying Mississinewa sh. and discon. underlying cherty Kenneth ls. in Markland Ave. quarry at Kokomo, and the 45 to 50 ft. of similar stone lying below the cherty Kenneth ls. in Big Blue Hole and Kenneth quarries W. of Logansport. Varies in thickness from few ft. to 60 ft. Fossils [listed] writers consider of Cayugan age and = Bertie of N. Y.

Named for exposures at Kokomo, Howard Co.

†Kolmakof series.

Tertiary (?) to late Paleozoic: Southern Alaska.

J. E. Spurr, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 161–163, 182). *Kolmakof series.*—Volcanic rocks of various types, changing laterally into or interbedded with volcanic tuffs, shales, impure lss., and fine-grained arkoses. Plant remains, ripple marks, etc. Folded and intruded by great masses of igneous rocks. Plants. Outcrops frequently along right bank of Kuskokwim River btw. Kolmakof and beginning of low silt plain just above entrance to Yukon portage route above Kalchagamut. Provisionally correlated with Holiknuk series and referred to Cret.

Now regarded as including 3 or 4 distinct units: (1) Upper Cret. sss. and shales which are W. extension of Spurr's Holiknuk series; (2) associated igneous rocks which are dikes and sills and not lava flows; (3) late Paleozoic or early Mesozoic tuff associated with Carbf. ls.; (4) possibly late Tert. volcanic rocks.

Kome beds.

A name long in use for Lower Cret. rocks in Greenland that underlie Atane beds (Upper Cret.).

Komooks beds.

Cretaceous: Vancouver Island.

F. B. Meek, 1862 (Phila. Acad. Nat. Sci. Proc., vol. 13, p. 315).

Kona dolomite.

Pre-Cambrian (lower Huronian): Northwestern Michigan (Marquette district).

C. R. Van Hise and W. S. Bayley, 1895 (U. S. G. S. 15th Ann. Rept., pp. 523+). *Kona dol.*—Chiefly cherty dol. interstratified with layers of sl., graywacke, and qtzite, and gradational sediments. Thickness 700 ft., possibly 1,400 ft. Conformably underlies Wewe sl. Grades into underlying Mesnard qtzite. Composes Kona Hills, on E. shore of Goose Lake.

Konawa formation.

Permian (?): Central Oklahoma.

G. D. Morgan, 1924 (Bur. Geol. [Okla.] Bull. 2, pp. 140–141, pls. 3, 27, and map). *Konawa fm.*—Chiefly typical red beds, such as cover a large part of western Okla. Red shales constitute greatest thickness of strata, but coarse red sss. are often prominent and sometimes outcrop over large areas. No lss. observed. Top of fm. is drawn at base of 30± ft. of coarse red and brownish red sss. that cap N. bluff of Canadian River from bridge S. of Asher to N. edge of Stonewall quad. and constitute basal memb. of Asher fm. The upward diminishing arkosic material common to Pontotoc strata entirely disappears near base of these sss. Base of fm. is drawn at base of typical red beds of the area. Thickness 500± ft. Constitutes upper part of Pontotoc terrane [group]. Is believed to overlie Stratford fm., and to overlap on it and older rocks. No fossils, but is thought to be early Perm.

R. H. Dott, 1927 (Okla. Geol. Surv. Bull. 40K, pp. 7–31). Writer is inclined to look upon *Konawa fm.* as merely a lateral phase of Stratford fm., due to depositional factors.

F. A. Melton, 1930 (Okla. Geol. Surv. Bull. 40LL). *Konawa fm.* may be a northern gradational facies of Vanoss and Stratford fms.

Named for development at and around Konawa, Seminole Co.

Koochiching granite.

Pre-Cambrian (Laurentian): Northern Minnesota (2 miles west of Rainy Lake).

A. N. Winchell, 1897 (Am. Geol., vol. 20, pp. 293–299). *Koochiching granite.*—Biotite-hornblende eruptive granite, but very poor in quartz. Occurs on N. bdy of Minn., 2 mi. W. of Rainy Lake. Assigned to Laurentian.

Above is spelling adopted by U. S. Geog. Bd. The name has also been spelled *Coutchiching.*

Koolau volcanic series.

Tertiary (and possibly early Pleistocene): Hawaii (Oahu Island).

C. K. Wentworth, 1926 (Bernice P. Bishop Mus. Bull. 30), and perhaps earlier publications, by others. On p. 40 Wentworth said *Koolau basalt*, the oldest fm. in Diamond Head region, makes up main mass of NE. Oahu, and that next younger is a complex series of calc. reef fms. which includes reef ls., marine calc. sss. and cgls., and eolian calc. sss. On p. 42 Wentworth maps *Koolau basalt* in Diamond Head dist.

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Koolau volcanic series.*—Includes all lava flows, intrusive rocks, pyroclastics, breccias, and intercalated soils making up Koolau Range, except those concurrent with the erosion of the great valleys on its slopes, which make up only a very small percentage of the bulk of the range. Its basalt, tuff, dike complex, and breccia members have each been mapped separately. In part of its area it overlies, without any apparent uncon., Kailua volcanic series (which is correlated with basal basalt memb. of Waianae volcanic series). It differs from Kailua series in that it is not generally amygdaloidal and has a much fresher appearance than the Kailua rocks. The main bulk of Koolau basalts was probably erupted at same time as upper basalt memb. of Waianae volcanic series, but its eruption continued after extinction of Waianae volcanic series, upon which part of Koolau series rests with erosional uncon. It is overlain, with great erosional uncon., by Honolulu volcanic series, of middle (?) and late Pleist. age.

Kootanie formation.
Kootenay formation.

Lower Cretaceous: Alberta and British Columbia.

Same as *Kootenai fm.*, the spelling approved by U. S. Geog. Bd.

Kootenai formation.

Lower Cretaceous: Southern Alberta and British Columbia and Montana (widespread except in southern and southeastern Montana).

Notes and News (J. W. Dawson?), Sci., vol. 5, 1885, pp. 531–532). Dr. G. M. Dawson has recently discovered a remarkable Jurasso-Cret. flora in Rocky Mountains, on branches of Old Man River, Martin Creek, Coal Creek, and one other locality far to NW. on Suskwa River. The containing rocks are sss., shales, and cgls., with seams of coal, in some places anthracite. It was proposed by Sir William Dawson, in his paper before recent meeting of Royal Society of Canada, to call these beds *Kootanie group*, from a tribe of Indians who hunted over that part of Rocky Mountains btw. 49th and 52d parallels. The beds lie in troughs in the paleozoic fms. of the mtns, and may be traced for a distance of 140 mi. N. and S. The plants found are conifers, cycads, and ferns, the cycads being especially abundant. Some are identical with species described by Heer from Jurassic of Siberia, while others occur in lower Cret. of Greenland. No dicotyledonous leaves have been found in these beds, which connect in a remarkable way the extinct floras of Asia and America and those of the Jurassic and Cret. periods.

G. M. Dawson, 1886 (Canada Geol. Surv., n. s., vol. 1, pp. 126B–134B, 162B–167B). *Kootanie series.*—Coal-bearing rocks of Bow Valley region, consisting of 5,000 to 7,000± ft. of shales and sss. of very varied texture and appearance, some cgls., and many coals, containing a flora of Lowest Cret. age, and older than the Dakota of Middle Cret. age. The flora has Jurassic affinities. The series overlies Triassic beds in S. part of dist. The volume of strata btw. the coal-bearing horizon and base of overlying volcanic rocks (2,200 ft. thick) on Crow Nest Pass was estimated at 3,350 ft. and on South Kootanie Pass at 2,400 ft. The summit of Kootanie series is not yet precisely defined, but is situated btw. the apparently constant coal-bearing horizon and base of the volcanic beds, as on North-west Branch of North Fork fossil plants believed to represent the horizon of the Dakota are found a few hundred ft. below these volcanic beds.

C. A. Fisher, 1909 (U. S. G. S. Bull. 356, pp. 28–35), applied *Morrison sh. (?)* to 120 to 130 ft. of apparently non-coal-bearing shales and sss. underlying a coal-bearing series (450 to 475 ft. thick in Great Falls region, Mont.) which he designated *Kootenai fm.*, his Kootenai fm. being overlain by Colorado sh. It is a question whether typical Kootenai of Canada did not include the true Morrison fm.

More recent Canadian repts subdivide the Cret. rocks of southern Alberta into (descending) Allison fm., Colorado sh., Crowsnest volcanics, Blairmore fm., and Kootenay fm. According to E. W. Berry (A. A. P. G. Bull., vol. 11, No. 3, p. 241, 1927) the flora of upper part of the Blairmore is Cenomanian (Upper Cret.), the flora of lower part is Aptian or Albian (both Lower Cret.), and the flora of the Kootenay as thus defined by Canada Geol. Surv. is Barremian (also Lower Cret.). The lower part of Colorado sh. is now believed to be of Cenomanian age and is therefore correlated with upper part of the Blairmore. The Kootenai fm. of Mont. therefore appears to be equiv. to the Kootenay and the lower part of the Blairmore of SW. Alberta.

Kootenay granite.

Jurassic (?): British Columbia.

S. J. Schofield, 1912, 1913, 1914, and 1915 repts on East Kootenay, B. C., listed in U. S. G. S. Bull. 746.

†Kootenayan series.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 42, p. 288). Sss., 600 ft. thick, composing all of early Cretaceous of Alberta. [Same as Kootenai fm.]

Kosciusko sandstone member (of Lisbon formation).

Eocene (middle): Mississippi.

C. W. Cooke, 1925 (U. S. G. S. P. P. 140, pp. 133–135). *Kosciusko ss. memb.*—Designation proposed for the ledges of saccharoidal to qtzitic ss. exposed in vicinity of Kosciusko, the county seat of Attala Co., Miss., and for unconsolidated sands of same age in Miss. Replaces preoccupied name "Decatur sand." Is middle memb. of Lisbon fm. and younger than Winona sand memb. of the Lisbon.

Koster joint clays.

Upper Cretaceous (Gulf series): Southwestern Arkansas.

R. T. Hill, 1888 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 2, pp. 79, 81): *Koster joint clays.*—Yellow calc. clays, or "joint clays," as they are locally called, rich in fossils of overlying and underlying fms. as well as the lime which has resulted from their disintegration. Greatly resemble *Exogyra ponderosa* marls, except that they have more clay and less lime. Possibly the northern and thinner edge of the great *Exogyra ponderosa* marls [Brownstown marl restricted] seen farther south. Thickness in one section 50 ft. Younger than Big De Gray horizon.

Named for occurrence at or near Nicholas Koster's house, sec. 13, T. 7 S., R. 21 W., Clark Co.

†Kotlo series.

Pre-Cambrian and lower Paleozoic: Southeastern Alaska.

A. H. Brooks, 1900 (U. S. G. S. 21st Ann. Rept., pt. 2, p. 357). On map the Birch Creek, Fortymile, and Rampart series of Spurr and the Nasina series and Tanana schist of my previous rept [U. S. G. S. 20th Ann. Rept., pt. 7, 1900] have been grouped together under name "*Kotlo series.*" Age not established, but assigned to Lower Paleozoic or pre-Camb.

A. H. Brooks, 1906 (U. S. G. S. P. P. 45, p. 214). In 1900 (U. S. G. S. 21st Ann. Rept., pt. 2, pp. 357, 358) writer grouped all the gold-bearing rocks under name *Kotlo series*, which would include Birch Creek, Fortymile, and Rampart series. Now that more detailed studies have been made "Kotlo" can be dropped.

Kotsina conglomerate.

Jurassic or Cretaceous: Central southern Alaska.

O. Rohn, 1900 (U. S. G. S. 21st Ann. Rept., pt. 2, p. 431, map, pl. 52). *Kotsina cgl.*—Massive cgl. characterized by greenish color, seemingly due to material derived originally from green volcanics. Occurs on Kotsina River. Overlain by rocks that are believed to be same as Kuskulana shales (Triassic).

This fm. is at present classified as Jurassic or Cret., in absence of fossils.

†Kougarok group.

See under †*Kugruk group.*

Kowak clay.

Pleistocene: Northwestern Alaska.

W. H. Dall and G. D. Harris, 1892 (U. S. G. S. Bull. 84, pp. 265, 327, map). *Kowak clays.*—On left bank of Kowak River at about W. long. 158° is a remarkable clay bluff, ¾ mi. long and 150 ft. high, containing quantities of mammoth tusks. They are of Plio. or Pleist. age. [In 1898 (U. S. G. S. 18th Ann. Rept, pt. 2, p. 335) Dall assigned this clay to Pleist.]

A. G. Maddren, 1907 (Smithsonian Misc. Coll., vol. 49, pp. 18–28). The Palisades form typical exposure of lacustrine phase of deposits Spurr and Collier designate "Yukon silts" and which Dall has called "Kowak clays." They are for most part Pleist., as shown by fossils.

Koyukuk group.

Lower Cretaceous: Northern Alaska (Koyukuk River region).

F. C. Schrader, 1902 (Geol. Soc. Am. Bull., vol. 13, p. 246). *Koyukuk series.*—Impure pink and reddish ls. (800 ft. thick), sl., dark sh., some ss. and arkose, all more or less associated with or intruded by igneous rocks. Lower Cret. fossils. Correlated with Anaktoovuk series. Occurs along Koyukuk River and may have very wide extent over Koyukuk Basin.

Krao limestone.

Age (?): British Columbia.

S. J. Schofield, 1920 (Canada Geol. Surv. Mem. 117, p. 16).

Kreyenhagen shale.

Eocene and Oligocene: Southern California (Diablo Range).

F. M. Anderson, 1905 (Calif. Acad. Sci. Proc., 3d ser., vol. 2, pp. 163–168). *Kreyenhagen shales.*—Brown bituminous or carbonaceous sh., more or less sandy in lower part; 600 ft. exposed on hills a few mi. N. of Coalinga, but thickens to S. and SE. and at Kreyenhagen wells, for which it is named, it is about 900 ft. thick. Thins to 250 or 300 ft. at head of the Jacalitos and on Zapata Chino. Underlies Domijean sands and overlies Avenal sss. Of Eocene age.

For many years *Kreyenhagen sh.* has been applied to beds described as uncon. underlying Vaqueros ss. and overlying (probably uncon.) Tejon fm. in Coalinga and neighboring districts.

F. E. von Estorff, 1930 (A. A. P. G. Bull., vol. 14, No. 10, pp. 1321–1336). Type loc. of *Kreyenhagen sh.* is on Canoas Creek, about 20 mi. S. of Coalinga, Fresno Co. Its max. thickness in vicinity of Canoas Creek and Big Tar Canyon is 1,000 ft. It consists of sh. with a very few lenticular beds of ss. and a few lenses or nodules of ls. The ss. is common only at base of fm., where the *Kreyenhagen* seems to grade into a transitional friable white ss. interbedded with sandy clay sh. which is tentatively included in the Kreyenhagen. It here overlies, with seeming conformity, but possibly with uncon., Domengine ss., of upper middle Eo. age, and uncon. underlies Temblor ss., of lower middle Mio. age.

O. P. Jenkins, 1931 (Min. in Calif., Rept. State Min., vol. 27, No. 2, pp. 141–149). A dual type loc. was originally given for *Kreyenhagen sh.* The name was applied to shales on Reef Ridge, S. of Coalinga, lying btw. Avenal and Temblor sss., whereas the originally collected Foraminifera employed to determine the age of the Kreyenhagen came from shales N. of Coalinga, beneath Domengine ss. The Federal Survey, however, in area N. of Coalinga, mapped as *Kreyenhagen* the series of diatomaceous strata lying above the "Tejon" (Domengine) and below the "Vaqueros" (Temblor). In this series are now found 2 unconformities which divide it into 3 distinct units and account for previous conflicts in stratigraphic correlation. The upper uncon. is at base of *Leda* zone (probably Olig), which zone, 0 to 150 ft. thick, lies uncon. beneath Temblor ss. and uncon. on sh. and ss. of Olig. or Eo. age, which is eroded away in places. The name *Kreyenhagen,* as used in present discussion, represents certain organic shales (not yet definitely assigned to any one age, though probably Eo. or possibly Olig.) lying discon. on hilly western side of San Joaquin Valley, above known Eo. sss. and sandy shales (variously called *Domengine, Tejon, Meganos,* or *Martinez?*). They contain white diatomite beds at top. The Kreyenhagen is not known to be Eo., but inference is made by writer that it is probably = type Tejon, which is definitely Eo. Writer places upper bdy of Kreyenhagen sh. at first uncon. encountered, the uncon. overlying beds in Cantua-Panoche region consisting of ss. and sh. of Eo. or Olig. age. This sh. series is considered by writer to include more strata N. of Coalinga than it does farther S. on Reef Ridge, on Kreyenhagen Ranch, where Kreyenhagen wells are located, but it is correlated, without hesitancy, by writer with the siliceous phase of Kreyenhagen sh. of Reef Ridge and Canoas Creek, regarded as first type loc. of fm. On Reef Ridge writer is inclined to place lower bdy of Kreyenhagen at base of the siliceous sh. and above the sandy clay zone in which diagnostic Eo. fossils (Foraminifera and Mollusca) have been found in abundance. The beds above this sandy clay zone are siliceous.

G. D. Hanna, 1933 (A. A. P. G. Bull., vol. 17, No. 1, p. 84). There is considerable objection among Calif. geologists whereby Anderson and Pack's error in interpretation of F. M. Anderson's name "Kreyenhagen" is perpetuated. Some geologists believe "Kreyenhagen" should be allowed to lapse because it was originally applied by F. M. Anderson to 2 distinctive units S. of Coalinga (in Canoas Creek), and N. of Coalinga he expressly excluded the part of section to which Anderson and Pack subsequently transferred the name. The first available name which was actually assigned to the fm. and about which there is no ambiguity is "Lillis fm., Ruckman," Merriam, 1915. There seems to be general agreement that the fm. is a distinctive and mappable unit and deserves a distinctive name. There probably will be less confusion if we continue to use "Kreyenhagen" in its erroneous and restricted sense than if we attempt to establish the unfamiliar but strictly applicable term "Lillis."

W. P. Woodring, 1934 (Map and structure sections of Kettleman Hills). *Kreyenhagen sh.* (*Eo. and Olig.?*) [according to micropaleontologic evidence] underlies Temblor ss. (Mio.) and overlies Avenal ss. (Eo.).

W. P. Woodring, March 1937 (personal communication). Type Kreyenhagen (of Reef Ridge) is Eo.; to N. of Coalinga anticline it is Eo. and Olig.; in Kettleman Hills it is Eo. and Olig. (?).

See also under *Lillis sh.*

Krider limestone. (In Sumner group.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., p. 60). *Krider ls.*—Middle memb. of Enterprise fm. Consists of (descending): (1) Light-gray to buff ls., 1 to 1½ ft.; (2) olive-drab to gray calc. massive sh. weathering buff, with usually a thin calc. concretion near middle, 2½ ft.; (3) light-gray to buff massive ls. weathering buff, 1½ ft. Thickness 4½ to 6 ft. from Nebr. to southern Kans. and Okla. Underlies Paddock sh. memb. and overlies Odell sh. memb. Type loc. road cut ¼ mi. S. of Krider, Gage Co., Nebr.

R. C. Moore, 1936 (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 12), discarded Enterprise and treated Krider ls. as basal memb. of his Nolans ls. (new).

Kruger schist.

Carboniferous (?): Southern British Columbia and central northern Washington.

R. A. Daly, 1906 (Geol. Soc. Am. Bull., vol. 17, pp. 329–376). *Kruger schists.*—Apparently Paleozoic (probably late Carbf.) schists, qtzites, greenstones, and other rocks, that occur on the roughly tabular Kruger Mtn.

Kruger alkaline body.

Tertiary: Southern British Columbia and central northern Washington.

R. A. Daly, 1906 (Geol. Soc. Am. Bull., vol. 17, p. 349). Crops out on W. surface of Kruger Mtn plateau.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, map 12, 119°30' to 120°). *Kruger alkaline body.*—Malignite and eleolite syenite.

†Kugruk group.

Ordovician, Silurian, and Devonian (?): Northwestern Alaska (Seward Peninsula).

A. J. Collier, 1902 (U. S. G. S. P. P. No. 2, p. 21, map). *Kugruk group.*—Lss. and calc. beds, argillites, mica schists, graphitic schists, many intrusive masses of schistose greenstone. Fossils (found at 1 loc. only) indicate Upper Sil. or Dev. age, Schuchert says. May be in part Mesozoic. Rests conformably on Port Clarence ls. Is upper part of Nome group, of which Port Clarence ls. is lower part. [The map shows Kugruk Mtn in midst of these rocks and Kugruk River flowing through them, but it seems that the river is Kougarok River, instead of Kugruk River, and that the rocks should have been called *Kougarok group.*]

Further work proved that the lss. included in Kugruk group as above defined are Port Clarence ls. (Sil. and Ord.), and that the schists are younger and of Dev. or Sil. age. The name *Kugruk group* has therefore been discarded (see A. J. Collier, U. S. G. S. Bull. 328, 1908, pp. 61–62, 65), as has *Kougarok group.*

Kummer series. (In Puget group.)

Eocene: Western Washington (Puget Sound region).

G. W. Evans, 1912 (Wash. Geol. Surv. Bull. 3, pp. 42–49). *Kummer series.*—Top div. of Puget fm. in King Co. Chiefly coarse-grained light-colored sss. with numerous sh. and clay beds and 9 coals that are worked at Kummer mine, ¼ mi. S. of Kummer. Basal 475 ft. of light-colored or white massive ss. with nodules or boulders of harder ss. is called *Kummer ss.*, and is line of div. btw. Kummer and underlying Franklin series. Total thickness of Kummer series 1,751 ft.

Kummer sandstone.

Eocene: Western Washington (Puget Sound region).

See under *Kummer series.*

Kupikipikio basalt.

Kupikipikio black ash.

Pleistocene (late): Hawaii (Oahu Island).

C. K. Wentworth, 1926 (Bernice P. Bishop Mus. Bull. 30, pp. 40, 41, 42, 44). *Kupikipikio basalt.*—Basalt flow covering higher part of Kupikipikio Point. Is similar to Kaimuki basalt, but evidence is lacking for any surface connection btw. the two flows. Rests on Diamond Head tuff. Believed to be essentially contemp. with *Kupikipikio black ash* and with Kaimuki basalt.

Same as Black Point basalt of H. T. Stearns. The meaning of Kupikipikio is Black Point.

Kushequa shale member.

Devonian or Carboniferous: Northwestern Pennsylvania.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61, pp. 47, 103). The Mississippian part of Riceville sh. is here named *Kushequa sh.* and included in base of Oil Lake series. It is basal memb. of Knapp monothem, and overlain by Wetmore cgl. memb. Is normally dark-brown to limonitic brown aren. sh., not materially different from underlying Oswayo sh. Fossils throughout. Includes, near middle, Marvin Creek ls. zone.

In his 1933 rept Caster named this sh. *Smethport sh. memb.*

Caster drew base of Miss. at base of this sh., but Chadwick (Geol. Soc. Am. Bull., vol. 46, No. 2, 1935) tentatively drew top of Dev. at base of Berea (Corry) ss.

Kushtaka formation.

Oligocene or Miocene: Southeastern Alaska (Controller Bay region).

G. C. Martin, 1905 (U. S. G. S. Bull. 250, p. 14). *Kushtaka fm.*—Series of coal-bearing strata exposed in valley of Bering River and its tributaries and on shores of Lake Kushtaka. Consists of at least many hundred and probably several thousand ft. of sh., arkosic ss., and coal seams. Lower bdy may be taken at base of lowest coal in Controller Bay region or at first mappable strat. break below that. Upper limit may be taken at top of highest coal or at next succeeding strat. break. Distinguished from Katalla fm. (which lies in an adjacent belt to S.) by presence of coal seams, predominance of ss. over sh., and coarseness of sediments. Probably *overlies* Katalla fm. Contains Kenai fossils.

G. C. Martin, 1906 (U. S. G. S. Bull. 284, p. 66), gave thickness of Kushtaka fm. as 3,500 to 4,000 ft.

G. C. Martin, 1908 (U. S. G. S. Bull. 335, pp. 24, 30), gave thickness of Kushtaka fm. in Controller Bay region as 2,500± ft., and applied new name *Stillwater fm.* to 1,000+ ft. of sh. and ss. underlying (probably conformably) Kushtaka fm. on W. shore of Kushtaka Lake. Did not mention any coal in Stillwater. This may or may not be a restriction of Kushtaka fm. He also stated that Kushtaka fm. occupies part of crest and much of E. slope of Kushtaka Ridge, and that largest known area extends in broad belt from E. edge of Kushtaka Glacier to NE. edge of area mapped. The fm. overlying the Kushtaka he named *Tokun fm.*

N. L. Taliaferro, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 3, p. 771). "Writer suggests that Tokun fm. is = lower part of Katalla fm., or the beds he herein names *Split Creek memb.*, and that this is *underlain* by Kushtaka fm., which probably owes its position to a thrust fault, now buried beneath Bering Lake and the mud flats fronting Bering Glacier, along which it may have overridden the later Katalla fm."

Kuskokwim gravels and silts.

Pleistocene: Central southern Alaska.

J. E. Spurr, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 175–176). *Kuskokwim gravels and silts.*—Stratified glacial drift, coarse stratified glacial gravel and sand filling bottom of Ptarmigan Valley on W. side of divide btw. the Skwentna and the Kuskokwim. Of Pleist. age.

Kuskulana formation.

Upper Triassic: Alaska (Kotsina-Kuskulana district).

O. Rohn, 1900 (U. S. G. S. 21st Ann. Rept., pt. 2, pp. 423, 424, 433). *Kuskulana shales.*—Hard, ringing, highly siliceous grits, shales, slates, and some schists, all much fractured and seamed. Occur along valley of Kuskulana River and its tributaries. Assigned to Triassic.

F. H. Moffit, 1923 (U. S. G. S. Bull. 745). *Kuskulana fm.*—Definition modified so as to include the lss., which are=Nizina ls., as well as the overlying McCarthy sh.

Kuzitrin formation.

Devonian(?): Northwestern Alaska (Seward Peninsula).

A. H. Brooks, G. B. Richardson, and A. J. Collier, 1901 (Reconn. in Cape Nome and Norton Bay regions, Alaska, in 1900: U. S. G. S. Spec. Pub., p. 28, map). *Kuzitrin series.*—Mass (2,000 to 3,000 ft. thick) of schistose rocks characterized by large percentage of graphite, and as a rule very aren. Type rock is well-jointed graphitic quartz schist. Intercalated graphitic slates not uncommon, and the schists sometimes very calc., especially toward top, approaching impure ls. Underlies Nome series and overlies Kigluaik series. Typically exposed in Kigluaik Mtns. Named for Kuzitrin River along whose lower course it is well exposed.

Kyle sandstone.

Tertiary: Southeastern Nevada.

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 52, 79). *Kyle sss.*—Clays, sands, and gravels occupying abandoned canyon of Old Virgen [Virgin] River. Compose upper fm. of Virgen [Virgin] series. Thickness 1,000 ft. Named for exposures at Kyle Station, in Meadow Valley, below Caliente [SE. Nev.]. "Pliocene perhaps."

Labadie limestone member (of Nelagoney formation).

Pennsylvanian: Central northern Oklahoma (Osage County).

C. F. Bowen, 1918 (U. S. G. S. Bull. 686F, p. 45). *Labadie ls.*—Where best developed is a crystalline ls. of steel-gray color on fresh surface; on weathered surface upper part is brownish and lower part gray. Thickness 8 to 10 ft. on the point S. of Mission Creek in NE¼ sec. 36, T. 28 N., R. 10 E., but only 3 to 4 ft. a mi. N. of that place. Thins so rapidly to N. that it cannot be recognized N. of E. quarter corner of sec. 24 but a ls. 2 in. thick at about same horizon was seen at several places farther N. in Twps 28 and 29 N., R. 10 E. Lies 175± ft. below middle bed of Oread ls. and 65 ft. above lower *Fusulina*-bearing ls.

D. E. Winchester, K. C. Heald et al., 1918 (U. S. G. S. Bull. 686G, p. 60). *Labadie ls.* is first ls. of any prominence below Oread ls. (in T. 25 N., R. 10 E.), which is about 180 ft. stratigraphically above it. In N. part of Twp it consists of two benches, each 2± ft. thick, separated by 10± ft. of gray sh.; outcrop not recognized W. of Bird Creek. Is both overlain and underlain by gray sh., in which are thin beds of ss. Lies 40± ft. below Cochahee ss. and 60± ft. above Cheshewalla ss.

Named for Labadie Point, sec. 9, T. 26 N., R. 10 E., Osage Co.

Labahia member (of Goliad formation).

Pliocene: Central Texas.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 752, 754). *Labahia memb. of Goliad fm.*—Top memb. of Goliad fm. in central Tex. Consists of (descending): (1) Upper ss. (grayish white, medium- to fine-grained, cross-bedded in places, massive in other places); (2) middle marl (greenish-gray, pink, or reddish calc. clay containing white calc. nodules); (3) lower ss. (grayish-white, medium to coarse-grained), in places grading into calc., cross-bedded cgl. lentils that change laterally into massive and poorly bedded layers. Overlies Lagarto Creek memb. Is typically exposed along San Antonio River near La Bahia Mission, S. of Goliad.

LaBelle series.

Pre-Cambrian: Quebec.

F. F. Osborne, 1935 (Quebec Bur. Mines Rept. Minister Mines 1934–35, pt. E pp. 15, 23, map).

Laberge series.

Jurassic or Cretaceous: Yukon Territory.

D. D. Cairnes, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 50).

Labette shale (distinct formation in Kansas and Oklahoma).
Labette shale member *(of Henrietta formation) in Missouri.*

Pennsylvanian: Eastern Kansas, northwestern Missouri, and northeastern Oklahoma.

E. Haworth, 1898 (Kans. Univ. Geol. Surv. vol. 3, pp. 36–37, 92, 94, 100). *Labette shales,* suggested by G. I. Adams, in field notes, for shales, with some ss., coal streaks, and thin lss., 30 to 75 ft. thick, underlying Pawnee ls. and overlying Oswego [Fort Scott] ls.

Has for years been treated as middle memb. of Henrietta fm. in Mo. In Kans. the Henrietta has for years been treated as a group by U. S. Geol. Survey and the Labette as a fm. In Okla. the Labette sh. is also treated as a fm. According to recent repts it includes Lexington coal. (See under *Cherokee sh.*) R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), has discarded Pleasanton and Henrietta fms. and treats Labette sh. as a fm. in his Marmaton group.

Named for exposures at Labette, Labette Co., Kans.

†Labette beds.

Pennsylvanian: Eastern Kansas.

L. C. Wooster, 1905 (The Carbf. rock system of eastern Kans.). *Labette beds* include (descending) Pawnee ls., Labette sh., and Fort Scott ls.

Preoccupied. Same as Henrietta fm.

La Biche shales.

Cretaceous (Upper): Alberta.

R. G. McConnell, 1893 (Canada Geol. Surv. Ann. Rept., vol. 5, pt. 1, pp. 27D–28D).

†Labrador system.

See 1877 entry under *Pemigewasset series* (Paleozoic).

See also U. S. G. S. Bull. 360, pp. 555–559, 1909.

The name originated with C. H. Hitchcock.

Labrador formation.

Quaternary: Canada.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 222).

†Labradorian.

A name applied in some early Canadian repts to all and to part of the Laurentian series (pre-Camb.). Named for development in Labrador and for prevalence of mineral labradorite, which was named for Labrador. (See U. S. G. S. Bull. 360, 1909, index.) The name appears to have originated with W. E. Logan and T. S. Hunt.

La Brisca formation.

Age (?): Mexico.

R. T. Hill, 1904 (Greene Consolidated Gold Co. [Prospectus], p. 16).

La Carriere shale.

Cretaceous: Trinidad.

G. A. Waring, 1926 (Johns Hopkins Univ. Studies in geol., No. 7, p. 36).

Lackawanna sandstone. (In Pocono formation.)

See under *Roaring Branch ss.*

Lackawaxen conglomerate.

Upper Devonian: Northeastern Pennsylvania.

I. C. White, 1882 (2d Pa. Geol. Surv. Rept. G_6, p. 73). *Lackawaxen cgl.*—Separated from overlying Montrose red sh. by 30 ft. of greenish gray sss. and from underlying Delaware flags by 350 ft. of sss. and shales. Thickness 50 ft. [On later pages of above rept (pp. 94, 99–101, 156, 157, 163) this cgl. is included in his

Delaware River flags, and is described as a very massive pebbly bed, 30 to 75 ft. thick. Exposed a short distance below Lackawaxen village and at other places in Lackawaxen Twp, Pike Co.]

I. C. White, 1883 (2d Pa. Geol. Surv. Rept. G_7). ***Lackawaxen cgl.*** (also ***Lackawaxen fish cgl.***) underlies Delaware flag series.

The Lackawaxen cgl. of I. C. White's Huntingdon County rept (2d Pa. Geol. Surv. Rept. T_3, 1885) was renamed *Saxton cgl. memb. of Chemung fm.* by C. Butts in 1918. because of doubt that it is same as typical Lackawaxen cgl. of NE. Pa.

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60, No. 2, p. 105). ***Lackawaxen cgl.*** of White has turned out to be figmentary.

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 591–592). Writer has yet to find type loc. of White's Lackawaxen cgl. White made much of it as a key bed, but he erred in trying to correlate local pebble-beds in fresh-water fms. in the NE. counties with marine cgls. in NW. and south-central areas.

Lac la Belle conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan (Keweenaw County).

L. L. Hubbard, 1898 (Mich. Geol. Surv. vol. 6, pt. 2, pp. 67–72, pl. 4). [***Lac la Belle cgl.*** as mapped occurs just N. of Lac la Belle, Keweenaw Co., and its strat. position is some distance below Bohemia cgl.]

A. C. Lane, 1911 (Mich. Geol. Surv. Pub. 6, geol. ser. 4, p. 225), described ***Lac la Belle cgl.*** as first marked cgl. beneath a heavy series of ophites, with a very heavy one (the Mabb ophite?) just above.

Belongs to Bohemian Range group, and according to B. S. Butler it may be=Baltic (No. 3) cgl. or it may be younger.

Lac La Rouge series.

Pre-Cambrian (Laurentian): Saskatchewan and Manitoba.

W. McInnes, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 153).

Laclede sandstone.

Upper Cambrian: Central Missouri.

G. H. Scherer, 1905 (Bradley Geol. Field Sta. Drury Coll. Bull., vol. 1, pt. 2, pp. 59, 61, 62). Friable ss., weathering dark brown, called *Laclede ss.* by Shepard. Included in Elvins fm. Probably=Fourth ss. of Swallow. Well exposed immediately S. of hotel at Decaturville, Camden Co.

E. M. Shepard, 1916 (letter dated Jan. 29, 1916), stated that this was not published by him, but was provisionally used in carbon prints given his students for field work.

J. Bridge, 1930 (personal communication), stated it is probably part of Elvins fm.

Probably named for Laclede Co.

Lacolle conglomerate.

Ordovician: Southern Quebec.

T. H. Clark and H. W. McGerrigle, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 5, pp. 665–674).

Lacoste series.

Pre-Cambrian: Quebec.

F. F. Osborne, 1935 (Quebec Bur. Mines Rept. Minister Mines 1934–35, pt. E, pp. 18, 22, map).

La Cruz marl.

Miocene: Cuba.

T. W. Vaughan, 1918 (Wash. Acad. Sci. Jour., vol. 8, p. 276).

Lac Seul series.

Pre-Cambrian: Ontario.

E. M. J. Burwash, 1922 (Jour. Geol., vol. 30, p. 395).

La Cygne shale member.

Pennsylvanian: Eastern Kansas.

R. C. Moore, 1920 (Kans. Geol. Surv. Bull. 6, pt. 2, pp. 18, 21, 28). *La Cygne sh. memb.*—Top memb. of Marmaton fm. Overlies Lenapah ls. memb. and underlies Hertha ls. memb. of Kansas City fm. Consists of 125 to 150 ft. of shales and intercalated sss., with some thin discontinuous beds of ls. Has previously been incorrectly called *Pleasanton sh.* Named for town of La Cygne, Linn Co. [In errata pasted on cover of Bull. 6, *LaCygne sh.* is withdrawn, because same as *Dudley sh.*]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 58, 67, 73), discarded *Dudley sh.*, introduced *Memorial sh.* for the beds overlying Lenapah ls. and extending up to uncon. at top of Des Moines "series" as restricted by Moore, and abandoned La Cygne sh. (=Memorial sh. and Bourbon fm.).

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Ladentown diabase.

Upper Triassic: Southeastern New York (Rockland County).

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 92). *Ladentown diabase (1899 Kümmel).*—This is small area of trap in Rockland Co., N. Y., on W. border of Newark beds near Ladentown, and about 2 mi. from extreme W. end of main Palisade trap, and may or may not be connected with it. The area is chiefly interesting in that to some extent it shows a ropy flow structure indicative of an intrusive sheet. [The compiler does not find that Kümmel 1899 used this name, but he did mention the rocks near Ladentown, N. Y.]

Ladiga sandstone.

Lower Cambrian: Eastern Alabama.

E. A. Smith, 1888 (Ala. Geol. Surv. Rept. Prog. 1884–88, geographic map of Ala.). *Ladiga (Potsdam) ss.*—Underlies Coosa Valley (Knox) sh. and ss. and overlies Talladega (Ocoee) group. [Only definition is on map legend.]

Probably same as Weisner qtzite.

Named for Ladiga, Calhoun Co.

Ladner series.

Jurassic: British Columbia.

C. E. Cairnes, 1924 (Canada Geol. Surv. Mem. 139, p. 45).

Ladore shale. (In Kansas City group, Kansas.)

Ladore shale member (of Kansas City formation, Missouri).

Pennsylvanian: Eastern Kansas, southeastern Nebraska, northwestern Missouri, and southwestern Iowa.

G. I. Adams, 1904 (U. S. G. S. Bull. 238, pls. 1, 2). *Ladore sh.*—Sh. [7 ft. thick, judging from description of Bronson fm. on p. 17] shown on maps as overlying Hertha ls. and underlying Mound Valley [Bethany Falls] ls. in Iola quad., Kans. Included in Bronson fm. [This definition conforms to that of Hinds and Greene, 1915.]

From 1912 until 1932 the Ladore sh., 3 to 40± ft. thick, was included in Kansas City fm. (or group), the U. S. Geol. Survey treating the Kansas City as a *fm.* in Mo. and Iowa and as a *group* in Kans., where minor subdivisions of these deposits had been named.

R. C. Moore and G. E. Condra in 1932 (correlation charts) restricted *Ladore sh.* to basal part of the unit to which it had previously been applied, and introduced 8 new names for the rest of the Ladore. They treated Ladore as top fm. of their Bourbon group (new name for lower part of their Bronson group of previous repts), and defined it as underlying Schubert Creek ls. (basal memb. of their Swope ls.) and as overlying Uniontown ls., which appears to correspond to the Hertha, but Moore in his May 1, 1935, table of Penn. fms. of Kans. (Kans. Geol. Surv. Bull. 20, table opp. p. 14) placed his Uniontown ls. a considerable distance below Hertha ls.

N. D. Newell, May 15, 1935 (Kans. Geol. Surv. Bull. 21), placed restricted *Ladore sh.*, 7± ft. thick, above Hertha ls. and below Swope ls. in Johnson and Miami Counties of NE. Kans., but stated (p. 26) that the Ladore of *southern* Kans. may include beds up to base of Bethany Falls ls. This classification therefore recognizes two definitions of Ladore sh., the larger one of which corresponds to Ladore sh. of Hinds and Greene.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 82). *Ladore sh.* includes beds btw. top of Hertha ls. and base of Swope ls. In region N. of Erie, Kans., the top of Ladore sh. is base of Middle Creek memb. of Swope ls., but S. of Erie, where Middle Creek ls. is absent, the top of Ladore is considered to extend up to base of Bethany Falls ls. The latter condition obtains at type loc. of the Ladore, and recognizes the probable inclusion at top of Ladore of southern Kans. of sh.=Hushpuckney and Middle Creek members of Swope fm. The Middle Cr. ls. belongs to the cyclothem that includes Bethany Falls ls., and should not be left as a parting in Ladore sh.

The U. S. Geol. Survey has not yet had occasion to give consideration to these innovations in the Penn. classification of Kans. for use in its publications. See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Named for exposures at Ladore, Neosho Co., SE. Kans.

Ladronesian series.

A term introduced by C. R. Keyes (Sci., n. s., vol. 23, p. 921, and Am. Jour. Sci., 4th, vol. 21, pp. 298–300, 1906) for 0 to 200 ft. of Carbf. [Penn.] shales, said to uncon. underlie his Manzanan series and to overlie his Socorran series (lss.) in SW. part of N. Mex. Appears to be named for Sierra Ladrones, 30 mi. N. of Socorro, N. Mex.

Ladystep intrusives.

Devonian (Middle or Upper): Quebec (Dartmouth River area).

I. W. Jones, 1935 (Quebec Bur. Mines, Rept. Minister of Mines 1934–35, pt. D, pp. 16, 19–21). Serpentine, amphibolite, and diorite.

Ladystep volcanics.

Silurian or Ordovician: Quebec (Dartmouth River area).

I. W. Jones, 1935 (same reference as for Ladystep intrusives). Consist of volcanic flows and tuff.

†Lady Washington sandstone.

Pennsylvanian: Southwestern Indiana (Spencer County).

E. T. Cox, 1871 (Ind. Geol. Surv. 2d Ann. Rept., pp. 145, 146, 160, 298). *"Lady Washington" ss.*—Heavy-bedded coarse-grained brownish-red ss., forming high bluff on Ohio River at Rockpoint, Spencer Co. Referred to millstone grit.

Probably same as Mansfield ss.

See also under †*Martha Washington ss.*

†Lafayette formation.

Cretaceous, Eocene, Neocene, and Pleistocene: Coastal Plain of southeastern United States.•

E. W. Hilgard, 1891 (Am. Geol., vol. 8, p. 130). *Lafayette* (Quaternary) adopted by McGee, LeConte, Loughridge, and Hilgard to replace Orange sand and Appomattox fm. Named for Lafayette Co., Miss., where I first discriminated it from Eocene sands. Overlies Grand Gulf rocks.

W J McGee, 1891 (U. S. G. S. 12th Ann. Rept., pt. 1, pp. 347–521), published a treatise on *Lafayette fm.* in which he defined it (p. 497) as a bed of loam, sand, and gravel, with several minor elements, notably kaolin or kaolinic clay, comminuted silica or siliceous clay, etc., in geographic distribution coinciding approx. with Coastal Plain of SE. United States. Thickness a mere veneer to 200 ft. or more about mouth of the Mississippi. Separated from the newer Columbia fm. by the strongest uncon. of Coastal Plain. In structural composition the fm. is a unit, varying from place to place in local characters yet indivisible throughout its area of 250,000 sq. mi., save on arbitrary grounds. Position in biotic scale unknown, its meager flora combining Laramie (Cret.) and Pleist. or modern features, and its still more meager fauna representing the entire Neocene. It is a littoral deposit of materials carried into Atlantic Ocean and Gulf of Mexico by rivers still in existence when the land stood from 200 to 800 ft. lower than today and when the waters of ocean and gulf extended 50 to 500 mi. inland of present coast. The Lafayette fm. as now defined was first discriminated in north Miss. in 1855 and 1856 by Dr. E. W. Hilgard, and was named by him after Lafayette Co., in which it is typically developed. It was then considered Quat. (or Pleist.). (Am. Geol. 1891, vol. 8, p. 130.) [On p. 502 McGee gave a table showing that Lafayette fm. included deposits of Cret. (Tuscaloosa), Eocene (Orange sand of Safford, 1869, and Lagrange of Loughridge), Neocene (Orange sand of Safford, 1888, and Appomattox of McGee), and Pleist. ages (Lafayette of Hilgard, Orange sand of Hilgard (1860) and other writers, Columbia of McGee), etc.]

E. W. Hilgard, 1892 (Am. Jour. Sci., 3d, vol. 43, pp. 389–402). *Lafayette fm.* may be either Tert. or Quat. It is="Orange sand," which is now dropped by agreement. It underlies, usually uncon., Port Hudson (=Columbia of McGee) and uncon. overlies Grand Gulf beds.

In succeeding years the term *Lafayette fm.* came to be generally applied throughout Atlantic and eastern Gulf Coastal Plains to the thin fm. underlying Columbia group and assigned by most writers to late Plio., but considered by other writers to be early Pleist. The U. S. Geol. Survey early accepted the Tert. age of this deposit, and in 1909 adopted *Plio. (?)* as its specific age designation, based chiefly upon studies of T. W. Vaughan. As work in Southern States progressed the undesirability of retaining *Lafayette fm.* became apparent to most workers, the name having been applied to different deposits in different areas, and E. W. Berry having shown that the typical deposits, in Lafayette Co., Miss., belong to Wilcox group (Eocene). In 1915 the U. S. Geol. Survey abandoned *Lafayette fm.* and adopted *Citronelle fm.* (see G. C. Matson, 1916, U. S. G. S. P. P. 98L and 98M) for the nonmarine Plio. deposits of Gulf Coastal Plain extending from western Fla. into Tex. and northward into Miss. The deposits formerly included in so-called Lafayette fm. of N. J., Del., Pa., and Md. are now divided into Brandywine fm. (Pleist.) and Bryn Mawr gravel (Plio.?); in N. C. and S. C. they are represented by Brandywine fm.; and in Ga. and Fla. they are now divided into Charlton fm. (Plio.?) and Citronelle fm. (Plio.).

Lafayette serpentine.

Pre-Cambrian: Southeastern Pennsylvania.

T. D. Rand, 1900 (Phila. Acad. Nat. Sci. Proc. 1900, pt. I). *Lafayette serpentine* is a part of Chestnut Hill schists [Wissahickon fm.].

Named for occurrence at Lafayette, Montgomery Co.

Lafayette granite porphyry.

Late Carboniferous (?): Northwestern New Hampshire (Ammonoosuc River region, Franconia quadrangle).

C. R. Williams, 1934 (Appalachia, vol. 20, No. 4, pp. 69–78). *Lafayette granite porphyry.*—Dark-gray or green rock. Extends length of Franconia Ridge trail from Mount Lafayette [in Franconia quad.] to Little Haystack [etc.]. Late Carbf.(?).

M. P. Billings and C. R. Williams in 1935 changed this name to ***Mount Lafayette granite porphyry,*** and assigned the fm. to White Mtn magma series of Billings.

Lafferty limestone.

Silurian: Central northern Arkansas (Batesville district).

H. D. Miser, 1920 (U. S. G. S. Bull. 715G). *Lafferty ls.*—Thin-bedded, compact, earthy ls.; upper part gray; lower part mostly red but partly gray. Thickness 0 to 85 ft. Uncon. underlies Penters chert and overlies St. Clair ls. Only known exposure is at the Tate Spring, 1¼ mi. N. of Penters Bluff Station. Named for West Lafferty Creek, which is ½ mi. E. of the exposure.

Lafonde gravel and marl.

Age (?): West Indies.

J. W. W. Spencer, 1901 (London Geol. Soc. Quart. Jour., vol. 57, p. 511).

Lagarto clay.

Miocene (?): Southern and eastern Texas.

E. T. Dumble, 1894 (Jour. Geol., vol. 2, p. 560). *Lagarto div.*—Light-colored clays (lilac, lavender, sea green, greenish brown, and mottling of these colors) and sands of different character from those of Lapara div. The clays contain quantities of semicrystalline ls. pebbles with manganese dendritions. Upper part usually a ss. Underlies Reynosa div. and overlies Lapara div. Assigned to Plio.

A. Deussen, 1924 (U. S. G. S. P. P. 126, pp. 21, 100, etc.). *Lagarto clay.*—Light-colored or mottled pink and green clays, with numerous lime nodules; stained heavily with manganese in places. Strings of ls. extend downward into the clay where it is capped by ls. Includes also sands and sss. Thickness 346 to 647 ft. Uncon. underlies Reynosa fm. and overlies (conformably?) Lapara sand in Nueces Valley, but N. of San Antonio River it rests uncon. on Oakville ss. Named by Dumble from Lagarto Creek, in Live Oak Co., where it is typically exposed.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 753, 754, errata dated Dec. 11, 1933). Dumble's Lagarto included beds both younger and older than Lapara sand, as it included all beds btw. Oakville and Lissie fms. The beds on Lagarto Creek uncon. overlie Lapara sand, and are here treated as middle memb. of Goliad fm. (new), under the name *Lagarto Creek beds.* The beds below Lapara sand and above the Oakville are here called *Lagarto fm.*, although the beds on Lagarto Creek are now included in overlying Goliad fm. The Lagarto fm. as here restricted is 500 to 1,000 ft. thick (2,500 in wells), and rests on Oakville ss. Type section of Lagarto as here restricted is the exposures along Brenham-Houston highway just W. of Brazos River bridge, Washington Co.

For further details see Plummer's 1933 rept.

The U. S. Geol. Survey now uses the restricted definition of Lagarto clay described above, i. e., for the beds uncon. underlying Goliad sand (of which Lapara sand is basal memb.) and overlying Oakville ss.

Lagarto Creek beds. (In Goliad sand.)

Tertiary (Pliocene): Southern Texas.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 753, 754). *Lagarto Creek beds.—Middle memb. of Goliad fm. (new).* Underlie Labahia memb. of Goliad and overlie [uncon. according to errata sheet dated Dec. 11, 1933] Lapara sand memb. of Goliad. They outcrop on Lagarto Creek, where, according to H. T. Richardson, they consist of pinkish brown and reddish mottled limy clay resembling the clays uncon. underlying the Lapara, but in most places having more pastel shades and a higher calcium carbonate content. Thickness of this unit is about 50 ft. The name *Lagarto fm.* is here restricted to the beds underlying Lapara sand and overlying Oakville ss., which are 500 to 1,000 ft. thick, and 2,500 ft. in wells.

Lagonda sandstone member (of Cherokee shale).

Pennsylvanian: Northern Missouri.

C. H. Gordon, 1893 (Mo. Geol. Surv. Sheet Rept. No. 2 (vol. 9), p. 19). *Lagonda sss. and shales.*—Sandy shales and sss., 18 to 50 ft. thick, overlying Bevier coal and forming top div. of Lower Coal Measures in Bevier quad. (covering parts of Macon, Randolph, and Chariton Counties).

Is now treated as a memb. of Cherokee sh.

Named for exposures at Lagonda, Chariton Co.

Lagonda shale.

A name applied by some geologists to *Lagonda ss. memb. of Cherokee sh.*

†Lagrange formation.

Eocene: Western Tennessee, southern Illinois, southeastern Missouri, Mississippi, and southern Alabama.

J. M. Safford, 1864 (Am. Jour. Sci., 2d, vol. 37, pp. 361, 369–370). *Orange sand or La Grange group.*—Generally great stratified mass of yellow, orange, red, or brown and white sands, usually more or less argill., with occasionally an interstratified bed of white, gray, or variegated clay, and patches, plates, and thin layers of ferruginous, sometimes argill., ss. and locally massive blocks of ss. on high points. Thickness 600 ft.; more than 100 ft. exposed at Lagrange. Forms more than third of entire surface of W. Tenn., in belt 40 mi. wide. Underlies Bluff lignite and overlies Porter's Creek group.

These deposits in Tenn. are now divided into Jackson fm. and Wilcox group, the latter being subdivided into Grenada fm., Holly Springs sand, and, in wells in SW. corner of State, Ackerman fm. It is now believed that there is no representative of Claiborne group in Tenn.

In early Miss. and Ala. repts "Lagrange fm." was applied to the beds underlying †Buhrstone (Tallahatta fm., basal fm. of Claiborne group) and overlying †Flatwoods (Porters Creek or Sucarnoochee) clay, or to Wilcox group and Naheola fm. (upper fm. of Midway group).

Named for exposures at Lagrange, Fayette Co., Tenn.

†La Grange sandstone. (In Chester group.)

Mississippian: Northwestern Alabama.

E. A. Smith, 1879 (Ala. Geol. Surv. Rept. Prog. 1877 and 1878, pp. 17, 34, 36). *La Grange ss.*—Fine to coarse-grained, sometimes heavy-bedded, sometimes flaggy ss. Only ss. in midst of Mountain ls. or Chester group. If a local name be desired, might be called *La Grange ss.* Thickness 20 to 75 ft. in Lawrence, Colbert, and Franklin Counties. In a few localities in Colbert Co. the ss. bed is duplicated, with ls. between.

Preoccupied. Replaced by Hartselle ss., Golconda fm., and Cypress ss.

Named for La Grange, Colbert Co.

Lagrange moraine.

Pleistocene (Wisconsin stage): Northeastern Indiana. Shown on moraine map (pl. 32) of U. S. G. S. Mon. 53. Named for Lagrange, Lagrange Co.

Laguna basalt flow.

R. L. Nichols, June 1931 (Geol. Soc. Am. Proc., 1933, p. 453), named 3 Quat. basalt flows in San José Valley, Valencia Co., NW. N. Mex., and stated: The *Laguna* and *Suwanee flows* are of Pleist. age; the *McCartys flow*, by reason of lack of weathering and presumed superposition on Laguna flow, is believed to be of recent and possibly historic age. The Laguna and Suwanee flows, at their lateral margins, usually rest on old valley slopes (Cret. and Jurassic rocks).

In a later paper (Jour. Geol., vol. 44, No. 5, 1936, p. 628) Nichols stated McCartys flow rests on Laguna flow, and he named a 4th flow (occurring in San José Valley btw. Blue Water and the Rio Puerco in Valencia Co.) the *Blue Water basalt*. The age relations of his Blue Water basalt to the other basalt flows are not explained.

Laguna formation.

Pliocene (?): Northern California (Mokelumne River Basin).

A. M. Piper, H. S. Gale, and H. E. Thomas (U. S. G. S. W. S. P. 780, in press). *Laguna fm.*—Stream-borne silt and sand, with some gravel and presumably some clay; nonandesitic; poorly bedded and poorly exposed. Thickness 0 to 400 ft. Uncon. underlies Arroyo Seco gravel (Pleist.) and overlies Mehrten fm. (Mio. and Plio?). Probably laid down in Plio. time but perhaps in early Pleist. time. Type loc. is in N. bank of Hadselville Creek, a short distance from its junction with Laguna Creek.

La Habra conglomerate.

Pleistocene (lower) and lower Pliocene (?): Southern California (South Coastal Basin).

R. Eckis, 1934 (Calif. Dept. Pub. Works, Div. Water Res. Bull. 45, pp. 38, 49). In W. part of South Coastal Basin the Saugus fm. (lower Pleist.) is locally called *La Habra cgl.* [p. 38]. The cgl. series in the upper Fernando that outcrops along S. margin of hills E. of Whittier is locally known as *La Habra cgl.* (H. M. Bergen, unpublished rept on geol. of Bastanchury ranch). It is 400± ft. thick in vicinity of La Habra, but thickens to W. to possibly 1,000 ft., and is principally lower Pleist. but may be in part upper Plio. Rests, with apparent conformity, on silts and sandy shales with occasional cgl. members. Overlain by upper Pleist. alluvium. Is composed in large part of granitic and Tert. volcanic materials, with some ss. and siliceous sh. pebbles [p. 49].

†Lahontan beds.

See *Lake Lahontan beds.*

Lahontan series.

A term applied by C. [R.] Keyes to Lake Lahontan beds of NW. Nev.

La Jara shale.

Name applied by C. [R.] Keyes (Conspectus of geol. fms. of N. Mex., 1915, pp. 2, 8) to "uppermost black shales section of the Coloradan series around the southern end of the Rocky Mtns." Thickness 1,000 ft. Derivation of name not given.

La Jolla formation.

Eocene: Southern California (San Diego County).

B. L. Clark, November 4, 1926 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 16, No. 5. pp. 103, 111, 117). At present there is in press a monograph on strat. and fauna of the Eo. beds of San Diego Co. by M. A. Hanna. In that monograph he refers major part of this section to a new fm. which he calls *La Jolla* and which he correlates tentatively with Domengine fm. described in this paper. Many species are common to La Jolla and Domengine fms. Overlying the La Jolla fm. are the Poway cgls., which previous workers have referred to Plio., but which Hanna has shown conclusively are Eo., and has tentatively correlated them with Tejon.

M. A. Hanna, 1926 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 16, No. 7, pp. 187–246). In previous publications the Delmar sand, Torrey sand, and Rose Cañon sh. have been mapped together and referred to Tejon Eocene. In present paper they are recognized as a distinct fm. and so designated, under name *La Jolla fm.* The whole of La Jolla fm. probably represents deposition along an oscillating coast. For most part the species found in La Jolla fm. are not present in either the Tejon or Meganos. The La Jolla fm. is therefore considered as stratigraphically btw. Meganos [as restricted by B. L. Clark] and Tejon fms., or approx.=Domengine fm.

Lake amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name locally in use many years. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. Is older than Forest amygdaloid and younger than cgl. No. 8 (Bohemia cgl.). The mineralized part is the Lake lode. Named for occurrence in Lake mine, Ontonagon Co. Belongs to Central Mine group.

Lake flow.

Includes Lake amygdaloid and the underlying trap.

†Lake gneiss.

Carboniferous to pre-Cambrian (?): Eastern New Hampshire (Lake Winnipesaukee region).

C. H. Hitchcock, 1874. [See 1874 entry under †*Lake Winnipesaukee gneiss*, of which it is an abbreviated form.]

Lake sandstone.

A subsurface unit of sss., 5 to 40 ft. thick, in Grove gas field, secs. 483, 484, 487, and 488, Southern Pacific R. R. survey, 5 mi. N. and W. of Cisco, Eastland Co., Tex. Lies in base of Smithwick sh., 45 to 80 ft. below Caddo ls.

†Lake quartzite schist.

Early Paleozoic or older: Northern Alaska (Chandalar Lake region).

F. C. Schrader, 1900 (U. S. G. S. 21st Ann. Rept., pt. 2, p. 474). *Lake qtzite schist.*—Chiefly micaceous qtzite schist, 6,000± ft. thick. Overlies Rapids schist and underlies Bettles series. Named for great prominence at Chandalar Lake. Provisionally referred to Birch Creek series.

Lake quartz syenite.

Devonian or Carboniferous: New Hampshire (Belknap Mountains). See 1936 entry (D. Modell) under *White Mtn magma series*.

Lake Agassiz clays.

Pleistocene: Mississippi Valley.

W J McGee, 1888 (Am. Jour. Sci., 3d, vol. 35, p. 462). *Lake Agassiz clays*.—Younger than the terminal moraine and 3d till of second glacial stage. Correlated with Champlain clays of Middle Atlantic slope.

Lake Agassiz silt.

Name applied to the silt deposited in Pleist. glacial Lake Agassiz in Minn. and N. Dak.

†Lake Albany clays.

A term applied (G. H. Chadwick, N. Y. State Mus. Bull. 140, pp. 157–160, 1910) to the Albany clay of early repts.

Lake Ardmore sandstone member (of Springer formation).

Pennsylvanian: Central southern Oklahoma (Carter County).

R. Roth, 1928 (Econ. Geol., vol. 23, p. 45). [See under *Overbrook ss. memb.*]

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z, p. 13). *Lake Ardmore memb. of Springer fm.*—A persistent ss., 15 to 20 ft. thick and very similar to Overbrook ss., which lies from 300 to 500 ft. lower in Springer fm. The Primrose memb. of Springer lies from 100 to 300 ft. above Lake Ardmore ss.

C. W. Tomlinson, 1929 (Okla. Geol. Surv. Bull. 46, pp. 17–19). *Lake Ardmore ss.* lies 250 to 500 ft. below Primrose memb. and 500± ft. above Overbrook ss. memb. It is named for a sportsman's lake in sec. 2, T. 4 S., R. 1 E., where it forms narrow peninsulas and islets.

Lake Aylmer series.

Devonian: Quebec.

F. R. Burton, 1931 (Quebec Bur. Mines Ann. Rept. 1930, pt. D, p. 118).

Lake Bonneville beds.

Pleistocene: Northern Utah and southeastern Idaho.

G. K. Gilbert, 1875 (U. S. Geol. and Geog. Surv. Terr. W. 100th M. vol. 3, pp. 89+). In fine, the *Bonneville beds* are the sediments of the lake whose successive margins are recorded by the series of beaches we have described, and their deposition has been continuous over a gradually restricted area from the date of Bonneville beach to present time. The lacustrine deposits which form part of the record of this lake I shall designate *Bonneville group*. These Quaternary deposits of northern Utah consist of fine, friable, white, calc. marl, passing into a cream-colored, partly oolitic sand of calc. and siliceous grains, feebly cemented by calcite into an impalpable clay.

Lake Border morainic system.

Pleistocene (Wisconsin stage): Western Michigan, northwestern Indiana, northeastern Illinois, and eastern Wisconsin. Shown in part on moraine map (pl. 32) of U. S. G. S. Mon. 53, and in part on moraine map (pl. 23) of U. S. G. S. P. P. 106. Named for development on E. and W. shores of Lake Michigan.

Lake Bridgeport shale.

Pennsylvanian: North-central Texas (Wise County).

G. Scott and J. M. Armstrong, 1932 (Univ. Tex. Bull. 3224, p. 29). *Lake Bridgeport shales* is name here given to the shales and sss. in Graford fm. that occupy interval btw. Willow Point ls. below and Rock Hill ls. above. They increase in thickness from less than 100 ft. 2 mi. NE. of Willow Point to 300± ft. btw. Bridgeport and Chico, to 550 ft. in Wise-Comanche No. 1 Spann well 2 mi. E. and 3/4 mi. N. of Chico. To W. and N. of Bridgeport they consist of (descending): (1) Sh. and flaggy sands, 45 ft.; (2) prominent scarp-forming ss., brown, massive, and fine-grained; (3) very dark shales that weather yellow and brown and leave many claystone concretions.

†Lake Champlain clays.

Same as †*Champlain clays.*

Lake Church formation.

Devonian: Southeastern Wisconsin.

E. R. Pohl, 1929. From Raasch ms. See under ***Thiensville fm.***

G. O. Raasch, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 260, 262–263). *Lake Church fm. novum.*—Divided into Ozaukee memb. above (0 to 27 ft. thick) and Belgium memb. below (0 to 8 ft. thick). Underlies Thiensville fm. and overlies Racine fm. (Sil.). Max. thickness at least 45 ft. Thins to S. by overlap, and disappears in vicinity of Ozaukee-Milwaukee Co. line, where Thiensville fm. rests on Sil. Fossiliferous throughout. Best known, most complete, and most accessible exposure of fm. is in and about old Lake Shore stone quarry near Lake Church, Ozaukee Co. Beds referred to by Cleland as ***Waubakee*** in the proposed type section are to be included with the Dev.

Lake Creek shale member (of Pierre shale).

Upper Cretaceous: Northwestern Kansas (Wallace County).

M. K. Elias, 1931 (Univ. Kans. Bull., vol. 32, No. 7). ***Lake Creek sh. memb. of Pierre sh.***—Mostly dark-gray and black flaky sh.; bentonite rare or absent; many limonite concretionary streaks and small soft ls. concretions; large tough ls. concretions very rare; poor cone-in-cone structure rarely developed; gyp. in places very abundant. Thickness 200± ft. in outcrops in secs. 5 and 7, T. 13 S., R. 41 W. Underlies Salt Grass sh. memb. of Pierre and overlies Weskan sh. memb. of Pierre. Differs from both Salt Grass and Weskan members by total absence or by great scarcity of the large ls. concretions that are so common in those members. Named for Lake Creek, in NW. part of Wallace Co., along which the most extensive outcrops occur.

Lake Escarpment morainic system.

Pleistocene (Wisconsin stage): Northern Ohio, northwestern Pennsylvania, and western New York.

F. Leverett, 1902 (U. S. G. S. Mon. 41). ***Lake Escarpment morainic system*** includes Girard moraine (youngest), Ashtabula moraine, Painesville moraine, and Euclid moraine (oldest). Covers part of brow and much of face of Lake Erie escarpment from Cleveland eastward into N. Y. The combined belt in western N. Y. has been referred to by writer as ***Dayton moraine*** (Am. Jour. Sci., 3d, vol. 50, p. 8, 1895), but it seems preferable to substitute the name ***Lake Escarpment system*** and to give names to each morainic ridge.

On moraine map of Ohio published as fig. 8 of U. S. G. S. Columbus folio (No. 197), 1915, the Lake Escarpment morainic system was erroneously called *Lake Shore morainic system.*

Lake Evans series.

Pre-Cambrian: Quebec.

H. C. Cooke, 1914 (Canada Geol. Surv. Summ. Rept. 1912, p. 389).

†Lake Flirt marl.

Recent (?): Southern Florida (De Soto County).

E. H. Sellards, 1919 (Fla. Geol. Surv. 12th Ann. Rept., pp. 73–74). ***Lake Flirt marl.***—Overlies Coffee Mill Hammock shell marl. Is strikingly different, both in lithologic appearance and fossils, from Coffee Mill Hammock marl. Consists of a calc. mud in which fresh-water shells, chiefly gastropods, are embedded. Has a thickness of 3 or 4 ft., and is best seen underlying the basin of Lake Flirt [De Soto Co.] from Old Fort Thompson to Coffee Mill Hammock, a distance of about 8 mi. This marl is of fresh-water origin and may be quite recent in age.

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept.), redefined Fort Thompson fm. so as to include in it the Coffee Mill Hammock marl of Sellards, and stated that Lake Flirt marl of Sellards is probably Recent, also that at some places it overlies Fort Thompson fm.

Lake Fork andesite.

Miocene (?): Southwestern Colorado (San Juan Mountains region).

W. Cross and E. S. Larsen, 1923 (U. S. G. S. P. P. 131, table opp. p. 184, and Bull. 718, table opp. p. 12). *Lake Fork breccia.*—Chiefly chaotic andesitic flows and breccias locally developed in Uncompahgre and adjoining quads. Thickness 0 to 1,000± ft. Named for exposures in Lake Fork of Gunnison River in Uncompahgre quad. Uncon. underlies San Juan tuff and uncon. overlies Telluride cgl. Is probably Eocene.

E. S. Larsen, 1935 (U. S. G. S. Bull. 843), changed name to *Lake Fork andesite.*

Lake Hanbury slate group.

Huronian: Northern Peninsula of Michigan (Menominee iron region).

C. Rominger, 1881 (Geol. Surv. Mich., vol. 4, pt. 2, p. 182). The most southern, *seemingly uppermost,* group of rocks in Menominee iron region, is a series of dark gray slaty or schistose beds, with interlaminated quartzose belts, perhaps over 2,000 ft. thick, which I will call *Lake Hanbury sl. group.* A second group, next succeeding [downward], which I will name *Quinnesec ore-fm,* is not less than 1,000 ft. thick, and locally perhaps much thicker. It consists of, in upper part, light-red or whitish, or gray hydromicaceous and argillitic strata, and in lower part of siliceous beds richly impregnated with iron oxide and constituting the valuable ore deposits. A third group is a series of light-colored qtzite and ls. beds of siliceous character, usually in part of brecciated structure, and also at least 1,000 ft. thick, which I will call *Norway ls. belt.*

J. Fulton, 1888 (Am. Inst. Min. Engrs. Trans., vol. 16, pp. 525–536). Huronian rocks of eastern Menominee region consist of 3 fms. (descending): (1) *Lake Hanbury sl group,* 2,000 ft.; (2) *Quinnesec ore-fm.,* 1,000 ft.; and (3) a basal fm. of crystalline siliceous ls., at least 1,200 ft. thick, which outcrops at many localities along the range, especially N. of the Norway, Quinnesec, and Chapin mines.

The pre-Camb. sl. (upper Huronian) of Menominee region was for many years called "Hanbury sl.," but that name was long ago discarded for *Michigamme sl.* The underlying iron-fm. is *Vulcan iron-fm.* (middle Huronian); and the older lss. are the Randville dol. (lower Huronian).

Lake Huron shale.

Upper Ordovician: Northern Indiana (Kokomo).

M. Thompson, 1886 (Ind. Dept. Geol. and Nat. Hist. 15th Ann. Rept., p. 325), listed following fms. in Kokomo gas well No. 2, in descending order: (1) Upper Sil. and Dev. ls., 434 ft.; (2) *Lake Huron sh.* (*Hudson River and Utica sh.*), 470 ft.; and (3) Trenton, 4 ft.

Lake Kemp limestone. (In Lueders formation.)

Permian: Central northern Texas (Baylor County).

M. M. Garrett, A. M. Lloyd, and G. E. Laskey, 1930 (Tex. Bur. Econ. Geol., geol. map of Baylor Co.). *Lake Kemp ls.* lies at top of Lueders fm. and 45± ft. higher than Maybelle ls. [The top ls. of Lueders fm. in Jones and Taylor Counties was called *Lueders ls.* by P. A. Meyers and H. T. Morley (Tex. Bur. Econ. Geol., geol. maps of Jones and Taylor Counties, 1929), but this name is preoccupied by *Lueders fm.*]

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 169, 174). *Lake Kemp ls.* is top memb. of Lueders fm. Occurs at E. end of Lake Kemp, Baylor Co.

Lake Lahontan beds.

Pleistocene: Northwestern Nevada.

I. C. Russell, 1885 (U. S. G. S. Mon. 11, p. 143). *Lahontan sediments.*—Sediments deposited in Lake Lahontan. Consist of upper lacustral clays, 50 to 75 ft. thick; resting uncon. on medial gravels, 50 to 200 ft. thick, which rest uncon. on lower lacustral clays, 100+ ft. thick.

Lake Louise shale.

Lower Cambrian: Alberta and British Columbia.

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804, pp. 2, 5). *Lake Louise fm.*—Siliceous shales, 105 ft. thick at upper end of Lake Louise. Type loc.

on both sides of Lake Louise at its upper end. Well shown on NW. and N. sides of Fairview Mtn. Lower Camb. fossils. Underlies St. Piran fm. and overlies Fairview fm. [Latter name preoccupied and later replaced by *Fort Mtn ss.*]

Lake Lytle limestone.

J. Hornberger, Jr., 1932 (Tex. Bur. Econ. Geol., geol. map of Throckmorton Co.), applied *Lake Lytle ls.* to top bed of Arroyo fm., and showed it as 40± ft. above Rainy ls. It therefore appears to be a synonym of Lytle ls.

Lake Mills morainic system.

Pleistocene (Wisconsin stage): Southern Wisconsin. Shown on moraine map (pl. 23) of U. S. G. S. P. P. 106. Named for Lake Mills, Jefferson Co.

Lake Missoula beds.

Pleistocene: Southwestern Montana (Missoula, Ravalli, and Granite Counties).

C. M. Langton, 1935 (Jour. Geol., vol. 43, pp. 34–35). [*Lake Missoula beds* used in table on p. 35 as underlying terrace gravels and overlying glacial drift, and on p. 34 he refers to Pardee's "Glacial Lake Missoula," Jour. Geol., vol. 18, 1910, pp. 376–386.]

Lake Monongahela deposits.

Pleistocene: Southwestern Pennsylvania.

R. R. Hice, 1905 (Am. Ceramic Soc. Trans., vol. 7, pt. 1). Lacustrine deposits laid down in glacial lake called *Lake Monongahela* by Dr. [I. C.] White, which existed near mouth of Beaver River [in SW. Pa.] during Kansan stage of ice sheet.

Lakemont formation.

Name proposed by E. O. Ulrich in 1923 for upper part of Clinton fm. in central Pa. and western Md., as explained under *Clinton fm.*, 1923 entry.

F. M. Swartz, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 101). Neither lithologic nor faunal evidence favors uniting the upper Rose Hill, Keefer, and Rochester in the *Lakemont fm.*, as has been proposed by some authors.

F. M. Swartz, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 8, p. 1169). The name "Lakemont fm." was proposed by Ulrich and Bassler for Upper Clinton of central Pa. from a section near Lakemont Park, btw. Hollidaysburg and Altoona. [Swartz's correlation table on p. 1167 shows this unit=his Rochester sh. and upper part of Rose Hill sh.]

Lake Pinto sandstone member (of Mineral Wells formation).

Pennsylvanian: Central northern Texas (Palo Pinto County).

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 25, 31; Univ. Tex. Bull. 2132, p. 77, and charts). *Lake Pinto ss. memb. of Mineral Wells fm.*—Massive ss. which caps the escarpments about Mineral Wells. Named for Lake Pinto, ½ mi. W. of Mineral Wells, which lies in a valley almost surrounded by an outcrop of the bed. The exposures in hills E. and W. of Mineral Wells locally contain lenses of fine to moderately coarse cgl. Thickness 22 ft. Underlies Salesville sh. memb. and overlies East Mtn sh. memb. of Mineral Wells fm.

Above is definition still in use. (See F. B. Plummer and J. Hornberger, Jr., Univ. Tex. Bull. 3534.)

Lakeport limestone.

Silurian: Central New York.

G. H. Chadwick, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 327–368). *Lakeport ls.*—Immediately below the typical fossiliferous Rochester sh. and above the Donnelly ore in the Lakeport hole [Madison Co.] there are 16 ft. of ls. with considerable sh. that have been interpreted by Hartnagel as summit Clinton [exclusive of Rochester sh.]. Corresponding to these in position in South Granby well, the next hole W. to penetrate this horizon, are but 18 inches of impure ls. with fossils, grading apparently into the Rochester. Without knowledge of their fauna the importance of these beds cannot well be evaluated, so it will be safe to employ temporarily a local designation for them. Overlie Donnelly ore. Uncertain whether Lakeport is (1) uppermost Irondequoit coordinate with the "reef" zone at Rochester, or (2) a new intercalated memb., or (3) a calc. eastern facies of lower true Rochester (above the "reef" horizon).

According to E. O. Ulrich, 1923 (Md. Geol. Surv. Sil. vol., p. 347), this ls. is of Rochester age. See under *Phoenix or Schroeppel sh.*

Lake Shore trap.

Pre-Cambrian (Keweenawan): Northern Michigan and Wisconsin.

R. D. Irving, 1883 (U. S. G. S. Mon. 5, pp. 186. etc., pls. 17 and 18). *Lake Shore trap.*—Diabase and diabase amygdaloid, including one or more thin porphyry cgls. Underlies Outer cgl. and overlies Great cgl. Thickness about 1,500 ft.

According to A. C. Lane (Mich. Geol. and Biol. Surv. Pub. 6, geol. ser. 4, 1911) the *Lake Shore trap* ranges in thickness from 0 to 1,800 ft., and is composed of an upper trap sheet, a middle cgl., and a lower trap sheet. In some repts the lower trap and the middle cgl. have been included in Great cgl.

Is middle fm. of Copper Harbor group.

Named for exposures on shore of Lake Superior at Keweenaw Point, Mich.

†Lake Shore morainic system.

Same as *Lake Escarpment morainic system.*

Lake Superior sandstone.

Upper Cambrian: Michigan (Northern Peninsula).

D. Houghton, 1840 (Mich. Geol. Surv. 3d Rept., for 1839. H. Doc. No. 8, p. 13). *Lake Superior ss.*—Red ss. Rests on Primary rocks. Its easterly prolongation is not very thick, but westerly it attains a thickness of several hundred ft. on S. shore of Lake Superior. No fossils found.

Later repts (by C. R. Van Hise and others) call it "Potsdam ss.," record Upper Camb. fossils from it, and include in it Munising and Jacobsville sss.

†Lake Superior group.

A. Winchell, 1871 (Mich. Geol. Surv. Rept. Prog., pp. 26–27), applied this name to a group of sss. lying stratigrapically btw. "Cincinnati group" above and Huronian "system" below in Upper Peninsula of Mich. Includes Upper Gray ss. of Houghton, the sss. E. and W. of Keweenaw Point, and a cgl. at base.

Laketown dolomite.

Silurian (Niagaran): Northeastern and western Utah and southern Idaho.

G. B. Richardson, 1913 (Am. Jour. Sci., 4th, vol. 36. pp. 407, 410). *Laketown dol.*—Massive light-gray dol., 1,000 ft. thick in northern Utah. Underlies Jefferson dol. and overlies Fish Haven dol.

Named for exposures in Laketown Canyon, Rich Co., NE. Utah.

Lake Trammel sandstone.

Permian: Central northern Texas (Taylor and Nolan Counties region).

W. E. Wrather, 1917 (SW. Ass. Pet. Geol. Bull., vol. 1, pl., pp. 95–96). *Lake Trammel ss.*—Massive, soft, red ss. 100 ft. thick. Disintegrates readily. Lies 130 ft. above base of Quartermaster fm. in section from Abilene to Sweetwater. Overlain by 2 ft. of white crystalline gyp. [Derivation of name not stated.]

C. N. Gould, 1926 (Jour. Geol., vol. 34, p. 419). *Lake Trammel ss.* of Tex. is strat. equiv. of Whitehorse ss. of Okla. and Kans., and the horizon can be traced continuously in the 3 States.

A. M. Lloyd and W. C. Thompson, 1929 (A. A. P. G. Bull., vol. 13, pp. 945–946). Typical Whitehorse ss. can be seen W. of Aspermont, Stonewall Co., and W. of Sweetwater [Nolan Co.], where occur the outcrops of Wrather's Lake Trammel ss., now correlated with Whitehorse ss.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 167). *Lake Trammel* ss. of Wrather is part or all of Whitehorse ss. and is discarded.

Lake Valley limestone.

Mississippian (early): New Mexico.

E. D. Cope, 1882 (Eng. and Min. Jour., vol. 34, p. 214). I was first to determine Carbf. age of *Lake Valley ls.*

C. R. Keyes, 19(… (Ores and Met., vol. 12, p. 48). The Lower Carbf. is clearly differentiated in N. Mex. at several localities. Principal of these places is Lake Valley, Sierra Co. Here have been found extensive lss. carrying fauna of Lower Burlington ls. of Mo., Iowa, and Ill. To this remarkable ls. the local geographic name *Lake Valley* appears appropriate.

C. R. Keyes, 1904 (Am. Jour. Sci., 4th, vol. 18, pp. 360–362). *Lake Valley fm.* consists of 200 ft. of lss., underlying Sandia fm. and overlying Dev.

C. R. Keyes, 1905 (Iowa Acad. Sci. Proc., vol. 12, pp. 169–171). *Lake Valley ls.* is a remarkable blue crinoidal ls. carrying typical Lower Burlington fauna.

C. H. Gordon, 1907 (Am. Jour. Sci., 4th, vol. 24, pp. 58–64). *Lake Valley ls.* at Lake Valley is divisible into (descending): (1) Coarse subcrystalline yellowish-white ls. in moderately thick beds, more shaly below, with some cherty beds, and abundant crinoids and other fossils, 60+ ft.; (2) blue sh. with thin beds of bluish ls., same fossils as No. 3 but not so many crinoids, 75 ft.; (3) grayish blue, hard, compact ls., more or less siliceous at top, 25 ft. (locally called "Foot-wall lime"); (4) compact grayish ls., filled with nodular chert, and sh. partings, usually rather thick, 50 ft. Rests on Percha sh. (Dev.) and is overlain by andesite.

Lakeview limestone.

Middle Cambrian: Northern Idaho (Pend Oreille district).

E. Sampson, 1928 (Idaho Bur. Mines and Geol. Pam. 31, p. 9). *Lakeview ls.*—Varies from a pure little-altered ls. to a coarse marble. Where unaltered two main varieties occur: Heavy-bedded extremely massive ls. and thin-bedded shaly ls., which has yielded large collection of fossils identified by Resser as Middle Camb. and contains a variable amount of argill. material. The heavy-bedded ls. varies btw. nearly pure calcite and nearly pure dol. Named for exposures at town of Lakeview, near SE. end of Pend Oreille Lake. Thickness not stated.

Lakeview quartz-hornblende diorite.

Late Jurassic (?): Southern California (Riverside County).

P. H. Dudley, 1935 (Calif. Jour. Mines and Geol., vol. 31, No. 4, map, pp. 491, 502). Late Jurassic (?) rock found throughout greater part of Lakeview Mtns, Riverside Co.

†Lake Winnipesaukee gneiss.

Carboniferous to pre-Cambrian (?): Eastern New Hampshire (Lake Winnipesaukee region).

C. H. Hitchcock, 1874 (Geol. N. H., pt. 1, pp. 508–545), used *Winnepiseogee gneiss (or, for short, Lake gneiss)*. In previous repts he had used *gneiss about Lake Winnepisseogee*. (*Winnipesaukee* is spelling adopted by U. S. Geog. Bd.) In this 1874 rept he stated: "I think this includes the Berlin and Manchester ranges." On pp. 55–58 he stated *Winnipiseogee Lake gneiss fm.* consists of granitic gneiss filled with segregated veins, and has not yet been observed away from vicinity of the lake. Where he placed it below his White Mtn series and above the porphyritic gneiss or granite ("the oldest fm. in the State"). In 1874, in his general descriptions of the rocks of the State, he placed his Bethlehem group btw. the porphyritic gneiss and the Lake gneiss.

In Geol. N. H., pt. 2, 1877, Hitchcock in parts of the rept used *Lake gneiss;* in other parts, *Winnipiseogee gneiss;* and in other parts *Lake or Winnipiseogee gneiss;* while in his description of White Mtns dist. in that rept he designated (p. 111) the fm. *Berlin or Lake gneiss*, apparently from either the town or Twp of Berlin, both of which are in White Mtns. In that area he placed the fm. uncon. above his Bethlehem gneiss and below his Montalban group. In the Atlas of N. H. (1878) and in Mcfarlane's Geol. Ry Guide (1879), Hitchcock designated the rocks *Lake Winnipiseogee gneiss.* He has given 18,600 ft. as thickness of the fm. In

1884 and subsequent repts Hitchcock sometimes used *Lake gneiss* and sometimes *Lake Winnipiseogee gneiss*, while some other writers designated the rocks as *Winnipesaukee gneiss*. The shorter form *Lake gneiss* has also been used by other geologists. The names seem to have fallen into disuse. On 1932 geol. map of U. S. the rocks around Lake Winnipesaukee are mapped as pre-Camb., but Billings later (1934) questioned presence of any pre-Camb. rocks in N. H.

M. Billings, 1935 (letter dated Aug. 27). We have abandoned *Lake Winnipesaukee gneiss*, as it included most every conceivable kind of rock.

Lakota sandstone. (In Inyan Kara group.)

Lower Cretaceous: Western South Dakota, eastern Wyoming, southeastern Montana (in wells), and northwestern Nebraska.

N. H. Darton, 1899 (Geol. Soc. Am. Bull., vol. 10, p. 387). *Lakota ss.*—Coarse buff sss. with fire clays and local coal beds. Overlie Beulah shales [Morrison fm.] in Black Hills, S. Dak. Is Lower Cret. or Jurassic.

N. H. Darton, 1901 (U. S. G. S. 21st Ann. Rept., pt. 4, p. 526). *Lakota fm.*—Massive buff coarse cross-bedded ss. with some intercalated sh. and locally coal beds. Top memb. is dull-yellow ss. Thickness 200 to 300 ft. If not Jurassic it represents earliest deposit of Lower Cret. Contains local unconformities. Underlies Minnewaste ls. and uncon. overlies Jurassic Beulah shales [Morrison fm.]. Included in Dakota ss. of early repts. Name derived from one of tribal divisions of Sioux Indians.

N. H. Darton and C. C. O'Harra, 1909 (U. S. G. S. Belle Fourche folio, No. 164, p. 4). Type loc. of Lakota ss. is Lakota Peak, a summit on hog-back range 4 mi. NW. of Hermosa, S. Dak.

W. W. Rubey, 1930. See under *Inyan Kara group.*

Lalor sands.

Quaternary (probably Recent): Southern New Jersey (Trenton region).

J. B. Woodworth, 1911 (Harvard Univ. Peabody Mus. Am. Arch. and Eth. Papers, App., pp. 238–241). *Lalor sands.*—Eolian sand and rain wash. No stratification, but a well marked secondary structure consisting of irregular bands of inosculating ferruginous clayey material usually horizontal but locally vertical and clearly due to segregation of iron oxides through action of percolating waters. Belong to postglacial period, but appear to be in part contemp. with Trenton gravels to S. and E., at least that part of Trenton gravels that shows signs of wind action. Named for Lalor farm, near Riverview Cemetery, Trenton.

La Luz schists.

Age (?): Mexico.

C. W. Botsford, 1909 (Eng. and Min. Jour., vol. 87, p. 691).

La Luz basalts.

Triassic: Mexico.

A. Wandke and J. Martinez, 1928 (Econ. Geol., vol. 23, p. 8).

Lamar limestone member (of Delaware Mountain formation).

Permian: Western Texas (Delaware Basin).

W. B. Lang, 1937 (A. A. P. G. Bull., vol. 21, No. 7). *Lamar ls. memb. of Delaware Mtn fm.*—Black calc. bed, 25 to 30 ft. thick, forming top memb. of Delaware Mtn fm. in Delaware Basin. Within the basin it is a carbonaceous and highly calc. ss. As basin rim is approached the rock grades into ls., and finally becomes pale-gray ls. at base of the escarpment. In places it is overlain by additional Delaware Mtn beds, of ls. and ss., of variable thickness up to probably 100 ft. Underlies Castile anhydrite. Type loc. is escarpment N. of Lamar Canyon, where the canyon is crossed by the Western Gas pipe line, about 15 mi. due E. of Guadalupe Point. This ls. was previously called *Frijole ls.* by Blanchard and Davis, from Frijole P. O., but the similar dark ls. that occurs at Frijole P. O. is an older ls., and the name *Frijole ls.* is therefore abandoned, to avoid confusion.

Lamb dolomite.

Upper Cambrian: Western Utah (Gold Hill district).

T. B. Nolan, 1930 (Wash. Acad. Sci. Jour., vol. 20, No. 17, Oct. 19, pp. 421–432). *Lamb dol.*—Lower third largely thick-bedded oolitic and pisolitic dolomites, some of them cross-bedded. Above this lies thick-bedded medium-gray dol. mottled by patches of dol. containing white rods which closely resemble parts of the older Young Peak dol. In upper 150 ft. thinner-bedded dolomites with sandy partings become increasingly abundant, and these grade upward into a ss. that weathers reddish brown, which was chosen to make top limit of fm. This ss. lenses out to N. but a similar lens starts at about same locality a short distance higher stratigraphically. Thickness 1,050 ft. No fossils, but believed to be Upper Camb. because lithologically similar to overlying Hicks dol., which contains Upper Camb. fossils. Overlies Trippe ls. Named for exposures in Lamb Gulch, on N. side of Dry Canyon, Gold Hill dist.

See also U. S. G. S. P. P. 177, 1934, by T. B. Nolan.

Lambton formation.

Devonian: Canada.

E. J. Chapman, 1864 (A popular and practical exposition of the minerals and geology of Canada, p. 195).

Lamoille glacial stage.

A name applied by E. Blackwelder (Geol. Soc. Am. Bull., vol. 42, pp. 911, 918, 1931) to time covered by a Pleist. glacial deposit in Ruby Mtns, NE. Nev., which he correlates with Iowan stage. The largest glacier of this stage, 15± mi. long, issued from Lamoille Canyon, and built a low bulbous moraine upon the plain.

Lamont stone.

Trade name for a stone used in Chicago, Ill., for basements and facings of buildings. Analysis given on p. 92 of Ind. Geol. Surv. 8th, 9th, and 10th Ann. Repts (for 1876, 1877, and 1878), 1879. [Derivation of name not stated.]

Lamotte sandstone.

Upper Cambrian: Eastern and central Missouri.

A. Winslow, 1894 (Mo. Geol. Surv. vol. 6, pp. 331, 347–358). *Lamotte ss.*—Great body of ss. in SE. Mo., more than 250 ft. thick, immediately overlying Archean crystallines about Mine La Motte Station, but overlying Cambrian Iron Mtn cgl. in Iron Mtn dist., St. Francois Co. Underlies St. Francois or St. Joseph ls.

C. R. Keyes, 1896 (Mo. Geol. Surv. vol. 11, pp. 35–47). *La Motte ss.*—Consists of ss., some sh. and clay, with cgl. at base. Underlies Fredericktown dol. and uncon. overlies Algonkian crystallines.

A. Winslow, 1896 (U. S. G. S. Bull. 132). *La Motte ss.*—Thick massive ss., thinly bedded or flaggy near top; generally yellow or reddish, sometimes white. Thickness 400 ft. Underlies St. Joseph ls. and overlies Iron Mtn cgl.

C. R. Keyes, 1901 (Am. Geol., vol. 28, pp. 51–53). The cgl. called *Iron Mtn cgl.* by Winslow (1896) should properly be part of La Motte ss. It cannot be considered a distinct geol. terrane unless the original signification of title be wholly changed and restricted to the cgls. encircling the peak of Iron Mtn alone. On same horizon of uncon. and over a large area similar cgls. occur. They are usually of local extent, and may properly be regarded as local basal facies of La Motte ss.

H. F. Bain and E. O. Ulrich, 1905 (U. S. G. S. Bull. 267, p. 21). *La Motte ss.*, 0 to 300 ft. thick, includes, in St. Francois Mtns, a cgl. which has been called Pilot Knob cgl. and Iron Mtn cgl. Some regard it as Algonkian, others as a part of La Motte ss. It is not older than La Motte ss.

M. E. Wilson, 1922 (Mo. Bur. Geol. and Mines, 2d ser., vol. 16). *Lamotte ss.* probably underlies most of State. Outcrops chiefly in NE. St. Francois and western Ste. Genevieve and Madison Counties. Well records show thicknesses of 50 to 400 ft. Overlies pre-Camb. granites, porphyries, and qtzites.

Named for Mine La Motte Station, Madison Co.

Lamoureux shale (also spelled Lamoureaux).

Devonian: Eureka district, Nevada.

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 52, 79). *Lamoureux shales*, 300 ft. thick, underlie Atrypa lss. and compose basal fm. of Nevadan series [Nevada ls.] and of Devonic section in Eureka dist. Highly fossiliferous. Named for exposures in Lamoureux Canyon, Eureka dist.

Lampkins sandstone member.

Mississippian: Southern Indiana.

P. B. Stockdale, 1931 (Ind. Dept. Cons., Div. Geol. Pub. 98, pp. 77, 118, 178, 183, 291, etc.). *Lampkins ss. memb. of Carwood fm.*—A stout, angular fine-grained gray to buff ss. bed, 1 to 4 ft. thick, lying 55 to 65 ft. below top of Carwood fm. and 45 to 50 ft. above base of Carwood fm. The overlying beds are alternating ss. ledges and sh. partings. The underlying beds are sh. Thickness ½ mi. E. of Lampkins Bridge (3 mi. SW. of Belmont) and ¾ mi. N. of Lampkins Bridge and 2½ mi. SW. of Belmont is 4 ft. Is absent at Gent. Named for Lampkins Bridge, being shown prominently in nearby ravines and hillsides.

La Muda limestone.

Cretaceous: Puerto Rico.

C. P. Berkey, 1915 (N. Y. Acad. Sci. Annals, vol. 26, p. 22). [No age assigned; but H. A. Meyerhoff, 1931 (N. Y. Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, vol. 2, pt. 3, p. 276) and 1933 (Geol. of Puerto Rico, p. 44), assigned this ls. to Cret.]

Lana conglomerate.

Pre-Cambrian: Northwestern Vermont (Addison County).

W. G. Foye, 1919 (11th Rept. Vt. State Geol., p. 85). *Lana cgl. (Camb.)*.—Arkose cgl., a few ft. thick, conformably underlying Lower Camb. qtzite and uncon. overlying Proterozoic Mendon dol. just above the Falls of the Lana, N. of Silver Lake [S. part of Addison Co., in Brandon quad.]. This cgl. is never so coarse-grained or thick as Ripton cgl., which writer believes underlies Mendon dol.

E. J. Foyles, 1929 (16th Rept. Vt. State Geol., p. 284). *Lana cgl.* consists of quartz cgl. with fragments of older rock in it. Metamorphism has reunited many of the pebbles. [Foyles seems to treat Lana cgl. as distinct fm. underlying Cheshire qtzite, and separated from Mendon dol. by Lana sh.]

Lana shale.

Pre-Cambrian: Northwestern Vermont (Addison County).

E. J. Foyles, 1929 (16th Rept. Vt. State Geol. p. 284). *Lana sh.*—A phyllite with foliation doubtfully cutting across the bedding planes. The mica in it is badly altered and it contains plagioclase feldspars. The rock alternates with slaty-banded ss. [Foyles seems to place his Lana sh. below Lana cgl. and above Mendon dol. Probably named for Falls of the Lana.]

Lanai basalt.

Age (?): Lanai, Hawaiian Islands.

C. K. Wentworth, 1925 (Bernice P. Bishop Mus. Bull. 24, p. 34).

†Lancaster limestone.

Ordovician and Cambrian: Eastern Pennsylvania.

J. P. Lesley and P. Frazer, Jr., 1880 (2d Pa. Geol. Surv. Rept. C_3, map of Lancaster Co.). *Lancaster ls., including argillites.*—Overlies Lower calc. slates and underlies Mesozoic ss. and shales.

Same as Shenandoah ls., which has been mapped over large areas and is now usually divided into several named fms.

Lancaster formation.

Devonian or Carboniferous: New Brunswick.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, pp. 207, 212).

Lance formation.

Upper Cretaceous (except as stated in last entry): Wyoming (widespread), Montana (widespread), western North Dakota and South Dakota, and northwestern Colorado.

J. B. Hatcher, 1903 (Am. Geol., vol. 31, pp. 369–375). *Lance Creek (Ceratops) beds.*—The name *Ceratops beds* cannot be used for these Wyo. deposits, and I give to them the above name, from the principal stream in the region where they are best represented, in Converse Co., Wyo. That these beds conformably overlie the Fox Hills in this region has been published by present writer, who spent nearly 4 full years collecting from them, and been abundantly corroborated by investigations of T. W. Stanton and F. H. Knowlton. [On p. 374 he calls these beds the *Laramie (Lance Creek) beds of Converse Co., Wyo.*] The beds are overlain by the Fort Union.

See definition of †*Ceratops beds.*

T. W. Stanton, 1910 (Am. Jour. Sci., 4th, vol. 30, pp. 172–188). *Lance fm. ("Ceratops beds").*—The name *Lance fm.* has recently been adopted by U. S. Geol. Survey for the "Ceratops beds" of eastern Wyo. and adjacent areas. It is an abbreviated form of *"Lance Creek beds"* which J. B. Hatcher applied to these deposits in 1903 (Am. Geol., vol. 31, p. 369), with the statement that the name is taken "from the principal stream in the region where they are best represented, in Converse Co., Wyo." At present one of most important points at issue is relationship of Lance fm. to Laramie fm. and to the conformable Cret. sequence beneath the Laramie. Some geologists hold that the Lance fm. wherever it has been studied rests uncon. on the Laramie or some older fm., and that the uncon. beneath it represents a long complex epoch of elevation and erosion. In this paper evidence will be presented to show that in the rather widely distributed areas discussed there is a real transition from the marine Cret. Fox Hills ss. into Lance fm. and that sedimentation was practically continuous from the one into the other and probably on through the [overlying] Fort Union. If it is true that there is a transition with practically continuous sedimentation from Fox Hills ss. into Lance fm. in region discussed, then Lance fm. includes or forms part of the Laramie.

See also under *Cannonball marine memb. of Lance fm.*

The age of the Lance fm. and its relation to true Laramie fm. of Denver Basin (of unquestioned Upper Cret. age) are still disputed questions among American geologists, in view of which the U. S. Geol. Survey for many years tentatively classified Lance fm. as *Tertiary? (Eocene?)*. In consideration, however, of the accumulated evidence of a large amount of additional field work, extending over a period of many years, this age designation was modified as follows, in Dec. 1935: (1) The Hell Creek and Tullock deposits (previously classified as members of Lance fm.) were raised to fm. rank; (2) the age of Hell Creek fm. was changed to *Upper Cret.*; (3) the age of Tullock fm. was changed from *Tert. (?)* to *Upper Cret. or Eo.*; (4) in areas in Mont. and NE. Wyo. where the Hell Creek and Tullock are not recognizable, the age of the Lance was changed to *Upper Cret.*, except where Eo. fossils are found above Cret. fossils, in which case the age of the Lance is to be *Cret. and Eo.*; (5) the age of the Lance in other parts of Wyo. (outside NE. part of State) is to be *Upper Cret.*, no Eo. flora having been reported from these areas; (6) the age of Arapahoe fm. was changed to *Upper Cret.*; and (7) the age of the Dawson arkose and Denver fm. was changed to *Upper Cret. and Eo. (?)*.

Named for exposures on Lance Creek, Niobrara Co., Wyo. (formerly a part of Converse Co.).

Lance Cove formation.

Lower Ordovician: Newfoundland.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4). *Lance Cove fm.*—Sss. and shales, underlying McGraw bed and uncon. overlying Little Bell Island fm. Included in Bell Island series.

†Lance Creek beds.

See *Lance fm.*

Landaff granite.

Late Devonian or late Carboniferous: Northwestern New Hampshire (Moosilauke quadrangle).

M. P. Billings, 1935 (Geology of Littleton and Moosilauke quads., N. H., Moosilauke map, p. 28). *Landaff granite.*—Fine-grained massive pink to gray hastingsite granite. Late Dev. or late Carbf. Is related to White Mtn magma series. [Mapped over NE. part of Landaff Twp.]

Lander sandstone member (of Bighorn dolomite).

Upper Ordovician (Richmond): Western Wyoming (Wind River Mountains).

A. K. Miller, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 196–213). *Bighorn fm.* of NE. slope of Wind River Mtns, Wyo., consists of: (1) A very fossiliferous, thin, basal ss. memb., 1 to 4 ft. thick (here named *Lander ss.*, from exposures about 10 mi. SW. of Lander, Wyo.); (2) a massive dol. memb. about 300 ft. thick in NW. part of range and less than 150 ft. in SE. part of range; and (3) an upper dol. memb., about 25 ft. thick (the *Leigh dol.* of Blackwelder). [Lists and discusses fauna of Lander ss. (135 sp.) and concludes that it is of Richmond age and a southern extension of a widespread Arctic fauna of that age.] "Available evidence indicates Lander ss. is to be correlated with basal ss. memb. of [typical] Bighorn fm. of Bighorn Mts." [He therefore concludes all of Bighorn dol. is of Richmond age.]

Landes limestone.

Middle Devonian: Northeastern West Virginia.

D. B. Reger, 1924 (W. Va. Geol. Surv. Rept. on Mineral and Grant Counties, pp. 313, 745). *Landes ls.*—Dark, highly fossiliferous ls., present in form of good-sized nodules scattered through 1 to 5 ft. of brown sh. at extreme top of Hamilton series [fm.] in Mineral and Grant Counties. Contains Hamilton fossils.

Named for occurrence in public road along North Mill Creek 0.2 mi. N. of Landes, S. part of Grant Co.

Landgraff sandstone. (In Pocahontas formation.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, p. 235). *Landgraff ss.*—Massive, medium grained, micaceous, buff, 0 to 25 ft. thick. Underlies Pocahontas No. 1 coal and overlies Landgraff coal. Once quarried at Landgraff, McDowell Co. Belongs in Pocahontas group.

Landisburg sandstone.

Silurian: Central Pennsylvania (Perry County).

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 2, pp. 761–777). In Rept. F_2 this is called *Bloomfield ss.*, but I have changed the name to ***Landisburg***, where it is equally remarkable, so as to avoid confusion btw. the names Bloomfield and Bloomsburg. The Landisburg ss. lies in Middle Salina shales. At Landisburg, Perry Co., it is 42 ft. thick, and consists of (descending): Hard olive sh. and ss. with *Leperditia alta*, 3 ft.; red sh. and ss., 15 ft.; gray ss. with *L. alta*, 4 ft.; and red sh. and ss., 20 ft. It is underlain by gray and yellow sh. and overlain by 6 ft. of ls. and sh. with wrinkled surfaces. [After giving above section of Landisburg ss. he says: The *Landisburg ss. proper* is a thin bed of soft friable sandrock, breaking up into brick-shaped fragments, varying in color from dull reddish to olive greenish. Its outcrop, sometimes 10 ft. thick, makes low ridge traceable across Centre Twp, passing under New Bloomfield. He also calls this soft friable sandrock the *Landisburg fish-bed ss.*, and says that *L. alta* occurs in great abundance in "this little group of beds."]

Landston formation.

Middle Cambrian: Utah.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, p. 38), in table giving "General geol. section of Utah," listed (descending): Spence sh., 100 ft.; *Landston* (lss.), 500 ft.; uncon.; Pioche (early Camb.). Derivation of *Landston* not stated.

Lane shale. (Of Lansing group, in Kansas.)

Lane shale member (of Lansing formation, in Missouri).

Pennsylvanian: Eastern Kansas, southeastern Nebraska, northwestern Missouri, and southwestern Iowa.

E. Haworth, 1895 (Kans. Univ. Quart., vol. 3, p. 277, and pl. opp. p. 290; Am. Jour. Sci., 3d, vol. 50, p. 460 and pl. opp. p. 466). *Lane shales*.—Shales, with heavy ss. at top and many ss. beds scattered throughout, varying in thickness from thin to 150 ft. Underlain by Carlyle ls. and overlain by Garnett ls.

E. Haworth and J. Bennett, 1908 (Univ. Geol. Surv. Kans., vol. 9), defined *Lane sh.* as overlying Iola ls. and as separated from the higher Vilas sh. by a ls. which they called *Allen ls.* (=*Carlyle ls.*), and stated that Garnett ls. of Haworth and Kirk included (ascending) Allen [Plattsburg] ls., Vilas sh., and Stanton ls.

H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines vol. 13). *Lane sh.* (basal memb. of Lansing fm.) overlies Iola ls. and underlies Plattsburg ls., which is lower bed of "Garnett" ls. and is the ls. exposed at Carlyle, Kans., according to Kans. Geol. Survey. [This definition of Lane sh. was followed by Kans. Geol. Survey until 1931, when R. C. Moore (Kans. Geol. Soc. 5th Ann. Field Conf. correlation chart) restricted *Lane sh.* to lower part of Lane sh. of previous repts, and defined it as separated from overlying Plattsburg ls. by (ascending) Argentine ls., Island Creek sh., Farley ls., and Bonner Springs sh.]

Early in 1932 (Jan. or Feb.) G. E. Condra, R. C. Moore, and C. O. Dunbar transferred Lane sh. and their overlying Argentine ls. to Kansas City group. (See Nebr. Geol. Surv. Bull. 5, 2d ser., p. 17, table opp. p. 18.) Later in 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3) Moore still further restricted *Lane sh.* by introducing two more named units (Frisbie ls. and Quindaro sh.) btw. Argentine ls. and Lane sh., and stated that this restricted Lane sh. was typical Lane sh. R. C. Moore and G. E. Condra adhered to this latter definition in their Oct. 1932 revised classification chart of Penn. rocks of Kans. and Nebr.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pp. 18, 55–58). Haworth applied *Lane* to 100 ft. of sandy sh. btw. 2 prominent lss. near town of Lane. The lower ls. was correctly identified by Haworth as Iola. The upper ls., capping the scarp at Lane, is not Allen (Plattsburg ls.), as Haworth thought, but is a third ls. lying btw. the Iola and the Plattsburg. This ls. (Wyandotte of this rept.), although very prominent around Lane and northward to Kansas City and beyond, pinches out near Greeley in NE. Anderson Co. It is clear the early workers recognized only 2 lss. immediately succeeding Lane sh., whereas there are 3 in NE. Kans.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 117). *Lane sh.* overlies true Iola ls. at Lane type loc. Field studies have shown that ls. next above Lane sh. at Lane is not †Allen (Plattsburg) ls., but a lower fm. that is absent in Allen Co. The base of Plattsburg ls. does not mark upper bdy of Lane sh., as inferred by several geologists. The ls. next above Lane sh. is traced into ls. now called *Argentine ls.* The Lane as thus defined is variable in lithology and thickness. In places, mostly where it is thin, i. e., 15 to 35 ft. thick, it is wholly dark bluish-gray clayey sh. Where thick (50 to 110 ft.) most of the sh. is sandy and micaceous, light gray to yellowish brown or buff, with carbonaceous streaks but no coal beds. It is persistent from E. part of Miami Co., Kans., to NE. and N. Has been recognized in northern Mo., Iowa, and in Platte Valley, Nebr. Disappearance of Wyandotte ls. a short distance S. of Lane makes it impossible to recognize upper bdy of Lane sh., and in that region Lane is combined with overlying sh. under designation *Lane-Bonner Springs sh.* This combined unit (75 ft. thick near Iola and 60± ft. in southern Kans.) is dark bluish or bluish-gray clayey to fine silty sh. [On p. 45 Moore showed *Lane sh.* of his "revised classification" as underlying Frisbie ls., as overlying Raytown memb. of Iola ls., and as included in Kansas City group.]

The U. S. Geol. Survey has not yet had occasion to consider, for its publications, the modified definitions of Lane sh. and its transfer to Kansas City group.

Named for exposures at Lane, Franklin Co., Kans.

Lanesboro member (of New Milford formation).

Upper Devonian: Northeastern Pennsylvania (Susquehanna County).

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 571–589). Where basal Kingsley red sh. is present the remainder of New Milford fm. may for convenience be referred to as *Lanesboro memb.*, from exposures near Lanesboro, Susquehanna Co. In general the Lanesboro memb., or *New Milford fm.* as a whole, where the Kingsley is absent, consists of greenish to grayish flags; some massive; many cross-bedded. Upper part often forms cliffs. Max. thickness in Susquehanna Co. 400–500 ft.

†Laneville shale.

Pennsylvanian: Eastern Kansas and northwestern Missouri.

E. Haworth and M. Z. Kirk, 1894 (Kans. Univ. Quart., vol. 2, p. 108). *Laneville shales.*—Shales, 75 to 100 ft. thick, with several beds of valuable ss. Overlies Oswego ls. [Fort Scott ls.] and underlies Erie ls. Includes Fort Scott flagstones.

As thus defined apparently extended from top of Fort Scott ls. up to base of Hertha ls., which is basal bed of †Erie ls., according to R. C. Moore, 1936.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 60, 62–67, 72). †Laneville sh. of Haworth and Kirk included Labette sh., Pawnee ls., Bandera sh., Altamont ls., Nowata sh., Lenapah ls., Memorial sh., Bourbon fm.

Named for exposures at Laneville, Labette Co., Kans.

Laney shale member (of Green River formation).

Eocene: Southwestern Wyoming (Sweetwater County) and northwestern Colorado (Moffat County).

A. R. Schultz, 1920 (U. S. G. S. Bull. 702). *Laney sh. memb. of Green River fm.*—Thin-bedded sh., ss., and lss., some of which are oolitic; also some dark-colored bituminous sh. Thickness 0 to 950 ft. Uncon. underlies Plant beds and Tower ss. of Powell, which compose upper part of Green River fm., and uncon. overlies Cathedral Bluffs red beds memb. of Green River fm. [now called Cathedral Bluffs tongue of Wasatch fm.]. Named for Laney Rim, Sweetwater Co., Wyo.

†Lang division.

Tertiary: Southern California (Los Angeles County).

O. H. Hershey, 1902 (Am. Geol., vol. 29, pp. 349–372). *Lang div.*—A great bed of gravel and sand of buff color; red and brown lava cobbles plentiful. Thickness 3,000 ft. Has appearance of delta of a large river flowing westward on approx. site of Soledad Canyon. May be marine in W. part of basin. Conformably underlies Soledad div. and uncon. overlies Mellenia series. Named for exposures at Lang, Los Angeles Co.

W. S. W. Kew, 1924 (U. S. G. S. Bull. 753, p. 81). The "Lang div." of Hershey is thought by writer to be equiv., in greater part at least, to upper part of Mint Canyon fm. (upper Mio.) of this rept.

Langara quartz diorite.

Jurassic: British Columbia.

J. D. MacKenzie, 1916 (Canada Geol. Surv. Mem. 88, p. 52).

Langston limestone.

Middle Cambrian: Northeastern Utah and southeastern Idaho.

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804, pp. 6, 7). *Langston fm.*—Massive-bedded bluish-gray ls. with many round concretions. Thickness 107 ft. in Blacksmith Fork Canyon, Cache Co., Utah, and 30 ft. W. of Liberty, Bear Lake Co., Idaho. Middle Camb. fauna. Most readily accessible locality is in Blacksmith Fork, Cache Co., Utah, but strike of beds carries fm.

into valley of Langston Creek, Bear Lake Co., Idaho. Underlies Ute fm. and overlies Brigham. fm. [qtzite].

†Lang Syne beds.

Eocene (lower): Central South Carolina (eastern part of Calhoun County).

E. Sloan, 1908 (S. C. Geol. Surv., ser. 4, Bull. 2, pp. 449, 451–452). At Lang Syne and Warley Hill the Congaree shales rest on fine-grained, black, slightly glauconitic sands, and partly indurated gray sands, both of which contain tender casts of small shells. We shall refer to them as the *Lang Syne beds.* Stratigraphically they belong below the Congaree shales, and are tentatively treated as part of the Black Mingo, pending further investigations. [In table on p. 449 Sloan tentatively placed his Lang Syne beds above his Williamsburg pseudobuhr.]

C. W. Cooke, 1936 (U. S. G. S. Bull. 867). Lang Syne beds of Sloan are here tentatively referred to lower part of Black Mingo fm. (of Wilcox age), and name is abandoned. They rest uncon. on Tuscaloosa fm. near Fort Motte, Calhoun Co.

Named for exposures at Lang Syne plantation, Calhoun Co.

Lanoria quartzite.

Pre-Cambrian: Western Texas.

G. B. Richardson, 1909 (U. S. G. S. El Paso folio, No. 166). *Lanoria qtzite.*—Mass of pre-Camb. qtzite that outcrops along E. flank of Franklin Range. Consists of alternating layers of thick- and thin-bedded qtzite; some beds almost white, others dark-colored, prevailing tint being gray. The qtzite is fine-textured and thoroughly indurated. Thickness 1,800± ft. No fossils. Is cut by thin sills and dikes. Uncon. overlain by rhyolite porphyry. Base not exposed. Named for exposures just W. of an old settlement near base of Franklin Mtns, 8 mi. NE. of El Paso.

†Lanphier beds. (In Cheyenne sandstone.)

Lower Cretaceous (Comanche series): Central southern Kansas.

F. W. Cragin, 1895 (Am. Geol., vol. 16, pp. 361, 367). *Lanphier beds.*—Incoherent, more or less shaly sands, sometimes passing into shales, often heavily charged with carbonaceous matter, pyrites of iron and selenite crystals, and including numerous fragments of lignite. Thickness 10 or 15 ft. Basal part of Elk Creek beds. Overlain by Stokes ss. and underlain by Corral ss.

This name was discarded by U. S. Geol. Survey in 1921, the beds being a local facies of Cheyenne ss. and without strat. value. (See also last entry under *Cheyenne ss.*)

Named for draw running through Lanphier claim ("which may be called Lanphier Draw"), in SE. corner of Kiowa Co.

Lansdale shale. (In Newark group.)

Upper Triassic: Southeastern Pennsylvania (Bucks and Montgomery Counties).

B. S. Lyman, 1893 (Pa. Geol. Surv. geol. and topog. map of Bucks and Montgomery Counties) and 1895 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 3, pt. 2, pp. 2589–2638). *Lansdale shales.*—Red shales with a few scattered green layers, 4,700+ ft. thick. Underlie Perkasie shales and overlie Gwynedd shales. Underlie Lansdale, Montgomery Co., and a broad area.

Corresponds to basal part of Brunswick sh. of Newark group.

L'Anse series.

Age (?): Northeastern Michigan.

T. B. Brooks, 1873 (Mich. Geol. Surv. vol. 1, pt. 1, pp. 151–155), described, but did not name, the rocks of L'Anse iron dist. On p. 155, under heading *Huron Bay slates,* he stated that those slates, with associated rocks, "may be regarded as belonging to L'Anse series, although more than 10 mi. away in a NE. direction."

Lanse à Loup series.

Pre-Cambrian: Newfoundland.

N. C. Dale, 1927 (Geol. Soc. Am. Bull., vol. 38, p. 421).

L'Anse au Loup limestones.

Cambrian: Canada (St. Lawrence Valley).

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 197).

Lansing group, in Kansas.

Lansing formation, in Missouri.

Pennsylvanian: Missouri, Kansas, southeastern Nebraska, Iowa.

H. Hinds, 1912 (Mo. Bur. Geol. and Mines, vol. 11, 2d ser., p. 7). *Lansing fm.*—Lower half or two thirds consists of sh. and ss. with ls. only locally important. Top of fm., however, is Stanton ls. memb., 14 to 25 ft. thick. Thickness of fm. 140 ft. in Platte Co. and 100 ft. farther NE., near Iowa line. Overlies Kansas City ls. and underlies Douglas sh.

H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines vol. 13, pp. 28, 156). *Lansing fm.*—Is distinct fm. from overlying Douglas fm., containing more ls. than Douglas. Includes (descending) following members: Stanton ls., Vilas sh., Plattsburg ls., and Lane sh. Overlies Kansas City fm., the top memb. of which is Iola ls.

R. C. Moore and W. P. Haynes, 1917 (Kans. Geol. Surv. Bull. 3, p. 99). A very important faunal break, clearly defined by Beede and Rogers and Girty, occurs at top of Kansas City fm. (the top memb. of which is Iola ls.). Accordingly the beds above Iola ls. which were formerly included in Pottawatomie fm. have been separated from underlying beds and named, from typical outcrops in vicinity of Lansing, near Leavenworth, Kans., the *Lansing fm.* Faunally the Lansing appears to be continuous with overlying Douglas fm., but as latter differs lithologically from the Lansing, and has been well defined in literature for some time, it seems desirable to recognize both fms. Includes (descending) following members: Stanton ls., Vilas sh., Plattsburg ls., and Lane sh. [This was generally accepted definition of Lansing group until 1931.]

R. C. Moore, 1931 (Kans. Geol. Soc. 5th Ann. Field Conf. correlation chart), redefined *Lansing group* by including in its top Weston sh., Iatan ls., and lower part of Lawrence sh. of established usage, and by excluding from its base the upper part of Lane sh. memb.

R. C. Moore, Aug. 28 to Sept. 3, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook), again redefined his *Lansing group* by excluding at top the Weston sh., Iatan ls., and lower part of Lawrence sh., to which latter bed he applied new name *Hardesty sh.* The 3 latter units he assembled under new name *Pedee group.*

R. C. Moore and G. E. Condra, Oct. 1932 (revised classification chart of Penn. rocks of Kans. and Nebr.), again redefined *Lansing group* by drawing its base at base of Plattsburg ls., and including in it the overlying Vilas sh. and Stanton ls.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, p. 70). Bdy btw. Kansas City and Lansing divisions as originally defined can not be recognized, either lithologically or faunally, in Kans. S. of Johnson Co., because Farley ls. coalesces with Argentine ls. Moore therefore proposes to redefine Lansing to include only Plattsburg ls., Vilas sh., and Stanton ls. This usage corresponds to *Garnett ls.* of early Kans. Surv. [which has long priority]. [See under *Garnett ls.*]

These modified definitions have not been considered by U. S. Geol. Survey for its publications. The 1933 (57th) Bien. Rept. of Mo. Geol. Surv. continues to draw top of the Lansing at top of Stanton ls. and base at top of Iola ls.

Lansing moraine.

Pleistocene (Wisconsin stage): Southern Michigan. Shown on moraine map (pl. 32) of U. S. G. S. Mon. 53. Named for Lansing.

Lantern Hill quartz rock.

Age (?): Connecticut.

H. E. Gregory, 1906 (Conn. State Geol. and Nat. Hist. Surv. Bull. 6, p. 136).

Laona sandstone.

Upper Devonian: Western New York (Chautauqua County).

J. Hall, 1841 (N. Y. Geol. Surv. 5th Ann. Rept., p. 177). Quarries have been opened at Shumla on Canadawa Creek, and at Laona on same stream. The mass at

Laona was noticed by Dr. Beck, and in his rept was called *Laona ss.* Is somewhat peculiar in character, being much thicker here than in other parts of county. Is about 5 ft. thick. Upper 3 ft. often forms a single course. Is highly bituminous. Thins to S. and at Westfield it is about 1 ft. thick and considerably changed in character. The *Laona ss.* appears to have been deposited in a depression of the strata below, which causes it to grow thinner on either side.

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, p. 25 and chart). *Laona ss.* of Chautauqua Co. is a basal memb. of Chemung series.

D. D. Luther, 1903 (N. Y. State Mus. Bull. 69, pp. 1026–1029). *Laona ss.* was named for exposures [in Canadaway Creek] at Laona. [Appears to be included in Portage group.] No other representatives of Portage fauna were found above Laona ss. On lower surface of thin ss. 10 ft. higher and in subjacent shales, Chemung brachiopods are common. Lies 260 to 280 ft. below Shumla ss. Rests on Portland gray sh.

J. M. Clarke, 1904 (N. Y. State Mus. Mem. 6, p. 214). In Lake Erie section (Erie and Chautauqua Counties) there comes in above the Portland light-colored shales and thin flags a ss., 22 ft. thick, carrying Chemung brachiopod fauna, termed by James Hall the *Laona ss.*, exposed at Laona [Chautauqua Co.], Forestville, Brocton, etc.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 79 and chart). *Laona ss.* (1903 Clarke) is=lower part of Nunda ss. The fauna, while mainly Chemung, contains a few cephalopods suggestive of the Portage. [Chart states that Nunda ss. of Portage beds includes at base the Laona ss.]

G. H. Chadwick, 1919 (Geol. Soc. Am. Bull., vol. 30, p. 157), and 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69), included Laona ss. and underlying Gowanda beds (also the still older Dunkirk sh.) in Chemung, and applied *Westfield sh.* to beds above the Laona.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369), divided Chemung of western N. Y. into (descending) Chadakoin beds, Cuba ss., Northeast sh., Shumla ss., Westfield sh., Laona ss., Gowanda sh., and Dunkirk sh. But G. H. Chadwick (1933, 1935, etc.) transferred to his Canadaway group (q. v.) all beds from top of Northeast sh. to base of Dunkirk sh.

Lapara sand member (of Goliad sand).

Tertiary (Pliocene): Southern Texas.

E. T. Dumble, 1893 (Brown coal and lignite of Texas, p. 154). [No definition except that *Lapara beds* rest uncon. on Fayette div.]

E. T. Dumble, 1894 (Jour. Geol., vol. 2, pp. 559–560). *Lapara beds or div.*—Coarse, sharp sands and light-red, green, and other colored clays interbedded and somewhat cross-bedded. Underlies Lagarto div. and overlies Miocene Oakville. Assigned to Plio.

A. Deussen, 1924 (U. S. G. S. P. P. 126, p. 100). *Lapara sand* consists of sand and interbedded and cross-bedded limy clay. The sand is sharp, coarse, and friable and contains clay pebbles and lime concretions. The clay is of several colors—pink, light red, green, etc. At some places it contains lime nodules and at others clay pebbles. Thickness 75 to 455 ft. in well records. Is exposed on Nueces River, where it lies uncon. (?) on Oakville ss. and conformably (?) below Lagarto clay. Named by Dumble after Lapara Creek, Live Oak Co., Tex., where it is typically displayed.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 751, 753, 754). San Antonio committee on geologic mapping decided to include Lapara sand in the new Goliad fm., and to draw base of Goliad at base of Lapara gravel beds [shown as basal bed of Lapara sand memb. of Goliad fm.], which rest on underlying Lagarto fm. [restricted]. The memb. is typically exposed on Nueces River SE. of Mikeska on Manahuilla Creek, 4 to 5 mi. NE. of Goliad, and on Guadalupe River SE. of Cuero. The type loc. comprises the exposures along Lapara Creek, in Live Oak Co. According to H. T. Richardson it is a more or less continuous layer of sand and gravel, 15 to 20 ft. thick, that can be traced across central Tex. and mapped from Nueces River to Guadalupe River. Consists of cgl., cross-bedded sand, and limy clay. The cgl. is composed of cobbles that range up to 6 inches diam., clay balls, sand, and much reworked material, such as bone fragments and bits of fossilized wood. The sand is coarse, friable, and contains clay pebbles, calc. concretions, and lentils of red and green clay. The clay is irregularly bedded and contains pebbles and nodules similar to those in the cgl. The Lapara sand memb. is uncon. [errata sheet dated Dec. 11, 1933] overlain by Lagarto Creek beds.

The U. S. Geol. Survey follows Plummer's definition of Goliad sand, and treats Lapara sand as basal memb. of the Goliad.

†La Plata sandstone.

Upper Jurassic: Southwestern Colorado and southeastern Utah.

C. W. Purington, 1898 (U. S. G. S. 18th Ann. Rept., pt. 3, p. 759; named by W. Cross). Lying directly on the Trias (mostly red sss.) in Telluride quad., Colo., is lower memb. of Jura. It consists of friable medium-grained white ss., of massive appearance, which has a thickness of 50 to 100 ft. It has been called La Plata ss. by W. Cross, owing to its extensive development in La Plata Mtns, to S. It includes a layer of black impure ls. 8± ft. thick. The upper memb. of Jura is Gunnison sh., about 700 ft. thick.

W. Cross, 1898 (geol. map accompanying rept cited above, the areal geology of which is by Cross). *La Plata ss.*—Two white ss. layers with dark ls. btw. them. Underlies Gunnison fm. and overlies Dolores fm.

W. Cross, 1899 (U. S. G. S. Telluride folio, No. 57). It is proposed to name lower memb. of Gunnison fm. after La Plata Mtns, on account of its prominent and characteristic exposures in peaks and on slopes of that mtn group. From dominant development of white ss. in Telluride and other quads, it is there quite appropriate to call this fm. *La Plata ss.*, but it is known that the thin ls. of Telluride area represents a much more extensive series of shales, etc., in some other regions. In this quad. *La Plata fm.* consists of 2 massive ss. members separated by a thin dense bluish or almost black ls. 6 to 16 ft. thick. Total thickness here is seldom more than 100 ft. The sss. here are very light gray or white, but in many places, especially to S. and W., a distinct or even brilliant coloring in varying shades of red or orange has been observed in the lower ss. But the contrast with the bright-red strata of underlying Dolores fm. is very striking. The 2 ss. members are usually of similar character, but in this quad. the upper one is sometimes thin bedded and shaly and much less prominent than the lower. The upper ss. layer is succeeded by a highly colored sh., taken as lowest stratum of McElmo fm. The McElmo is Gunnison fm. restricted of Purington. Type Gunnison includes McElmo and La Plata.

See explanation under †*McElmo fm.*, for reasons for abandonment. Also see U. S. G. S. P. P. 183, 1936, by A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., for details regarding the units into which the La Plata ss. of different authors, in different areas, is now divided.

†La Plata limestone.

Name locally applied by miners to ½ ft. to 8 ft. of ls. forming basal bed of Morrison fm. (Upper Jurassic) in La Plata dist., SW. Colo.

Lapoint horizon. (In Duchesne River formation.)

Oligocene: Eastern Utah (Uinta Basin).

See under *Randlett horizon.*

La Posta quartz diorite.

Late Jurassic or early Cretaceous: Southern California (San Diego and Imperial Counties).

W. J. Miller, 1935 (Calif. Jour. Mines and Geol., vol. 31, No. 2, pp. 115–141, map). *La Posta quartz diorite.*—Large typical exposures occur in general vicinity of La Posta Valley, southern Peninsular Range. Probably youngest of late Jurassic or early Cret. intrusive series.

Laramian series.

A term used by C. R. Keyes to cover Laramie fm. and supposedly contemp. deposits. He calls the underlying deposits "Masukian series."

Laramide revolution.

A period of mountain building and erosion in Rocky Mountain region that began in late Cret. time and ended in early Tert. time. "The Laramide system of mtn ranges, including Wasatch Range, extends along summit of Rocky Mtns far northward into B. C. and southward into Mexico. In B. C. just N. of Mont. the upturned belt lies E. of the Archean protaxis. In U. S. it occupies the summit region of the mtns, btw. the line of the Wasatch Archean and the Front Range or protaxis." (J. D. Dana, 1895, Textbook geol. 4th ed., p. 359.)

Laramie formation.

Upper Cretaceous: Denver Basin region of eastern Colorado.

C. King, 1876 (U. S. Geol. Expl. 40th Par. Atlas, maps 1 and 2). [The maps are dated 1875, and copies were distributed before issuance of the Atlas, which is dated 1876. *Laramie* (latest Cret.) is shown as overlying Fox Hill and underlying Vermilion Creek (Eo.) in NW. Colo. and southern Wyo. On map 1 the Laramie is mapped as far S. as S. part of Weld. Co. in NE. Colo., where it is shown as overlain by Quat. Beds around Carbon, Wyo., and far to W. are mapped as *Laramie*.]

F. V. Hayden, 1876 (U. S. Geol. Surv. Terr. 8th Ann. Rept., pp. 20–27, 40–46). *Lignitic or Laramie group.*—Occupies very large area along Upper Missouri and Yellowstone Rivers and extends far N. into British Possessions. Has been traced S. in broad continuous belt across Yellowstone River, btw. Black Hills and Big Horn Mtns, until overlapped by White River group about 60 mi. N. of Fort Laramie. Southward along E. base of Laramie Range it reappears about 10 mi. S. of Union Pacific R. R. The Laramie Range formed a barrier that prevented White River group from extending into Laramie Plains, but evidence is clear that at time of existence of the great Lignitic lake or sea this barrier did not prevent water communication with Laramie Plains. With exception of Bear River and Coalville group we may connect the coal-bearing beds of Laramie Plains and Colo. with the vast group in the Northwest. Everywhere it rests on Fox Hills group. [Hayden's 1874 rept. stated that he had traced "Lignitic group" without interruption along E. base of Rocky Mtns S. to near Laramie Peak, "where it is overlapped by White River deposits." As defined above Laramie "group" included Lance, Fort Union, and Wasatch fms. of present terminology.]

On pp. 40 to 46 of above (1876) rept Hayden described *Lignitic or Laramie group* of Colorado Springs and vicinity as older than his Monument Creek group, and as overlying Fox Hills "group", as he called it. According to G. B. Richardson (U. S. G. S. Castle Rock folio, No. 198, 1915) Hayden's Monument Creek group included (descending) Castle Rock cgl. (Olig.) and Dawson arkose (=Denver and Arapahoe fms.), of Eo. age. The beds btw. Monument Creek group of Hayden and Fox Hills ss. in Denver Basin region, or Laramie fm. as originally defined in this area, consist of 600 to 1,200 ft. of brackish and fresh-water sandy and clay sh. with some thin sss. and in places 200 ft. of white ss. at base.

A. Hague, 1877 (U. S. Expl. 40th Par. Rept., vol. 2, pp. 28, 58–65), described *Laramie div.* of the Cret. plains of Colo. E. of the Colorado or Front Range. (Vol. 1, in which King defined the Laramie, was not published until 1878.) Hague gave thickness in eastern foothills of Colo. as 1,500 ft., and defined Laramie as uncon. overlain by Plio. or Quat. and as grading into underlying Fox Hills ss. His measured section was on Denver Pacific R. R. 5 or 6 mi. W. of Carr Station and about 18 mi. SE. of Cheyenne, Wyo.

C. King, 1878 (U. S. Expl. 40th Par. Rept., vol. 1, pp. 298, 331, 350, etc.). *Laramie group.*—Marine sss. of variable character; beds of lignite and seams of carbonaceous clay characterized throughout by molluscan forms of both salt- and brackish-water types and by several important zones of plant-bearing beds. Thickness 1,500 to 5,000 ft. The last of the conformable marine Cret. It is Lignitic series of Meek and Hayden in Upper Missouri section. Dr. Hayden has successively considered these rocks as Tert. and as transitional btw. Cret. and Tert. They conformably overlie Fox Hill of Meek and Hayden, and are developed throughout large part of Wyo. as well as upon the great plains E. of Rocky Mtns S. of 41st par. That there might be no misunderstanding as to strat. position and nature of the rocks themselves, Dr. Hayden and I mutually agreed to know them hereafter as *Laramie group*, and to leave their age for present as debatable ground, each referring them to the horizon which the evidence seemed to him to warrant. The result of our investigations leads me to distinct belief of their Cret. age. Le Conte, Newberry, Stevenson, and Powell have all committed themselves to view advanced by me in 1870, that the whole of the conformable series is Cret. Dinosaurs are found at very summit of *Laramie group*. The fauna up to base of Laramie is strictly marine. The Laramie itself carries the remains of an estuarial or brackish-water life associated with strictly Mesozoic saurians. The most important uncon. in whole Cordilleran region is at top of Laramie group, which is overlain by Vermilion Creek group (=Wasatch group of Hayden).

F. V. Hayden, 1878 (U. S. Geol. Surv. Terr. Rept., Mon. 7, pt. 2, p. iv). If objection is made to use of *Lignitic group* I would say that in this work it is restricted to a series of coal-bearing strata lying above Fox Hills group, or Upper Cret., and these are embraced in the Laramie and Fort Union groups. It is well known that there are in various parts of the West, especially along fortieth parallel and southwestward, very thick beds of coal in the divisions of the Cret., extending down even into upper Jurassic. Had this not been the case, the more general term *Lignitic* would not have been retained by the Survey in preference to any other. The facts as we understand them at the present time would seem to warrant this general division, viz, a marine series, Cret.; gradually passing up into a brackish water series, Laramie; gradually passing up into a purely fresh-water series, Wasatch. It is also probable that the brackish-water beds on the Upper Missouri must be correlated with the Laramie, and that Wasatch group as now defined and Fort Union group are identical as a whole, or in part at least. [Although deposits now recognized as belonging to true Fort Union fm. have in the past been included in both Wasatch fm. and so-called Laramie fm. of southern Wyo. and NW. Colo., the Wasatch fm. as now recognized overlies Fort Union fm. as now interpreted. See under *Fort Union fm.*]

See further explanation under †*Lignite fm.* The Laramie as mapped by King, Hayden, and other early workers covered large areas in Rocky Mtn region, and as more detailed geologic work in that region progressed it was found that the name *Laramie fm.* had been applied to rocks of different origin and of definitely both Upper Cret. and Eo. age, and also to rocks whose age is still questioned. Thus "What is the Laramie fm.?" became a burning question among American geologists. In order to retain the name in the literature the U. S. Geol. Survey in 1910 decided to, for the present, restrict *Laramie* to Denver Basin region, and, after 20 years of disconnected study, it is still thus restricted, while the age of the probably equiv. Lance fm. of Wyo. and other areas to N. and E. long remained undecided, being classified as *Tert.* (?). (See *Lance fm.*) The rocks in Carbon Co., Wyo., that were called *Laramie* by the early workers are now divided into (descending) Ferris fm. (Eo. and Upper Cret.) and Medicine Bow fm. (Upper Cret.). The so-called Laramie of other parts of Wyo., of Mont., of the Dakotas, and of NW. Colo. is now divided into Fort Union fm. (Eo.) and Lance fm. (Upper Cret.). The so-called Laramie of SW. Colo. is now divided into (descending) McDermott fm., Kirtland sh., Fruitland fm., and Pictured Cliffs ss., all Upper Cret.

Lardeau diabase schists.

Post-Carboniferous (?): British Columbia.

M. F. Bancroft, 1918 (Canada Geol. Surv. Summ. Rept. 1917, pt. B, p. 36).

Lardeau series.

Pre-Cambrian: British Columbia.

J. F. Walker and M. F. Bancroft, 1929 (Canada Geol. Surv. Mem. 161, p. 11).

Larder Lake series.

Pre-Cambrian: Ontario and Quebec.

M. E. Wilson, 1912 (Canada Geol. Surv. Mem. 17, p. 20) and 1918 (Canada Geol. Surv. Mem. 103, p. 52).

Lares shales.

Tertiary: Puerto Rico.

C. P. Berkey, 1915 (N. Y. Acad. Sci. Annals, vol. 26, p. 61).

Lares formation of Puerto Rico assigned to Olig. by H. A. Meyerhoff, 1933 (Geol. of Puerto Rico, p. 67).

Lares limestone of Puerto Rico assigned to upper Olig. by C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 466).

†Largo beds.

Eocene (lower): Northwestern New Mexico.

W. Granger, 1914 (Am. Mus. Nat. Hist. Bull., vol. 33, pp. 205–207). Wasatch group of NW. N. Mex. consists of red, gray, and ocherous bands of sh. and ss., with no evident uncon. throughout the series. It is here separated into two faunal divisions, the upper, here named *Largo beds*, 333± ft. thick, characterized by genus *Meniscotherium*, and similar in appearance to the lower (Almagre) beds, except that red strata are more dominant. The lower, or *Almagre beds* are 666± ft. thick, characterized by absence of all perissodactyls except *Eohippus*. The Largo beds are named for Largo Arroyo and Almagre beds for Almagre watershed. The Wasatch uncon. overlies Torrejon fm.

The U. S. Geol. Survey does not apply geographic names to faunal zones, and has therefore discarded the use of "Largo beds" and "Almagre beds."

Larimer sandstone member (of Pierre shale).

Upper Cretaceous: Central northern Colorado (Larimer County).

M. W. Ball, 1924 (A. A. P. G. Bull., vol. 8, pp. 81–87). *Larimer ss.*, 141 ft. thick, was first discriminated by A. T. Schwenneson, E. W. Krampert, and C. H. Henley as distinct from Hygiene ss., and was mapped and named by them [unpublished repts] "Waverly ss.," but that name being preoccupied, writer substitutes for it the name *Larimer ss.* It lies 171 ft. below Richard ss. and 163 ft. above Rocky Ridge ss. Is exposed in Larimer Co. canal in sec. 24, T. 8 N., R. 69 E., on W. flank of Fort Collins structure. Can also be studied about 1 mi. E. of village of Waverly, Larimer Co. [See also 1924 entry under *Hygiene ss. memb.*]

K. F. Mather, J. Gilluly, and R. G. Lusk, 1928 (U. S. G. S. Bull. 796B). *Larimer ss. memb. of Pierre sh.* is 0 to 150 ft. thick, lies 100 to 200 ft. below Richard ss. memb. and 0 to 170 ft. above Rocky Ridge ss. memb.

Larke dolomite.

Lower Ordovician (Beekmantown): Central Pennsylvania (Blair and Huntingdon Counties).

C. Butts, 1918 (Am. Jour. Sci., 4th, vol. 46, pp. 527, 534, 537). *Larke dol.*—Thick-bedded, coarse, steely blue ls., 250 ft. thick. Uncon. underlies Beekmantown group and overlies Mines dol. Named for Larke P. O., S. of Williamsburg, Blair Co.

This fm. is now classified by U. S. Geol. Survey as of Lower Ord. (Beekmantown) age.

Larsen limestone.

Miners' local name for an ore-bearing ls., 15 ft. thick, in middle part of Oquirrh fm. (Penn.) of Stockton dist., NW. Utah. Lies 500± ft. below their Ben Harrison ls., and 2,000± ft. above their Paisley ls. Outcrops in Muerbrook mine, which is owned by Mrs. Larsen. (See U. S. G. S. P. P. 173, 1932.)

Larsh shale. (In Deer Creek limestone.)

Pennsylvanian: Southeastern Nebraska, southwestern Iowa, northwestern Missouri, and northeastern Kansas.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 40, 43, 49, 50). *Larsh sh.*, near base of Deer Creek ls., is 1⅔ to 2 ft. thick in SE. Nebr. and SW. Iowa, 6 to 8 ft. thick in NW. Mo., and 8+ ft. thick in NE. Kans. Underlies Haynies ls. and overlies Rock Bluff ls. Named for Larsh farm, on Ervine Creek, NE. of Union, Nebr.

See under *Mission Creek sh.*, also Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936, and 1937 entry under *Topeka ls.*

La Salle limestone member (of McLeansboro formation).

Pennsylvanian: Northeastern Illinois (La Salle County).

G. H. Cady, 1908 (Ill. Geol. Surv. Bull. 8, pp. 128–134). *LaSalle ls.*—Blue-gray to light cream-colored ls., 20 to 30 ft. thick, forming topmost part of Coal Measures where it outcrops. Upper ls. bed is 5 to 15 ft. thick, lower ls. bed is 6 to 16 ft. thick, the two lss. being separated by 8 in. to 3½ ft. of calc. sh. At La Salle is about 400 ft. above base of Coal Measures,

G. H. Cady, 1919 (Ill. Geol. Surv. Bull. 37, pp. 64–69), described typical LaSalle ls. of LaSalle, NE. Ill. He stated: Base of LaSalle ls. is arbitrarily taken as top of a black fissile sh. about 1 ft. thick, commonly associated with a coal seam 1 in. thick. This black sh. forms floor of quarry of LaSalle Cement Co., E. of LaSalle. The ls. terminates below 20 ft. of red concretionary sh. Typical LaSalle ls. is found only on W. flank of anticline in strip not much over 1 mi. wide. At cement quarries it is a succession of 30± ft. of ls. varying from white crinoidal and oolitic strata to brecciated nodular dense thin-bedded layers associated with argill. material. Is highly calc. but contains variable amounts of argill. material. West of Vermilion Rivers the LaSalle becomes more argill., even essentially sh.

G. H. Cady, 1921 (Ill. Geol. Surv. Cooperative Min. Ser. Bull. 26, pp. 36, 38), applied this name in N. part of dist. 4, central western Ill. (including Peoria, Fulton, Tazewell, Logan, Menard, Sangamon, Macon, De Witt, McLean, Mason, Cass, and Schuyler Counties), where he stated it is 180± ft. above coal No. 7 and 25± ft. above Spring Valley ls., which he placed 10 to 15 ft. above coal No. 8.

G. E. Ekblaw, 1933 (Ill. Acad. Sci. Trans., vol. 25, pp. 143–145). *LaSalle ls.* (called *Shoal Creek ls.* by Wallace Lee in U. S. G. S. Mount Olive-Gillespie folio, No. 220, 1926) lies 52± ft. above Shoal Creek ls. (called *Carlinville ls.* by Lee).

J. E. Lamar and H. B. Willman, 1934 (Ill. Geol. Surv. Bull. 61, pp. 129–138). In Clark Co., SE. Ill., the LaSalle ls. has been called *Livingston, Marshall, Casey* and *Quarry Creek ls.* It also embraces the 16 to 20-foot ls. in Vermilion Co. that has been called Fairmount ls., also the *Baldwinsville ls.* of Edgar Co., and the *Ryans Ford ls.* of Coles and Cumberland Counties.

†La Salle formation.

Pennsylvanian: Northeastern Illinois.

F. W. De Wolf, 1910 (Ill. Geol. Surv. Bull. 16, p. 180). *LaSalle fm.*—Shales, sss. and thin coals lying btw. base of coal No. 2 (below) and base of coal No. 5 (above). Thickness 160 to 190 ft. in northern Ill. and 250 to 320 ft. in southern Ill. Overlies Pottsville fm. and underlies Petersburg fm.

Preoccupied by *La Salle ls. memb.* Strata constitute lower part of Carbondale fm.

Named for La Salle Co.

Las Cahobas formation.

Miocene: Haiti.

W. F. Jones, 1918 (Jour. Geol., vol. 26, p. 737). [Assigned to Tert.]

W. P. Woodring (1922 and 1924) and others assign it to Mio.

Las Cascades agglomerate.

Eocene (?): Panama Canal zone.

D. F. MacDonald, 1913 (Geol. Soc. Am. Bull., vol. 24, p. 708). [See also MacDonald, 1919 (U. S. Nat. Mus. Bull. 103, p. 526).]

Las Esperanzas formation.

Cretaceous: Mexico.

E. Ordóñez, 1908 (Min. and Sci. Press, vol. 96, p. 363).

Las Matas gravels.

Pliocene: Dominican Republic.

C. W. Cooke, 1920 (Geol. Soc. Am. Bull., vol. 31, p. 219).

Lasoya Creek conglomerate.

See *Losoya Creek cgl.*

Las Posas formation.

Pleistocene: Southern California (Ventura County).

E. D. Pressler, 1929 (Univ. Calif. Pub., Dept. Geol. Sci. Bull. vol. 18, No. 13, pp. 325–345). *Las Posas fm.*—In South Mtn area consists of 1,500± ft. of loose sands and cgl. alternating with beds of silty sand and gravel. In Las Posas Hills it consists of 75 ft. of light-colored cgls. and yellow to tan fine to medium-grained sands. Overlaps Pico in some places and in other places appears to rest conformably on Santa Barbara beds (Upper Pico, Plio.). Divided into *Long Canyon memb.* (above) and *Kalorama memb.* (below). Is marine Pleist.; equiv.

to Upper San Pedro, Lower San Pedro, and "San Pedro Pliocene" of Deadman's Island. Is=Saugus, which typically is terrestrial. It seems very unsatisfactory to use same name for both marine and terrestrial strata, which are so situated that their integrating phases cannot be traced, and for this reason the term *Las Posas fm.* has been applied to the beds containing the Kalorama and Long Canyon faunas that come above the coolwater Santa Barbara in W. part of the basin.

B. L. Clark, 1930 (Geol. Soc. Am. Bull., vol. 41, p. 766). *Las Posas fm.* is marine Saugus of Kew.

U. S. Grant, IV, and H. R. Gale, 1931 (Mem. San Diego Soc. Nat. Hist., vol. 1, pp. 42–43, 61). *Las Posas zone* in Los Angeles Basin is most characteristically exposed at Lomitas Quarry and in Hilltop Quarry. It uncon. underlies Timms Point zone (=Deadman Island "Plio." of repts) and overlies Santa Barbara zone. Correlation with Las Posas of Ventura Basin practically certain. [See *Lomita fm.*]

D. Cassell and A. J. Tieje, 1933 (Pan-Am. Geol., vol. 59, p. 376), stated Las Posas fm. overlies Timms Point. (See under *Timms Point fm.*)

T. L. Bailey, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 3, pp. 492–494). Kalorama memb. of Las Posas fm. contains a typical Santa Barbara fauna and is here included in Santa Barbara fm. The upper half of the Santa Barbara is here tentatively placed in Lower Pleist., instead of Upper Plio.

Las Puercas marl.

Pleistocene (?): Cuba.

S. Taber, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 4, p. 589).

Las Salinas formation.

Miocene: Dominican Republic.

C. W. Cooke, 1920 (Geol. Soc. Am. Bull., vol. 31, p. 219).

Lassen dacites.

See under *Divide Peak andesite.*

Last Chance andesite.

Tertiary: Mogollon district, New Mexico.

H. G. Ferguson, 1927 (U. S. G. S. Bull. 787). Andesite, breccia, and aggl. The flows thin (rarely exceeding 50 ft. to a flow) and alternating with pyroclastic rocks. In places the breccias and aggls. exceed the lavas in volume, and in places they have been more or less reworked by water. Thin beds of fine-grained ss. also occur. Thickness 300 to 600 ft. Younger than Fanney rhyolite and older than Deadwood Gulch rhyolite tuff.

Named for exposures at Last Chance Mine, S. of Silver Creek, Mogollon dist.

Las Vigas formation.

Lower Cretaceous (Comanche series): Southwestern Texas (Presidio region) and northern Mexico.

R. H. Burrows, 1909 (Min. and Sci. Press, vol. 99, p. 293) and 1910 (Soc. Geol. Mexicana, Bol., t. 7, p. 93).

W. S. Adkins, 1933 (Univ. Tex. Bull. 3232, pp. 271, 293). *Las Vigas fm.*, of basal Trinity age, was named by Burrows, from exposures in Conchos River Valley, northern Chihuahua, W. of Presidio, Tex. According to interpretation of C. Burckhardt it overlies upper Jurassic Plumosas fm. of Burrows. It consists of gray, black, and red qtzitic ss., gray limy ss., black shales, and sandy lss. Some of sss. and shales contain veins of copper. The upper part, transitional to overlying Cuchillo fm., contains gyp. and fossiliferous lss. (*Exogyra*). Thickness in Conchos Valley reaches 1,968 ft. Outcrops in southern Quitman Mtns with est. thickness of 500+ ft.

Las Virgenes sandstone.

Eocene (lower): Southern California (Ventura County).

R. N. Nelson, 1925 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 15, No. 11, pp. 400–401 and map). *Las Virgenes ss.*—Beds of coarse-grained ss. conformably overlying and in part grading laterally into Simi cgl., and conformably underlying and in part grading laterally into the marine memb. of Martinez group on W.

side of the faults south of Simi Valley. Thickness 311 ft. 1 mi. W. of head of Las Virgenes Canyon. Is middle div. of Martinez group (lower Eo.). Named for typical development at head of Las Virgenes Canyon, on S. side of Simi Hills, Ventura Co.

Latah formation.

Miocene (upper or middle): Eastern Washington and western Idaho.

J. T. Pardee and K. Bryan, 1926 (U. S. G. S. P. P. 140, pp. 4–12). *Latah fm.*—Chiefly clay and sh., with some beds of sand and gravel and one or more beds that contain sufficient quantities of diatom skeletons to be classed as impure diatomaceous earth. Many sh. beds appear to be composed largely of very fine volcanic ash. The sh. generally contains plant remains classified by F. H. Knowlton as middle or lower Mio. [Berry assigned the flora to middle or upper Mio.; R. W. Brown considers it middle Mio. The fm. is mapped in this rept as far N. as 25± mi. from Spokane and 10± mi. S. of Spokane.] Evidence indicates it extends E. into the open valleys near Coeur d'Alene, Idaho. Thickness at least 250 ft. in area of typical exposure on slope W. of Latah Creek (a short distance S. of Spokane), and 0 to 1,500 ft. in Spokane-Coeur d'Alene [Idaho] area. In Spokane area, so far as known, it everywhere rests on the granite-schist group, and apparently it is or was at one time everywhere covered by the lava flows comprising the "rim rock," which are somewhat later than Yakima basalt. It formerly extended continuously over the area from Silver Hill-Cheney Ridge N. and E. to the mtns, except for the "islands" or "steptoes" of crystalline rock, many of which were not covered even by the highest lava flow. To S. and W. of the ridge the extent of the fm. is not definitely known and the upper beds are surely missing.

V. R. D. Kirkham and M. M. Johnson, 1929 (Jour. Geol., vol. 37, No. 5, pp. 483+). The Latah fm. at Spokane, Wash., by definition occupies position underlying Columbia River basalt instead of being interstratified with the lava. But plants collected from 7 localities described by Russell are all typical of Latah flora. The fm. has been identified in Benewah, Latah, and Nez Perce Counties, Idaho. [Describes exposures at 40 places in these counties.] The material in Idaho differs little from that at Spokane. Although defined in type loc. as being essentially a pre-basalt fm., the Latah, as shown by a large number of localities over a much greater area, appears to be more commonly a series interbedded with lava flows of Columbia River basalt. In nearly all Idaho localities the greater part of the series has basalt underlying as well as overlying it. In some places, however, the Latah beds lie directly on the pre-basalt terrain. At all places where this was observed, except at Moscow, higher and thicker members interstratified with the overlying basalt were also present. The beds consist chiefly of fine sediments which contain plant fossils that indicate their Latah age. Where two members of the series are thought to be separated by as much as 400 ft. of lava the fossil assemblage shows neither notable break nor evolution, so far as observed. The various members of Latah series as found in Idaho appear to occur within a range of 800 ft. The geographic extent of the series is many times greater than was at first surmised. The lake beds are interstratified with the basalt without angular uncon., but both basalt and sediments abut uncon. against pre-basalt fms. The greatest measured thickness of any one memb. in Idaho is 350± ft. At no Idaho locality is the combined thickness of the various sed. layers believed to be more than 400 ft. The usual thickness of upper layer is 100± ft., and that of lower layer 150 to 200 ft.

Latonia shale. (In Eden group.)

Upper Ordovician: Southwestern Ohio and northern Kentucky.

N. M. Fenneman, 1916 (Ohio Geol. Surv., 4th ser., Bull. 19, p. 63). *Latonia sh.*—More distinctly blue than underlying Utica [Fulton] sh. Is soft and calc.; contains some thin beds of ls.; weathers greenish yellow or drab. Thickness 180 to 230 ft. Latonia sh. and Utica [Fulton] sh. comprise Eden group. Is overlain by Mount Hope sh. memb. of Fairview fm. Named for Latonia, Kenton Co., Ky.

Latour formation.

Tertiary (middle or upper Miocene): Northern Idaho (Coeur d'Alene region).

O. H. Hershey, 1912 (Geol. Soc. Am. Bull., vol. 23, pp. 529–536). *Latour fm.*—White and variegated silts, 500 ft. thick, in region btw. Medimont and Kellogg. Deposited in [ancient] Lake Latour, which was of an extent and depth comparable with present Coeur d'Alene Lake. There is evidence of their extent to a point several mi. above Kellogg.

†Latrania sands.

Miocene (lower): Southern California (Imperial County).

G. D. Hanna, 1926 (Calif. Acad. Sci. Proc., 4th ser., vol. 14, No. 18, p. 435). [See quotation under *Imperial fm.*] Contains large assemblage of marine Mollusca. [Letter from G. D. Hanna, dated August 19, 1926, states that the name "is derived from latrans, the Latin name for a barker, such as a dog or a wolf," the rocks being exposed in Coyote Mtn, and the name *Coyote* having been previously used.]

An undiff. part of Imperial fm. (See W. P. Woodring, 1930, under *Imperial fm.*)

†Lauderdale chert.

Mississippian: Northern Alabama.

E. A. Smith, 1892 (Sketch of geol. of Ala., Birmingham, Ala., Roberts & Son, pam. of 36 pp.). *Lauderdale* (*Keokuk*).—Basal div. of Sub-Carbf., and the lower Siliceous of Safford. More cherty than beds above. Underlies St. Louis or Huntsville (=upper Siliceous of Safford) and overlies Dev. Black sh.

E. A. Smith, 1894 (Ala. Geol. Surv. map of Ala., with explanatory chart). *Lauderdale* (*Keokuk, etc.*).—The Lauderdale cherty ls. is generally a highly siliceous ls., with beds of rather pure crinoidal ls. at base. Occurs chiefly N. of Tennessee River in Lauderdale, Limestone, and Madison, in the "Barrens." Overlies Dev. black sh. and underlies Tuscumbia ls. Is=lower part of Fort Payne chert.

Replaced by Fort Payne chert as restricted by C. Butts in 1910, the name *Fort Payne* having been applied to these cherty rocks in several States. Named for great development in Lauderdale Co.

Laughery formation. (In Richmond group.)

Upper Ordovician: Southeastern Indiana.

A. F. Foerste, 1912 (Denison Univ. Sci. Lab. Bull., vol. 17, p. 22). The Waynesville and Liberty, taken together, contain that part of the Richmond fauna along Cincinnati geanticline which most nearly is related to Mississippi Valley Richmond. The two fms. appear more closely linked together in their fossil content than the other Richmond fms. For that reason the term *Laughery fm.* is proposed for the Waynesville and Liberty as exposed along Laughery Creek in Ripley Co.

Laurel limestone.

Laurel dolomite.

Laurel limestone member (of Wayne formation).

Silurian (Niagaran): Southern Indiana and west-central Kentucky and Tennessee.

A. F. Foerste, 1896 (Cincinnati Soc. Nat. Hist. Jour., vol. 18, pp. 190–192). *Laurel bed.*—White or bluish white pure lss., with intercalations of chert in upper half. [Thickness not given.] Richly fossiliferous basal part might be appropriately called *Osgood phase of Laurel fm.* Overlain by Waldron sh. and underlain by Clinton rock or Montgomery bed.

A. F. Foerste, 1897 (Ind. Dept. Geol. and Nat. Res. 21st Ann. Rept., pp. 217, 230), restricted *Laurel ls.* to 35 to 45 ft. of hard white ls. overlying *Osgood beds* and underlying *Waldron sh.*

Adopted by U. S. Geol. Survey to exclude the Osgood. In southern Ind. and north-central Ky. the rocks are treated as a distinct fm., underlain by Osgood sh. and overlain by Waldron sh. In west-central Tenn. the rocks become *Laurel ls. memb.* of Wayne fm., being overlain by Waldron clay memb. of Wayne fm. and underlain by Osgood earthy ls. memb. of the Wayne. In Jefferson Co., Ky., the Laurel deposits consist of dol., and are called *Laurel dol.* The Laurel fossils are of Rochester age, according to E. O. Ulrich.

A. F. Foerste, 1935 (Denison Univ. Bull., Jour. Sci. Lab., vol. 30, pp. 152–153). In vicinity of Laurel, Ind., only lower part of *Laurel ls.* is exposed, and this part nowhere exceeds 12 ft. in thickness. To W., in Decatur Co., several sections are known, which are at least 30 ft. thick, and at St. Paul, in SE. part of Shelby Co., it is 37 ft. thick. This suggests Laurel ls. thins out E. of St. Paul at least as far as Yellow Springs, Ohio, where it is overlain by Massie clay sh., 5½ ft. thick. It may be present at Cedarville, Ohio, but is not exposed. The identification of Laurel ls. in Preble and Miami Counties, Ohio, is based solely on strat., the fossiliferous part of the Laurel being limited chiefly to upper part of the fm.

Named for Laurel Franklin Co., Ind.

Laurencic period.

C. [R.] Keyes, 1914 (Iowa Acad. Sci. Proc., vol. 21, p. 201). *Laurencic period.*—Older than Huronic period and younger than Varennesic period.

Includes part of Keewatin series and later lavas and granites.

Laurens member.

Upper Devonian: Eastern New York (Susquehanna, Otego, and Butternut Valleys).

G. A. Cooper, 1933 (Am. Jour. Sci., 5th, vol. 26, p. 544) and 1934 (Am. Jour. Sci., 5th, vol. 27, p. 10). *Laurens memb.* (of Tully ls.) is suggested for rocks btw. New London and Schenevus that carry *Hypothyridina* and a modified Ithaca fauna. Name is needed because *Hypothyridina* zone in eastern N. Y. is a different facies from that of the Tully and actually represents only basal part of Tully. It appears that the 88 ft. of Laurens memb. in Otego Valley is = the 4-inch thick oolite with *Hypothyridina* in Chenango Valley. Underlies Sherburne and overlies Moscow (Hamilton).

G. A. Cooper and J. S. Williams, 1935 (Geol. Soc. Am. Bull., vol. 46, pp. 803, 809–815, 827). *Laurens memb.* was proposed in 1933 for the thicker *Hypothyridina* beds of Otego Valley. These beds in Butternut Valley, to which *Laurens* is applicable, are thinned equiv. of Otego Valley exposures. In Butternut Valley it is overlain by 89 ft. of West Brook memb. of the Tully and underlain by New Lisbon memb. of Tully. In Otego and Susquehanna Valleys and at Schenevus it rests on Hamilton. The Laurens is chiefly ss. but contains some sandy sh., and includes 3 *Hypothyridina* zones. Thickness 21 to 88 ft. Exposed in Houghtaling's Glen, 1½ mi. NE. of Laurens [Otsego Co.], also in ravine 1 mi. NE. of Laurens. Fossils listed.

Laurentian epoch (or **series**).

A period of pre-Camb. granitic intrusion following the Keewatin epoch. (For definition see U. S. G. S. Bull. 769, pp. 127–128.) Formerly included in Archean period (and system), but U. S. Geol. Survey no longer uses "Archean" except as a rock type term. As now defined the Laurentian series precedes the Knife Lake series (lower Huronian?) and follows the Keewatin series. (See U. S. G. S. P. P. 184, 1935, by C. K. Leith, R. J. Lund, and A. Leith.)

†Laurentian clay.

Term that has been applied to the marine Pleist. clay of Northeastern States and Canada that has also been called "Lawrencian clay" and "Champlain clay."

ùrie formation.

Pre-Cambrian: British Columbia.

R. A. Daly, 1913 (12th Int. Geol. Cong. Guidebook 8, p. 134).

Lauzon formation.

Ordovician or Cambrian: Quebec.

J. Richardson, 1866 (Canada Geol. Surv. Rept. 1863–66, pp. 32–36). *Lauzon div.*—Lower Sil.; eastern Canada; included in Quebec group.

Some later Canadian repts include this fm. in Ord. and others include it in Camb.

La Ventana sandstone member (of Mesaverde formation).

Upper Cretaceous: Northwestern New Mexico (La Ventana region).

C. H. Dane, 1937 (U. S. G. S. Bull. 860C). *La Ventana ss. memb.*—Buff marine fossiliferous ss. and gray sh., including, in upper part W. of Rio Puerco, some white ss., carbonaceous sh., and coal beds. Thickness 0 to 1,256 ft. Is top ss. of Mesaverde fm., along Puerco River, where it replaces Cliff House ss. of Renick. Named for town of La Ventana, on Rio Puerco, near which it outcrops, and, perhaps more appropriately, from the exposure of its basal part on top of La Ventana Mesa E. of Rio Puerco, on S. edge of T. 19 N., R. 1 W. The La Ventana memb. grades laterally into upper part of Allison memb. (continental).

Laventille limestone.

Pre-Cretaceous (?): Trinidad.

G. A. Waring, 1926 (Johns Hopkins Univ. Studies in geol. No. 7, p. 33). [Assigned to pre-Cret.; but Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 704), assigns *Laventille fm.* of Trinidad to Lower Cret.]

Laverne formation.

Tertiary: Northwestern Oklahoma.

C. N. Gould, 1927 (Obsolete Okla. geol. names: Univ. Okla. Bull., Proc. Okla. Acad. Sci., vol. 6, pt. 2, pp. 235–238). *Laverne fm.*, Tert., used by Waite [where?] to include some leaf-bearing beds of Tert. age in Harper and Beaver Counties. The name has never come into popular use.

La Vieille formation. (In Chaleur series.)

Silurian (Niagaran): Quebec (Gaspe Peninsula).

C. Schuchert and J. D. Dart, 1926 (Canada Geol. Surv. Bull. 44, p. 45).

S. A. Northrop, 1932 (Geol. Soc. Am. Bull., vol. 43. No. 1, p. 271). Faunas of Clemville and La Vieille fms. of middle Sil. Chaleur series are of Clinton age.

Lawrence shale. (In Douglas group, Kansas.)

Lawrence shale member (of Douglas formation, Missouri).

Pennsylvanian: Eastern Kansas, southeastern Nebraska, northwestern Missouri, and southwestern Iowa.

E. Haworth, 1894 (Kans. Univ. Quart., vol. 2, p. 122). *Lawrence shales.*—Shales, interbedded with sss., 210 ft. thick, including a thin ls. exposed at Haskell Institute, Lawrence, Kans., and called *Institute ls.* Underlies Oread ls. and overlies Ottawa ls.

In 1899 C. R. Keyes used *Lawrence sh.* in a broader sense, and some early writers applied the name to all beds down to top of Plattsburg ls. H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines, vol. 13), defined Lawrence sh. as underlying Oread ls. and overlying Iatan ls., and for many succeeding years that was the generally accepted definition, the (descending) Oread ls., Lawrence sh., Iatan ls., and Weston sh. all being included in Douglas group (or fm.). For the innovations in this terminology introduced by R. C. Moore in 1931 and 1932 see under *Weston sh.* Also see Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936. N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21) followed Moore's restricted definition of Lawrence sh. R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 146, 154, etc.), still further restricted Lawrence sh. by transferring (under new name *Robbins sh.*) to his Stranger fm. the basal part of his previously restricted Lawrence sh. of southern Kans. (See 1936 entry under *Stranger fm.*)

The U. S. Geol. Survey has not yet had occasion to consider, for its publications, these redefinitions of Lawrence sh.

Named for exposures at Lawrence, Douglas Co., Kans.

Lawrence clay. (In Allegheny formation.)

A bed of clay, 0 to 8 ft. thick, underlying Lawrence coal in SE. Ohio, and lying 0 to 3 ft. below Lower Kittanning clay. (W. Stout, personal communication, Feb. 1930.) Probably named for persistency in Lawrence Co.

†Lawrencian clay.

Term applied by E. Desor to the marine Pleist. clay of Northeastern States and Canada that has also been called "Laurentian clay" and "Champlain clay." (See under *†St. Lawrencian terrane.* Also see H. D. Rogers, Geol. of Pa., vol. 2, 1858, p. 775.)

Lawrencic period.

Term used by C. [R.] Keyes. Same as his Laurencic period.

Layton sand.

A subsurface sand, of Penn. age and 0 to 500± ft. thick, in Okla., which is correlated with upper part of Coffeyville fm. Named for Layton farm, in Cleveland field, in NW¼ sec. 2, T. 20 N., R. 8 E., Pawnee Co.

Layton lime.

A subsurface ls., of Penn. age and 0 to 20± ft. thick, in central northern Okla., said to correlate with Hogshooter ls. It lies higher than Layton sand. D. A. McGee and W. W. Clawson, Jr. (A. A. P. G. Bull., vol. 16, No. 10, 1930) give thickness in Oklahoma City field, NE. Okla., as few ft. to 100 ft.

Lazeart sandstone member (of Adaville formation).

Upper Cretaceous: Southwestern Wyoming.

A. C. Veatch, 1907 (U. S. G. S. P. P. 56). [See under *Adaville fm.*, of which it is basal memb.]

Lazy Bend member (of Millsap Lake formation).

Pennsylvanian: North-central Texas.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 106, 107), from ms. of rept. by G. Scott and J. M. Armstrong, on geol. of Parker Co. Named for Lazy Bend on Brazos River. See 1933 entry under *Millsap Lake fm.*

As defined in above-cited publication, *Lazy Bend beds* was applied to strata underlying Kickapoo Falls ls. and overlying Dickerson beds.

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, p. 16). *Lazy Bend memb.*—Middle memb. of Millsap Lake fm. as defined by G. Scott and J. M. Armstrong, in unpublished rept. on Parker Co. Includes the series of shales, sss., and lss. btw. base of Kickapoo Falls ls. up to top of Brannon Bridge ls., which are identified by Scott and Armstrong, who have the sequence exposed along Brazos River and its tributaries in vicinity of Lazy Bend of Brazos River, but only uppermost strata occur in Palo Pinto Co. The Lazy Bend memb. as defined by Scott and Armstrong underlies Grindstone Creek memb., overlies Dickerson memb., and includes, in interval btw. Brannon Bridge ls. and Kickapoo Falls ls., 2 other lss.—Meek Bend ls. and Dennis Bridge ls. [This is a modification of definition given by Sellards in 1933 rept. cited above.]

Lead system.

Pre-Cambrian: Western South Dakota (Black Hills).

J. J. Runner, 1934 (Am. Jour. Sci., 5th, vol. 28, pp. 354–372). The pre-Camb. rocks of Black Hills, S. Dak., are divided into (descending) Lead system, Estes system, and Nemo system. The *Lead system*, which is believed to correlate with the fms. of Lead dist., is divided into (descending) Garfield fm., Northwestern fm., Ellison fm., Homestake fm., and Poorman fm. It overlies, with possible uncon., Estes system.

Lead Creek limestone.

Pennsylvanian: Western Kentucky (Hancock County).

A. F. Crider, 1913 (Ky. Geol. Surv., 4th ser., vol. 1, pt. 1, p. 279). *Lead Creek ls.*—Three or four ledges of ls. ranging in thickness from 8 to 10 ft., extending through an interval of 30 to 40 ft. in Coal Measures of Tell City and Owensboro quads. Base is 255 ft. above top of cgl. forming basal part of Penn. The bdy btw. Allegheny and Pottsville fms. of Appalachian field is placed by D. White at about top of this ls.

D. B. Chisholm, 1931 (Ky. Geol. Surv., ser. 6, vol. 41, pp. 224–225). *Lead Creek ls.* is in upper part of Tradewater fm., lying 190 ft. below top of the Tradewater in Hancock Co. and 85 ft. below Lewisport ls. Thickness 5 to 11 ft. Fossiliferous. Upper part blue and shaly and weathers to a buff fissile "ss." or "sh."; lower 3 to 5 ft. thick-bedded hard ls., blue when fresh, but weathers to buff porous "ss." Usually rests on Lead Creek coal, but in places is separated from that coal by 15 ft. of sh.

Named for Lead Creek, Hancock Co.

Lead King lime.

Name locally applied to the ls. memb. (of Niobrara age) of Mancos sh. in the Snowmass Mtn area of Gunnison Co., Colo., and also applied by prospectors to the indurated lower part of underlying sh. memb. of the Mancos of that area. The name was probably derived from fact the lime is the ore horizon in Lead King mine, in Lead King Basin.

Lead Point argillite.

Paleozoic (?): Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 79, map). *Lead Point argillite.*—Chiefly well-bedded argill. sl. with minor bands of quartz-mica schist and ls.; medium to dark gray; usually fine-grained and distinctly argill. Thickness 2,200 ft. Lies parallel to and just N. of Republican Creek ls. [Derivation of name not stated, and there is no geographic feature called Lead Point on map.]

Leadville limestone.

Mississippian (lower): Colorado.

G. H. Eldridge, 1894 (U. S. G. S. Anthracite-Crested Butte folio, No. 9). *Leadville ls.*—Upper third, massive blue and cavernous ls.; lower two-thirds bedded gray to brown lss., somewhat dolomitic and carrying a few beds of dark-gray or black chert, and sometimes separated by bands of calc. sh. Thickness 400 to 525 ft. Carries Sub-Carbf. [Miss.] fossils. Uncon. underlies Weber ls. [Penn.] and overlies Yule ls. [Ord.]. Known to miners as the "Blue" ls.

S. F. Emmons, 1898 (U. S. G. S. Tenmile folio, No. 48). *Blue or Leadville ls.*, the principal ore-bearing horizon of Leadville, Red Cliff, Aspen, and other mining dists, is not exposed in this dist. Near Leadville it rests uncon. on Parting qtzite.

E. Kirk, 1931 (Am. Jour. Sci., 5th, vol. 22, pp. 222–240). *Leadville ls.* here restricted to the Miss. lss. of Colo., and the new name *Chaffee fm.* is introduced for the Dev. rocks of Colo. in areas to N. and E. of SW. Colo., where the Dev. ls. will continue to be called Ouray ls. and the underlying Dev. fm. will continue to be called Elbert fm. The Miss. part of Ouray ls. of SW. Colo. to hereafter be called Leadville ls. The typical Leadville ls. rests uncon. on Dev. lss., which overlie the Dev. Parting qtzite.

Named for occurrence in Leadville dist.

†Leadville porphyry.

See under *White porphyry.*

†Leaf Hills moraine.

Pleistocene (Wisconsin stage): Western Minnesota (Douglas, Todd, and Ottertail Counties).

W. Upham, 1888 (Minn. Geol. and Nat. Hist. Surv. vol. 2, pp. 549–571; also see Minn. Geol. Surv. 22d Ann. Rept., map (pl. 1) and p. 47, 1894). Ninth or *Leaf Hills moraine.* Named for fact it forms Leaf Hills, Ottertail Co.

F. Leverett, 1932 (U. S. G. S. P. P. 161). The Leaf Hills moraine of Upham is not ninth moraine, but is at latest an early part of second or Altamont morainic system, and may prove to be earlier than Altamont system.

†Leander beds.

Local name, incidentally applied (but not defined) to upper part of *Caprina* (*Edwards*) *ls.*, by R. T. Hill in 1890 (Tex. Geol. Surv. 1st Ann. Rept., pp. 105, 126). Exposed in country btw. Florence and Leander, Williamson Co., Tex.

Leaning Tower quartz monzonite.

Probably Cretaceous: Yosemite National Park, California.

F. C. Calkins, 1930 (U. S. G. S. P. P. 160, p. 123, map). On fresh fracture, dull-gray color and moderately fine texture. Under the microscope appears to be porphyritic. On weathered surfaces deeply decayed and rusty.

Named for fact it forms considerable part of slopes of Leaning Tower, Yosemite Nat. Park.

Lea Park formation.

Cretaceous: Alberta.

S. E. Slipper, 1918 (Canada Geol. Surv. Summ. Rept. 1917, pt. C, p. 8) and 1919 (Canada Geol. Surv. Mem. 116, p. 21).

Leatherwood granite.

Pre-Cambrian: Central southern Virginia (Henry and Pittsylvania Counties).

A. I. Jonas, 1928 (Va. Geol. Surv. prel. ed. of geol. map of Va.). *Leatherwood granite.*—Biotite muscovite granite with porphyritic facies. Intrusive into Glenarm series. Mapped at and around Leatherwood, Henry Co. Is pre-Camb.

A. A. Pegau, 1932 (Va. Geol. Surv. Bull. 33, pp. 15, 29, pls. 2, 3). *Leatherwood granite* is named for Leatherwood, the home of Patrick Henry near Martinsville, Henry Co. It occurs as irregular bodies of variable size intruding Wissahickon schist in Henry and Pittsylvania Counties.

L'Eau Frais shale.

Eocene: Southwestern Arkansas.

See explanation under *Manchester sh.*

Leavenworth limestone. (In Oread limestone.)

Pennsylvanian: Eastern Kansas, northwestern Missouri, southeastern Nebraska, and southwestern Iowa.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 32, 33, 38). *Leavenworth ls.*—Middle ls. bed of Oread ls. Dark-gray, dense, vertically jointed, fossiliferous, and in 1 or 2 beds. Thickness 1½ ft. in Nebr., 2½ ft. at Atchison, Kans., and at St. Joseph, Mo. Underlies Heebner sh. and overlies Snyderville sh. Named for a roadside exposure high in the upland spur NW. of Federal Penitentiary at Leavenworth, Kans.

Lebanon limestone. (In Stones River group.)

Lower Ordovician: Central and western Tennessee.

J. M. Safford, 1851 (Am. Jour. Sci., 2d, vol. 12, pp. 353, 354–356). *Lower Lebanon ls.* and *Upper Lebanon ls.*—[See descriptions under *Stones River group.*]

In 1869 (Geol. Tenn.) Safford substituted "Trenton or Lebanon group" for the rocks previously named *Stones River group*, replaced "Upper Lebanon ls.," with "Carter's Creek ls.," replaced "Lower Lebanon ls." with "Glade ls.," and divided underlying beds of his Trenton or Lebanon group (=Stones River group) into three named fms. In 1900 Safford and Killebrew substituted *Carter ls.*, for ls. previously called "Upper Lebanon ls." and "Carter's Creek ls.," and substituted *Lebanon ls.* for ls. previously called "Lower Lebanon ls." and "Glade ls."

Included in Stones River group. Underlies Carters ls. and overlies Ridley ls. Named for exposures at Lebanon, Wilson Co.

†Lebanon group.

Lower Ordovician (Chazy): Tennessee.

J. M. Safford, 1869 (Geol. Tenn., pp. 151, 159, 258–268). *Trenton or Lebanon group.*—Divided into (descending): (1) Carter's Creek ls. [=Upper Lebanon ls. of earlier repts and Carters ls. of later repts]; (2) Glade ls. [=Lower Lebanon ls. of earlier repts and Lebanon ls. restricted, of later repts]; (3) Ridley ls.; (4) Pierce ls.; and (5) Central ls. [=Murfreesboro ls. of later repts]. Underlies Nashville group and overlies Knox dol.

Same as Stones River group, older name.

Named for Lebanon, Wilson Co.

†Lebanon beds.

Upper Ordovician: Southwestern Ohio and northern Kentucky.

J. S. Newberry, 1873 (Ohio Geol. Surv. vol. 1, table opp. p. 89, pp. 103, 119), and E. Orton, 1873 (same vol., pp. 371–399). *Lebanon beds.*—Fossiliferous even-bedded semicrystalline blue lss., alternating with blue shales; 300 ft. thick. Lie stratigraphically higher than highest stratum of Cincinnati hills (Hill Quarry beds) and underlie Upper Sil. Medina ss. Topmost fm. of Cincinnati group. Not present at Cincinnati, Ohio.

A. F. Foerste, 1903 (Am. Geol., vol. 31). *Lebanon beds* of Orton included Saluda at top and Warren [Arnheim] at base.

Preoccupied by J. M. Safford's name for older Ord. rocks in Tenn. Replaced by *Richmond group.*

Named for Lebanon, Warren Co., Ohio.

Lebanon granite.

Late Paleozoic (?): Southwestern New Hampshire (Hanover quadrangle, Grafton County).

C. H. Hitchcock, 1908 (Vt. State Geol. 6th Rept., pp. 155–156, etc.), in description of rocks of Hanover quad., N. H., referred many times to *Lebanon granite.* The village of Lebanon is in Hanover quad., SW. part of Grafton Co., N. H.

J. W. Merritt, 1921 (Vt. Geol. Surv. Rept. State Geol. 1919–20, pp. 1–36, map). *Lebanon granite.*—First described by Hitchcock (Geol. N. H., vol. 2, 1878) as "protogene gneiss," and several areas in N. H. and Vt., the rocks of which resembled each other, were grouped together and given the name *Bethlehem gneiss.* Later he revised his opinion, making this rock the youngest, instead of the oldest, in Hanover region. His latest map, however, shows the area under name "protogene." Hawes calls it "protogene gneiss;" Iddings calls it "epidote-micagneiss." Is of medium to fairly coarse grain; texture tends to gneissic. Is intruded underneath or into a schist, and probably has a laccolitic form. Igneous origin.

M. Billings, 1935 (letter dated Aug. 27). *Lebanon granite* belongs to Oliverian magma series [which Billings classified as late Dev. or late Carbf.].

Lebo andesitic member (of Fort Union formation).

Eocene: Central northern, southern, and eastern Montana.

R. W. Stone and W. R. Calvert, 1910 (Econ. Geol., vol. 5, p. 746). *Lebo andesitic memb.*—Basal memb. of Fort Union fm. NE. of Crazy Mtns. Thickness 450 to 2,200 ft. Overlain by massive sss. and intercalated shales composing upper part of Fort Union fm., and underlain by Lance fm. (1,000 to 2,400 ft. of light-gray ss. and variegated sh.). Named for exposures on Lebo Creek, NE. of Crazy Mtns.

To E. (in Bull Mtn coal field and elsewhere) the Lebo strata become so shaly that they are called *Lebo sh. memb.*

Le Boeuf conglomerate.

Upper Devonian or Mississippian: Northwestern Pennsylvania.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. Q_4, pp. 101, 103, 104, 112, 239, etc.). The Venango Lower ss. (Third oil sand), 30 ft. thick, is without doubt=*Le Boeuf* *cgl.* and Panama cgl. which is exposed in Le Boeuf Twp, Erie Co., along French Creek, and has been quarried on left bank of the creek 1 mi. SW. of Le Boeuf Station, where it consists of 7 ft. of pebbly rock underlain by 8 ft. of bluish white ss. East of Le Boeuf Creek it is partly coarse cgl. containing a great many pebbles of metamorphic rock.

G. H. Chadwick, 1925 (Geol. Soc. Am. Bull., vol. 36, pp. 455–464). *Le Boeuf cgl.* underlies Amity sh. and overlies Chadakoin beds, all of which are considerably below Riceville sh., and correlate with lower part of Chagrin sh. [which U. S. Geol. Survey classifies as Upper Dev.]. It can be traced into Panama cgl.

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 203), says Panama cgl. memb. of Cattaraugus fm. is same as Le Boeuf cgl. and Wolf Creek cgl. (The U. S. Geol. Survey classifies Cattaraugus fm. as *Dev. or Carbf.*) K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, pp. 77–83), repeats the statement that Le Boeuf and Panama are same cgl.

Leclaire dolomite.

Silurian (Niagaran): Central eastern Iowa.

J. Hall, 1858 (Iowa Geol. Surv. vol. 1, pt. 1, pp. 46, 73–75). *Leclaire ls.*—Gray or whitish gray mag. ls., semi-crystalline, very porous and vesicular; some brecciated beds in upper, middle, and lower parts. Thickness 100–540 ft. Fossils distinct from Niagara. Overlies Niagara ls. and underlies Onondaga Salt group.

S. Calvin, 1895 (State Univ. Iowa Lab. Nat. Hist. Bull., vol. 3, No. 3) and 1896 (Iowa Geol. Surv. vol. 5, pp. 50–56). *Leclaire ls.* restricted to 80 ft. of generally heavy-bedded chertless, highly crystalline dol. underlying Anamosa ls. and overlying Delaware ls.; all included in Niagara. [This is definition that has since been followed in Iowa repts.]

See also under *Gower dol.*

A. C. Trowbridge, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 42). Type loc. of LeClaire dol. (Leclaire, Scott Co., Iowa) is just across Miss. River from type loc. of Port Byron ls. of Ill. Fauna is somewhat different from that of Port Byron, and LeClaire strata have reef structure, but the two fms. are probably of equiv. age, and *Port Byron* might prove more satisfactory than earlier term *Leclaire.*

See also A. H. Sutton, p. 274 of 1935 book cited above: Port Byron of Ill. includes all beds of Sil. age in Ill. above the Racine, and is more nearly= Gower rather than Leclaire of Iowa. [Suggests restricting Leclaire to "reef" phase of Gower, and retaining *Port Byron* for use in Ill. See also 1935 entry under *Anamosa dol.*]

Lecompton limestone. (In Shawnee group, Kansas.)

Lecompton limestone member (of Shawnee formation, Missouri).

Pennsylvanian: Eastern Kansas, southeastern Nebraska, central northern Oklahoma, northwestern Missouri, and southwestern Iowa.

E. Haworth, 1895 (Kans. Univ. Quart., vol. 3, p. 278 and pl. opp. p. 290; Am. Jour. Sci., 3d, vol. 50, pl. opp. p. 466). *Lecompton ls.*—Three fossiliferous lss. separated by thin shales. Thickness 25 ft. Overlain by 75 ft. of sh. [Tecumseh sh. memb.], and separated from underlying Oread ls. by a little more than 60 ft. of sh. [Kanwaka sh. memb.].

Is now treated by U. S. Geol. Survey as a memb. of Shawnee fm. in Mo. and Iowa. In Kans. the Shawnee is treated as a group and Lecompton ls. as a fm. In northern Okla. it is a memb. of Pawhuska fm.

Named for exposures at Lecompton, Douglas Co., Kans.

†Lecompton shale.

Pennsylvanian: Eastern Kansas and northwestern Missouri.

E. Haworth, 1898 (Kans. Univ. Geol. Surv. vol. 3, pp. 64, 94). *Lecompton shales.*—Name suggested by G. I. Adams. Persistent and heavy shales, 90 ft. thick, in places containing much ss., in other places almost no ss. Basal memb. of Shawnee fm. Underlies Lecompton ls. and overlies Oread ls.

Preoccupied. Replaced by *Kanwaka sh.*, according to H. Hinds and F. C. Greene (1915) and R. C. Moore (1936).

Named for exposures at Lecompton, Douglas Co.

†Lecompton beds.

Pennsylvanian: Eastern Kansas.

L. C. Wooster, 1905 (The Carbf. rock system of Kans.). *Lecompton beds.*—Include Calhoun shales, Deer Creek ls., Tecumseh shales, Lecompton ls. and Kanwaka shales.

Preoccupied and conflicts with established classification. Includes lower half of Shawnee group.

†Leda clay.

A paleontologic term applied in early repts on Northeastern States to beds of marine clay, of so-called †Champlain period of Pleist. epoch (late Wisconsin), which are not all of same age but which are characterized by the fossil *Leda truncata.*

Ledger dolomite.

Lower Cambrian: Southeastern Pennsylvania.

G. W. Stose and A. I. Jonas, 1922 (Wash. Acad. Sci. Jour., vol. 12, pp. 359, 363). *Ledger dol.*—Granular gray to white dol., mostly thick-bedded, some siliceous beds, which weather to rust-stained granular cherty layers. Thickness 1,000± ft. Uncon. underlies Elbrook dol. and overlies Kinzers fm. No fossils found, but Ledger, Kinzers, and underlying Vintage believed=Tomstown dol. Named for Ledger, Lancaster Co.

Ledyard member. (In Ludlowville shale.)

Middle Devonian: Central and western New York.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 218, 224, etc.). *Ledyard memb. of Ludlowville fm.*—Black fissile sh., 100 ft. thick, overlying Centerfield ls. (basal memb. of Ludlowville) on Paines Creek, Ledyard Twp, Cayuga Lake. At type section is characterized by *Leiorhynchus laura* and a fauna with a "Marcellus facies." Is Third *Leiorhynchus* zone of Cleland. Overlain by Wanakah memb. of Ludlowville fm. to W. and by contemp. Kings Ferry memb. to E. Can be traced from Cayuga Lake to Lake Erie, and is coextensive with Centerfield ls. From Lake Erie to Genesee Valley it is overlain by *Strophalosia* bed, 6 inches thick; from the Genesee to Cayuga Lake it is overlain by *Pleurodictyum* or *Michelinia* zone. At Lake Erie has been erroneously called Skaneateles and Marcellus, but its true position above the Centerfield can be seen on Buffalo Creek btw. Blossom and Elma.

B. Smith, 1935 (N. Y. State Mus. Bull. 300, p. 45). Writer has examined *Ledyard* type section and agrees with Cooper that the name is inappropriate for Skaneateles Lake region.

See also *Avery sh.*

Lee quartz diorite.

Pre-Cambrian: Western Massachusetts and Connecticut.

B. K. Emerson, 1892 (U. S. G. S. Hawley sheet, i. e., proof sheets of geol. maps and text intended for a geol. folio, but never completed and published in that form, although cited in U. S. G. S. Bull. 191, 1902), first used *East Lee gneiss.*

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, p. 18). [*East Lee black biotite-hornblende gneiss* shown as older than Tyringham gneiss and younger than Hinsdale ls. On pp. 20 and 29–30 of Mon. 29 the fm. is called *Lee gneiss,* and is described as a heavy black hornblende or hornblende biotite gneiss.]

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, p. 153 and map). *Lee quartz diorite.*—Black fine-grained heavy hornblende, hornblende-biotite, or biotite-quartz diorite. Is believed to be a contact zone of Becket granite gneiss. Named for exposure in East Lee.

Lee formation. (In Pottsville group.)

Pennsylvanian: Southwestern Virginia and eastern Kentucky and Tennessee.

M. R. Campbell, 1893 (U. S. G. S. Bull. 111, pp. 28, 36). *Lee cgl.*—Heavy sss. and cgl., shales, and coals, 1,200 to 1,600 ft. thick. At Big Stone Gap contains massive ss. (Bee Rock), 95 ft. thick, at top; heavy cgl., 250 ft. thick, at base; and, in middle, 566 ft. of ss. with a few thin beds of sh. Overlies Pennington sh. and underlies Norton fm. Is basal fm. of Coal Measures in Bigstone Gap coal field of Va. and Ky.

Basal fm. of Pottsville group. In east-central Tenn. the Lee itself becomes a group, composed of (descending) Rockcastle ss., Vandever sh., Bonair ss., Whitwell sh., Sewanee cgl., and Gizzard fm. In some early Ky. repts the name *Lee fm.* was applied to all beds up to top of Corbin cgl. memb., but later repts place top of Lee at top of Rockcastle cgl. memb. This is U. S. Geol. Survey definition.

Named for Lee Co., Va.

Leech River group.

Carboniferous: Northwestern Washington (San Juan Islands) and British Columbia.

C. H. Clapp, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 87). *Leech River fm.*, Upper Paleozoic (?), British Columbia, included in Victoria group.

R. D. McLellan, 1924 (Am. Jour. Sci., 5th, vol. 8, p. 217). The upper part of San Juan series, which will be referred to as *Leech River group* (G. M. Dawson Rept. on Reconn. of Leech River and vicinity: Geol. Surv. Canada, Rept. Prog. 1876–77, pp. 95–102, 1878), since it no doubt includes Clapp's Leech River "fm.," is composed of black argillites, schists, tuffaceous graywackes, slates, and volcanics. Also includes occasional thin ls. beds containing the Penn. foraminifer *Fusulina*, and the argillites have scattered thin seams of semi-anthracite. Most of sediments were derived from underlying Orcas group, the lower part of San Juan series. [In 1927 (Wash. Univ. Pub. Geol., vol. 2, p. 99) McLellan assigned these rocks to Perm., Penn., and upper Miss., and stated that the basal graywackes, several thousand ft. thick, are=Malahat volcanics of B. C.]

Leesport limestone.

Middle Ordovician: Southeastern Pennsylvania (Berks County).

G. W. Stose and A. I. Jonas, 1927 (Geol. Soc. Am. Bull., vol. 38, pp. 505–536). *Leesport ls.*—The uppermost beds of the lss. which underlie Martinsburg sh. from Steelton, Dauphin Co., to Leesport, Berks Co. Consists, generally, of thin-bedded dark slaty impure ls. containing fossils of probable lower Trenton age. Extensively quarried as "cement rock" to E., at Schlemville, N. of Reading. Thickness at Leesport, Berks Co., 130 ft.; from Hummelstown to Womelsdorf 81 ft. Best exposed at Leesport, Berks Co. In general uncon. on Beekmantown dol., but from Hummelstown to Womelsdorf it is underlain by a considerable thickness of very pure, white, sugary marble and fine-grained blue ls. believed to be of Stones River age.

G. W. Stose (personal communication). *Leesport ls.* is of Trenton age and is a calc. phase of Martinsburg sh.

Leesville limestone member (of Harrodsburg limestone).

Mississippian: Southern Indiana.

P. B. Stockdale, 1929 (Ind. Acad. Sci. Proc., vol. 38, pp. 233–242). *Leesville ls. memb. of Lower Harrodsburg ls.*—Heavy coarse-grained blue-gray crystalline and crinoidal ls., 1½ to 8 ft. thick, underlying Guthrie Creek memb. and overlying Ramp Creek memb. of Lower Harrodsburg ls. Named for exposures at Leesville, on E. edge of Lawrence Co.

Legion shale member.

Pennsylvanian: Southeastern Nebraska, Kansas, and northern Oklahoma.

G. E. Condra and C. E. Busby, 1933 (Nebr. Geol. Surv. Paper No. 1). *Legion sh. memb. of Grenola fm.*—The newly established Grenola fm. is divided into following members (descending): Neva ls., Salem Point sh., Burr ls., Legion sh., and Sallyards ls. The Legion sh. is largely gray argill. sh. with few fossils in north, becoming nearly black at top N. of Manhattan and at Elmdale, Kans. In central and southern Kans. it is indurated and more calc. locally, with numerous pelecypods, some brachiopods, crinoids, Bryozoa, etc. In Okla. it grades into red sandy sh. Thickness 4 to 8 ft. Type loc., cuts on U. S. Highway 40, just SW. of American Legion Golf Club grounds, about 1¾ mi. SW. of Manhattan, Kans.

G. E. Condra, 1935. (See under *Roca sh.*)

Lego limestone member (of Wayne formation).

Silurian (Niagaran): West-central Tennessee.

A. F. Foerste, 1903 (Jour. Geol., vol. 11, pp. 565, 578–582, 694). *Lego or Louisville ls.*—Lss., 30 to 45 ft. thick, overlying Waldron bed and underlying Dixon red clays in Tenn. River Valley. Of Niagaran age. Occupies same strat. position as Louisville bed. Usually no sharp line btw. Lego ls. and overlying Dixon red clay. Lithologically the lss. forming middle and lower parts of Lego bed often resemble Laurel bed so closely that when intervening Waldron horizon can not be identified it is impossible to distinguish the Lego. In that case the name *Glenkirk ls.* may be used to designate the combined Laurel-Lego section.

Named for Lego, Decatur Co.

†Le Gore limestone.

Lower Ordovician (Beekmantown): Western Maryland (Frederick County).

G. W. Stose and A. I. Jonas, 1935 (Wash. Acad. Sci. Jour., vol. 25, No. 12, pp. 564–565). *Le Gore ls.*—A ls. of Ozarkian age that underlies Frederick ls. E. of Le Gore quarry, in a small triangular area at N. edge of Frederick ls. valley. Was erroneously called Beekmantown ls. in previous repts.

G. W. Stose and A. I. Jonas abandoned this name in Jan. 1936, further collections of fossils proving that this ls. is same as Grove ls., and that it is of lower Beekmantown age.

Le Grand beds.

Mississippian: Central northern Iowa (Marshall, Tama, and Grundy Counties).

C. R. Keyes, 1893 (Iowa Geol. Surv. vol. 1, p. 57). *Le Grand beds.*—Chiefly rather soft, somewhat irregularly bedded buff ls., probably containing considerable magnesia, with blue calc. ss. at base. Thickness 80 ft. Exposed along Iowa River and some of its tributaries. Probably to be correlated with Burlington and Kinderhook.

S. W. Beyer, 1897 (Iowa Geol. Surv. vol. 7, pp. 221–226). *Le Grand beds* in Marshall Co. consist of (descending): 30 ft. of brown and gray subcrystalline ls.; 35 ft. of buff mag. ls., cherty below; 15 ft. of gray white oolite; and 20 ft. of argill. blue ss. Thickness 135 ft. They underlie Marshalltown sh. and overlie Hannibal (?) sh., all of which are included in Kinderhook group.

F. M. Van Tuyl, 1925 (Iowa Geol. Surv. vol. 30, pp. 88–90). *Le Grand beds* are probably transitional from Kinderhook to lower Burlington.

L. R. Laudon, 1931 (Iowa Geol. Surv. vol. 35, pp. 419–431). *Le Grand beds* belong to Hampton fm. They uncon. overlie English River fm. but it is highly probable that over greater part of their area they lie uncon. on Sheffield fm. Thickness 80 ft. Divided into 6 faunal zones, which correlate the beds with upper part of Chapin memb., the Maynes Creek memb., and lower part of Eagle City memb. of Hampton fm. of other parts of central northern Iowa. The beds consist of (descending): (1) Very thin-bedded brown ls., 10 ft. (*Camarotoechia* zone); (2) thin-bedded hard brown ls. occasionally oolitic, 12 ft. (*Spiriferina* zone); (3) thin-bedded brown banded ls., 8 ft. (*Cactocrinus* zone); (4) hard brown crystalline crinoidal ls., locally carrying chert and oolite, 18 ft. (*Orophocrinus* zone); (5) massive, soft, gray ls., chert and calcite abundant, 16 ft. (*Pachylocrinus* zone); (6) massive white hard oolitic ls., 18 ft. (*Schellwienella* zone). No. 1 correlates with lower part of Eagle City memb.; Nos. 2 to 5 correlate with Maynes Creek memb., and No. 6 correlates with upper part of Chapin memb. Occur along Iowa River in E. part of Marshall Co. and W. part of Tama Co., also in north-central part of Marshall Co. and in S. part of Grundy Co.

Named for Le Grand, Marshall Co.

Lehigh limestone.

Middle Ordovician: Northeastern Pennsylvania (Lehigh and Northampton Counties).

E. C. Eckel, 1904 (U. S. G. S. Bull. 225, pp. 449, 450). *Trenton ls. (Lehigh cement rock)*, underlies Hudson sh. and overlies Kittatinny ls. in Lehigh dist. of Pa. and N. J. Thickness 150 to 250 ft.

F. B. Peck, 1911 (Pa. Topog. and Geol. Surv. Rept. No. 5, p. 30). *Lehigh ls.*—Shaly argill. ls., 0 to 200 ft. thick. Uncon. underlies Martinsburg sh. and overlies Nazareth ls. Reaches max. development where it crosses Lehigh River. It is the rock generally called "Cement Rock." Is unquestionably=Trenton of N. Y.

Lehigh Valley cement rock.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, p. 563).

Evidently same as Lehigh ls. of Peck.

Lehmer limestone member. (In Admire shale.)

Pennsylvanian: Southeastern Nebraska.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, pp. 5, 9). *Lehmer ls.*—Gray, usually weathering brownish, soft, porous; 3 to 4 ft. thick. Top memb. of Falls City ls. fm. Underlies West Branch sh. fm. and overlies Reserve sh. memb. of Falls City ls. fm. Is top bed at old Lehmer quarry, 4 mi. SW. of Falls City [Richardson Co.], Nebr.

Leidecker sand.

A subsurface sand, 25 ft. thick, of early Penn. (Cherokee) age, in central eastern Okla., which is reported to correspond to one of the sands of Dutcher sand series. In Boynton pool, Muskogee Co., it lies at 1,400 ft. depth, the Booch sand at 1,000 ft., and the Boynton sand at 1,500 ft.

Leigh dolomite member (of Bighorn dolomite).

Upper Ordovician (Richmond): Western Wyoming.

Leigh dol. memb. of Bighorn dol. was approved for U. S. G. S. publications in Jan. 1916, having been originally submitted to U. S. G. S. by E. Blackwelder in May 1913. It composes middle part of Bighorn dol. The first appearance of *Leigh* in print appears to be in paper by C. W. Tomlinson, Jour. Geol., 1917.

C. W. Tomlinson, 1917 (Jour. Geol., vol. 25, pp. 118, 255–257). *Bighorn dol.* is divisible into 9 members, of which members Nos. 6 and 7 compose *Leigh fm.* The lower memb. of the Leigh (No. 6, with a thickness of 93 ft.) contains lowest Richmond fauna, and in western Wyo. (Crandall Creek, Dead Indian Creek, Teton Range, and Absaroka Range) it is uncon. on memb. No. 5 (of Trenton age), with, on the two creeks mentioned, a basal breccia at its base. The upper memb. (No. 7) has a thickness of 38 ft. and is uncon. with overlying memb. (No. 8), which is also of Richmond age. Blackwelder (personal note) proposes recognition of members Nos. 6 and 7 in Teton Range, and of corresponding strata in Gros Ventre Range, as a distinct fm., to be called *Leigh*, from typical development on Leigh Creek, Teton Range. In view of fact that this group of strata, in its type loc., is bounded both above and below by uncon., and is lithologically quite distinct from underlying massive memb., which is not present in Teton River section, its recognition as separate fm. seems justified.

E. Blackwelder, 1918 (Wash. Acad. Sci. Jour., vol. 8, p. 419). *Leigh dol. memb. of Bighorn dol.*—From Teton Range eastward at least to middle of Wind River Mtns and N. into Absaroka Range, the massive memb. of well-known Bighorn dol. is overlain by a thin but persistent layer which deserves special recognition. In almost every section it is 30 to 40 ft. thick, and in most if not all localities it is limited both above and below by discon. Differs from rest of Bighorn in being characterized by thin, dense, and brittle flaggy strata with smooth milk-white surfaces. Is discon. overlain by Darby fm. (Dev.). Although it appears generally to be barren of organic remains, a characteristic fauna, consisting largely of ostracods with some pelecypods and gastropods, has been found at several localities. This fauna is assigned by Ulrich and Kirk to Richmond horizon of late Ord. The memb. is named for Leigh Canyon, on W. slope of Teton Range, for on S. side of that valley there are excellent exposures of the dol. in its typical condition. [Detailed section of Leigh dol. in Wind River Range is given.]

Leighton gray shale member (of Pembroke formation).

Silurian (post-Niagaran): Southeastern Maine.

E. S. Bastin and H. S. Williams, 1914 (U. S. G. S. Eastport folio, No. 192, pp. 6–7). *Leighton gray sh. memb.*—Chiefly bluish gray sh. distinctly stratified; thin bedded; in many places forming flagstones. Only here and there does it contain calc. layers. Some beds are largely fine volcanic débris, which grade into distinctly tuffaceous beds. Lower sh. memb. of Pembroke fm. Separated from underlying

Edmunds fm. by diabase tuffs and flows (the basal memb. of the Pembroke) and from overlying Hersey red sh. memb. by rhyolite flows and tuffs. Named for exposures on Leighton Neck, Pembroke Twp, Washington Co.

†Leighton's Cove series.

Silurian: Southeastern Maine.

N. S. Shaler, 1886 (Am. Jour. Sci., 3d, vol. 32, pp. 53, 56). *Leighton's Cove series* consists in main of shales, generally thin bedded and containing but little lime. About 200 ft. in thickness is exposed, but of this only upper half is fossiliferous. Fossils [listed] show relation to Clinton and Niagara in N. Y. Included in Cobscook series.

Replaced by *Leighton gray sh. memb. of Pembroke fm.*

Named for exposures at Leighton's Cove, Cobscook Bay dist., E. coast of Washington Co.

Leipers limestone.

Upper Ordovician (Maysville): Western Tennessee.

C. W. Hayes and E. O. Ulrich, 1903 (U. S. G. S. Columbia folio, No. 95, p. 2). *Leipers fm.*—Granular crystalline ls. in W. half of quad., changing in E. part of quad. to knotty earthy ls. overlying certain shaly and highly fossiliferous beds, and there divisible into 8 members. Thickness 0 to 100 ft. Contains Lorraine fossils. Uncon. underlies Fernvale fm. and uncon. overlies Catheys ls.

In Waynesboro quad. is overlain by Arnheim ls. of Richmond group and underlain by Hermitage fm.

Named for Leipers Creek, Maury Co.

†Leipers Creek limestone. (In Richmond group.)

Upper Ordovician: Western Tennessee.

A. F. Foerste, 1901 (Geol. Soc. Am. Bull., vol. 12, pp. 432–433). *Leiper's Creek bed*, including the lss. and clays carrying Richmond group fauna. Consists of a so-called marble bed (gray, crinoidal, and coralline rock, spotted with red and having a flesh-colored appearance, associated with red, gray, and green layers) 6 to 10 ft. thick, overlain by about 6 ft. of clay sh. Similar beds occur near Fernvale Springs. Underlies Clinton ls. [In 1903 (Jour. Geol., vol. 11, pp. 41–43) Foerste excluded from his Leipers Creek ls. the upper clay sh., which he correlated with the beds there named by him "Mannie sh."]

Is lower part of Fernvale fm., and name conflicts with later but better established name *Leipers ls.*, which is of Maysville age.

Named for exposures on Leipers Creek, Maury Co.

Leitchfield marl. (In Chester group.)

Mississippian: Western central Kentucky.

C. J. Norwood, 1876 (Ky. Geol. Surv. vol. 1, n. ser., pt. 6, pp. 12, 13). *Leitchfield marls.*—Green, purple, red, and blue marly shales, 25 to 60 ft. thick, in middle of Chester group. Separated from underlying Big Clifty ss. [not true "Big Clifty"] by 20 to 70 ft. of ls. and shaly ss.

According to C. Butts (personal communication in 1918) the ss. referred to is not the "Big Clifty," which is absent at Leitchfield, but is either Tar Springs ss. or Hardinsburg ss., both of which are present at Leitchfield, and the marl described therefore lies in either Glen Dean ls. or Buffalo Wallow fm. According to P. N. Moore, 1878 (Ky. Geol. Surv., 2d ser., vol. 4, pt. 11, btw. pp. 423 and 444), 30 ft. of Leitchfield marls of Norwood are finely exposed in Buffalo Wallow, Hancock Co., about 3 mi. from Cloverport.

Named for exposures at Leitchfield, Grayson Co.

Leitchfield formation. (In Chester group.)

Mississippian: Western Kentucky (Webster and Edmonson Counties).

L. C. Glenn, 1922 (Ky. Geol. Surv., ser. 6, vol. 5, p. 60). *Leitchfield fm.*—Oldest rocks exposed at surface in Webster Co. Thickness 400–600± ft. A series of lss., sss., shales, and marly clay; shales believed to be of Leitchfield age. Seemed not practical to subdivide. Has been mapped as one fm. called *Leitchfield*. Underlies Caseyville fm. May all belong to Birdsville fm., or may represent Birdsville and Tribune. Deep well on W. A. Duncan farm penetrated 598 ft. of Miss. rocks and ended at top of ss. that may be Cypress ss. The Leitchfield is underlain by older (unexposed) Miss. lss., sss., and shales.

J. M. Weller, 1927 (Ky. Geol. Surv., ser. 6, vol. 28, p. 136). *Leitchfield fm.*—Greenish gray and variegated shales, 0 to 125 ft. thick, underlying Caseyville fm. and overlying (probably uncon.) Glen Dean ls. in Edmonson Co. In part of county is completely eroded away. Is same as Buffalo Wallow fm. of Butts, except that Butts excluded Tar Springs ss. from Buffalo Wallow fm., but as this ss. is only locally developed in Edmonson Co. it is here treated as basal memb. of Leitchfield fm.

Leithsville formation.

Middle and Lower Cambrian: Eastern Pennsylvania (Lehigh Valley district).

E. T. Wherry, 1909 (Sci., n. s., vol. 30, p. 416). *Leithsville fm.*—Gray dol. with abundant sandy and cherty layers and buff-colored sh. beds. Thickness 1,500 ft. Underlies Allentown ls. and overlies Hardyston qtzite. Assigned to Middle and Lower Camb.

Probably named for Leithsville, Northampton Co.

Lemieux Creek formation.

Carboniferous (?): British Columbia.

J. F. Walker, 1931 (Canada Geol. Surv. Summ. Rept. 1930, pt. A, p. 131).

Lemont argillaceous limestone member (of Carlim limestone).

Lower Ordovician (Chazy): Central Pennsylvania (Blair to Center Counties).

C. Butts, 1918 (Am. Jour. Sci., 4th, vol. 46, pp. 526, 533, 537). *Lemont argill. ls. memb.*—Richly fossiliferous ls. forming top memb. of Carlim ls. Underlies Lowville ls. Carries Chazyan fauna, which correlates with Crown Point ls. of N. Y. Named for Lemont, near State College, Center Co. [Thickness 0 to 105 ft.]

Lenapah limestone.

Pennsylvanian: Northeastern Oklahoma and southern Kansas.

C. N. Gould, D. W. Ohern, and L. L. Hutchison, 1910 (Okla. State Univ. Research Bull. 3, pp. 6, 10, 11, 12). *Lenapah ls.*—A ls. lying at approx. horizon of Upper Parsons or Coffeyville ls. of Kans. Basal memb. of Sapulpa group. Rests on Tulsa group.

D. W. Ohern, 1910 (Okla. State Univ. Research Bull. 4). *Lenapah ls.*, 8 to 20 ft. thick, overlies Nowata sh. (top fm. of Tulsa group) and underlies Curl fm.

D. W. Ohern and R. E. Garrett, 1912 (Okla. Geol. Surv. Bull. 16). *Lenapah ls.* underlies Coffeyville fm. and overlies Nowata sh. Is well exposed in quarry N. of Lenapah, Nowata Co., Okla. Not known to extend S. of Nowata, its position to S. being marked approx. by Dawson coal. [This is commonly accepted definition of Lenapah ls.]

In Kans. Lenapah ls. has been treated as top memb. of Parsons fm., which as defined was overlain by Dudley sh. and underlain by Bandera sh. But R. C. Moore has recently abandoned both Dudley and Parsons, and treats Lenapah ls. as a distinct fm. (See Kans. Geol. Surv. Bull. 22, 1936.) The U. S. Geol. Survey has not yet had occasion to consider these changes in definitions and classification.

Lennep sandstone. (Of Montana group.)

Upper Cretaceous: Central southern Montana (Little Belt Mountains to Bighorn County).

R. W. Stone and W. R. Calvert, 1910 (Econ. Geol., vol. 5, p. 746). *Lennep ss.*—Dark-colored ss. with intercalated sh. Thickness 250 to 400 ft. Underlies Lance fm. and overlies Bearpaw sh. Not definitely correlated with Fox Hills ss. Named for Lennep Station, on C., M. & P. S. R. R., at N. end of Crazy Mtns.

Lenoir limestone. (Of Stones River group.)

Lower Ordovician (Chazy): Eastern Tennessee, northern Alabama, and western Virginia.

J. M. Safford and J. M. Killebrew, 1876 (Elements of geol. of Tenn., pp. 108, 123, 130–131, 137). *Lenoir ls.*—Soft blue shaly fossiliferous ls. 100 to 600 ft. thick. Same as *Maclurea* ls. of Rept. on geol. of Tenn. In W. part of valley, next to Cumberland Plateau, is not separated from overlying ls. by any well-marked characters. Is of Chazy age. Older than Lebanon [Stones River] group. Overlies Knox dol.

There is no conclusive evidence to show whether Mosheim ls. (Ulrich, 1911) was originally included in Lenoir ls. or in Knox dol. It is uncon. separated from overlying and underlying beds, and according to E. O. Ulrich and C. Butts it differs from the Lenoir in lithology, color, and fauna, but is of Chazy age, as is the Lenoir. According to A. Keith (personal communication) all of the chertless lss. were excluded from the Knox by Safford in his definition and in his mapping.

The Lenoir ls. is now considered by E. O. Ulrich and C. Butts to be top fm. of Stones River group of eastern Tenn. and western Va., where it overlies Mosheim ls., and this is adopted definition of U. S. Geol. Survey.

Named for exposures at Lenoir Station, Loudon Co., Tenn.

Lenore erosion cycle.

Pleistocene: Central western Wyoming.

E. Blackwelder, 1915 (Jour. Geol., vol. 23, pp. 310, 319–340). Interglacial erosion cycle following Bull Lake glacial stage and preceding Pinedale glacial stage. Valleys cut during this cycle locally accommodate ranches at Lenore.

Lenox limestone member (of Bingham quartzite).

Pennsylvanian: Central northern Utah (Bingham district).

A. Keith, 1905 (U. S. G. S. P. P. 38, p. 37, map, sections). *Lenox ls. memb. of Bingham qtzite.*—In Lenox mine consists of dark siliceous ls., either bluish or blackish. Much of silica is in chert nodules and layers, but more is disseminated through ls. mass in microscopic grains. Top passes by sandy lss. and marbles into overlying qtzites. About 50 ft. below top is a layer of ls. cgl. a few ft. thick. At 50 ft. below the cgl. are layers of qtzite that grade through calc. ss. into the lss. above and below. Thickness 200± ft. in Lenox mine but considerably less at other places. [Sections show Lenox ls. as lying much lower than Jordan ls. memb. of Bingham.]

Lenoxdale moraine.

Pleistocene (Wisconsin stage): Western Massachusetts (Berkshire County). (See F. B. Taylor, 1903, Jour. Geol., vol. 11.)

Leon series.

Upper Cambrian and Lower Ordovician(?): Central Texas.

T. B. Comstock and E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. lxii, 295–301). *Leon series.*—Consists of (descending): Compact ls. (Hoover div.); siliceous mag. lss. (Wyo div.); sandy, shaly, buff, sometimes yellow, dol. (Beaver div.). Overlies Katemcy series (Potsdam) and underlies San Saba series.

Is a part of Ellenburger ls.

Named for Leon Creek, Mason Co.

Leona formation.

Pleistocene: Southern Texas.

R. T. Hill and T. W. Vaughan, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, pp. 253–254, 275–276). *Leona fm.*—Pleist. flood-plain deposit of fine calc. silt grading down into coarse gravel, composing first wide terrace of Nueces and Leona Rivers below level of Uvalde fm., and flood-plain deposit extending W. from Uvalde, on Leona River, to Nueces River. May ultimately be correlated with Onion Creek marl of central Tex.

Named for Leona River, Uvalde and Zavalla Counties.

Leona rhyolite.

Tertiary (Pliocene?): Western California (San Francisco region).

A. C. Lawson. 1914 (U. S. G. S. San Francisco folio, No. 193). *Leona rhyolite.*—Pyritic lava that forms a discontinuous belt along W. front of Berkeley Hills, from Hamilton Gulch in Berkeley nearly to Decoto, a distance of 21 mi. Reaches max. width a little S. of Leona Heights, Alameda Co. Is in general an acidic or rhyolitic lava, but includes local masses of darker, more basic rock. Is of about same age and same chemical composition as Northbrae rhyolite, but has certain physical differences. Thickness about 500 ft. Classified as Plio., but its age is not proved, and it may belong to some other series of the Tert.

Leonard formation.

Permian: Western Texas (Marathon region, Brewster County).

J. A. Udden, C. L. Baker, and E. Böse, 1916 (Univ. Tex., Bur. Econ. Geol. and Tech. Bull. 44, p. 51). *Leonard fm.*—In Leonard Mtn and to N, consists of (descending): (1) Thinly laminated yellowish ss. interbedded with layers of gray ls., yellow chert, and gray shales; (2) heavy and thinly bedded gray ls., in part conglomeratic or containing pebbles of different sizes; (3) shales and soft sss. interbedded with a dark gray ls.; (4) at base cgl. 20 to 200 ft. thick. Thickness of fm. 1,800 to 2,300 ft. Underlies Word fm. and uncon. overlies Haymond fm. (Penn.). [Included Hess fm. of later repts.]

J. A. Udden, 1917 (Univ. Tex. Bull. 1753, pp. 43–46, pl. 3). *Leonard fm.*—Upper 600 ft. consists chiefly of sh. intercalated with well-cemented calc.-sh. breccias; in lower two-thirds lss. and cgls. are predominant, but cherty and sandy shales are interbedded, also some ss. beds. Thickness 206 to 1,878 ft. in Glass Mtns. Distinguished from underlying Hess fm. by regular development of bedding planes, by far less perfect sorting of clastic components, and by general abundance of fossils. Distinguished from overlying Word fm. by coarser and less well sorted nature of its sands and by relatively less amount of bituminous material in lss. and sands. It makes greater part of S. face of Leonard Mtn.

P. B. and R. E. King, 1928 (Univ. Tex. Bull. 2801). Lower half of beds provisionally referred by Udden to Leonard fm. on Leonard Mtn is in reality Hess, a fact suspected by Udden.

P. B. King, 1931 (Univ. Tex. Bull. 3038, pp. 57–69). [See 1931 entry under *Hess fm.*] Leonard fm. thins from W. to E. across Glass Mtns, and can be divided into a western and an eastern facies. The W. facies is 1,800 ft. thick in vicinity of Lenox, where it consists of lss., mostly in thin beds of radiolaria-bearing siliceous shales and cherts, and of sss. and shales. The ls. and ss. beds are nearly all conglomeratic. The E. facies as exposed E. of Hess Canyon resembles the W. facies but is only 300 ft. thick. It is 900 ft. thick N. of Leonard Mtn, 7 mi. from Sullivan Peak, where it is 1,800 ft. thick. The E. and W. facies interfinger, but the Hess and Leonard fms., although in part contemp., do not seem to intergrade. Conformable with overlying Word fm. NE. of Word Ranch, but W. of Leonard Mtn contact is not well enough exposed over distances great enough to furnish decisive evidence as to relations.

P. B. King, 1932 (Am. Jour. Sci., 5th, vol. 24, pp. 337–354). There is good evidence to show a partial lateral intergradation btw. Leonard and Hess fms., and even a probability that the whole of one fm. is actually the lateral facies of the other.

P. B. King, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 697–798). The Hess fm. of previous repts is contemp. with and grades into lower part of Leonard fm. It is therefore here designated *Hess thin-bedded ls. memb. of Leonard fm.* [This is definition of Leonard fm. now recognized by U. S. Geol. Survey.]

Forms greater part of S. face of Leonard Mtn, Hess Canyon quad., Brewster Co.

†Leopard sandstone.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. C. Lane, 1911 (Mich. Geol. and Biol. Surv. Pub. 6, p. 456). The "*Leopard*" *sss.* of old Hancock quarry underlie Nonesuch sh. group.

†Leptauchenia beds.

A paleontologic name that has been applied to upper part (*Leptauchenia* zone) of Brule clay (Olig.) of western Nebr. and S. Dak.

Lequire sandstone member (of McAlester shale).

Pennsylvanian: Eastern Oklahoma (Muskogee, Haskell, McIntosh, and adjacent counties).

C. W. Wilson, Jr., 1935 (A. A. P. G. Bull., vol. 19, No. 4, pp. 503–520). *Lequire ss. memb. of McAlester sh.*—Massive ss.; medium texture; friable; brown to gray; plant remains. Thickness in Muskogee-Porum area 12 to 25 ft. Lies 8 to 40 ft. above Warner ss. memb. and 40 ft. below Cameron ss. memb. Named for exposure a little N. of Lequire, secs. 4 and 5, T. 7 N., R. 22 E., and secs. 32, 33, and 34, T. 8 N., R. 22 E.

Leray limestone member (of Lowville limestone).

Middle Ordovician: Central to eastern New York.

R. Ruedemann, 1910 (N. Y. State Mus. Bull. 138, p. 72), mentioned the "cherty ls. or the *Leroy* [misprint for Leray] *memb.* of the Lowville fm."

R. Ruedemann, 1910 (N. Y. State Mus. Bull. 145, pp. 79–90, 97). *Leray ls. memb.*—The uppermost part of Lowville beds, which has been mentioned by earlier authors as "cherty beds," has been found by Professor Cushing and writer to be quite distinct from typical Lowville beds and separated from them by uncon. It has for that reason been here distinguished as a subdivision under name *Leray ls.* Underlies Watertown ls. and rests on lower part of Lowville fm., here called *Lowville ls. s. str.* Named for exposures in town of Leray [Lerayville, Jefferson Co., according to W. Goldring, 1931 rept. cited below].

See further explanation under *Lowville ls.*, of which Leray ls. constitutes top memb., according to present classification of U. S. Geol. Survey and N. Y. State Survey (W. Goldring, 1931, N. Y. State Mus. Hdb. 10).

†Leroux formation.

Upper Triassic: Northern Arizona.

L. F. Ward, 1901 (Am. Jour. Sci., 4th, vol. 12, pp. 401–413). *Le Roux beds.*—Consist of (descending): Calc. marls. sometimes worn into buttes, 200 ft.; mortar beds, 80 ft.; ls. ledge, 20 ft.; ss. ledge, 100 ft.; and variegated marls, argill. and calc., 400 ft. Underlie Painted Desert beds and rest on Shinarump cgl.

Is upper part of Chinle fm. of present nomenclature. See U. S. G. S. P. P. 93, 1917, by H. E. Gregory.

Named for Le Roux Wash, Navajo Co.

†Le Roy shale.

Pennsylvanian: Eastern Kansas.

E. Haworth and M. Z. Kirk, 1894 (Kans. Univ. Quart., vol. 2, p. 110). *Le Roy shales.*—Sh. and ss., 150 ft. thick, underlying Burlington or Garnett ls. and overlying Carlyle ls. in section along Neosho River from Indian Territory to White City, Kans.

In broad sense in which name was subsequently used it represents all of Douglas group as originally defined except Oread ls.; in restricted sense it is same as Weston sh.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 139, 140, 146, 152). †LeRoy sh. of Haworth and Kirk (1894) included Weston sh., Iatan ls., Stranger fm., and Haskell ls., and is discarded.

Named for development in vicinity of LeRoy, Coffey Co.

Le Roy moraine.

Pleistocene (Wisconsin stage): Northeastern Illinois. Regarded as probably=Cerro Gordo moraine.

Lester limestone member (of Dornick Hills formation).

Pennsylvanian: Central southern Oklahoma (Carter County).

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z, p. 14). [See under *Bostwick memb.*]

C. W. Tomlinson, 1929 (Okla. Geol. Surv. Bull. 46, pp. 32–33). Above Bostwick memb. of Dornick Hills fm. occur 5 or 6 richly fossiliferous lss., which were included by Goldston in his Cup Coral memb. to N. of Ardmore, but in his Deese memb. to S. of Ardmore. The lowest of these which is substantial enough to be mappable for considerable distances is called *Lester ls. memb.*, from a good exposure on D. B. Lester farm beside the paved highway, about 800 ft. S. of NE. cor. sec. 13, T. 4 S., R. 1 E. It is white, rather coarsely crystalline, and carries considerable oolite at type loc., but much less elsewhere. Max. thickness 20± ft. This ls. at type loc. was mapped by Goldston as Otterville. Interval btw. Bostwick and Lester members N. of Ardmore is 400 to 500 ft., but to S. increases to twice this figure. Included in this interval are 2 or 3 other highly fossiliferous lss. from a few in. to 2 ft. thick.

Lester River group.

Pre-Cambrian (Keweenawan): Northeastern Minnesota.

R. D. Irving, 1883 (U. S. G. S. 3d Ann. Rept., pl. 14, pp. 143–146). *Lester River group.*—Succession of heavy distinct beds of fine-grained brown rocks, largely of "ashbed" type; some diabase porphyrites, ordinary diabases, two or three belts of granite porphyry; amygdaloids almost unknown, and no detrital material. Thickness 2,600 ft. Included in Keweenaw series. Overlies Duluth group and underlies Agate Bay group.

Named for exposures on Lester River, Minn.

†Lesueur dolomite.

Upper Cambrian or Lower Ordovician: Southeastern Missouri.

C. R. Keyes, 1895 (Mo. Geol. Surv. Sheet Rept. No. 4 (vol. 9), pp. 18, 52–53). *Lesueur dol.*—Very cherty dol., 250 ft. thick, overlying Fredericktown ls. and underlying Recent alluvium in Mine La Motte dist.

C. R. Keyes, 1901 (Am. Geol., vol. 28, pp. 51–53). *Le Sueur dol.* (Keyes, 1895) represents only lower third of Winslow's (1896) Potosi ls., and it is doubtful if it occurs at all in Potosi ls. farther N. near typical Potosi locality.

E. M. Shepard, 1904 (Bradley Geol. Field Sta. Drury Coll. Bull., vol. 1, pt. 1, pp. 41–42). *Lesueur ls.*, 200 ft. thick, overlies Fredericktown ls. and underlies Decaturville ls. (=Proctor ls.).

H. F. Bain and E. O. Ulrich, 1905 (U. S. G. S. Bull. 260, p. 234, and Bull. 267, p. 12). *Lesueur ls.* is=Gasconade ls. [broad sense], which overlies Elvins fm. and underlies Roubidoux fm. [Same definition was given by G. H. Scherer, 1905 (Bradley Geol. Field Sta. Drury Coll. Bull., vol. 1, pt. 2, p. 67).]

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, p. 254). *Le Sueur dol.*, 250 ft. thick, is older than Davis fm. and overlies Fredericktown ls.

J. Bridge, 1930 (personal communication). Lesueur dol. includes some Gasconade at top and Eminence and Potosi at base, with Proctor dol. and Gunter ss. absent in Lesueur region.

Named for Lesueur Hill, St. Francois Co.

Letchworth shale.

Upper Devonian: Western New York (Genesee River region).

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60, No. 2, pp. 96–99, 193). I am proposing now to restrict *Gardeau* to that part that is common to Clarke's and Hall's usages, calling all those shales that Hall included in his original Portage, but which Clarke transferred to the Gardeau, namely, those beginning with *Table Rock ss.* at top of lower Portage Falls, by the new name *Letchworth sh.*, derived from Letchworth Park (State reservation) [SW. of Mount Morris, in Livingston Co.], in which they are completely displayed. *Table Rock ss.* is basal stratum of this sh., which underlies Portage (Nunda) ss. in type section of Portage on Genesee River.

G. H. Chadwick, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, p. 352), included this sh. in *Chemung group*.

Levanna shale. (In Hamilton formation.)

Middle Devonian: Western and central New York.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 217+). *Levanna sh.* is here proposed for the sh. btw. Stafford or Mottville memb. of Skaneateles fm. and Centerfield memb. of Ludlowville fm., where it is essentially the "Marcellus or Leiorhynchus facies" of Skaneateles fm. and can not be differentiated into members.

Clarke in 1903 proposed *Shaffer sh.* for Skaneateles equiv. on Schaffer Creek. But Shaffer sh. only represents part of the Skaneateles; the sh. is poorly exposed along this creek; and *Shaffer sh.* is dropped in favor of *Levanna sh.*, taken from a locality where the rocks are better exposed and the section is complete. The Levanna memb. extends from Cayuga Lake to Lake Erie. It is mostly dark gray or black sh. characterized by fauna with a Marcellus facies. To W. black sh. increases. To E. of type section (in Skaneateles Lake region) the Levanna can be divided into several members. It is Second *Leiorhynchus* zone of Cleland. Thickness 45±ft. (at Lake Erie) to 250± ft. (at Seneca Lake). [His diagrams show that his Levanna sh. comprises all of Skaneateles sh. except Stafford ls. (3 to 15 ft. thick) at base, which has heretofore been included in Marcellus sh. Probably named for Levanna, Cayuga Co.]

This is only record of this name.

†Levant series.

Nongeographic name introduced by H. D. Rogers (Am. Jour. Sci., 1st, vol. 47, pp. 153–158, 1844) to include "waterlime fm." of N. Y. at top and all intervening rocks to base of Medina group of N. Y. Redefined by Rogers in 1858 (Geol. Pa., vol. 1, pp. 105, 126–131, 271+, and vol. 2, p. 753) and restricted to Medina group and Oneida cgl. Divided into (descending): *Levant white ss.* 450 ft. thick (divisions II, III, and IV of Medina ss. of N. Y.); *Levant red ss.* (lowest memb. of div. I of Medina ss. of N. Y.), 500–700 ft. thick in Centre and Huntingdon Counties, Pa.; and *Levant gray ss.* (Oneida cgl. of N. Y.), 250–400 ft. thick in Centre and Huntingdon Counties.

Named to indicate "sunrise period of great Appalachian Palaeozoic day," according to Rogers, 1844 citation.

†Levant sandstone.

See under †*Levant series*.

Leverett breccia.

Upper Triassic: Western Massachusetts (Sunderland).

D. D. Reynolds and D. H. Leavitt, 1927 (Am. Jour. Sci., 5th, vol. 13, pp. 167–171). *Leverett breccia*.—A typical breccia, unlike any other encountered in Conn. Valley. Forms core of E. scarp of Mount Toby, just W. of old station, with height of about 200 ft. and width of about ⅛ mi. About 70 percent of fm. consists of a dark fine-grained metamorphic rock, which in places composes all of deposit. Elsewhere there are basic schists, a gray granite, a pink coarse-grained granite, and small amounts of quartz. Color gray to black. Contains no trace of water action. Grades into Mount Toby cgl. through a reddish transition zone. Is believed to be a talus breccia in midst of alluvial fan forming Mount Toby cgl. Named for nearest town.

Levias limestone member (of Ste. Genevieve limestone).

Mississippian: Western Kentucky and adjacent part of southern Illinois.

A. H. Sutton and J. M. Weller, 1932 (Jour. Geol., vol. 40, No. 5, pp. 430, 439). The Ohara as originally defined should not be considered a strat. unit, because it transgresses an important uncon. and is capable of easy subdivision. The part that has been termed "Upper Ohara" is strictly=the Renault of Ill. The "Lower Ohara" is a well-defined memb. of the Ste. Genevieve and is worthy of a distinctive name. Were it not for persistent use of Ohara by Butts and Ulrich for beds of Renault age in western Ky. and probably elsewhere, this name might be redefined and restricted to lower part of original memb. Under the circumstances, however much the writers regret doing so, it seems advisable to reject *Ohara* as a name made useless by nearly 30 years of misinterpretation, and the name *Levias*, with type loc. just E. of town of that name in Crittenden Co., Ky., is now proposed for *uppermost memb. of the Ste. Genevieve* btw. Rosiclare ss. [below] and Renault fm. [above] in western Ky. and adjacent part of southern Ill.

Levis formation.

Ordovician and Cambrian: Quebec.

W. E. Logan, 1863 (Canada Geol. Surv. Rept. 1843–63, pp. 225–297). *Levis fm.*—Lower Sil.; eastern Canada; exact synonym of Calciferous; included in Quebec group.

Canada Geol. Surv. repts continued to include this fm. in Ord., but W. A. Parks, 1931 (Geol. Soc. Am. Bull., vol. 42, p. 788), suggested Camb. (?) age.

The paleontologists of U. S. Geol. Survey interpret the faunas of Levis fm. as Lower Ord. and Upper Camb.

Levis shale.

Devonian: Quebec.

J. F. McMahon, 1933 (Canada Dept. Mines, Mines Branch Pub. 726, p. 56). *Levis sh.*, Devonian, Quebec.

†Levyville formation.

Eocene (upper): Northern Florida.

L. C. Johnson, 1888 (Am. Jour. Sci., 3d, vol. 36, pp. 230–236). *Levyville fm.*—Possibly these irregular deposits may be remnants of Nummulitic ls., which is really in stratum overlying the Vicksburg rocks, well seen at old iron works near Levyville, Levy Co. At Levyville it is a beautiful soft porous building stone, about 20 ft. thick, which was utilized in erection of Confederate iron-works. It is often struck in artesian borings and easily identified by the peculiar nummulites. It has a greater thickness under the Neocene fms. to E. In these western regions it has probably suffered general removal by erosion. Apparently conformable in deposition with the Vicksburg stage; the Levyville fm. is evidently not identical with it, and demands a further investigation. It is a mistake, however, to suppose that this Nummulitic fm. everywhere hides the Vicksburg rocks of the *Orbitoides Mantelli*, or ever did overlie the whole of it. Numerous exposures prove the contrary. In many places, especially in Alachua Co. and northward, the outcrops can not be distinguished from the rocks of Vicksburg and of the Chickasawhay, Miss.

Now considered to be same as Ocala ls., and older than Vicksburg group, which it was originally supposed to overlie.

Lewes River series.

Triassic: Canada (Yukon).

E. J. Lees, 1934 (Roy. Canadian Inst. Trans., vol. 20, pt. 1).

Lewis shale.

Upper Cretaceous (of Montana age): Western Colorado, northwestern New Mexico, southern and central Wyoming.

W. Cross and A. C. Spencer, 1899 (U. S. G. S. La Plata folio, No. 60). *Lewis sh.*—A series of more or less sandy shales and clays, of gray or drab color, very similar in character to Mancos sh. Includes, in varying abundance, thin calc. lenses or concretions of impure ls. Only 200 or 300 ft. of fm. now remains in this quad., but in adjoining Durango quad. the entire thickness of 2,000 ft. is exposed. Rests on Mesaverde fm. It occurs as a band btw. the Mesaverde and *Piedra* [not defined in this or any subsequent rept. by Cross; probably refers to deposits later called "Laramie fm." in this area] fms. as far as these divisions of the Cret. have been traced in this part of Colo. Is the "Sand Shale Group" of Holmes' general section of SW. Colo. [which was defined as overlain by Pictured Cliffs ss.]. In this quad. it is overlain by Pleist. gravels. Named for occurrence at Fort Lewis, in La Plata Valley [sec. 3, T. 34 N., R. 11 W., La Plata Co.]. Its fossils are of Pierre age.

N. M. Fenneman and H. S. Gale, 1906 (U. S. G. S. Bull. 297). In Yampa coal field of NW. Colo. the beds here called *Lewis sh.* consist of 1,000 to 2,000 ft. of soft dark-gray or black clay sh., with layers or lenticular beds of a compact blue ls. and secondary calcite seams. They grade, through rapid transition, into overlying Laramie fm. [so-called] and into underlying Mesaverde fm., and are thought to be entirely analogous to typical Lewis sh. of SW. Colo. The entire fm. is of late Montana age.

J. B. Reeside, Jr., 1924 (U. S. G. S. P. P. 134). The marine *Lewis sh.* of N. side of San Juan Basin of SW. Colo. is in part contemp. with major upper part of Mesaverde group of W. and S. sides of that basin and is in part younger. It can be traced continuously some distance N. from type loc., and except for some interruptions on E. side has been identified clear around San Juan Basin. It has not been identified, if present, to W., S., or E. of San Juan Basin. The time interval of typical Lewis sh. is unquestionably represented outside of San Juan Basin by sediments that cover wide areas. It is impossible, however, to fix upon its equiv. exactly. In a general way it is synchronous with some part of middle and upper portions of Pierre sh. to E. of Rocky Mtns, but more exact correlation must wait upon a more detailed knowledge of the ranges of species within the Montana group. The so-called Lewis sh. of various parts of Wyo. certainly is not the same as Lewis sh. of San Juan Basin. In Wyo., at several localities, the upper part of the fm. contains a true Fox Hills fauna, later than fauna of any part of Lewis sh. or Pictured Cliffs ss. of San Juan Basin, and it does not fit the lithologic definition of Lewis sh., because it contains at many places thick fresh-water deposits with coal beds and heavy sss.

†Lewis series.

A term applied by R. A. Daly (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 49, table opp. p. 178, 1913) to rocks in Lewis Range (Montana-British Columbia) which he assigned chiefly to Lower, Middle, and Upper Camb., but which he correlated with rocks classified by U. S. Geol. Survey as pre-Camb. Includes Kintla argillite (at top) down to Waterton dol. (at base), the latter not known to be present in Mont.

†Lewisburg limestone.

Mississippian: Virginia and West Virginia.

W. M. Fontaine, 1876 (Am. Jour. Sci., 3d, vol. 11, pp. 276–284, 374–384). *Umbral or Lewisburg ls.*, the base of the Umbral series of New River region, W. Va. Is more than 822 ft. thick. Rests on Vespertine series and is overlain by 320 ft. of blood-red shales and sss.

W. M. Fontaine, 1877 (Am. Jour. Sci., 3d, vol. 13, pp. 37–48, 115–123). The *Lewisburg or Lower Carbf. ls.* is absent in Pa. It is probably = St. Louis and Chester groups. Rogers put it in his Umbral. It rests on Vespertine or No. X group. Along Greenbrier River it is underlain by 250 ft. of red beds which lie on the coal-bearing memb. of the Vespertine.

C. A. Ashburner, 1877 (Am. Phil. Soc. Proc., vol. 16, pp. 521, 536), reported 49 ft. of Lewisburg ls. in Pa., and stated that in Greenbrier Mtn, Pocahontas Co., W. Va., it is 822 ft. thick.

Same as Greenbrier ls., the better-established and commonly accepted name. Probably named for Lewisburg, Greenbrier Co., W. Va.

†Lewisburg group.

Upper Triassic: Central southern Pennsylvania (Dauphin and York Counties).

G. H. Ashley, 1931 (Topog. and Geol. Surv. Pa. Bull. G_1, p. 77). *Lewisburg group.*—Soft red sh. with some red ss., 3,500 ft. thick, underlying Lisbon group and overlying Conewago group in Dauphin and York Counties. All of Upper Tr. age. [Credited to [M. H.] Bissell. "Lewisburg" (preoccupied) is apparently a misprint for *Lewisberry* and "Lisbon" (preoccupied) is apparently a misprint for *Lisburn*. When the Triassic of New Cumberland quad. (in which occur the geographic features *Lisburn* and *Lewisberry*) was differentiated for 1931 geol. map of Pa. these rocks were included in Gettysburg sh.]

Lewisport limestone.

Pennsylvanian: Western Kentucky (Hancock County).

D. B. Chisholm, 1931 (Ky. Geol. Surv., ser. 6, vol. 41, pp. 221, 225). *Lewisport ls.*—Lies near top of Tradewater fm. in Hancock Co., Ky. Present at many places in county. Rests on Lewisport coal. Is overlain by 90 ft. of shales and sss. in which are interbedded 1 or 2 thin coals. Very fossiliferous, and of same color and physical characteristics, both when fresh and weathered, as Lead Creek ls., which lies 85 ft. lower in Tradewater fm. Fossils not so large as those in Lead Creek ls. [Probably named for Lewisport, Hancock Co.]

Lewis Run sand.

Drillers' name for a sand in Bradford dist., McKean Co., NW. Pa., lying 60 or 70 ft. below 3d Bradford sand and 70 or 80 ft. above 1st Kane sand. Probably=*Windfall sand*, which is called the Fourth in NE. part of Bradford dist. These sands do not seem to occur outside Bradford dist. (See Pa. Geol. Surv., 4th ser., Bull. M19, 1933, pls. 17, 20, p. 28.)

†Lewiston shale.

Upper Ordovician (Richmond): Western New York and Ontario.

G. H. Chadwick, 1908 (Sci., n. s., vol. 28, pp. 346–348). *Lewiston sh.* (*Richmond*).—The "lower Medina" of [C. A.] Hartnagel's early descriptions. Is true time equiv. of Richmond beds. These shales are continuous with underlying Oswego ss., of Lorraine div., and underlie, with suggestion of discon., *true Medina ss.* [Medina restricted].

Replaced by *Queenston sh.*, which has slight priority of publication.

Named for exposures at Lewiston, Niagara Co., N. Y.

Lewiston limestone.

Devonian and Silurian: Appalachian region.

See *Lewistown ls.*

Lewistown limestone.

Devonian and Silurian: Central Pennsylvania.

F. Platt, 1875 (2d Pa. Geol. Surv. Rept. H, pp. 1–9). *Lewistown ls.* included in Lower Helderberg series. Underlies Oriskany ss. and overlies Waterlime series. [As thus defined the name applied to rocks now called Helderberg group and differentiated into several named fms., but as used in some repts it included beds of Cayuga age.]

J. P. Lesley, 1878 (2d Pa. Geol. Surv. Rept. F, pp. xvii–xxxii). Lower Helderberg ls. divided into *Lewistown ls. sh.* and *Lewistown ls.*, the latter resting on the Waterlime. The Lewistown ls. consists of heavy bed of subcrystalline bluish gray ls.; in some places it carries a bed of chert at top. The ls. is 185 ft. thick at Lewistown [Mifflin Co.], 215 ft. thick at McVeytown, and only 35 ft. thick at Mount Union.

This ls. has also been called "Lewiston ls." In parts of central Pa. it has been divided into several named units. (See Pa. chart.)

Lewistown limestone shale.

Lower Devonian: Central Pennsylvania.

J. P. Lesley, 1878 (2d Pa. Geol. Surv. Rept. F, pp. xvii–xxxii). Lower Helderberg ls. divided into (descending) *Lewistown ls. sh.* and Lewistown ls. The *Lewistown ls. sh.* consists of a shaly ls., an argill. and in part siliceous sh., with some thin beds of hard blue ls. It is 140 ft. thick at Lewistown [Mifflin Co.], 130 ft. thick at McVeytown, and 18 (?) ft. thick at Mount Union. Underlies Oriskany shales.

†Lewistown chert lentil.

Lower Devonian: Northeastern West Virginia.

N. H. Darton and J. A. Taff, 1896 (U. S. G. S. Piedmont folio, No. 28). *Lewistown chert-lentil.*—Cherty ls., 130 to 300 ft. thick, forming top memb. of Lewistown ls. Underlies Monterey [Ridgeley] ss.

Apparently same as Shriver chert.

Lewisville marine member (of Woodbine sand).

Upper Cretaceous (Gulf series): Northeastern Texas.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, pp. 114–115, 297). *Lewisville beds.*—Lignitic sandy clays and sands, frequently accompanied by sulphate of iron, mag. salts, etc. Thickness not determined. Middle part of Woodbine sand. Replaces "Timber Creek bed." Overlies Dexter sands and underlies less ferruginous sands and clays composing upper part of Woodbine. [The latter ferruginous sands and clays are now known to belong to the Eagle Ford.]

Is upper memb. of Woodbine sand.

Named for exposures at Lewisville, Denton Co.

†Lexington group.

Pennsylvanian: Western Missouri.

G. C. Broadhead, 1873 (Mo. Geol. Surv. Prel. Rept. on Iron Ores, pt. 2, pp. 169, 187). *Lexington group*.—Shales and lss., with little ss. and clay, 70 ft. thick, including beds Nos. 43 to 55 of detailed section of lower Coal Measures from Sedalia to Kansas City. Underlies Holden group and overlies Warrensburgh group.

Replaced by better-established name *Henrietta fm.*, of which it is approx. equiv.

Probably named for exposures at Lexington, Lafayette Co.

Lexington limestone.

Middle Ordovician: Central western Virginia.

J. L. Campbell, 1879 (Am. Jour. Sci., 3d vol. 18, p. 29). [See under *House Mtn. shales.*]

J. L. Campbell, 1880 (The Virginias, vol. 1, pp. 41–45). *Lexington lss.*—Of Trenton age. Underlie House Mountain shales and overlie Coralline lss. in Great Valley of Va., central Va.

H. D. Campbell, 1905 (Am. Jour. Sci., 4th, vol. 20, pp. 445–447). Liberty Hall ls. replaces Lexington ls., preoccupied. Mohawkian fossils are abundant in lower beds.

Lexington limestone.

Middle Ordovician: Central Kentucky.

M. R. Campbell, 1898 (U. S. G. S. Richmond folio, No. 46, p. 2). *Lexington ls.*—Thin-bedded gray ls., with chert nodules at base and persistent band of chert at top; 140 to 160 ft. thick. Overlain by Flanagan chert and underlain by Highbridge ls.

A. M. Miller, 1905 (Ky. Geol. Surv. Bull. 2), placed top of *Lexington stage* at top of the cherty horizon, which is Flanagan chert of Campbell.

J. M. Nickles, 1905 (Ky. Geol. Surv. Bull. 5), A. F. Foerste, 1906 (Ky. Geol. Surv. Bull. 7), and A. M. Miller, 1913 (Ky. Geol. Surv., 4th ser., vol. 1, pt. 1, pp. 317–342), drew top of *Lexington ls.* at top of Perryville.

G. C. Matson, 1909 (U. S. G. S. W. S. P. 233), treated *Flanagan chert memb.* as top div. of Lexington ls., and described it as 75 ft. thick and usually lighter-colored and more cherty than underlying beds of Lexington ls.

The *Flanagan ls.* is now treated as a distinct fm., and the underlying Lexington ls. of Campbell has been divided into several named units. (See Ky. correlation chart.)

Named for development at and around Lexington, Fayette Co.

See also under *Bourbon series*.

Leyden argillite.

Silurian (?): Central northern Massachusetts and southeastern Vermont (Windham County).

B. K. Emerson, 1892 (U. S. G. S. Hawley sheet, i. e., proof sheets of geol. maps and text intended for a geol. folio, but never completed and published in that form, although cited in U. S. G. S. Bull. 191, 1902). *Leyden phyllite* (argillite).—Overlies Conway schist.

B. K. Emerson, 1894, as reported by R. Pumpelly (U. S. G. S. Mon. 23, pp. 29–30). *Leyden argillite*, with intercalated quartz schist, overlies Conway schist.

B. K. Emerson, 1898 (U. S. G. S. Holyoke folio, No. 50; also U. S. G. S. Mon. 29, pp. 196–208). *Leyden argillite* consists of dark coarse sl. or fine-grained mica schist, with chiastolitic contact zone at base. Thickness 300 ft. Rests on Conway schist. Named for occurrence in Leyden [Twp], Mass. Is widespread in Vt. [See also B. K. Emerson, U. S. G. S. Bull. 597, 1917.]

Lias.
Liassic. } Terms applied by European geologists to Lower Jurassic series.

Liberty formation.
Liberty limestone (in Ohio). } (In Richmond group.)

Upper Ordovician: Southeastern Indiana, southwestern Ohio, and north-central Kentucky.

J. M. Nickles, 1903 (Am. Geol., vol. 32, p. 207). *Liberty or Strophomena planumbona beds.*—Even-bedded lss. in layers averaging 3 inches in thickness, prevailingly blue in color, with intervening clayey and shaly layers, also usually of blue color, thickness 35 ft. Overlain by Whitewater or *Homotrypa wortheni* beds and underlain by Waynesville or *Bythopora meeki* beds.

In many subsequent repts the overlying fm. was stated to be Saluda ls. (see under *Saluda ls.*), but more recent repts describe Saluda as a wedge in lower part of Whitewater fm., and define Whitewater as resting on Liberty fm. The U. S. Geol. Survey still treats Saluda ls. as a distinct fm.

J. J. Wolford, 1930 (Ohio Jour. Sci., vol. 30, No. 5, p. 304). Base of Turkey Track ls. layer has been designated by Dr. Geo. M. Austin as plane of div. btw. Whitewater and Liberty fms. in SW. Ohio.

Named for Liberty, Union Co., Ind.

†Liberty Hall limestone.

Lower Ordovician (Chazy): Central western Virginia.

H. D. Campbell, 1905 (Am. Jour. Sci., 4th, vol. 20, pp. 445–447). *Liberty Hall ls.*—Usually a succession of rather evenly banded beds of fine-grained dark-blue ls. and darker, more argill. ls. that weathers shaly. Upward in the fm. calc. sh. predominates and ls. beds are less frequent. Thickness 1,000± ft. Mohawkian fossils abundant in lower beds. Is same as Lexington ls. (preoccupied) of J. L. Campbell, 1879. Overlies Murat ls. Named for old historic ruin, which is constructed on and of this rock, which has been standing for more than a century and is as well known as Lexington itself.

E. O. Ulrich, 1913 (12th Int. Cong. Geol., Canada, p. 22). Upper part of Liberty Hall ls. is of Black River age. Age of lower part is in doubt.

R. S. Bassler, 1915 (U. S. Nat. Mus. Bull. 92, vol. 2, pl. 1). *Liberty Hall ls.* is all of *late* Black River age and = Moccasin ls.

R. S. Bassler, 1919 (Md. Geol. Surv. Camb. and Ord. vol., p. 51). [Same as 1915.]

The Moccasin ls. was in 1922 assigned to Lowville epoch (lower Black River) by E. O. Ulrich.

Now considered by C. Butts to be same as Athens ls. (older name) and has been discarded. The Athens is classified as Lower Ord.

Lick Creek sandstone member (of Pottsville formation).

Pennsylvanian: Central Alabama.

C. Butts, 1910 (U. S. G. S. Birmingham folio, No. 175, p. 9). *Lick Creek ss. memb.*—Cgl. and thin-bedded ss. of wide extent, the cgl. varying somewhat in character. Thickness about 50 ft. Is a memb. near middle of Pottsville fm. in Warrior coal field. Is overlain by Jagger coal in some places, and in other places the Jagger coal is included in the ss., near its top. The Lick Creek ss. overlies Ream coal.

Named for exposures along Lick Creek in vicinity of Kimberly, Jefferson Co.

Lick Creek sandstone member. (In Pottsville formation.)

Pennsylvanian: Southwestern Illinois (Carbondale quadrangle).

J. E. Lamar, 1925 (Ill. State Geol. Surv. Bull. 48, pp. 23, 85–91, and map). In general the Lick Creek ss. memb. of Pottsville fm. is a massive medium to coarse-grained brown to buff ss. Locally, where it is conglomeratic, it contains pebbles of vein quartz. The conglomeratic materials occur mostly in zones or beds from ½ to 10 ft. thick, averaging about 3 ft. and are lenticular. In places sh. is present and the ss. is in part thin-bedded. Cross-bedding is pronounced throughout the memb. Thickness 80 to 140 ft. in W. part of quad. and 125 to 170 in central and E. parts of quad. Lies, probably conformably, on Wayside sh. and ss. memb. and is conformably overlain by Drury sh. and ss. memb. of the Pottsville. Named for village of Lick Creek, Union Co., where it is prominently exposed in that part of Pottsville scarp known as Cedar Bluff.

Licking shale.

Mississippian: Central Ohio.

L. E. Hicks, 1878 (Am. Jour. Sci., 3d, vol. 16, p. 216). *Licking shales.*—Top fm. of Waverly group in central Ohio. Consists of 100 to 150 ft. of beds, divided into (descending): (1) 3 to 10 ft. of compact fine-grained fossiliferous drab ss.; (2) friable earthy gray or olive shales; and (3) fossiliferous shaly drab ss. which comprises about one-third of whole. Underlain by Black Hand cgl. and Granville beds, and overlain by Coal Measures cgl.

Named for Licking River, from Newark to Black Hand.

Light House granite.

Pre-Cambrian: Central southern Connecticut.

F. Ward, 1909 (Am. Jour. Sci., 4th, vol. 28, p. 131 and map). *Light House granite.*—Medium-grained pink or reddish granite. Named for Light House Point, its most westerly occurrence. Extends to Branford Harbor. Imperceptibly grades into Branford granite. The Light House and Branford granites are subdivisions of Branford granite gneiss, are very much alike mineralogically and chemically, and are both phases of same original magma.

Is a pink feldspar facies of Branford granite gneiss.

Lightning Creek diorite.

Miocene (?): British Columbia and Washington.

R. A. Daly, 1913 (Canada Dept. Int., Rept. Chief Ast. 1910, vol. 2, p. 490).

†Lignite formation. (†Great Lignite formation.)

†Lignitic group.

Late Cretaceous and Eocene: Rocky Mountain States.

Terms applied in early repts (1852 to 1876 and later) to coal-bearing rocks of Rocky Mtn region now known to range in age from Upper Cret. to mid Eocene.

In 1862 (Phila. Acad. Nat. Sci. Proc., vol. 13, pp. 415–435) F. B. Meek and F. V. Hayden called the "Lignitic group" of previous repts the *Fort Union or Great Lignite group,* and assigned it to Eocene (?), describing it as consisting of 2,000+ ft. of clay and sand, with round ferruginous concretions and numerous lignite seams, overlying Fox Hills beds and underlying Wind River deposits in Nebraska (which at that time included Wyo., Mont., and Dak). In 1874 Hayden, who had studied these rocks over wide areas, stated (U. S. Geol. and Geog. Surv. Terr. Bull. 1, No. 2, pp. 1–2): It seems conclusive that the lignitic group began in Cret. period, in marine seas, and continued upward, through brackish-water times, into purely fresh-water deposits. Later Hayden and King agreed to replace the descriptive term "Lignitic group" with the geographic name *Laramie group.* (See quotations under *Laramie fm.*) The Laramie as they defined it everywhere rested on Fox Hills ss. King assigned the deposits to latest Cret., and described them as overlain, in the region covered by 40th Par. Surv., by "*Vermilion Creek Eocene* (=Wahsatch group of Hayden)"; but Hayden stated (U. S. Geol. Surv. Terr. 8th Ann. Rept., pp. 20–27, 1876): "I still regard the lignitic group proper as transitional or Lower Eocene, and shall so regard its age until the evidence to contrary is much stronger than any which has been presented up to present time. When, however, the proof is sufficient to decide the Cret. age of the group I shall accept the verdict without hesitation. It is somewhat doubtful whether the age will ever be decided positively to the satisfaction of all parties." In the same year (U. S. Geol. Surv. Terr. Bull. 5, pp. 405–411) Hayden stated that those who worked from S. and SW. toward the N. have been thoroughly impressed with Cret. age of "Lignitic group," while those who have studied the deposits from the N. and NW. toward interior basin received their first impressions they were of Tert. age.

In 1878 (U. S. Geol. Surv. Terr. Rept., Mon. 7, pt. 2, p. iv) Hayden stated that his "Lignitic group" included Laramie and Fort Union and that the latter was identical with the whole, or at least a part, of Wasatch group. (See quotation under *Laramie fm.*) The Fort Union fm. is now generally recognized as underlying Wasatch fm. and overlying Lance fm., of Upper Cret. age.

For further explanations see under *Laramie fm.*, *Fort Union fm.*, and *Lance fm.* The descriptive term "Lignitic group" has long since fallen into disuse.

†Lignite group.

†Lignitic beds.

†Lignitic group.

Early Eocene: Gulf Coastal Plain.

Descriptive terms applied in early repts on Gulf Coastal Plain (1) to Wilcox group; (2) to Wilcox and Midway groups; (3) to Wilcox group and most of Claiborne group; (4) to Claiborne group; and (5) to lower part of Claiborne group. The Claiborne group has also been called "Upper Lignitic," and the Wilcox and Midway combined have been called "Lower Lignitic," "Northern Lignitic group," and "Eo Lignitic." The Wilcox group alone has also been called "Lower Lignitic" and "Lignitic." The Yegua fm. alone in La. has also been called "Upper Lignitic," as has St. Maurice fm. of La. The name was introduced by J. M. Safford, of Tenn., in 1856 (Geol. reconn. State of Tenn., pp. 162–163), as "*Lignite group*, sands, laminated clays, and lignite, overlain by post-Pliocene Bluff and Drift series and underlain by Orange Sand group;" and was subsequently applied in Miss., Ala., La., Ark., and Tex. repts.

†Ligonier sandstone.

See *Connellsville ss. memb.*, which replaces it.

Lilac argillite.

Lower Jurassic: Northern California (Mount Jura).

C. H. Crickmay, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 81). [See under *Combe ss.*]

C. H. Crickmay, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 5, pp. 896–897). *Lilac ss.* (also *Lilac fm.*).—Calc. dark-gray ss. and argillite, 725 feet thick, occurring at various localities along W. base of Mount Jura and elsewhere. Carries middle Lower Jurassic fossils; the upper zone *Parapecten praecursor;* the lower zone *Euechioceras exoletum.* "Rests on Middle Triassic volcanics, the oldest rocks in Mount Jura column." [Derivation of name not given. Does not say whether geographic or nongeographic.]

Lilley formation.

Silurian (Niagaran): Southwestern Ohio (Highland and Adams Counties).

A. F. Foerste, 1917 (Ohio Jour. Sci., vol. 17, pp. 189, 190). *Lilley memb.*—Upper memb. of West Union fm. at Hillsboro, Highland Co. [West Union as here used extends up to base of Cedarville dol.] Consists of 2 or 3 ft. of clay underlain by 20 ft. of massive ls. Exposed at various localities on Lilley Hill. Overlies Bisher memb. (lower memb. of West Union) and immediately underlies Cedarville dol.

A. F. Foerste, 1919 (Ohio Jour. Sci., vol. 19, pp. 367–375). *Lilley memb. of West Union fm.* is 20 to 30 ft. thick. Overlies Bisher memb. of West Union, but at any distance from Hillsboro area it has proved so rarely possible to discriminate

Bisher and Lilley members, if indeed the latter is present, that a collective term seems desirable. For this service *West Union*, used by Orton [but not in sense used by Orton], has been regarded as serviceable and as much more in keeping with exposures at West Union, Ohio, where no trace of Lilley memb. can be identified. It corresponds to Upper or Blue Cliff of Orton, who incorrectly identified it with Springfield dol. Is faunally distinct from Bisher memb.

A. F. Foerste, 1923 (Denison Univ. Sci. Lab. Jour., vol. 20, pp. 41–43). *Lilley fm.* of Hillsboro area, Highland Co., was erroneously identified many years ago by Prof. Orton as the Springfield stone. It is overlain by beds here tentatively called Guelph dol. The base of this so-called Guelph in quarries in E. part of Hillsboro is formed by a *Pentamerus* horizon which corresponds approx. to Springfield dol. of Green, Clarke, Miami, Montgomery, and Preble Counties. A fauna somewhat similar to underlying Bisher fauna is contained in beds immediately beneath Springfield ls. along creek ½ mi. W. of Port William, NE. of Wilmington, Ohio, but no trace of Lilley fauna is to be found so far N.

A. F. Foerste, 1931 (Ky. Geol. Surv., ser. 6, vol. 36, pp. 172, 173) assigned these rocks to Lockport epoch. Further details regarding *Lilley fm.* were given by Foerste in Denison Univ. Bull., Jour. Sci. Lab., vol. 30, 1935, pp. 127–202.

Lillibridge sandstone member.

Upper Devonian: Southwestern New York (Olean region).

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 62, pp. 59, 63). *Lillibridge ss. memb.*—Basal memb. of Chadakoin stage. Hitherto known as "Quarry ss.," from occurrence in stone quarries (now abandoned) in and about Olean, N. Y. Named for outcrops along Lillibridge Creek, which flows S. to Allegany River 1 mi. NE. of Portville, N. Y., and in quarries adjacent to the creek. Is predominantly flaggy, with intercalated shales. Usually pinkish to purple red, and not abundantly fossiliferous.

G. H. Chadwick states (letter dated Jan. 2, 1936) that when Caster published *Lillibridge ss.* he thought it was the same ss. as that named *Hinsdale* by Chadwick, but that the ss. exposed in Lillibridge Creek Valley lies up in Haymaker beds of Chadwick or higher.

Lillis formation.

Tertiary (Oligocene?): Southern California (North Coalinga region).

J. H. Ruckman, as reported by J. C. Merriam, 1915 (Am. Phil. Soc. Trans., n. s., vol. 22, pt. 3, p. 194), placed *Lillis fm.* (in table of North Coalinga region) opposite *Olig.*, and called the overlying Mio. beds *Monterey* ("*Temblor*") and the underlying beds *Tejon Eocene*. No description of lithology, thickness, or derivation of name was given.

J. H. Ruckman, as reported by O. P. Jenkins (Min. in Calif., Rept. State Min., vol. 27, No. 2, April 1931, pp. 159–161, 178, 179), after examination of Ruckman's *unpublished* thesis, entitled "Faunal succession of the Coalinga East Side field, Fresno Co., Calif.," on file in Univ. of Calif. Under heading *Eocene-Oligocene*, Ruckman described "*Lillis group*," which he said includes "Domengine sands" and overlying "*Oilfield shales*" with every evidence of conformity btw. the two. Jenkins stated that the beds btw. Domengine sands and Temblor oil sands consist of white and brown diatomaceous shales "which it is apparent correspond to Kreyenhagen sh. as mapped by Robert Anderson and Pack." In these shales Jenkins discovered 2 unconformities. He gave Ruckman's detailed section of the beds, which aggregates 951 ft., and listed fossils enumerated in Ruckman's ms. The upper 100 ft. of this section he called *Leda zone*, at base of which Jenkins reported an uncon., which "apparently was not known to Ruckman." Lower down he found another uncon. Jenkins proposed to restrict *Kreyenhagen sh.* to beds beneath the lower uncon. and above Domengine sands, which he stated are probably Eo. but possibly are Olig. (See also Jenkins, 1931, under *Kreyenhagen sh.*)

G. D. Hanna, F. M. Anderson, and C. C. Church, 1931 (Geol. Soc. Am. Bull., vol. 42, No. 1, pp. 302, 303, 305, 306), applied *Lillis sh.* to the younger sh. to which *Kreyenhagen* had been applied in earlier repts on area N. of Coalinga, and stated that it is probably Mio.

G. D. Hanna, 1933. [See 1933 entry under *Kreyenhagen sh.*]

Lillydale shale. (In Bluefield formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Tazewell County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 301, 437). *Lillydale sh.*—Dark green or greenish gray at top; black and carbonaceous at base; fissile; some included lenses of iron carbonate and ls.; marine fossils. Thickness 80 to 125 ft. Underlies Glenray ls. and overlies Greenbrier series. Is basal memb. of Bluefield group [fm.]. Includes Edray ss. 0 to 50 ft. above base. Type loc. about 4 mi. SW. of Union, in vicinity of Lillydale, Monroe Co. Also observed in Mercer and Summers Counties, W. Va., and in Tazewell Co., Va. Can be traced to head of Greenbrier Valley.

Lime Creek shale.

Upper Devonian: Central northern Iowa.

H. S. Williams, 1883 (Am. Jour. Sci., 3d, vol. 25, pp. 97–104), causally used *Lime Creek beds* for fossiliferous beds exposed along Lime Creek near Rockford, Iowa, and said to contain same fauna as High-point beds of Chemung of N. Y.

C. R. Keyes, 1893 (Iowa Geol. Surv. vol. 1, pp. 46–47). *Lime Creek shales.*—Rather dark-colored argill. shales, highly fossiliferous. Strat. position not fully understood. It seems best therefore to retain name usually applied to them, since Rockford has proved unavailable. Thickness 100 ft. [In columnar section (pl. 2 of book cited) *Lime Creek shales* are shown as highest Dev. fm. in Iowa, and as overlain by Kinderhook and underlain by Montpelier ss., which is said to contain one Hamilton species.]

S. Calvin, also W. H. Norton, in 1897 (Iowa Geol. Surv., vol. 6, p. 148, and vol. 7, pp. 161–170) divided *Lime Creek sh.* into Owen substage above and Hackberry substage below. According to C. L. Fenton their Hackberry substage included the pre-Owen part of Webster's Hackberry plus Sheffield fm. of Fenton. The name *Lime Creek sh.* as for many years used in geol. literature of Iowa usually applied to the beds of northern Iowa btw. Kinderhook above and Cedar Valley ls. below. Some repts apparently included Montpelier ss. in the Cedar Valley, and some writers have regarded Sweetland Creek sh. of SE. Iowa as contemp. in whole or in part with Lime Creek sh., while other authorities consider Sweetland Creek as younger than Lime Creek, and some regard it as of Kinderhook age. E. O. Ulrich classifies it as Upper Dev. and=Genesee sh. and upper Tully of N. Y. C. L. Fenton (Am. Jour. Sci., 4th, vol. 48, pp. 355–376, 1919) applied *Sheffield fm.* to basal part of Lime Creek sh., and A. O. Thomas (Iowa Geol. Surv., vol. 30, p. 116, footnote, 1925) replaced that name by *Juniper Hill fm.* The Nora ls. as originally defined by Thomas (1913) was included in Lime Creek sh., but C. L. and M. A. Fenton (1924) included it in Cedar Valley ls.

A. C. Trowbridge, M. A. Stainbrook et al., 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., fig. 1, pp. 256+), divided Lime Creek sh. into (descending) Owen, Cerro Gordo, and Juniper Hill members, and placed it beneath Sheffield and above Shellrock, which they excluded from Cedar Valley. This corresponds to present usage of U. S. Geol. Survey.

Named for exposures on Lime Creek, in Cerro Gordo and Floyd Counties.

Limekiln conglomerate.

Upper Ordovician: Quebec (Percé).

C. Schuchert, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 163+).

Limerick keratophyre.

Triassic (Middle?): Northwestern Nevada (Humboldt Range).

C. P. Jenney, 1935 (Univ. Nev. Bull., vol. 29, No. 6, pp. 18–23, map, etc.). *Limerick keratophyre.*—Dark greenish-gray schistose tuffs and flows of andesitic appearance and spotted with phenocrysts of feldspar. Thickness 6,000+ ft. Basal div.

of Koipato fm. Best exposed on Lone Mtn, covering considerable area on N. side of Limerick Canyon, in upper Sacramento Canyon, and in Spring Valley E. of area mapped.

Limestone Creek beds.

Oligocene: Southeastern Mississippi.

M. A. Hanna and D. Gravell, 1934 (11th Ann. Field Trip Shreveport Geol. Soc., pp. 17, 41, and table opp. p. 30). *Limestone Creek beds* is upper fm. of Limestone Creek group, and rests on Bucatunna memb. [According to B. W. Blanpied (p. 17 of book cited above) this is same as Blanpied's *Lower Chickasawhay memb.* In section of Limestone Creek, Wayne Co., on p. 41, the beds are called *Lower Chickasawhay memb.*]

Limestone Creek group.

Oligocene: Southeastern Mississippi.

M. A. Hanna and D. Gravell, 1934 (11th Ann. Field Trip Shreveport Geol. Soc., table opp. p. 30). *Limestone Creek group*, includes Limestone Creek beds [=Lower Chickasawhay of Blanpied] and underlying Bucatunna memb.

Limon clays.

Pliocene: Costa Rica.

W. H. Dall, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, p. 337).

Limon beds.

Cretaceous: Mexico.

E. T. Dumble and E. R. Applin, 1924 (Pan-Am. Geol., vol. 41, p. 336).

Limpia.

Name applied by C. [R.] Keyes (Pan-Am. Geol., vol. 65, No. 1, Feb. 1936, pp. 42, 45, 46) to "the great Limpia or Wylie reef, characterized by the narrow Limpia ls. ridge 2,200 ft. in thickness. The Wylie or Limpia reef appears to have had this narrow Limpia ls., of the Limpia, Apache, or Davis Mtns, as its reef-rock, landward of which were the lagoon sands and silts, known as the Eddy sss., or by the Texan name Delaware fm."

Lincoln porphyry.

Eocene: Central Colorado (Alma, Tenmile, and Leadville districts).

S. F. Emmons, 1882 (U. S. G. S. 2d Ann. Rept., pp. 215–230) and 1886 (U. S. G. S. Mon. 12, p. 78). *Lincoln porphyry*.—Light-gray porphyry, consisting of quartz, orthoclase and plagioclase feldspar, and biotite. [Petrographic description by Whitman Cross on p. 328 of Mon. 12.]

Belongs to Gray porphyry group of Emmons.

Named for fact it forms summit of Mount Lincoln, N. of Alma, Park Co.

Lincoln limestone member (of Greenhorn limestone).

Upper Cretaceous: North central and western Kansas.

W. N. Logan, 1897 (Kans. Univ. Geol. Surv. vol. 2, p. 216). *Lincoln ls.*—Two to five layers of hard, flinty, bluish gray ls. intercalated with shales, lying near base of Russell fm. of Benton group. Thickness 15 ft. Rests conformably on bituminous sh. forming basal part of Benton group. Overlain conformably by Flagstone horizon of Russell fm.

Adopted as basal memb. of Greenhorn ls. (See W. W. Rubey and N. W. Bass, Kans. Geol. Surv. Bull. 10, 1925.) Is separated from overlying Jetmore chalk memb. by 28 to 40 ft. of chalky sh. with some chalk beds, which in 1926 were named *Hartland sh. memb.*

Named for Lincoln, Lincoln Co., where it is quarried.

Lincoln slate.

Pre-Cambrian: Eastern Massachusetts (Boston Basin).

Walter E. Hobbs, 1899 (Am. Geol., vol. 23, pp. 109–115). *Lincoln sl.*—Micaceous sl. or schist, including lenticular masses of impure cherty ls., one of which yielded borings of Annelida about 1 mi. NW. of R. R. Station of South Lincoln. Overlies Kendall Green sl. and lies stratigraphically uncon. lower than Roxbury cgl.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597), mapped the rocks at and around Lincoln, Middlesex Co., as Marlboro fm. The Marlboro includes considerable sl.

Lincoln formation.

Oligocene: Southwestern Washington and Puget Sound region.

C. E. Weaver, 1912 (Wash. Geol. Surv. Bull. 15, pp. 10–22). In southern Thurston Co. strata occur containing a fauna having a very close relationship to underlying Tejon. No distinct uncon. can be recognized btw. them. So far as observed the strata are entirely marine. Area so small it has not been shown on accompanying map. Best exposed on Lincoln Creek near bdy btw. Lewis and Thurston Counties, hence designated *Lincoln fm.* Thickness less than 1,000 ft. Grades up into *Porter shales,* which are correlated with lower part of Blakeley fm. in type section in Kitsap Co. Many species at Lincoln Creek are identical with those at Porter, but fauna as a whole contains more Tejon species. Assigned to Olig.

R. Arnold and H. Hannibal, 1913 (Am. Phil. Soc. Proc., vol. 52, p. 605), in referring to Weaver's 1912 paper (see under *Lincoln fm.*) made the following statements: *Lincoln Creek fm.* is very vaguely defined. [Weaver used *Lincoln fm.*] The area shown on map comprises 2 different things, Chehalis beds underlying the basalts of Balch syncline, and a conformable sequence of a late phase of San Lorenzo fm. and an early phase of the Seattle. The fauna listed appears to have come from basal San Lorenzo beds at Oakville, about 15 mi. away.

C. E. Weaver, 1916 (Wash. Geol. Surv. Bull. 13). *Lincoln fm.,* the ***Molopophorus lincolnensis*** zone, occupies a small isolated area of 40 sq. mi. in SW. Thurston Co. and NW. Lewis Co. Is lowest Olig.

D. L. Frizzell and R. E. Blackwelder, 1933 (Micropal. Bull., vol. 4, No. 2, p. 61), assigned fauna of this fm. to middle Olig., and stated that fm. is uncon. on Eo. sed. and volcanic rocks.

Lincoln Creek formation.

See 1913 entry under *Lincoln fm.*

Lincolnville chert. (In Boone limestone.)

Mississippian: Northeastern Oklahoma (Ottawa County).

S. Weidman, 1932 (Okla. Geol. Surv. Bull. 56, p. 17). A thick bed of cherty ls. in upper part of Boone fm. is exposed along Spring River 10 mi. below Baxter Springs at "Devils Promenade," in SE¼NW¼ sec. 5, T. 28 N., R. 23 E. This cherty ls. has been referred to as the "Lincolnville chert" and the "Quapaw chert," as it was approx. from this zone that the lower runs of ore at Lincolnville and Quapaw were mined.

Lindavista terrace material.

Quaternary: Southern California (San Diego County).

M. A. Hanna, 1926 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 16, No. 7, pp. 187–246). *Lindavista terrace material.*—Sand and gravel scattered over Lindavista terrace, a cut terrace in La Jolla quad. Color prevailingly red and brown. Boulders largely from Poway cgl. Thickness 25 to 100 ft. No fossils found, so that its marine origin has not been determined with certainty.

Linden group.

Lower Devonian (Helderberg): Western Tennessee.

J. M. Safford and J. B. Killebrew, 1876 (Elements of geol. of Tenn., pp. 108, 142, 146–148). *Linden ls.*—Blue, highly fossiliferous thin-bedded, sometimes shaly ls., 0 to 100 ft. thick. Of Helderbergian age. Underlies Black sh. at Linden, Perry Co. Overlies Clifton ls.

C. O. Dunbar, 1918 (Am. Jour. Sci., 4th, vol. 46, pp. 732–755). *Helderbergian or Linden group.*—Divided into (descending) Decaturville chert, Birdsong sh., Olive Hill fm., and Rockhouse sh. Discon. overlies Decatur ls. and uncon. underlies Quall ls. (basal fm. of Oriskanian group).

C. O. Dunbar, 1919 (Tenn. Geol. Surv. Bull. 21, pp. 113–115), gave 3 sections at Linden, showing absence there of all fms. btw. Birdsong sh. and the much younger Hardin ss., except 2½ ft. that may represent Quall ls.

Lindley sand.

A subsurface sand in Chester group (Miss.) of Bond Co., Ill.

Lindside sandstone. (In Pocono sandstone.)

Mississippian: Southeastern West Virginia and southwestern Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 505, 518). *Lindside ss.*—Greenish gray or reddish brown, sometimes ferruginous; 0 to 50 ft. thick. Lies 0 to 9 ft. below Merrimac coal and overlies Langhorne coal, all members of Pocono series [ss.]. Type loc. in Monroe Co., on Dry Creek, about 0.6 mi. SE. of Lindside and just S. of Ernest Fleshman coal prospect. Also observed in Greenbrier Co., W. Va., and in Montgomery Co., Va.

Lindsley Bay granite porphyry.

Pre-Cambrian: Northwest Territory.

C. Riley, 1935 (Jour. Geol., vol. 43, No. 5, p. 504).

Lindwurm member.

Middle Devonian: Southeastern Wisconsin (Milwaukee County).

G. O. Raasch, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 262, 265). *Lindwurm memb.* (*novum*).—Middle memb. of Milwaukee fm. Consists of hard, dull-gray, shaly ls., in beds of moderate thickness. Weathers to stocky mud full of weathered-out fossils and blocks of vitreous fossil ls. Many fossils (listed). In lower 3 ft. a rather distinct faunule. Thickness btw. 30 and 45 ft. Underlies North Point memb. and overlies, possibly uncon., Berthelet memb. Type loc. in Milwaukee Cement Quarry.

Probably named for village in Milwaukee Co.

Lineham member.

Cretaceous: Alberta.

R. L. Rutherford, 1927 (Alberta Sci. and Indus. Research Council, Geol. Surv. Div. Rept. 17, p. 26).

Lingle limestone.

Middle Devonian: Southwestern Illinois and eastern Missouri.

T. E. Savage, 1920 (Am. Jour. Sci., 4th, vol. 49, pp. 171, 176). *Lingle ls.*—Dark-colored, somewhat shaly hard, brittle ls., carrying characteristic Hamilton fossils (listed). Conformably overlies Misenheimer sh. along a branch of Lingle Creek, in SW¼ sec. 26, T. 13 S., R. 2 W. [Union Co.], Ill. Where Misenheimer sh. is absent the Lingle rests uncon. on Grand Tower ls. or older beds. Underlies Upper Dev. Alto fm. in SW. Ill. In eastern Mo. is overlain by post-Dev. rocks and underlain by Grand Tower ls.

According to T. E. Savage, 1925 (Ill. Acad. Sci. Trans., vol. 18, p. 408), his Mountain Glen sh. (Upper Dev.) "does not appear to be represented in Mo." According to C. F. Bassett, 1925 (p. 362 of same pub.), the Lingle ls. in eastern Mo. is uncon. overlain by Mountain Glen sh. Thickness is 75 to 90 ft.

Linietta clay.

Mississippian: Central northern Kentucky.

A. F. Foerste, 1905 (Ky. Geol. Surv. Bull. 6, pp. 145, 156). *Linietta clay.*—Great mass of clays, 40 ft. thick, with phosphatic nodules. Included in base of Waverly series. Occupies about same horizon as Bedford clay of Ohio, but may include a greater part of Waverly series. Overlies Ohio sh.

A. F. Foerste, 1906 (Ky. Geol. Surv. Bull. 7, p. 15). *Linietta clay* is identical with New Providence sh. of Ind.

C. Butts, 1922 (Ky. Geol. Surv., ser. 6, vol. 7, p. 32). *"Linietta clay"* of Foerste is New Providence fm.

C. B. Read, 1936 (Jour. Pal., vol. 10, No. 3, pp. 215–216), stated that Linietta clay of Foerste is 40 ft. thick at its type loc.; that it represents only lower part of New Providence sh. of Butts at that place; that its basal 2 ft. has yielded a flora of New Albany (Upper Dev.) age; that overlying part of the clay (or clay shales, as Read describes it) is barren. Read suggests this basal bed be transferred to underlying New Albany sh. (The U. S. Geol. Survey now includes this basal bed in New Albany sh.)

Named for exposures in immediate vicinity of Linietta Springs, near Junction City, Boyle Co.

Linley conglomerate.

Tertiary (post-Eocene?): Central southern Montana (Carbon County).

W. R. Calvert, 1916 (U. S. G. S. Bull. 641, p. 203). *Linley cgl. (post-Eocene).*—Conglomeratic ss., bedded throughout, composed mainly of grains and well-rounded pebbles, 6 in. or less in diam., of greenish porphyry, with smaller amounts of ls. and pink granite, all presumably originating in Beartooth Mtns. Maximum thickness 300± ft. To N. thins to mere film. No fossils. Is not of glacial age or origin, but was laid down as a fan or delta deposit by Red Lodge Creek. Is overlain by glacial drift. Lies with marked uncon. on highly tilted and eroded Fort Union rocks. Occupies about 5 sq. mi. btw. Linley, Carbon Co., and Beartooth Mtns. Named for development in vicinity of Linley.

†Linville slates.

Cambrian and pre-Cambrian: Western North Carolina.

W. C. Kerr, 1869 (N. C. Geol. Surv. Rept. 2, pp. 13–36). *Linville slates.*—Semimetamorphic argill. slates and shales, sss., lss., and gneissoid grits. Limit Buncombe group on SE. Is narrow belt stretching for most part along the Blue Ridge. Beyond the Blue Ridge it has a breadth of 2 to 3 mi. and consists of ash-colored and bluish slates and shales and lss. with occasional outcrops of thin-bedded light-colored ss. or qtzite. Linville Mtn consists almost exclusively of ss. and qtzitic slates, in places very thin bedded and flexible (itacolumite) and in a few places interbedded with thin layers of a greenish shaly sl. In this fm. E. of Blue Ridge there are frequent interpolations of rocks having a gneissoid aspect, as in the light-colored coarse-grained ledge at foot of Table Rock and many other points E. of that, and again in the apparently very coarse porphyroidal gneiss 1 mi. S. of Blowing Rock on the turnpike.

The rocks described above are now divided into many fms. (See North Carolina chart.)

Named for exposures on Linville Mtn, on bdy btw. McDowell and Burke Counties.

Linville metadiabase.

Pre-Cambrian: Western North Carolina and eastern Tennessee.

A. Keith, 1903 (U. S. G. S. Cranberry folio, No. 90, p. 3). *Linville metadiabase.*—Altered dull yellowish-green diabase and gabbro. Near line of Blue Ridge is associated with Montezuma schist, Flattop schist, and Camb. qtzites, and in several narrow bands S. of Blue Ridge in Cranberry granite.

Named for Linville, Mitchell Co., N. C.

Linwood shale.

Pennsylvanian: Eastern Kansas.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 87, 97). *Linwood sh.*—A lower memb. of Stanton ls. along Kansas River. Underlies Meadow ls. memb. of Stanton and overlies Naish ls. memb. of Stanton. [Derivation of name not stated. On p. 46 *Linwood sh.* is described as consisting of 1 to 2½ ft. of gray aren. sh.]

R. C. Moore and G. E. Condra also used this name in their Oct. 1932 revised classification of Penn. of Kans. and Nebr., but there is no other record of the name. R. C. Moore in his 1936 classification of Penn. rocks of Kans. (Kans. Geol. Surv. Bull. 22) dropped this name, without explanation, and defined *Captain Creek ls.* as basal memb. of Stanton ls., underlying Eudora sh. memb. and overlying Vilas sh. The bed appears to be included in his Captain Creek ls.

Linwood member (of Cedar Valley limestone).

Upper Devonian: Eastern Iowa.

A. C. Trowbridge, M. L. Thompson, and E. H. Scobey, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., fig. 1, pp. 36, 434). *Linwood memb.*—Basal memb. of Cedar Valley fm. At Linwood quarry, Scott Co., the type loc., it consists of 7 ft.

of cherty shaly ls., underlying Littleton memb. [restricted] of the Cedar Valley and overlying Davenport memb. of Wapsipinicon fm.

See also M. A. Stainbrook, 1935 entry under *Littleton memb.*

Lion sandstone.

Miocene (lower): Southern California (San Bernardino Mountains).

F. E. Vaughan, 1922 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 13, No. 9, pp. 344, 375–376, 378, and map). *Lion ss.*—Ss. containing small marine fauna consisting of forms found by Kew in Carrizo Creek region, which are regarded by T. W. Vaughan as not older than lower Plio. This fauna belongs to that of Gulf of Calif. and not to that of southern Calif. coast. Is older than Hathaway fm. and younger than Potato ss.

W. P. Woodring, 1931 (Carnegie Inst. Wash. Pub. 418, pp. 1–25). Lion ss. of F. E. Vaughan is late lower Mio. and of same age as marine Imperial fm. as here redefined.

Named for Lion Canyon, Riverside Co., near which (on third ridge to W. of canyon) it crops out.

Lion Canyon sandstone member (of Williams Fork formation).

Upper Cretaceous: Northwestern Colorado (Meeker quadrangle).

E. T. Hancock and J. B. Eby, 1930 (U. S. G. S. Bull. 812, pp. 197, 206). *Lion Canyon ss. memb.*—Lies in Williams Fork fm., about 3,000 ft. above Trout Creek ss. memb. Projects boldly toward main road immediately E. of mouth of Lion Canyon, forms prominent ledge along W. side of west fork of Lion Canyon, 3 mi. W. of Meeker, and occurs at other places.

Lion Canyon coal group. (In Williams Fork formation.)

Upper Cretaceous: Northwestern Colorado (Meeker quadrangle).

E. T. Hancock and J. B. Eby, 1930 (U. S. G. S. Bull. 812, pp. 197, 206). The group of coal-bearing beds that crops out in the 1,000 ft. of Williams Fork fm. immediately above Lion Canyon ss. memb. is called *Lion Canyon coal group.*

Lion Hill formation.

Mississippian (upper): Central northern Utah (Ophir district).

S. G. Olmstead, 1921 (Econ. Geol., vol. 16, p. 452). Humbug fm. is locally known, in Ophir dist., as *Lion Hill* or *Utah Queen.* Exposed over a large area on Lion Hill.

Lion Mountain sandstone member (of Cap Mountain formation).

Upper Cambrian: Central Texas (Burnet region).

J. Bridge, 1937 (U. S. G. S. P. P. 186L). *Lion Mtn ss. memb.*—Top memb. of Cap Mtn fm. in Central Mineral Region of Tex. Named for Lion Mtn, NW. part of Burnet quad.

Lipalian.

Term proposed by C. D. Walcott, 1910 (Smithsonian Misc. Coll., vol. 57, p. 14), "for the era of unknown marine sedimentation between the adjustment of pelagic life to littoral conditions and the appearance of the Lower Cambrian fauna. It represents the period between the formation of the Algonkian continents and the earliest encroachment of the Lower Cambrian sea."

†Lipan beds.

Eocene: Southern Texas Coastal Plain.

E. T. Dumble, 1924 (A. A. P. G. Bull., vol. 8, pp. 424–436). *Lipan beds.*—The lower or true Fayette. Consists of a series of lignitic clays and sands with bands of ss., qtzite, volcanic ash and beds of peaty material, capped by an indurated ss. with a highly reticulated surface. Thickness probably 150 ft. Uncon. underlies Whitsett beds (previously included in Fayette) and overlies Yegua fm. Exposed in Lipan Hills, E. of Campbellton [Atascosa Co.], and their extensions to NE. and SW., where they form a north-facing escarpment which is traceable in a broken line for 20 mi. or more.

For several years considered same as Fayette ss.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 680, 685, 686). *Lipan memb. of Fayette fm.* underlies Whitsett memb. of the Fayette in central and southern Tex., and is=McElroy and Caddell members of Fayette as now defined in eastern Tex. It is limited at top by the ss. that caps Lipan Hills and at base by Yegua fm.

A. C. Ellisor, 1933 (A. A. P. G. Bull., vol. 17, No. 11, p. 1311). The Whitsett fm. of this paper includes all beds from top of Manning beds of McElroy fm. to base of the Frio; therefore it includes *Lipan beds* and Whitsett beds of Dumble.

Lisbon formation.

Ordovician or Cambrian: Northwestern New Hampshire (Ammonoosuc River region).

C. H. Hitchcock, 1874 (Am. Jour. Sci., 3d, vol. 7, pp. 468–476). *Lisbon group.*—Greenish cgl., hydro-mica and cupriferous schists, qtzites, and dolomites. To W. abounds in copper schists. Comprises: (1) Diabase at top; (2) hydromica schists with cupriferous layers, 3,539 ft., often including nodular mass of nearly white quartz 50 to 150 ft. thick; (3) hydromica cgls., 756 ft. Older than Lyman group and younger than gneiss somewhat allied to Bethlehem gneiss. Included in Huronian. Named for Lisbon.

C. H. Hitchcock, 1877 (Geol. N. H., pt. 2). *Lisbon group (Huronian)* overlies Swift Water series (also Huronian).

C. H. Hitchcock, 1904 (Geol. Soc. Am. Bull., vol. 15, pp. 461–482), stated that *Lyman schist, Lisbon,* and Swiftwater "may be Ord."

C. H. Hitchcock, 1905 (Geol. of Littleton, N. H., Univ. Press, Cambridge), assigned *Lisbon "group"* and overlying *Lyman schists* to *Lower Sil.* [Ord.] *or Camb.*

C. P. Ross, 1923 (Am. Jour. Sci., 5th, vol. 5, pp. 267–302). *Lisbon fm.*—Fairly coarse schistose cgls. and sandy schists, with very subordinate amount of calc. sediment; greenish and grayish color; includes hydromica and cupriferous schists, qtzites, and dolomites; much of material is of volcanic origin. Corresponds to Lisbon group of Hitchcock. Includes Hitchcock's "copper belt," which he included in original definition. Is younger than Swift Water fm. and appears to be older than Lyman and Littleton fms. No fossils, but considered to be Ord. or Camb.

M. Billings in 1934 (see 1934 entry under *Swift Water fm.*) dropped Lisbon, Lyman, and Swift Water from the nomenclature of Littleton and Moosilauke quads. and assigned the rocks to Upper Ord. (?). (See N. H. correlation chart.)

Exposed over large area in Lisbon Twp and at Lisbon Station, in NW. part of Grafton Co., N. H.

Lisbon formation. (In Claiborne group.)

Eocene (middle): Southwestern Alabama and Mississippi.

T. H. Aldrich, 1886 (Ala. Geol. Surv. Bull. 1, pp. 44–60), divided the Claiborne into (descending) Claiborne sand, Calcareous sand bed, and *Lisbon horizon,* the latter overlying the Buhrstone (excluded from the Claiborne).

E. A. Smith and L. C. Johnson, 1887 (U. S. G. S. Bull. 43, p. 30), gave a detailed section of Lisbon bluff, on Alabama River, and explained relations of the beds in that bluff (which constitute basal beds of their Claiborne—from which they excluded the †Buhrstone) to the beds in Claiborne bluff, farther down the river. The two lowermost beds in Claiborne bluff are stated to be same as two uppermost beds in Lisbon bluff. In explanation of this section the term *Lisbon beds* is casually used once.

D. W. Langdon, 1891 (Geol. Soc. Am. Bull. 2, pp. 598–604). *Claiborne series* is divided into (descending): *Scutella* bed, 25–30 ft.; Ferruginous sands or Claiborne proper; *Ostrea sellæformis* bed, 75 ft. of gray calc. sand; and *Lisbon bed,* 45 ft. The latter differs from above mainly in fossils, and appears to be confined to region drained by Alabama and Conecuh rivers. It rests on the Buhrstone [excluded from the Claiborne].

G. D. Harris, 1894 (Am. Jour. Sci., 3d, vol. 47, pp. 303–304). *Lower Claiborne stage* is divided into (descending) *Ostrea sellæformis* beds (substage), *Lisbon beds* (substage), and Buhrstone (substage). [The rocks are not described.]

In present usage of names the Claiborne group in Ala. is divided into (descending): Gosport sand (highly glauconitic sands in which *Ostrea sellæformis* zone is included); Lisbon fm.; and Tallahatta fm. (†Buhrstone). The Lisbon fm., according to E. A. Smith (Ala. Geol. Surv. Undgd. water res. Ala., 1907), consists of 115 ft. of calc., clayey sands and sandy clays. In Miss. the Lisbon consists of fossiliferous calc. sands, clay, and greensand underlying the Yegua fm. and overlying the Tallahatta, and is now divided into an upper (unnamed) memb. 100 to 120 ft. thick, underlain by Kosciusko ss. memb., 25 to 400 ft. thick, succeeded below by Winona sand memb., 45 to 350 ft. thick. It has not been subdivided in Ala. It is middle fm. of Claiborne group, and of marine origin.

Named for exposures in Lisbon Bluff, on Alabama River, in Clarke Co., Ala.

†Lisbon shale.

Upper Cretaceous: Northwestern Kansas and eastern Colorado.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, p. 52). *Lisbon shales.*—Fossiliferous dark-bluish and brownish shales containing concretions of yellow phosphate of iron. Supposed to be lower Fort Pierre. Overlie Smoky Hill chalk and underlie Arickaree shales. Named for Lisbon, Logan Co., Kans.

Preoccupied and same as Pierre sh., older name.

†Lisbon group.

Upper Triassic: Central southern Pennsylvania (Dauphin and York Counties).

G. H. Ashley, 1931 (Topog. and Geol. Surv. Pa. Bull. G1, p. 77). *Lisbon group.*—Purplish nonfeldspathic ss., red sh., and cgl., 10,500 ft. thick. Top fm. of Upper Triassic in Dauphin and York Counties. Overlies Lewisburg group. [Credited to [M. H.] Bissell. "Lisbon" (preoccupied) is apparently a misprint for *Lisburn,* and "Lewisburg" (preoccupied) is apparently a misprint for *Lewisberry.* When the Triassic of New Cumberland quad. (in which occur the geographic features *Lisburn* and *Lewisberry*) was differentiated for 1931 geol. map of Pa., these rocks were included in Gettysburg sh.]

†Lisbon quartzite.

Pre-Silurian (Upper Ordovician?): Northwestern New Hampshire (Ammonoosuc River region).

M. Billings, 1933 (Am. Jour. Sci., 5th, vol. 25, No. 146, p. 149), placed *Lisbon qtzite* beneath what he called "Swiftwater-Lyman fm." in this paper on Littleton and Moosilauke quads. of Ammonoosuc River region. In Jan. 19, 1934, issue of Sci., pp. 55–56, he applied new name *Albee qtzite* to 4,000 ft. of qtzite and sl. occupying similar position, and assigned his Albee to pre-Sil. (Upper Ord.?).

M. Billings, 1935 (letter dated July 19). *Lisbon qtzite* was a term taken from C. H. Hitchcock, who, however, called it *Lisbon group.* As far as I can find, Hitchcock is not very specific as to his type loc., but there can be no question but what it was Lisbon Twp, and, more specifically, the outcrops in the village itself and for 1 mi. to NW. I have since abandoned *Lisbon qtzite* in favor of *Albee fm.* [For Hitchcock's *Lisbon group* see under *Lisbon fm.*]

Lisburne limestone.

Mississippian (upper): Northern Alaska.

F. C. Schrader, 1902 (Geol. Soc. Am. Bull., vol. 13, p. 241). *Lisburne fm.*—Medium-bedded lss., with some sh., 3,000 ft. thick. Assigned to Dev., tentatively, on basis of fossils in surface fragments near top of mtns. Rests, apparently conformably, on Stuver series.

J. B. Mertie, Jr., 1936 (U. S. G. S. Bull. 872). *Lisburne ls.* (Miss.) extends from Cape Lisburne, on Arctic Ocean, east almost if not quite continuously for 600 mi. to int. bdy. It is composed of ls. and chert.

Named for Cape Lisburne, NW. Alaska. Fossils of upper Miss. age have been obtained from the fm.

Liskeard formation.

Ordovician: Ontario and Quebec (Lake Timiskaming).

G. S. Hume, 1925 (Canada Geol. Surv. Mem. 145, pp. 13, 14).

L'Islet formation.

Cambrian: Quebec.

J. K. Knox, 1917 (Canada Geol. Surv. Summ. Rept. 1916, p. 234).

†Lisman formation.

Pennsylvanian: Western Kentucky.

L. C. Glenn, 1912 (Ky. Geol. Surv. Rept. Prog. 1910 and 1911, p. 26). *Lisman fm.*—Chiefly soft shales, in places colored and calc., with some ss. and thin lss. (including Madisonville ls.), and, at base, Anvil Rock ss. Thickness 900 to 1,000 ft. Rests uncon. on Mulford fm. (Penn.) and uncon. underlies Dixon fm. (Penn.).

Corresponds to McLeansboro fm., older name.

Apparently named for Lisman, Webster Co.

Lismore formation.

Carboniferous (Pennsylvanian): Nova Scotia.

W. A. Bell, 1925 (Canadian Min. and Met. Bull. 158, p. 607).

Lissie formation.

Pleistocene: Eastern Texas and northwestern Louisiana.

A. Deussen, 1914 (U. S. G. S. W. S. P. 335, pp. 27, 78–80). *Lissie gravel.*—Gravels and coarse sands, with some small lenses and pockets of red clay in places, and limy clays, gravels, and limy cgls. or "adobe" in other places. Thickness thin to 900 ft. Underlies Beaumont clay. Lies higher than Uvalde and Dewitt fms. Where the Dewitt is replaced seaward by marine Mio. beds the Lissie rests directly on latter.

Later work resulted in dropping *Uvalde fm.* for *Reynosa fm.* Still later, *Reynosa fm.* was replaced by Tex. Geol. Surv. (Univ. Tex. Bull. 3232, 1933) with *Goliad sand*, upon which Lissie fm. rests. The Beaumont clay is uncon. on Lissie (p. 789). Still later, certain deposits of Plio. (?) age were removed from the Lissie and named *Willis sand*, q. v.

Named for Lissie, Wharton Co., Tex.

Lista Blanca complex (or division).

A term applied by E. T. Dumble (Am. Inst. Min. Engrs. Trans., vol. 29, 1900, and vol. 31, 1902) to a volcanic complex of andesitic lavas, aggls., and tuffs, 2,000 ft. thick in Sonora, Mexico, and Cochise Co., SE. Ariz. Assigned by him to Triassic, but now assigned to Comanche series of SE. Ariz.

Listmore formation.

Pennsylvanian: Nova Scotia.

M. Y. Williams, 1911 (Canada Geol. Surv. Summ. Rept. 1910, p. 245).

Liston Creek limestone member (of Liston Creek formation).

Silurian (Niagaran): Northeastern Indiana (Wabash County).

E. R. Cumings and R. R. Shrock, 1927 (Ind. Acad. Sci. Proc., vol. 36, pp. 75–76). *Liston Creek ls.*—A series of thin slabby ls. beds with considerable associated chert, 26 ft. thick along Liston Creek, Wabash Co. Lower part is slabby and contains less chert than upper part. Top of fm. unknown. In a few outcrops a drusy brown or yellow very fossiliferous dol. is associated with the Liston Creek. Exact position of this dol. is not certain. It may represent an overlying fm. distinct from the Liston Creek, or it may be only a local development of it found only adjacent to the coral reefs. Niagaran fossils sparingly throughout. Rests on Red Bridge ls.

E. R. Cumings and R. R. Shrock, 1928 (Ind. Cons. Comm., Div. Geol. Pub. 75, pp. 71–94). *Liston Creek ls.* treated as a *memb. of Liston Creek fm.*, as explained under *Liston Creek fm.* Fossils listed. Thickness 0 to 60 ft. Underlies Huntington ls. and overlies Red Bridge ls. memb. of Liston Creek fm.

Liston Creek formation.

Silurian (Niagaran): Northeastern Indiana (Wabash County).

E. R. Cumings and R. R. Shrock, 1928 (Ind. Cons. Comm., Div. Geol. Pub. 75, pp. 53, 71–94). *Liston Creek fm.*—In view of fact that Red Bridge ls. is rather local bed belonging stratigraphically with Liston Creek ls. as defined by authors in 1927, the authors now prefer to include it as basal bed of *Liston Creek fm.*, which they would define as consisting of the strata lying btw. top of Mississinewa sh. and base of overlying Huntington dol., with both of which it is conformable. As thus defined *Liston Creek fm.* consists of Red Bridge ls. memb. (0 to 12 ft. thick) at base and *Liston Creek ls.* (few to 60 ft. thick) at top. Good exposures at mouth of Liston Creek, Wabash Co., where the *ls.* is 28 ft. thick. In following discussion the Red Bridge and Liston Creek lss. will be considered as individual units. Where Red Bridge ls. memb. thins out there is no evidence of discon. btw. Liston Creek ls. memb. and underlying Mississinewa sh. Along Pipe Creek ½ mi. NW. of Bunker Hill the Liston Creek ls. is discon. overlain by Dev. lss. We believe Louisville ls. is represented in Liston Creek fm.

A. F. Foerste, 1935 (Denison Univ. Bull., Jour. Sci. Lab., vol. 30, p. 159). *Liston Creek fm.* not known S. of Ingalls, near S. line of Madison Co.

Litchfield marl.

Mississippian, Grayson County, Ky. See *Leitchfield marl*, 1876.

Litchfield norite.

Age (?): Western Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 74, 111). *Litchfield norite.*—Certain dark gray rocks forming parts of Mount Prospect, near Litchfield, have been called by Prof. Hobbs [unpublished?] *Litchfield norite.* Does not form large masses, but is associated with granodiorite, diorite, and amphibolite.

Litchfield sand.

A subsurface sand in Pottsville fm. (Penn.) of western Ill. (See Ill. Geol. Surv. Bull. 54, index.)

†Lithodendron member.

†Lithodendron formation.

Upper Triassic: Northern Arizona.

L. F. Ward, 1905 (U. S. G. S. Mon. 48). *Lithodendron memb.*—Cgls. and cross-bedded sss., often with pink and white striped clay lenses interstratified with gray argill. shales and variegated marls. Thickness 800 ft. Underlie Leroux memb. and uncon. overlie Moencopie [Moenkopi] fm. Lithodendron Creek lies in region where Lithodendron beds attain their max. development and only a short distance from Petrified Forest.

Includes Shinarump cgl. and lower part of Chinle fm. of present nomenclature.

†Lithographic limestone.

A descriptive term applied in early Missouri repts to the Miss. fm. later named *Louisiana ls.*

Lithopolis member. (In Cuyahoga formation.)

Mississippian: South-central Ohio.

J. E. Hyde, 1915 (Jour. Geol., vol. 23, pp. 656, 657, 670). *Lithopolis memb.*—Thin, horizontal, interbedded sss. and shales; sss. usually light gray or bluish, moderately fine-grained and evenly bedded; shales argill. and usually sandy and gray. Thickness 118 to 140 and possibly 200 ft. Basal memb. of Cuyahoga fm. in central Fairfield and Hocking Counties. Underlies Fairfield memb. of Cuyahoga and overlies Sunbury sh. Lower 50 ft.=Buena Vista memb. of Prosser and Cumings.

Named for Lithopolis, Fairfield Co.

Littig glauconitic member (of Kincaid formation).

Eocene: Eastern Texas.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 535, 536, 550, 554). *Littig glauconite memb.*—A bed of greenish-black calc. glauconitic sand, from 8 in. to 15 or more ft. thick, forming basal memb. of Kincaid fm. Underlies Pisgah memb. Weathers yellowish green or buff; contains phosphate nodules, small pebbles, shark's teeth, casts of fossils, and spherical calc. concretions. Type exposure is in the road 1½ mi. by road S.-SW. of Littig, Travis Co., on S. side of Wilbarger Creek.

Little lime.

Drillers' term; western Pa.; applied to upper part of Greenbrier ls. memb. of Mauch Chunk fm. (Miss.).

Little Alvord Creek rhyolite.

Tertiary (late): Southeastern Oregon (Steens Mountain).

R. E. Fuller, 1931 (Univ. Wash. Pub. Geol., vol. 3, No. 1, p. 66). [See under *Pike Creek volcanic series*.]

Little Bell Island formation.

Lower Ordovician: Newfoundland.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4). *Little Bell Island fm.*—Sss. carrying *Lingulella billingsi*, uncon. underlying Lance Cove fm., and overlying Kelly Island fm. Included in Bell Island series. [Derivation of name not stated.]

Little Brazos limestone lentil. (In Claiborne group.)

Eocene (middle): Eastern central Texas (Brazos, Robertson, and Burleson Counties).

B. C. Renick and H. B. Stenzel, 1931 (Univ. Tex. Bull. 3101, pp. 78, 92). In Crockett clay memb. of Cook Mtn fm., from 24 to 28 ft. above Moseley ls. lentil and from 65 to 70 ft. below top of Crockett memb, is another impure argill. glauconitic ls., 2 to 4 ft. thick, sometimes occurring as a concretionary bed. It is here named *Little Brazos ls. lentil*, because it is best exposed and has its best faunal representation along Little Brazos River in neighborhood of the old interurban crossing on W. T. James est., 70 acres, W. Matthis survey, about 1.4 mi. NE. of Bryan Junction. Also exposed at other places in Brazos, Robertson, and Burleson Counties. The clays separating Little Brazos ls. from overlying Yegua fm. are gray, buff, and gypsiferous.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, p. 612), showed *Little Brazos ls.* lying higher in the Crockett than Moseley ls.

Little Cabin sandstone memb. (of Cherokee formation).

Pennsylvanian: Northeastern Oklahoma (Craig County) and southern Kansas.

C. L. Cooper, 1928 (Univ. Okla. Bull., Proc. Okla. Acad. Sci., vol. 7, pp. 160-164). *Little Cabin ss.*—Named by D. W. Ohern in unpublished ms. on geol. of Vinita and Nowata quads. A series of distinct beds lying close together, making a heavy memb. 10± ft. thick, in lower part of Cherokee sh. Forms prominent scarp just S. of Miami and extends southward, W. from Afton and along W. bank of Little Cabin Creek (Craig Co.) as far S. as Vinita. Is not traceable farther S. Lies 150± ft. below Bluejacket ss. memb. of Cherokee sh.

Little Chief porphyry.

Mesozoic (?): Southeastern California (Inyo County).

F. MacMurphy, 1930 (Econ. Geol., vol. 25, p. 311). *Little Chief porphyry.*—Intrudes Telescope group (lower Paleozoic?). [Derivation of name not stated.]

F. MacMurphy, 1933 (Calif. State Div. Mines, Rept. 28 of State Min., July-Oct. 1932, p. 351 and map). *Little Chief porphyry* (*granite porphyry*) forms crest of S. part of Panamint Range near head of Surprise Canyon. Intrudes Telescope group. Assigned to Mesozoic (?). [Derivation of name not stated and not apparent from his map.]

Little Clarksburg ls. (In Conemaugh formation.)

B. L. Miller, 1925 (Pa. Geol. Surv., 4th ser., Bull. M7, p. 250), applied this name to a ls. btw. Connellsville and Morgantown ss. members, which is position of Clarksburg ls.

Little Compton shales.

Pre-Cambrian: Southeastern Rhode Island.

A. F. Foerste, 1899 (U. S. G. S. Mon. 33, pp. 281–283, 383). *Little Compton shales.*—A series of greenish slates and shales with thin dol. layers, which evidently constitute a geol. unit. Extend from Browns Point to S. side of Pachet Brook southward, within ½ mile of road running N. from Little Compton, thence westward and along the shore as far as the granite area. Believed to be pre-Carbf. and may be Camb.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, map), mapped the rocks of the area described as Marlboro fm. (pre-Camb.).

†Little Cottonwood granite.

A name that has been applied by some geologists to the stock of quartz monzonite (of late Cret. or early Tert. age) in Little Cottonwood region of central northern Utah. It is exposed in Little Cottonwood Canyon. Has also been called *Cottonwood granite.* (See S. F. Emmons, 1903, Am. Jour. Sci., 4th, vol. 16, pp. 141–147, and F. F. Hintze, Jr., 1913, N. Y. Acad. Sci. Annals, vol. 23, pp. 85–143.) As there is only one quartz monzonite in the region, the U. S. Geol. Survey has not adopted a geographic name for the rock, but uses the term "Little Cottonwood stock" for the structural feature which it forms.

Little Dry glacial stage.

Pleistocene: Northeastern Utah and southwestern Wyoming.

W. H. Bradley, 1936 (U. S. G. S. P. P. 185–I, pp. 194–195). Oldest glacial stage in Uinta Mtns of NE. Utah and SW. Wyo. Named for Little Dry Creek, which flows along W. side of a large terminal moraine on Cottonwood bench, a broad remnant of Bear Mtn surface btw. Little Dry and Cottonwood Creeks, NE. Utah.

Little Dunkard sand.

Drillers' name for a sand in Conemaugh fm. (Penn.) of SW. Pa. that lies at or near horizon of Saltsburg ss. memb. In W. Va. the name is applied to an older sand, which is believed to correspond to Buffalo ss. memb. Named for Dunkard Creek, Greene Co., SW. Pa.

Little Falls dolomite.

Upper Cambrian: East-central and eastern New York.

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, p. 16 and chart). *Little Falls dol.* is employed to express the highly mag., sparsely fossiliferous phase of "Calciferous sandrock" [Beekmantown] in Mohawk Valley. [Assigned to "Champlainic or Lower Siluric," and shown as uncon. underlying Lowville ls. and overlying *Greenfield ls.* (Camb.). The latter he defined as heavy beds of ls. overlying the shore deposits of Potsdam ss. in Saratoga Co. *Greenfield* being preoccupied, it was in 1910 replaced by *Hoyt ls.*, which has been both included in and excluded from Little Falls dol., as explained below.]

In 1905 (N. Y. State Mus. Bull. 77, map) H. P. Cushing mapped *Beekmantown fm. and Little Falls dol.* in Little Falls quad., and assigned them to Lower Sil. [Ord.]. In 1907 (N. Y. State Mus. Bull. 114) C. A. Hartnagel assigned *Beekmantown dol.* (*Little Falls dol.*) to "Champlainic or Lower Siluric." In 1908 (Geol. Soc. Am. Bull., vol. 19, p. 171) H. P. Cushing excluded Little Falls dol. from Beekmantown, and stated that it is uncon. with overlying Beekmantown. In 1909 (Sci., n. s., vol. 29, pp. 351–356) A. W. Grabau considered Little Falls dol. a local subdivision of the Beekmantown. In 1910 (Geol. Soc. Am. Bull., vol. 21, pp. 780–781) E. O. Ulrich and H. P. Cushing restricted *Little Falls dol.* of Mohawk Valley (type region) to lower part of the fm. as heretofore defined, as explained in item 11 under *Beckmantown group*, and assigned it to "late Camb. (Saratogan or Ozarkian)." The same year (N. Y. State Mus. Bull. 140) they described *Little Falls dol. as thus restricted* as consisting of (descending): (1) Dol., largely dark-gray, finely crystalline beds running up into more coarsely crystalline very light-gray beds which are apt to be full of chert and containing a ponderous Cryptozoon reef 30 ft. below top at Little Falls and other Cryptozoon reefs lower down; (2) *Hoyt ls.*, a local basal phase, called *Greenfield ls.* by Clarke, which rests on Theresa fm. (passage beds to Potsdam ss.). They assigned the Little Falls to "Saratoga (Ozarkic)," stated that it is everywhere uncon. with overlying Tribes Hill ls., gave many details and several sections, and stated that "the gastropods described by Cleland from the upper chert zone of the Little Falls dol. at Little Falls are clearly Ozarkic types."

In 1910 (N. Y. State Mus. Bull. 145, p. 97) H. P. Cushing and R. Ruedemann treated Hoyt ls. as distinct fm. btw. Little Falls dol. and Theresa fm. and assigned all three to Saratogan. In 1911 (Am. Jour. Sci., 4th, vol. 31, pp. 135-144) H. P. Cushing treated *Hoyt ls.* "as a local calc. phase of basal portion of Little Falls dol.," assigned it to Saratogan, stated that Walcott had determined its fauna to be Upper Camb., and that it was very local, its exposures being confined to immediate vicinity of Saratoga. In 1911 (Geol. Soc. Am. Bull., vol. 22, p. 643) E. O. Ulrich treated *Hoyt ls.* as distinct from Little Falls dol. and from *Theresa passage beds*, although on pl. 27 of that vol. he placed it as=lower part of [typical] Little Falls dol. of east-central N. Y.; and he assigned Little Falls, Hoyt, Theresa, and Potsdam ss. to Saratogan epoch of his Ozarkian system. He showed Little Falls dol. of Champlain Valley as=div. A and lower part of div. B of Beekmantown [of Brainerd and Seely] and as uncon. below Beekmantown, which he restricted to divisions E, D, C, and upper part of B. He also showed basal part of Chepultepec dol. of Ala.=top part of Little Falls dol., the rest of the Chepultepec being absent in both type Little Falls region and in Champlain Valley. In 1912 (Smithsonian Misc. Coll., vol. 57, No. 9) C. D. Walcott assigned *Hoyt ls.* fauna to Upper Camb. In 1912 (N. Y. State Mus. Hdb. 19) C. A. Hartnagel treated *Hoyt ls.* as a fm. btw. Little Falls dol. (above) and Theresa dol., and assigned all three to Camb. He stated that the name is now extended to strat. equiv. of the fm. in Champlain Valley. In 1914 (N. Y. State Mus. Bull. 169) H. P. Cushing and R. Ruedemann transferred *Hoyt ls.* to Theresa fm., calling it *Hoyt ls. memb.*, and classified the Little Falls and Theresa as "Upper Cambric or Ozarkic of Ulrich."

In 1915 (U. S. Nat. Mus. Bull. 92, vol. 1, p. vii, and vol. 2, pls. 1 and 2) R. S. Bassler, who collaborated with Ulrich, correlated top part only of *Little Falls dol.* of Champlain Valley, N. Y., with Chepultepec of Ala. and with Gasconade of Mo., placed them all as older than Beekmantown, and showed a big hiatus in midst of Little Falls dol. The part of the Little Falls beneath this hiatus he assigned to div. A and lower part of div. B of Brainerd and Seely's subdivisions of Beekmantown, which parts have not for many years been included in Beekmantown.

In 1916 W. J. Miller (N. Y. State Mus. Bull. 182) included Little Falls and Theresa in Camb. The same year (Geol. Soc. Am. Bull., vol. 27, p. 589) A. W. Grabau stated that Little Falls dol. is lowest Beekmantown and that Theresa or *Hoyt lss.* are transitional beds to Little Falls dol. In 1919 (N. Y. State Mus. Bull. 213, 214) W. J. Miller assigned Little Falls dol. to Upper Camb.

In 1919 (Md. Geol. Surv. Camb. and Ord. vol., p. 51) R. S. Bassler divided *Little Falls dol.* of Champlain Valley into: "Little Falls dol. (top bed), upper Ozarkian," lying uncon. below Beekmantown (including divisions E, D, C, and part of B) and separated by a big hiatus from "Little Falls dol. (div. A and B), lower Ozarkian." Bassler correlated this top bed of Little Falls dol. with Gasconade of Mo. and Chepultepec of Ala., and showed it as absent in "east-central N. Y.," where occurs type loc. of Little Falls dol. He placed all of his Ozarkian in the Camb., including the top bed of Little Falls dol. of Champlain Valley. The latter bed is not shown as=any part of div. B.

In 1923 (Smithsonian Misc. Coll., vol. 67, No. 8) C. D. Walcott treated *Hoyt ls.* as a fm. btw. Little Falls and Theresa dolomites, and assigned Hoyt, Theresa and Potsdam to "Ozarkian," which he recognized as a distinct system, although he stated (pp. 469, 470) that fauna of *Hoyt ls.* and upper part of Potsdam ss. is comparable with that of lower Mons of Alberta, and that fauna of lower Mons is "predominantly Upper Cambrian."

In 1924 (Tenn. Dept. Ed., Div. Geol. Bull. 28, p. 34 and Bull. 31, p. 16) Ulrich showed Tribes Hill as basal fm. of his Canadian system, and uncon. on Chepultepec, top fm. of his Ozarkian system.

Repts give thicknesses of *Little Falls dol.* of 74 to 124 ft. in Hamilton Co.; 160 to 200 in Broadalbin quad. (Fulton and Saratoga Counties); and 300 to 400 at Saratoga Springs and vicinity; and of *Hoyt ls.* as 100+ and 120 ft. in Saratoga Co., and 300+ ft. in Dutchess Co., where according to E. B. Knopf (Am. Jour. Sci., 5th, vol. 14, pp. 429–458, 1927) it consists of aren. ls. and dol. carrying Hoyt fauna, overlain by Rochdale ls. and discon. underlain by Stissing dol.

R. Ruedemann, 1929 (Geol. Soc. Am. Bull., vol. 40, pp. 412, 414), assigned *Little Falls dol.* to Upper Camb. and placed it above Theresa fm. and uncon. below Amsterdam ls. (Black River).

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 241, 242, 263). Late studies show *Little Falls dol.* (formerly included in Beekmantown) to be uppermost memb. of Lower Ozarkian series in N. Y. and to be separated from overlying Tribes Hill ls. of Canadian system by uncon. It overlies *Hoyt ls.*, which is a more calc. and more fossiliferous phase of lower part of Little Falls dol. [On p. 233 she stated Hoyt is "basal phase" of Little Falls. In tables on pp. 191 and 194 she assigned Little Falls dol. to "Ozarkian (Saratogan) = Uppermost Cambrian of authors," and placed it above Hoyt ls., which she excluded from Theresa. The U. S. Geol. Survey treats Hoyt as a memb. of Theresa fm.] She also stated: The Little Falls consists of light-gray to dark-gray crystalline or subcrystalline dol.; black and gray cherts are found frequently at certain horizons, and certain layers are full of nodules of crystalline calcite; the summit is very apt to be formed of a massive *Cryptozoon* reef, often heavily silicified; max. thickness of fm. 200± ft.; except for the *Cryptozoon*, fossils are very scarce.

In Jan. 1936 the U. S. Geol. Survey further restricted *Little Falls dol.*, to the lower (major) part of the beds included in it since 1910, as explained under *Beekmantown group.*

The U. S. Geol. Survey treats *Hoyt ls.* as a memb. of Theresa dol. and classifies it and *Little Falls dol. restricted* as Upper Camb.

Named for exposures at the pass in Mohawk Valley at Little Falls, Herkimer Co., east-central N. Y.

Little Genesee conglomerate.

Upper Devonian: Southwestern New York.

C. S. Prosser, 1892 (Rochester Acad. Sci. Proc., vol. 2, pp. 55, 57, 93, 94, 96). *Little Genesee cgl.*, exposed N. of Little Genesee, Allegany Co., is believed to be same as Olean cgl.

†Little Grizzly Creek beds.

Pennsylvanian: Northern California (Taylorsville region).

H. W. Turner, 1894 (Am. Geol., vol. 13, pp. 230–231). *Little Grizzly Creek beds.*—At SW. base of Mount Ingalls [Plumas Co., in Downieville quad.], by road to Cascade gravel mine and to E. of Little Grizzly Creek, there occurs a highly metamorphic tuff, in a fine-grained part of which fossils were collected, which were identified by Charles Schuchert as Upper Carbf. and closely related to Robinson beds. These beds are stratigraphically nearly in line with Robinson beds.

H. W. Turner, 1894 (U. S. G. S. 14th Ann. Rept., pt. 2, p. 448). *Little Grizzly Creek beds,* which consist of highly metamorphic tuff containing many fossils, will probably be correlated with Robinson fm. [In Downieville folio, No. 37, these beds were mapped by Turner as Robinson fm. The latter name has priority over "Little Grizzly Creek beds."]

Little Hominy limestone member (*of Pawhuska limestone*).

Pennsylvanian: Central northern Oklahoma (Osage County).

K. C. Heald and K. F. Mather, 1919 (U. S. G. S. Bull. 686M, pp. 150, 152). *Little Hominy ls.*—Light-gray on weathered surface, somewhat darker where freshly broken, and very coarsely crystalline. In many places uppermost 3 to 6 in. consists of very impure conglomeratic ls. containing many shell fragments. Few fossils. In S. half of T. 25 N., R. 8 E., and wherever seen in T. 24 N., R. 8 E., it is unusually sandy, and in places impossible to separate from overlying massive ss. that forms top memb. of Pawhuska ls. The abrupt disappearance of this ls. at many localities is probably due to its transition from a sandy lime into a calc. ss. that is indistinguishable from overlying sands. Thickness 3 to 15 ft. Lies 12 to 30 ft. above Deer Creek ls. memb. of Pawhuska ls. Named for outcrops on Little Hominy Creek in SW. part of T. 25 N., R. 8 E.

†Littlehorn limestone.

Mississippian (lower): Northern Wyoming (east side of Bighorn Mountains).

N. H. Darton, 1904 (Geol. Soc. Am. Bull., vol. 15, pp. 394–401). *Little Horn ls.*—Light-gray massively bedded ls., many of lower beds of darker color and containing some sand admixture; uppermost 100 ft. of fm. is pure ls. Total thickness 1,100 ft. Typical Miss. fossils at several horizons. No fossils from basal 25 to 30 ft., and Dev. and Sil. may possibly be represented. Is in main = Madison ls. of Mont. and Pahasapa ls. of Black Hills. Overlies Bighorn ls. and underlies Amsden fm. without apparent uncon. Named for fine exposures in Little Horn Canyon, on E. side of Bighorn Mtns.

Same as Madison ls.

Little Kaw limestone member.

Pennsylvanian: Central eastern and northeastern Kansas.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pt. 1, pp. 76–79). *Little Kaw ls. memb.*—Bluish gray blocky ls., 2± ft. thick, forming top memb. of Stanton ls. in Johnson and Miami Counties. Underlies Weston sh. and overlies Victory Junction sh. memb. of the Stanton. Named for Little Kaw Creek, N. of Loring, Leavenworth Co.

See also N. D. Newell, 1936 (Jour. Geol., vol. 44, No. 1, pp. 23–31); R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22); and Kans.–Nebr. chart compiled by M. G. Wilmarth, 1936.

Little Loop oil sand.

A subsurface sand in lower part of Rico fm. (Perm.) in southern San Juan Co., SE. Utah.

Little Medicine tongue (*of Dinwoody formation*).

Lower Triassic: South-central Wyoming (Rattlesnake Hills-Medicine Bow-Laramie Basin region).

H. D. Thomas, 1934 (A. A. P. G. Bull., vol. 18, No. 12, pp. 1664, 1669). *Little Medicine tongue of Dinwoody fm.*—A tongue of Dinwoody consisting of a widespread bed of variegated limy ss., separated from the older Ervay tongue of Phosphoria fm. by a tongue of red Chugwater sh., and overlain by upper part of the Chugwater. Thickness usually about 10 ft. Type along N. bank of Little Medicine Bow River (locally known as the "Little Medicine") in the Flat Top anticline 8 mi. N. of town of Medicine Bow on road from Medicine Bow to Casper. The tongue is also exposed in Rattlesnake Hills of Natrona Co., at Alcova, in Freezeout Hills, in Ferris and Seminoe Mtns, and at places in Laramie Basin. Not yet known which bed in type section of the Dinwoody represents Little Medicine tongue.

Little Missouri lignites or ligneous shales.

Eocene: Southwestern Arkansas.

R. T. Hill, 1888 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 2, pp. 50, 188). *Little Missouri lignites or ligneous shales*, with white sand btw. layers, of same character as those seen at mouth of the Little Missouri. Thickness 20 ft. Occur near top of Camden series. Underlie 32 ft. of laminated sand with greensand specks and overlie 10 ft. of buff-colored micaceous sand and clay shales which change on exposure to pink or light yellow.

Probably belong to Wilcox fm.

Little Oak limestone.

Lower Ordovician (late Chazy): Northern central Alabama.

C. Butts, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14, map, p. 112). *Little Oak ls.*—Generally thick-bedded dark, rather coarsely crystalline ls., in places containing many chert nodules. At top a considerable portion of fm. is very argill. Thickness 0 to 500 ft. Fossils of latest Chazy age. Uncon. overlies Athens sh. Occurs in Cahaba Valley. Named for exposures on W. front of Little Oak Ridge, S. of Leeds, Jefferson Co.

†Little Pine Ridge sandstone.

Upper Cretaceous: Central Wyoming (Salt Creek oil field, Natrona County).

C. E. Jamison, 1912 (Wyo. State Geol., ser. B, Bull. 4, p. 19). *Little Pine Ridge ss.*—Bluish gray ss., 50 to 90 ft.; in upper part 2 coal beds, 10 in. to 3 ft. thick. Forms ridge which usually bears sparse growth of pine trees, from which it derives its name. Lies 570 ft. below top of Pierre fm. in Salt Creek oil field, and 480 ft. above Parkman ss. memb. of Pierre fm.

V. H. Barnett, 1915 (U. S. G. S. Bull. 581, pp. 109, 113, on Big Muddy dome). A ss., lying 320 ft. above Parkman ss. and 400 ft. below top of Pierre fm. in Big Muddy dome [SE. of Salt Creek oil field], seems to agree in strat. position and character with ss. described by Wegemann in U. S. G. S. Bull. 452 as forming Little Pine Ridge, E. of Salt Creek oil field. When Wegemann's rept was published the geographic extent and value of this ss. as a key were not known, but work of Hares W. of Casper and of writer E. of Casper has shown it is probably most easily identified memb. of Pierre fm., and it seems desirable to map and name it. Wegemann stated this memb. forms Little Pine Ridge, a name given by him to an escarpment of ss. next E. of that formed by Parkman ss., but he did not apply the name to the ss. As *Little Pine Ridge* is cumbersome name, and not in current use in the county, it is thought best to name the ss. *Teapot ss. memb.*, from "Teapot Rock," a well-known topog. feature carved from this ss., about ½ mi. E. of Casper-Salt Creek road. The memb. consists of gray and buff ss., including some carbonaceous sh., and is 50 ft. thick at type loc. and 160 ft. thick in Big Muddy dome.

It seems apparent Jamison's use of this name was unknown at time Barnett's rept was published, as it is not listed in U. S. G. S. alphabetic list of geologic names in the literature, and was only recently (1936) discovered by the compiler of this lexicon. Barnett treated this ss. as a memb. of Pierre sh., but later work resulted in differentiating (1915) the deposits of Pierre age in this region into Mesaverde fm. (above) and Steele sh. (below), and the Teapot ss. has for many years been treated as a memb. of Mesaverde fm.

†Little Pittsburgh limestone. (In Conemaugh formation.)

Pennsylvanian: Western Pennsylvania and Maryland and northern West Virginia.

F. Platt, 1877 (Pa. Geol. Surv. Rept. H_3, pp. 55–104). *Little Pittsburg ls.*, 4 to 5 ft. thick, underlies Little Pittsburg coal and lies 50 ft. below Pittsburg coal.

[As thus defined is same as Upper Pittsburgh ls. memb. of Conemaugh fm. of present nomenclature.]

J. P. Lesley, 1878 (2d Pa. Geol. Surv. Rept. Q, pp. 305–308). In NW. part of Allegheny Co. *Upper Little Pittsburg ls.* lies 30 ft. below Pittsburg coal and *Lower Little Pittsburg ls.* lies lower, the two being separated by variegated shales.

Little Pittsburgh member. (In Conemaugh formation.)

A term employed by Pa. Geol. Surv. (M. E. Johnson, Topog. and Geol. Atlas Pa. No. 27, Pittsburgh quad., p. 31, 1929) to include Lower Pittsburgh ss., Little Pittsburgh coal, and Pittsburgh ls.

Little River.

Lower Cretaceous: Arkansas.

See *Upper Little River ls.*

Little River group.

Silurian or Devonian: New Brunswick.

G. F. Matthew, 1863 (Canadian Nat., vol. 8, pp. 244, 251–253).

Little Saline limestone.

Lower Devonian (Oriskany): Eastern Missouri (Ste. Genevieve County) and southwestern Illinois.

C. L. Dake, 1918 (Mo. Bur. Geol. and Mines vol. 15, 2d ser., pp. 88, 174; name taken from unpublished ms. by S. Weller). *Little Saline* underlies Grand Tower ls. and overlies Bailey ls.

T. E. Savage, 1920 (Am. Jour. Sci., 4th, vol. 49, pp. 170–171). *Little Saline River ls.* uncon. overlies Bailey ls. in Mo. and uncon. underlies Clear Creek chert.

S. Weller and S. St. Clair, 1928 (Mo. Bur. Geol. and Mines vol. 22, 2d ser., pp. 136–141). *Little Saline fm.*—Has not heretofore been recognized. Name taken from exposures at quarries of Ozora Marble Co., in E. bank of Little Saline Creek, just S. of abrupt bend of the stream from a northerly to an easterly direction, a little less than 1¼ mi. W. of road crossing S. of Ozora, where max. thickness of 103 ft. is exposed. No known occurrence outside of Ste. Genevieve Co. Is a very pure thick-bedded, more or less coarsely crystalline ls., nearly white or with slight pinkish tint, and filled with fossils in lower half. One bed toward top is decidedly crinoidal. Resting in the lower fossiliferous crystalline beds is a 10 ft. bed of dense hard, close-textured, nearly white ls. with great numbers of bryozoans resembling *Lichenalia*, and a similar bed 8 ft. thick occurs at top of fm. The fm. is apparently entirely free from chert. Rests uncon. on Bailey ls. Conformably [?] overlain by Grand Tower fm. Fossils (listed) correlate it certainly with Upper Oriskany.

T. E. Savage, 1925 (Am. Jour. Sci., 5th, vol. 10, pp. 139–144), extended *Little Saline ls.* into Ill., and substituted it for his *Backbone ls.* of Jackson Co.

†Little Saline River limestone.

Same as *Little Saline ls.*

Littles Corner limestone member.

Devonian or Carboniferous: Northwestern Pennsylvania (Crawford County).

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, pt. 1, p. 202). Hayfield sh. memb. of Knapp fm. includes *Littles Corner ls.*, new name. [All there is about *Littles Corner ls.*]

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61, p. 120). *Littles Corner ls. memb.*—A rather persistent, hard, bluish gray siliceous ls. in upper part of Hayfield sh., which in past has been known as *Cussewago ls.* Was called *Hayfield ls.* by Chadwick. It lies from 15 to 20 ft. below Berea (Corry) ss.; in one or two instances has been reported to lie immediately below Corry ss. Is of restricted distribution. Named for village of Littles Corner in Cussewago Valley, Crawford Co. [On p. 116 he says Cussewago ls. of I. C. White is Hayfield ls. of Chadwick.]

Littleton formation.

Lower Devonian (Oriskany): Northwestern New Hampshire (Ammonoosuc River region).

C. P. Ross, 1923 (Am. Jour. Sci., 5th, vol. 5, pp. 267–302). *Littleton argillite.*—Almost wholly fine black argillite. Contains 2 types of rock, one a group of black argillite and the other a group of alternating bands of black argillite and lighter colored rock, both of which are present in both of mapped areas (in Ammonoosuc mining dist.). Few fossils indicate Lower Dev. marine. Is the "clay slates" of Hitchcock and correlates with "banded argillites" and "dark gray ss. with dark sh. layers" of upper part of Lahee's Blueberry Mtn series. Younger than Lyman fm. Named for Littleton Twp. Grafton Co.

M. Billings, 1934 (Sci., Jan. 19, pp. 55–56). *Littleton fm.* (Lower Dev.) consists of 5,000 ft. of sl., ss., and volcanics, overlying Fitch fm. (middle Sil.). [This corresponds to Littleton argillite of Ross, but is applied over larger area where volcanic rocks are present and included.]

M. P. Billings, 1935 (Geology of Littleton and Moosilauke quads., N. H., pp. 17, 23). C. P. Ross's suggested name "Littleton argillite" is not very satisfactory, as the rocks are slates, sss., and volcanics. The term *Littleton fm.*, from the Twp in which the rocks are typically developed, is proposed instead. More specifically the type loc. is around Slate Ledge, Walker Mtn, and dist. lying a mi. to SW. The fm. is dominantly black sl. and black and gray ss. with one important volcanic memb. that lies 700 to 1,000 ft. above base of fm. That part of fm. below the volcanic memb. is dominantly sl., well exposed in quarry at Slate Ledge. The first 1,000 ft. above the volcanic memb. is a hard, resistant, black ss. The upper part of fm. is interbedded ss. and sl., in which the individual beds are 1 to 6 inches thick. The volcanic memb. consists of (ascending): (1) Porphyritic greenstone metamorphosed to andesite or basalt; (2) white volcanic cgl. of well-rounded boulders 1 to 18 inches diam.; (3) greenish-gray rock which microscope shows to be altered basalt. Fossils are Lower Dev., Oriskany.

Littleton member (of Cedar Valley limestone).

Upper Devonian: Eastern Iowa.

C. L. and M. A. Fenton, 1930 (Am. Mid. Nat., vol. 12, No. 1, pp. 12–13). On right bank of Wapsipinicon River, near town of Littleton, Buchanan Co., is an exposure of Dev. rocks of Cedar Valley age, which are considered as the typical exposure of *Littleton sub-stage of the Cedar Valley.* [Details of 11 beds are given, all fossiliferous ls., except one 3 in. bed of sh., and aggregating 15 ft. 10 in.] Forms lower part of Cedar Valley stage. Overlain by 12 ft. of highly fossiliferous, shaly, yellowish ls. weathering to chips and calc. clay, and composing rest of Cedar Valley.

A. C. Trowbridge, M. L. Thompson, and E. H. Scobey, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., figs. 1, 2, and pp. 36, 424). *Littleton memb. of Cedar Valley fm.*—At Linwood quarry, Scott Co., it consists of 30 ft. of very fossiliferous ls. underlain by 13 ft. of cherty shaly ls., and overlies Linwood memb. of Cedar Valley fm. Is older than Coralville memb. of Cedar Valley fm.

M. A. Stainbrook, 1935 (pp. 249 and 255 of 1935 vol. cited above), restricted Littleton of Fentons, by removing from its base 7 ft. of beds, which he transferred to Linwood memb., "to which they belong faunistically and lithologically." At Littleton thickness of *Littleton memb.* is 21 ft., at Brandon 30 ft., in Johnson Co. 55 ft., and in Buffalo-Linwood region 67 ft. Lithology varies as to locality, being mostly ls., but often argill. and shaly phases predominate. Underlies Coralville memb. of Cedar Valley.

†Little Traverse group.

Same as *Traverse fm.*

Little Traverse Bay limestone.

Middle Devonian: Michigan (northwestern part of Lower Peninsula).

C. C. Douglass, 1839? (Mich. Leg. H. Doc. 27, btw. pp. 97 and 111). *Little Traverse Bay ls.*—Limestone intermixed with clay and chert. Thickness 26 ft. Corresponds in geol. position and character to lss. of cliff of Thunder Bay. Underlies Corniferous ls. (light-gray ls. containing beds of hornstone) and overlies black bituminous ls.

E. R. Pohl, 1930 (U. S. Nat. Mus. Proc., vol. 76, art. 14). Douglass's loosely defined locality of outcrop of his "Little Traverse Bay ls." exhibits several distinct strat.

units, and since he unquestionably applied this term to all beds occurring on shores of Little Traverse Bay, it is suggested that the term be dropped, to avoid conflict with *Traverse group*.

†Little Traverse Bay group.

Same as *Traverse fm.*, which see.

Little White River beds.

Pliocene: Central southern South Dakota.

C. C. O'Harra, 1920 (S. Dak. Geol. Surv. Bull. 13, p. 36). *Little White River beds*, the lower Plio. *Hipparion* zone of White River Badlands. Uncon. overlies upper Mio. *Procamelus* zone or Nebraska beds in Little White River valley and the valley of the Niobrara. Fossiliferous. Local names have been used to designate the beds in the localities where fossil hunting has been carried on. Among these names are Snake Creek, Oak Creek, Little White River, Niobrara River, and Spoon Butte.

See also under *Oak Creek fm.*

Livengood chert.

Mississippian: Yukon Basin, Alaska.

J. B. Mertie, Jr., 1926 (Wash. Acad. Sci. Jour., vol. 16, No. 3, p. 79). Southward, in Yukon Basin, several fms. of Carbf. rocks are known. The Miss. rocks include Rampart volcanics, Calico Bluff fm. (composed of thin-bedded sh. and ls.), *Livengood chert fm.*, and a chert-argillite group of rocks. These fms. occur at different localities, and strat. relations btw. them are therefore obscure. [All there is about the fm.]

J. B. Mertie, Jr., 1936 (U. S. G. S. Bull. 872). *Livengood chert (Miss.)*.—Dominantly chert; some interbedded ls., chert cgls., and argill. rocks. Intrusive rocks are not separated on map. Exposed in vicinity of Livengood, on Livengood Creek, at Livengood Dome, and elsewhere. Thickness probably several thousand ft.

Livermore gravel.

Pliocene (upper): Northern California (Mount Diablo region).

B. L. Clark, 1930 (Geol. Soc. Am. Bull., vol. 41, pp. 774, 779, pls. 15, 20). *Livermore fm.* (also *Livermore gravels*), upper Plio., S. of Livermore Valley, Mount Diablo region, = major part of Siesta fm. Rests uncon. on Briones (middle Mio.). [On p. 779 he says Livermore gravels are Plio. (?) and of continental origin.]

Liverpool cyclical formation.

A name applied by H. R. Wanless (Ill. Geol. Surv. Bull. 60, 1931, pp. 179–193) to a portion of lower part of Carbondale fm. (Penn.) of central western Ill., based upon the rhythmic-cycle theory of sedimentation. Includes coal No. 2. Derivation of name not stated.

Livingston limestone. (In McLeansboro formation.)

Pennsylvanian: Southeastern Illinois (Clark County).

A. H. Worthen, 1875 (Ill. Geol. Surv., vol. 6, pp. 11–19). *Livingston ls.*—Two beds of ls. separated by 7 to 8 ft. of sh. with a thin coal (No. 12?); upper ls. of gray color and 5 to 8 ft. thick; lower ls. 7 to 8 ft. thick. Underlain by 30 to 35 ft. of argill. and sandy shales overying coal No. 11 (?).

Named for Livingston, Clark Co.

See also 1934 entry under *LaSalle ls. memb.*

Livingston formation.

Upper Cretaceous and Eocene: Central southern Montana.

W. H. Weed, 1893 (U. S. G. S. Bull. 105) and 1894 (U. S. G. S. Livingston folio, No. 1). *Livingston beds*.—Waterlaid and assorted volcanic material, including sss. shales, grits, cgls., and intercalated beds of true volcanic aggl. Thickness 7,000 ft. Uncon. underlie Fort Union fm. and uncon. overlie Laramie fm. Typically developed in vicinity of Livingston, Mont.

R. W. Stone and W. R. Calvert, 1910 (Econ. Geol., vol. 5, pp. 551–557, 652–669, 741–764). *Livingston fm.* is a lithologic unit, of limited geographic extent, consisting of andesitic material, 1,000 to 7,000± ft. thick, and includes equivalents of (descending order) Lebo andesitic memb. of Fort Union fm., Lance fm., Lennep ss., Bearpaw sh., and Judith River and Claggett fms. The underlying beds (called Laramie by Weed) are in reality Eagle ss. [This is present generally approved definition.]

Livingston conglomerate. (In Pottsville group.)

Pennsylvanian: Southeastern Kentucky (Rockcastle County).

A. M. Miller, 1908 (Ky. Geol. Surv. Rept. Prog. 1906, 1907, p. 28). *Livingston cgl.*—Cgl. in Lee fm. in dist. somewhat central about Livingston, Rockcastle Co., Ky., that can not be positively identified with Rockcastle cgl. Rests on or close to Lower Carbf. ls. and appears to fill erosion channels in it.

A. M. Miller, 1910 (Ky. Geol. Surv. Bull. 12). The very pebbly cgl. showing up suddenly at mouth of Roundstone Creek and extending in a narrow belt up the drainage area of this stream to the head and over onto headwaters of Silver Creek, and which also appears in patches on Horse Creek and has been somewhat doubtfully correlated by Campbell with his Rockcastle, appears to writer to be in all probability a different lens of ss. It lies in a channel cut out of St. Louis ls., and is doubtfully of marine origin. The name *Livingston cgl.* is suggested for it.

Llajas formation.

Eocene (middle): Southern California (Simi Valley, Ventura County).

J. H. McMasters, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, pp. 217–218). *Llajas fm.*, middle Eo., is typically exposed immediately NW. of mouth of Las Llajas Canyon, on NE. side of Simi Valley, Ventura Co. It was recently extensively cored in Richfield Oil Co. well "Tapo No. 42." Surface and subsurface data afford basis for accurate opinion of strat. and paleontology of the fm. Two zones are recognized, the upper or *Cyclammina* zone, and the lower or *Discocyclina clarki* zone. The 2 zones aggregate 2,020 ft. in the well and approx. 1,150 ft. in most easterly complete surface exposure of the fm. Study of 150 core samples and many surface samples not only verifies previous correlations of Llajas fm. with Rose Canyon sh. of San Diego region, but also indicates that it correlates with both type Domengine ss. and underlying "Meganos" sh. of dist. N. of Coalinga.

T. F. Stipp and F. B. Tolman, 1934 (Pan-Am. Geol., vol. 62, No. 1, p. 79). *Llajas fm.* on N. side of Simi Valley is divisible into 6 mappable members. It is overlain with apparent conformity, by "Sespe fm." (upper Eo.-Olig.?) and underlain by Santa Susanna fm.

Llanfair sandstone member (of Allegheny formation).

Pennsylvanian: Southern central Pennsylvania (Cambria County).

C. Butts, 1905 (U. S. G. S. Ebensburg folio, No. 133). At Llanfair, Cambria Co., a heavy ss. crops out in gorge opp. Henriette shaft No. 1, and, as shown in shaft section, extends to within 40 ft. of Lower Kittanning coal. It has considerable extent in this region and is called *Llanfair ss.* Its top is exposed along the track near Llanfair shaft No. 2, about 2 mi. S. of Llanfair, where it is very coarse and heavy. On Bens Creek the Lower Kittanning coal is closely overlain by a heavy ss. that may be a downward extension of Llanfair ss. [Columnar section shows Llanfair ss. as lying in interval btw. Upper Kittanning and Middle Kittanning coals and as in part of area extending down to near top of Lower Kittanning coal.]

Llano series.

The provincial series of metamorphosed sed. rocks of pre-Camb. age present in central Tex. Is divided into Valley Spring gneiss below and Packsaddle schist above. Originally called Llano "group." For definition see U. S. G. S. Bull. 769, pp. 120–121.

Llano de Oro formation.

Pleistocene (Wisconsin stage): Southwestern Oregon (Josephine County).

P. J. Shenon, 1933 (U. S. G. S. Bull. 846B). *Llano de Oro fm.*—Terrace deposit, consisting of poorly assorted clay and sand with small rock fragments and lenses of gravel. Uncon. overlies Tert. cgl. and is overlain by later Pleist. deposits. Thickness 1 to 80+ ft. Is probably of early Wisconsin age. Named for exposures at Llano de Oro mine, Takilma-Waldo dist.

†Llano Estacado formation.

Pliocene: Western Texas (Panhandle) and southeastern New Mexico.

R. T. Hill, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 87–100; Am. Geol., vol. 10, pp. 108–109). *Llano Estacado fm.*—Unconsolidated porous sediments of Llano Estacado, consisting mostly of waterworn gravel, sand, and silt in horizontal layers, averaging 200 ft. in thickness. Uncon. overlies Cret. and older rocks. Assigned to Neocene (Mio.-Plio.).

Replaced by *Ogallala fm.* (in this area all Plio.; no Mio. in this part of Tex., according to recent work).

Llano Estacadan series.

Tertiary: New Mexico.

C. R. Keyes, 1906 (Am. Jour. Sci., 4th, vol. 21, p. 298). *Llano Estacadan series.*—Shales, 200 ft. thick, overlying Arriban series and forming top div. of Tert. in N. Mex.

Probably same as †Llano Estacado fm., now replaced by Ogallala fm. (regarded as all Plio. in this region).

Llanos formation.

Pleistocene (?): Trinidad.

G. A. Macready, 1920 (Am. Inst. Min. and Met. Engrs., Trans., [preprint 1017], p. 8).

Lloyd sand.

Upper Cretaceous: Southeastern New York (Long Island).

A. C. Veatch, 1906 (U. S. G. S. P. P. 44, p. 21). *Lloyd sand.*—Yellow to white quartz sand and gravel, with occasional layers of clay; contains much decayed white chert and in one place marine fossils. Thickness 80 to 90 ft. Is overlain by varicolored clay 0 to 500 ft. thick and underlain by 0 to 200± ft. of clay. Extends into N. J., where it is an horizon in Raritan fm. about 200 ft. below top.

Named for occurrence in deep well at Lloyd Point, Lloyd Neck, Long Island.

Lloyd zone.

A subsurface oil zone, 2,620 ft. thick, in Repetto siltstone (lower Plio.) of Ventura Co., Calif. Top lies 1,300 ft. below base of Gosnell sh. Formerly included in Pico fm.

Lobelville shaly limestone member (of Brownsport formation).

Silurian (Niagaran): Western Tennessee.

W. F. Pate and R. S. Bassler, 1908 (U. S. Nat. Mus. Proc., vol. 34, pp. 410–432). *Lobelville fm.*—Upper 0 to 45 ft., called Coral zone, usually consists of whitish shales so prolific in fossils that their disintegration upon hillsides leaves ground covered with the specimens, and thin-bedded clayey ls. Lower 9 to 31 ft., called Bryozoan zone, consists of red and purple shales overlain by soft blue to white shales. Of Niagaran age. Top fm. of Brownsport group. Overlies Bob fm. and underlies Decatur ls.

Now treated as top memb. of Brownsport fm. (See H. D. Miser, Tenn. Geol. Surv., Resources of Tenn., vol. 7, 1917, p. 201; and Tenn. Geol. Surv. Bull. 26, 1921, p. 21.)

Named for Lobelville, Perry Co.

Lobo formation.

Triassic (?): Southwestern New Mexico (Deming region).

N. H. Darton, 1916 (U. S. G. S. Bull. 618, pp. 19, 39). *Lobo fm.*—Largely reddish and gray sh. and gray to pinkish impure ls., but includes much cgl. at base. Uncon. underlies Sarten ss. (Lower Cret.) and uncon. overlies Gym and older lss. in Deming quad. Thickness at Lobo Draw, on E. slope of Florida Mtns, 350± ft. In its overlap on granite SE. of Capitol Dome there is some basal arkosic ss. No fossils. May be Penn., Perm., Triassic, or even earliest Cret. Is tentatively classified as Triassic (?).

Lobster Lake series.

Silurian: Western Maine (Piscataquis County).

F. W. Toppan, 1932 (Geol. of Maine, Contr. Dept. Geol. Union Coll., Schenectady, pp. 70–72). *Lobster Lake series.*—Light-gray aren. lss. rich in stromatoporids, the entire group being strongly reminiscent of the Ripogenous lss., which contain Niagara fossils. At least 1,000 ft. thick. Well exposed on shores of Lobster Lake [Lobster Pond?], Piscataquis Co. Assigned to Sil.

Lockatong formation. (In Newark group.)

Upper Triassic: New Jersey and southeastern Pennsylvania.

H. B. Kümmel, 1897 (N. J. Geol. Surv. Ann. Rept. State Geol. 1896, pp. 40–47, and Jour. Geol., vol. 5, pp. 544–547). *Lockatong series.*—Hard dark-colored shales and dark-gray and green flagstones, much harder and darker than overlying Brunswick shales or underlying Stockton series. Also includes carbonaceous shales, hard massive black and bluish-purple argillites, dark-red shales, and some thin layers of highly calc. shales. Thickness 1,700 to 3,660± ft. Middle fm. of Newark system [group]. Named for Lockatong Creek, Hunterdon Co., N. J.

†Lockhart formation. (In Chester group.)

Mississippian: Western Kentucky.

F. J. Fohs, 1907 (Ky. Geol. Surv. Bull. 9, p. 67). *Lockhart fm.*—Lss., shales, and some ss., 100 to 175 ft. thick, composing topmost fm. of Chester group in Caldwell, Crittenden, and Livingston Counties. Overlain by Pottsville fm. and underlain by Birdsville fm. [See †*Birdsville fm.*]

May be=Clore ls.

Probably named for Lockhart, Livingston Co.

Lockport dolomite. (Of Niagara group.)

Silurian: New York, Michigan, and Ontario.

J. Hall, 1839 (N. Y. Geol. Surv. 3d Rept., pp. 289, 327). *Lockport ls.*—The ls. at Lockport [N. Y.] excavated for passage of the [Erie] canal. At this place the rock possesses in an eminent degree the geodiferous character which has hitherto given it its name. To E. it becomes a dark, nearly black, compact ls. Overlies Rochester sh. and underlies the red sh. [Salina fm.] forming basal part of Onondaga saliferous group. Is top fm. of Protean group of Vanuxem.

In subsequent repts the Guelph dol. has been both included in and excluded from Lockport dol. (See under *Guelph dol.*) The U. S. Geol. Survey uses the original and commonly accepted definition of Lockport dol., which includes the beds that carry the Guelph fauna. The Lockport consists largely of dol. and is treated as upper fm. of Niagara group, the Clinton fm. (including Rochester sh. memb. at top) being the lower fm. of that group. In some early repts the Lockport dol. was called "Niagara ls." The N. Y. State Survey now includes Guelph in Lockport dol. (See W. Goldring, 1931, N. Y. State Mus. Hdb. 10, pp. 191, 335.)

†Lockport group.

A name applied in some early N. Y. repts (L. Vanuxem 1842) to the blackish impure ls. and bluish slaty sh. underlying Onondaga salt group and overlying Clinton group, as he used the names. As thus used the term included Lockport dol. and Rochester sh. memb. of Clinton fm. of present nomenclature.

†Lockport group.

A time term used by E. O. Ulrich and R. S. Bassler (12th Int. Geol. Cong., Canada, pl. opp. p. 666, 1913; and Md. Geol. Surv. Sil. vol., pp. 244, 259–270, 1923) to include not only Lockport dol. of N. Y. but in Central States all beds btw. base of Laurel ls. and top of Louisville ls., the latter of post-Guelph age according to their charts. Ulrich's 1911 charts show some of these beds to be older and some younger than Lockport dol. of N. Y. The U. S. Geol. Survey uses *Lockport* in a rock or formational sense, applying it to the dol. that underlies Salina fm. and overlies Clinton fm. in N. Y. and Mich.

†Lockport marble.

†Lockport Encrinal marble.

Names applied in some early repts to Gasport ls. memb. of Lockport dol.

†Lockport moraine.

Same as *Barre moraine*. Named for Lockport, N. Y.

Loco diorite.

Eocene: Central Montana (Little Belt Mountains).

W. H. Weed, 1899 (U. S. G. S. Little Belt Mtns folio, No. 56). *Loco diorite.*—Granular rock forming stocks or central cores of Crazy Mtns. Prevailing form is a typical diorite grading into quartz diorite and even into granitite. At N. end of Loco Mtn stock the prevailing rock is an augite-biotite diorite with no hornblende and very little quartz. Assigned to Eo., as it cuts sed. rocks containing post-Cret. plants and is overlain by Neocene lake beds and cut by Neocene eruptives.

Locust Grove diorite.

Pre-Cambrian: Northeastern Virginia.

J. T. Lonsdale, 1927 (Va. Geol. Surv. Bull. 30). *Locust Grove diorite* closely parallels the granite near Locust Grove. Extends from 1 mi. E. of Verdiersville on R., F. & P. Ry. to 1½ mi. SW. of Flat Run P. O., a distance of 8½ mi. Is definitely older than Locust Grove granite and is probably pre-Camb.

A. I. Jonas, 1928 (Va. Geol. Surv. prel. ed. of geol. map of Va.), mapped the diorite near Locust Grove as pre-Camb. quartz diorite, intrusive into Glenarm series.

Locust Grove granite.

Pre-Cambrian: Northeastern Virginia.

J. T. Lonsdale, 1927 (Va. Geol. Surv. Bull. 30). *Locust Grove granite* is typically developed near Locust Grove, Orange Co. Corresponds fairly closely to quartz monzonite. Is believed to be late pre-Camb. or Camb. Is younger than Locust Grove diorite.

A. I. Jones, 1928 (Va. Geol. Surv. prel. ed. of geol. map of Va.), mapped the granite at and near Locust Grove as pre-Camb. and as intrusive into Glenarm series.

Locust Point formation. (In Borden group.)

Mississippian: Southeastern Indiana.

P. B. Stockdale, 1931 (Geol. Soc. Am. Bull., vol. 42, No. 3, pp. 708–716). *Locust Point fm.*—Mainly massive or shaly siltstone in southern part of Ind. outcrop area. Northward the fm. becomes a succession of fine-grained ss. beds and alternating shaly zones. Fossils rare, aside from worm marks. Average thickness 125± ft. Underlies Carwood fm. and overlies New Providence fm. [In 1929 (Ohio Jour. Sci., vol. 29, No. 4, p. 170) Stockdale named the beds underlying Carwood fm. and overlying New Providence fm. in southern Ind. the *St. Joseph,* a name that is preoccupied.]

P. B. Stockdale, 1931 (Ind. Dept. Cons., Div. Geol. Pub. 98, pp. 52, 77, 94, 120–126+). *Locust Point fm.*—Underlies Carwood fm. and overlies New Providence fm. Is more sandy than latter. Includes rocks called "Knob sh.," "Upper Knobstone sh.," etc., by early Ind. writers and Rosewood sh. by Butts (Ky. Geol. Surv., ser. 4, vol. 3, 1915, pp. 157–158). For lack of a better term, and in absence of detailed strat. knowledge, *Rosewood sh.*, the most recent name, has been used with some misgiving in various writings that have appeared since Butts' 1915 proposal. The name *Locust Point fm.* here used is selected from a well-known topog. prominence on Ohio River bluff, about 1 mi. S. of Floyd-Harrison Co. line, S. center sec. 12, T. 4 S., R. 5 E., and from nearby Locust Point P. O., center SE¼ same section. The sandy sh. extending from base of bluff upward 127 ft. is this fm. [Describes and names many local *facies* of the fm.]

Lodgepole limestone. (Of Madison group.)

Mississippian (lower): Central northern Montana (Little Rocky Mountain region).

A. J. Collier and S. H. Cathcart, 1922 (U. S. G. S. Bull. 736 F, p. 173). In this part of Mont. (Little Rocky Mtn region) the Madison ls. becomes a group, divisible into two distinct fms., here named *Lodgepole ls.* (the lower one) and *Mission Canyon ls.* (the upper one). The Lodgepole ls. consists of 800 ft. of thin-bedded ls. and sh. containing many fossils. It overlies Jefferson ls. Named for exposure in Lodgepole Canyon.

Lodi shale member (of St. Lawrence formation).

Upper Cambrian: Southern Wisconsin and eastern Minnesota and Iowa.

F. T. Thwaites, 1923 (Jour. Geol., vol. 31, p. 547). Trempealeau fm. is divided by E. O. Ulrich [unpublished at this time] into four members: Norwalk fine-grained dolomitic ss. at top, underlain by *Lodi yellow and purple sandy thin-bedded dol.*, locally called "sh.," which in turn rests on St. Lawrence or Black Earth dol. [restricted use of St. Lawrence]. Along Wisconsin River the Lodi "shales" predominate.

E. O. Ulrich, 1924 (Trans. Wis. Acad. Sci., Arts, and Lett., vol. 21, pp. 83, 86–87). *Lodi sh. memb.* (*of Trempealeau fm.*).—This term is proposed for the usually yellow, calc., sh.-like ss. that lies btw. Norwalk ss. and St. Lawrence ls. [Ulrich's restricted definition of St. Lawrence]. This sh. memb. is widely distributed, the outcrops being everywhere recognizable from Stillwater, Minn., and Osceola, Wis., on the N. to Spring Green on the S. and vicinity of Madison on the E. Locally the characteristically yellow sh. is interbedded with purple sh., as in vicinity of Mazomanie, or with layers of ss., and in other places with dolomitic ls., but even without considering the fossils there is seldom any difficulty in recognizing the Lodi sh. Thickness rarely less than 15 ft., with 50 ft. max. and 25 ft. approx. average. Usually fossiliferous, and so far as known its fauna is almost entirely confined to this memb.

The U. S. Geol. Survey at present treats these beds as a memb. of St. Lawrence fm., and does not use the name "Trempealeau fm." A. C. Trowbridge and G. I. Atwater, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 21–79), also used *St. Lawrence fm.* instead of *Trempealeau fm.;* but in 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., passim) Trowbridge et al., expanded Trempealeau fm. so as to include at top *all* of Jordan ss. as well as overlying Madison ss., and treated Lodi and St. Lawrence [restricted] as members of the Trempealeau. This classification has not yet been adopted by U. S. Geol. Survey.

Type locality not stated, but presumably named for exposures at or near Lodi, Columbia Co., Wis.

Lodore formation (also **Lodore shale**).

Cambrian: Northwestern Colorado and northeastern Utah (Uinta Mountains).

J. W. Powell, 1876 (Geology of eastern portion of Uinta Mtns, pp. 41, 56, 58, 144–147). *Lodore group.*—A group of soft sss. and aren. shales, with cgls. at base, 465 ft. thick, conformably underlying Redwall group of lss. in Lodore and Whirlpool Canyons, where Green River cuts through eastern part of Uinta Mtns, and uncon. overlying Uinta ss. Believed to be same as Tonto group [Middle Camb.] of Grand Canyon, but assigned to Carbf. Named for Lodore Canyon [Moffat Co., NW. Colo.].

F. B. Weeks, 1907 (Geol. Soc. Am. Bull., vol. 18, pp. 432–434). *Lodore shales.*—Argill. and sandy green, red, purple, and black shales; green shales containing many nodules. Thickness 500 to 1,200 ft. in Uinta Range. Assigned to Camb. and correlated with Tonto group of Grand Canyon.

H. S. Gale, 1910 (U. S. G. S. Bull. 415, p. 48). *Lodore shales* not studied in connection with this rept on coal fields of NW. Colo. and NE. Utah. They are now thought to be of middle or upper Camb. age, although no authentic record of fossils from this fm. is known for this general region.

Logan formation.

Mississippian: Ohio and northeastern Kentucky.

E. B. Andrews, 1870 (Ohio Geol. Surv. Rept. Prog. 1869, pp. 62, 76, 79, 80, 87). *Logan ss. group* (also *Upper Waverly or Logan ss.*).—Fine-grained buff-colored ss., 133½ ft. thick, underlying Maxville ls., or, where that is absent, the coal measures. Overlies 85 ft. of alternate fine-grained Waverly-like seams and cgl. exposed at Black Hand, where it is 50 to 60 ft. thick. [In this and later repts Andrews called this cgl. "Waverly cgl." But that name was later replaced by *Black Hand fm.*]

According to Jesse E. Hyde (Jour. Geol., vol. 23, p. 659, 1915) and C. S. Prosser (Ohio Geol. Surv., 4th ser., Bull. 7, p. 17, 1905) there is a difference of opinion regarding the rocks originally included in Logan ss. by E. B. Andrews, also regarding the correct definitions of Black Hand and Cuyahoga. (See under *Black Hand memb.* and *Vinton memb.*) Hyde's expanded Logan fm. (which includes, descending, his Vinton, Allensville, Byer, and Berne members) and his restricted Black Hand memb. appear to be the definitions at present followed by Ohio Geol. Surv. The U. S. Geol. Survey, however, has not yet adopted these modifications for its publications.

Named for Logan, Hocking Co., Ohio.

†Logan limestone or flint. (In Logan formation.)

Mississippian: Southeastern Ohio.

E. Orton, 1878 (Ohio Geol. Surv., vol. 3, pp. 900–901, pls. opp. pp. 889, 900, 921, 933). *Logan ls. or flint* (also *Logan flint ls.*).—Thickness 1 to 2 ft. in Vinton and Jackson Counties. Overlain by iron ore and underlain by thin coal. Lies about 50 ft. above Waverly cgl. and about 55 ft. below Maxville ls.

Probably named for occurrence in Logan fm.

Logan fire clay. (In Pottsville formation.)

Pennsylvanian: Southeastern Ohio.

E. Orton, 1878 (Ohio Geol. Surv., vol. 3, pp. 713, 901). *Logan fire clay.*—One of most valuable clay seams of Ohio, lying immediately above Maxville block ore and Maxville ls. in Perry and Hocking Counties. Probably belongs to same horizon as Sciotoville and Webster fire clays of Scioto Co.

Occurs in basal part of Pottsville fm. Appears to be a lower clay than the Sciotoville. (See Outlines of field trips in geol. in central Ohio, by C. S. Prosser and W. C. Morse, 1915, p. 16.)

Named for Logan, Hocking Co.

†Logan group.

Mississippian: Ohio.

E. Orton, 1880 (Review Strat. Geol. Eastern Ohio, p. 14). *Logan group.*—A series of shales, sss. and cgls., 150 to 250 ft. thick, held together by common fossils, included in Cuyahoga sh. by some authors, but overlying (Lower) Cuyahoga sh. and underlying Maxville ls. or a well-marked horizon of coal, fire clay, and iron ore. Includes Logan ss. and Waverly or Black Hand cgl. and contemporary beds.

Preoccupied by *Logan fm.*

Apparently named for Logan, Hocking Co.

Logan limestone.

Silurian: Central Pennsylvania (Mifflin County).

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 2, pp. 787, 790, 805). *Logan ls.*—A peculiar stratum, 3½ ft. thick, outcropping near Logan Furnace. Differs in character from the other ls. beds of Logan section, but may not have any strat. importance. Consists of 3 layers, the upper and lower ones being heavy compact dull-blue ls. breaking into square blocks and weathering blue gray. Between them is a very hard layer heavily charged with iron and breaking with rough semi-crystalline surfaces. Overlies Logan sh., 72 ft. thick. All included in upper part of Salina shales.

Logan shale.

Silurian: Central Pennsylvania (Mifflin County).

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 2, p. 787). *Logan sh.*, 72 ft. thick, underlies Logan ls. and overlies Salina Upper red sh. in Logan section. Included in Salina shales, lying much higher in section than Bloomsburg red sh.

†Logan sandstone. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and D. B. Reger, 1914 (W. Va. Geol. Surv. Rept. Logan and Mingo Counties, p. 178). *Logan ss.*—Massive, persistent, gray, medium-grained, micaceous. Thickness 20 to 50 ft. Lies 0 to 5 ft. below Alma coal and 1 to 10 ft. above Little Alma coal. Named for Logan, Logan Co., W. Va.

C. E. Krebs and D. D. Teets, Jr., 1915 (W. Va. Geol. Surv. Rept. Boone Co., p. 443). Name of *Logan ss.* changed to *Monitor ss.*, because Logan is preoccupied.

Logan sills.

A name that has long been in use for pre-Camb. sills, of Keweenawan age, on NW. coast of Lake Superior, in northern Minn. and Canada. Name was given in honor of Sir Wm. E. Logan.

Logana bed.

Middle Ordovician (Trenton): Central Kentucky.

A. M. Miller, 1905 (Ky. Geol. Surv. Bull. 2, pp. 9, 19). *Logana substage.*—Argill. ls. and sh., 10 ft. thick, characterized by *Modiolidon oviformis.* Overlies Curdsville ls. and underlies Hermitage ls. All included in Lexington stage.

A. F. Foerste, 1906 (Ky. Geol. Surv. Bull. 7), and A. M. Miller, 1906 (Ohio Nat., vol. 6, pp. 447–448). *Logana* underlies Wilmore and overlies Curdsville.

A. F. Foerste and A. M. Miller, 1913 (Ky. Geol. Surv., 4th ser., vol. 1, pt. 1). *Logana* is same as Hermitage of Tenn., and Wilmore overlies Logana.

Named for Logana, Jessamine Co.

†Loganian.

Name proposed in early repts for pre-Laurentian rocks of Great Lakes region which correspond to Keewatin series of U. S. Geol. Survey. For definition see U. S. G. S. Bull. 769, p. 135.

Logie Green.

Cretaceous: Jamaica.

R. T. Hill, 1899 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 34, p. 42).

Lohali sandstones.

Jurassic: Northeastern Arizona.

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, pp. 250, 337). *Lohali sss.*, 250 ft. thick, underlie Mancos shales, and compose main body of Dakotan series as developed near Lohali, Apache Co., W. of Chinle, and NW. of Fort Defiance.

C. [R.] Keyes, 1936 (Pan-Am. Geol., vol. 65, No. 4, pp. 303, 306). *Zunian series* divided into (descending) McElmo shales, Lohali ss., Montezuma shales, and Arido ss. The latter 3 fms. correspond to La Plata beds of Cross, and are present in Colo, N. Mex., and Ariz.

C. [R.] Keyes, 1936 (Pan-Am. Geol., vol. 66, No. 1, pp. 71–72). *Lohali* is preoccupied and is here replaced with *Tyende ss.*

This ss. appears to correspond to Navajo ss. of U. S. G. S. classification. (See U. S. G. S. P. P. 183, chart opp. p. 37.)

Lohn shale member (of Thrifty formation).

Pennsylvanian: Central Texas (Colorado River region).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 387, 408). *Lohn bed.*—Fossiliferous, bluish, red, yellowish, and purple clay, with some shaly clay, sh., ss., and ls., and the Chaffin coal. Thickness 20 to 75 ft. Memb. of Cisco div. Underlies Parks Mtn bed and overlies Speck Mtn ls.

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132), include this bed in Thrifty fm., of Cisco group. Named for Lohn, McCulloch Co.

Lohrville granite.

Name applied by C. C. Wang (Geol. Soc. China Bull., vol. 11, No. 4, pp. 426–428, 1932) to a pre-Camb. granite in Wis. (area not stated), which occurs in a small mound not far from the mound of Waushara granite and which is similar to latter granite.

†Lolo series.

Pre-Cambrian (Belt series): Central western Montana (northern Bitterroot Mountains) and adjacent area in Idaho.

W. Lindgren, 1904 (U. S. G. S. P. P. 27, pp. 16, 34). *Lolo series.*—The sed. series of Lolo Fork, near extreme N. end of Bitterroot Range [in Mont., according to Lindgren's map]. Apparently does not enter watershed of Clearwater River, though continuing close to its limits. Consists of moderately metamorphosed qtzites, ls., and banded slates, some of purple color. Apparently conformable, but evidently folded, overturned, and repeated series. Probably identical and continuous with series occupying entire width of Coeur d'Alene Mtns, and extending from lake of same name on W. to Clark Fork of Columbia on E. No fossils ever found in either series. My belief is Lolo series should be coordinated with thick pre-Camb. series of central Mont.

F. L. Ransome, 1905 (U. S. G. S. Bull. 260, p. 278). The Algonkian sed. rocks near Lolo Pass [just over the line in Idaho], described by Lindgren in U. S. G. S. P. P. 27, p. 16, are probably part of the same series that prevails in Coeur d'Alene Mtns, but, as shown by Lindgren, are cut off by the great granite batholith of central Idaho.

Lomita formation.

Pleistocene: Southern California (San Pedro Hills, Los Angeles Basin).

U. S. Grant, IV, and H. R. Gale, 1931 (Mem. San Diego Soc. Nat. Hist., vol. 1, pp. 42–43, 61). Las Posas zone in Los Angeles Basin is most characteristically exposed at Lomitas quarry and in Hilltop quarry. It uncon. underlies Timms Point zone (=Deadman Island "Plio." of repts) and overlies Santa Barbara zone. Correlation with Las Posas of Ventura Basin practically certain.

R. D. Reed, 1933 (Geol. Calif., pp. 259, 260, 261, 264, 303, 304). *Lomita fm.*—Marine deposits. To S. in San Pedro Hills the *calc. Lomita* underlies Timms Point fm. and overlies lower Plio.; to N., at San Pedro, the *sandy Lomita* underlies San Pedro ss. and overlies lower Plio. Repetto fm. The two facies are fairly well separated by a small anticline. Fossiliferous. Assigned to Pleist.

U. S. Grant, IV, 1935 (Pan-Am. Geol., vol. 64, No. 1, pp. 73–74). *Lomita fm.*, 0 to 300 ft. thick, underlies Timms Point fm. (both marine Pleist.) at San Pedro. Fossils listed.

Lonaconing sandstone. (In Conemaugh formation.)

Pennsylvanian: Western Maryland (Allegany and Garrett Counties).

C. K. Swartz, W. A. Price, and H. Bassler, 1919 (Geol. Soc. Am. Bull., vol. 30, p. 573). *Lonaconing ss.*—Underlies Franklin coal and overlies Lonaconing coal; all included in Conemaugh fm.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, p. 68, pl. 6). *Lonaconing ss.*—A thin-bedded ss. found locally btw. Lonaconing and Franklin coals. Exposed at various places along Georges Creek S. of Lonaconing.

Lone quartzite.

Upper Cambrian: Southwestern New Mexico (Silver City region).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257–259; Conspectus of geol. fms. of N. Mex., pp. 4, 8). *Lone qtzite.*—Late Camb. section of alternating qtzites and metamorphosed lss. well displayed in Lone Mtn, near Silver City. Thickness 300 ft.

The Upper Camb. qtzite of Silver City region has for many years been called *Bliss ss.* by U. S. Geol. Survey.

†Lone limestone.

A name applied by C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, p. 53) and 1924 (Pan-Am. Geol., vol. 41, p. 37), to the upper or Sil. part of Lone Mtn ls. of Nev.

Lone Butte limestone member.

Middle Devonian: Northwestern Montana.

C. F. Deiss, 1933 (Mont. Bur. Mines and Geol. Mem. 6, pp. 43 and passim). *Lone Butte ls. memb.*—Underlies Spotted Bear ls. and overlies Coopers Lake ls., all members of Jefferson ls. Known only in 5 sections: Lone Butte, Spotted Bear Mtn, Pentagon Mtn, Prairie Reef-White Ridge, and Dearborn; eroded in other sections. Thickest (637 ft.) on White Ridge; thinnest (87 ft.) on Monitor Mtn. Most striking characteristics are drab, dark-brown color, vitreous luster on fresh surfaces, and very petroliferous content. Type loc. on SE. side of S. spur of Lone Butte, in NE¼ sec. 26, T. 23 N., R. 13 W., where it is 421 ft. thick and consists of (descending): (1) Massive brown to steel-gray mag. petroliferous ls., thin-bedded in lower part, thicker-bedded and more massive upward, 170 ft.; (2) massive chocolate to chocolate-gray fine-grained mag. ls. that weathers white buff and to sharp angular surfaces; (3) steel-gray vitreous dolomitic aren. fine-grained petroliferous ls. that weathers light buff-brown, 141 ft.; (4) thick-bedded tan to steel-gray vitreous, very petroliferous aren. ls., porous in upper part, and weathering drab brown, 34 ft.

Lone Camp limestone. (In Mineral Wells formation.)

Pennsylvanian: Central northern Texas (Parker County).

G. Scott and J. M. Armstrong, 1930 (Tex. Bur. Econ. Geol., geol. map of Parker Co.), show *Lone Camp ls.* (5 ft. thick) beneath Salesville sh. and 40 ft. above Lake Pinto ss., but the name is not listed by E. H. Sellards in Tex. Univ. Bull. 3232, 1933. The Salesville sh. as defined overlies Lake Pinto ss.

†Lone Grove series.

Pre-Cambrian (Llano series): Central Texas.

T. B. Comstock and E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. lv, 255–267). *Lone Grove series.*—Granites, gneisses, and allied rocks forming basal part of Burnetan system. Underlies Long Mtn series.

Same as Packsaddle schist.

Named for Lone Grove, Llano Co.

Lone Land formation.

Pre-Cambrian: Mackenzie.

M. Y. Williams, 1924 (Geol. Soc. Am. Bull., vol. 35, pp. 97, 458).

Lone Mountain limestone.

Silurian and Upper Ordovician: Eastern Nevada (Eureka region).

A. Hague, 1883 (U. S. G. S. 3d Ann. Rept., pp. 253, 262, 267). *Lone Mtn ls.*—Light-gray siliceous rock, with all traces of bedding obliterated, and with black gritty beds at base. Thickness 1,800 ft. Uncon. overlies Eureka qtzite and underlies Nevada ls. (Dev.).

The fm. contains Sil. fossils (of Niagaran age) in upper part, and Upper Ord. fossils (of Richmond and probably Maysville age) in lower part.

Type loc., Lone Mtn, 18+ mi. NE. of Eureka. Has also been mapped by S. H. Ball (U. S. G. S. Bull. 308, 1907) in Inyo Co., Calif.

For slight modification of definition see under *Eureka qtzite,* E. Kirk, 1932.

†Lone Mountain dolomite.

Silurian: Mackenzie, Canada.

E. M. Kindle, 1921 (Canada Geol. Surv. Summ. Rept. 1920, pt. B, p. 44).

E. M. Kindle, 1936 (Sci., n. s., vol. 83, No. 2140, pp. 14–15). *North Nahanna River dol.* replaces *Lone Mtn dol.* (preoccupied).

Lone Oak limestone lentil. (In Kincaid formation.)

Eocene: Northeastern Texas (Hunt County).

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 536, 539, 553). *Lone Oak ls. lentil.*—Impure oolitic ls. containing a few fossils. Typically exposed at Lone Oak quarry W. of Lone Oak, Hunt Co. Occurs near base of Pisgah memb. (upper memb. of Kincaid fm.), and can be traced some distance NE. and SW. of Lone Oak.

Lone Star formation.

Pre-Cambrian: Southern British Columbia and northeastern Washington.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, map 7, 117° to 117°30′). *Lone Star fm.*—Dark-gray carbonaceous phyllite with quartz schist and qtzite. Overlies Beehive fm. and underlies Pend D'Oreille schist.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 158, tables at pp. 178, 194). *Lone Star fm.*—Chiefly dark-gray or greenish-gray, often carbonaceous phyllite, with some lighter-tinted greenish sericite-quartz schist and thin beds of light-gray qtzite. Extremely metamorphosed. Thickness 2,000 ft. Top fm. of Summit series. Overlies Beehive fm. with apparent conformity. Named for exposures on E. slope of Lone Star Mtn, [B. C. ?]. [Assigned to Middle Camb. but correlated with Striped Peak, Kintla, Sheppard, and other fms. which U. S. G. S. classifies as pre-Camb.]

Lone Tree white layer.

Name applied by W. D. Matthew and W. Granger (Am. Mus. Nat. Hist. Mem., vol. 9, 1909, p. 295) to "a persistent calc. stratum" marking base of their horizon D of Bridger fm. in Bridger Basin, Wyo., the Bridger being divided by them into (descending) Bridger E (500 ft. thick), D (375 ft.), C (350 ft.), B (450 ft.), and A (200 ft.).

†Lone Wolf sandstone.

Permian: Southwestern Oklahoma (Kiowa County).

L. T. Patton, 1926 (Am. Jour. Sci., 5th, vol. 12, pp. 194–196). Approx. 100 ft. below the dol. ledges forming top part of Double Mtn fm. in N. part of Kiowa Co. is a series of ss. ledges whose strike is approx. parallel to that of the dol. ledges. This ss. is gray and calc., and varies from thin-bedded to rather massive ledges 3 and 4 ft. thick. As many as three ledges separated by sh. occur in some localities. Forms basal memb. of Double Mtn fm. Rests on red and gray shales of Clear Fork fm. These ss. ledges were mapped by writer in summer of 1922 and in the unpublished rept rendered to Okla. Geol. Survey it was suggested that name *Lone Wolf* be given to them on account of their development near town of Lone Wolf. In a recent publication (Gould, C. N., A. A. P. G. Bull., vol. 7, No. 3, p. 325, 1924) the name Duncan ss. has been proposed for these beds, for reason that it is thought they are NW. extension of strata described by Wegemann in Stephens Co. A reference to Wegemann's paper cited in this connection shows, however, that Wegemann did not propose any name for these strata. The name Duncan has also been previously proposed for a fm. in Canada. For these reasons the name *Lone Wolf* [sandstone] is used in this paper.

Duncan ss. was adopted by U. S. Geol. Survey in 1924, Canadian geologic fms. that do not cross the bdy being treated as foreign.

Long Beards Riffs sandstone.

Upper Devonian: Western New York.

D. D. Luther, 1902 (N. Y. State Mus. Bull. 52, p. 619). A band of flags and thin sss. that appear in N. wall of ravine above the falls at Wiscoy, and in the sides and bottom of the river channel 1 mi. S. of Fillmore, where they form "Long Beards riffs." The lowest coarse sss. with fossils of Chemung group in immediate vicinity of Genesee River.

J. M. Clarke, 1902 (N. Y. State Mus. Bull. 52, pp. 630–631). [The name *Long Beard's riffs* appears in his Genesee River section as lying a short distance above Wiscoy shales, and is assigned to Chemung.]

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, p. 25 and chart). *Long Beards riffs ss.* is basal memb. of Chemung series in Allegany Co.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, pp. 84–85). *Long Beards Riffs ss.* is from the riffs on Genesee River in Allegany Co., 8 mi. S. of Portage. Is lowest fm. in Genesee River section in which Chemung brachiopods have been found. Has not been traced far from type section. Is probably = Shumla ss. of Lake Erie section. Overlies Wiscoy sh.

G. H. Chadwick, 1924 (N. Y. State Mus. Bull. 251, pp. 149–157), applied *Dunkirk sh.* to the 160 ft. of black shales overlying Wiscoy sh. in Cattaraugus Co., and stated that the fossiliferous *Long Beard Riff ss.* is included in the sss. that occupy lower half of Dunkirk sh.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 407). The sss. in Dunkirk black sh. increase until E. of Genesee Valley very little black sh. remains in lower 150 ft. of aren. beds with full Chemung fauna, and these beds are called *Canaseraga ss.* These sss. include Longbeards Riffs ss.

†Long Branch sand.

Eocene: Eastern New Jersey.

S. Weller, 1905 (N. J. Geol. Surv. Ann. Rept. 1904, pp. 147, 157, and Jour. Geol., vol. 13, p. 76). If it is thought worth while to designate the "yellow sand" facies of Vincentown fm. by a separate name, it may be called the *Long Branch sand*, as has been suggested [unpublished] by Knapp. The fauna is = that of Vincentown limesand.

A geographic name for this facies of Vincentown sand has been deemed unnecessary, and "Long Branch sand" is not in use.

Long Canyon member (of Las Posas formation).

Pleistocene: Southern California (Ventura County).

E. D. Pressler, 1929 (Univ. Calif. Pub., Dept. Geol. Sci. Bull., vol. 18, No. 13, pp. 325–345). *Long Canyon memb.* (also *Long Canyon horizon*).—Cross-bedded sands, some thin layers of calc. sand, and a group of tan to yellow, fine-grained sands. Thickness 200+ ft. Upper part of Las Posas fm. Contains a warmer water (marine Pleist.) fauna than underlying Kalorama memb. Occurs in Long Canyon, on S. slope of South Mtn, Ventura Co. Correlates with Upper San Pedro.

Long Creek limestone.

Pennsylvanian: Southeastern Nebraska and northeastern Kansas.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 84, 85, 88). *Long Creek ls.*—Named for exposures on Longs Creek, at foot of bluff W. of cemetery at Auburn, Nemaha Co., Nebr. Usually weathers buff to yellowish, somewhat cavernous and irregular. Thickness 3¼ to 5 ft. in Nebr. and 3 to 6 ft. in NE. Kans. Underlies Johnson sh. and overlies Hughes Creek sh., all in Elmdale sh. memb.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 8), extended Foraker ls. into Nebr. and divided it into (descending): Long Creek ls., 3 to 6 ft.; Hughes Creek sh., 36 to 38 ft.; and Americus ls., 2 to 3 ft.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), transferred this unit to Perm. This change in Perm.-Penn. bdy has not been considered by U. S. Geol. Survey for its publications.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Longdale limestone.

Lower Devonian: Central western Virginia.

R. J. Holden, 1920 (Geol. Soc. Am. Bull., vol. 31, p. 137). *Longdale ls.*—Top memb. of Lewistown ls. Thickness 50 to 80 ft. Has two lithologic phases—(1) a flint-free ls. 30 to 50 ft. thick, and (2) flinty ls. 20 to 30 ft. thick. Is correlated with Becraft ls. Overlies Craigsville ls. [Probably named for Longdale, Alleghany Co.]

Longfellow limestone.

Lower Ordovician (Beekmantown) and Upper Cambrian: Southeastern Arizona (Clifton-Morenci region).

W. Lindgren, 1905 (U. S. G. S. P. P. 43). *Longfellow ls.*—Consists of lss., usually more or less dolomitic and gradually growing more siliceous near lower limit. Upper 150 ft. always form a prominent bluff of brownish ls.; lower 250 ft. contain more shaly strata. Rests conformably on Coronado qtzites, from which it is in places separated by an intrusion of porphyry. Is conformably overlain by Morenci sh. Is exposed in Longfellow incline and Longfellow mine, Morenci dist. Walcott says fossils from near base may be Camb. Fossils from top are early Ord. according to Ulrich.

Long Grove series.

U. S. G. S. Bull. 191, 1902, p. 244. Misprint for *Lone Grove series.*

†Long Island division.

W. W. Mather, 1843 (Geol. N. Y., pt. 1, p. 246). The strata that belong to the tertiary epoch, if they exist on Long Island, as they probably do, will in this report be embraced in the description of the *Long Island div.* Consists of clay, sand, gravel, and pebbles.

See *Far Rockaway gravels.*

Long Lake series.

Middle Devonian: Northeastern Michigan (Presque Isle and Alpena Counties).

A. W. Grabau, 1902 (Mich. Geol. Surv. Rept. 1901, p. 184). *Long Lake series.*—Shales and thin-bedded lss., 298 ft. thick, exposed N. and S. of Long Lake. Underlies Alpena ls. and overlies Bell shales; all included in Traverse group.

W. A. VerWiebe, 1927 (Papers Mich. Acad. Sci., Arts, and Lett., vol. 7, pp. 181–192), redefined Alpena ls. by adding to its base 91 ft. of ls. included in Long Lake series by Grabau. He stated that these 90 ft. of beds are same type of rock as Alpena ls. of Grabau, and that there is no good reason for not including them in the Alpena. He restricted *Long Lake* to members Nos. 7 to 14 of Churchill well, and placed max. thickness at 196 ft.

E. R. Pohl, 1930 (U. S. Nat. Mus. Proc., vol. 76, art. 14, p. 25), reporting from unpublished ms. of A. W. Grabau, showed *Long Lake beds* (top memb. of Presque Isle series) as separated from *Bell shales* (basal memb. of Presque Isle series) by Grand Lake ls. memb. of Presque Isle series.

A. S. Warthin, Jr., and G. A. Cooper, 1935 (Wash. Acad. Sci. Jour., vol. 25, No. 12, pp. 524–526), redefined *Long Lake stage* by including in its top the lower part of Alpena ls. of VerWiebe (which they named *Killians ls.*) and by treating Rockport ls. as a distinct fm. underlying Long Lake stage and overlying Bell sh. (See 1935 entry under *Traverse fm.*)

Probably named for Long Lake, in Presque Isle and Alpena Counties.

Long Lake gneiss.

Pre-Cambrian: Long Lake quadrangle, Adirondack Mountains, New York.

H. P. Cushing, 1907 (N. Y. State Mus. Bull. 115, pp. 463–469). *Long Lake gneiss* for most part consists of two sharply contrasted varieties of gneiss, both unquestionably of igneous origin, and without sed. admixture. Frequent intermediate varieties occur. Varies in composition from a red granitic gneiss to a black gabbroic one. Black amphibolitic gneisses constitute 20 to 30 percent of mass. Age relations to Grampus gneiss and Piercefield gneiss undetermined.

H. I. Alling, 1919 (Am. Jour. Sci., 4th, vol. 48, pp. 47–68). Cushing's *Long Lake gneiss* is the ancient granite that he later assigned to the Laurentian, with the associated metagabbro chiefly as inclusions.

Named for exposures on both sides of Long Lake, Hamilton Co.

Long Lake diorite.

Pre-Cambrian: Ontario.

B. C. Freeman, 1934 (Jour. Geol., vol. 42, No. 1, p. 29).

Longmeadow sandstone. (In Newark group.)

Upper Triassic: Central Massachusetts and Connecticut.

B. K. Emerson, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 451–456). *Longmeadow brownstone* or the fucoidal ss. A central area of sss. in the Triassic of Mass.

B. K. Emerson, 1898 (U. S. G. S. Holyoke folio, No. 50; see also U. S. G. S. Mon. 29). The deposits of the Juratrias comprise four sediments, which are partly contemp., namely: *Mount Toby cgl.*, a very coarse basal cgl. of sl. and crystalline rocks, along eastern shore; *Sugarloaf ss. or cgl.*, a coarse feldspathic ss. and cgl. (4,660 ft. thick) on western shore; *Longmeadow ss.*, a medium-grained feldspathic ferruginous ss. (1,000 ft.); and *Chicopee sh.*, a sandy carbonaceous sh. (200? ft.), which accumulated in central channel of the bay. These were cut through by volcanic eruptions of three distinct periods, the earlier two represented by t: interstratified lava beds (350 ft.) of *Holyoke diabase* and the *Granby tuff*, an aggl. of diabase (580 ft.) interstratified with the [Longmeadow] ss., and the latest by the volcanic cores and dikes of *Blackrock diabase*. The Longmeadow ss. was deposited in the shallower and quieter off-shore area, and in the central zone of this latter area, where the basin was widest, the still finer Chicopee sh. was laid down.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 91, 94–97). *Longmeadow ss.*, named for occurrence at Longmeadow, Mass., represents an offshore facies of the sediment spread over bottom of the Triassic valley. It is a quartzose brownstone, commonly somewhat feldspathic, and is cemented mainly by iron oxide. Abounds in ferruginous concretions. Many layers are covered with tracks of animals of every size, ripple marks, mud cracks, raindrop impressions, and a multitude of other unexplained markings. Is a fm. of Newark group. Overlies and is interbedded with upper part of Sugarloaf arkose to W. and Mount Toby cgl. to E. Middle and upper part is contemp. with Chicopee sh. Includes Holyoke diabase (flow) and Hampden diabase (flow). Upper part is contemp. with Granby tuff [and from description it appears to include the "rusty sands" overlying Granby tuff, mentioned in quotation under 1917 entry under *Chicopee sh.*].

†Long Mountain series.

Pre-Cambrian (Llano series): Central Texas.

T. B. Comstock and E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. lv, lvi, 255–267). *Long Mtn series.*—Hornblende and pyroxene schists, schists containing garnets, and with these steatite or soapstone, actinolite, etc. Overlies Lone Grove series and probably underlies Bodeville series. Included in Burnetan system.

Same as Packsaddle schist.

Named for Long Mtn, Llano Co.

Long Point series.

Middle Ordovician: Newfoundland.

C. Schuchert and C. O. Dunbar, 1934 (Geol. Soc. Am. Mem. 1, p. 69).

Long Pond formation.

Cambrian: Newfoundland.

B. F. Howell, 1925 (Bulls. Am. Pal., vol. 11, No. 43, p. 59).

Long Rapids shale.

Devonian: Ontario.

T. E. Savage and F. M. Van Tuyl, 1919 (Geol. Soc. Am. Bull., vol. 30, pp. 341, 373, 377).

Longs Peak granite.

Pre-Cambrian: Central northern Colorado (Larimer County).

M. B. Fuller, 1924 (Jour. Geol., vol. 32, pp. 51–63). Coarse pinkish granite with well-defined tabular crystals of feldspar. Intrudes Big Thompson schist and is intruded by Mount Olympus granite. Named for the famous peak, a large part of whose bulk is made of this porphyritic granite.

Long Trail shale member (of Great Blue limestone).

Mississippian (upper): Central northern Utah (Oquirrh Mountains region).

J. Gilluly, 1932 (U. S. G. S. P. P. 173). *Long Trail sh. memb. of "Great Blue" ls.*—Black carbonaceous sh., 85 ft. thick, lying about 500 ft. above base of "Great Blue" ls. Named for excellent exposures at head of Long Trail Gulch, in Ophir Canyon, Fairfield quad.

Longview limestone.

Lower Ordovician (early Beekmantown): Northern Alabama and eastern Tennessee.

E. O. Ulrich, 1924 (Tenn. Dept. Ed., Div. Geol. Bull. 28, p. 34, and Bull. 31, p. 16). [*Longview dol.* used in chart for 1,000 ft. of beds underlying †Upper Canadian and uncon. overlying Chepultepec dol. in W. part of Valley of Tenn. and about same thickness in Knoxville trough of Tenn.]

C. Butts, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14). *Longview ls.*—Cherty ls. and dol., mostly ls., thick bedded and of light-gray color. The chert is compact but brittle and fragile, and differs from chert of underlying Chepultepec dol., which is mealy and cavernous. Thickness about 500 ft. Conformably underlies Newala ls. and uncon. overlies Chepultepec dol. Contains fossils characteristic of div. D of Beekmantown of N. Y. Named for fact that town of Longview, Shelby Co., Ala., is located on a rather wide area of the fm. Best exposures are on Little Cahaba River, in sec. 17, T. 24 N., R. 11 E.; on Buck Creek btw. Helena and Pelham; and in Cahaba Valley just N. of reservoir of Birmingham waterworks in NE¼ sec. 16, T. 18 S., R. 1 W.

Longwood shale.

Silurian: Northern New Jersey and southeastern New York.

N. H. Darton, 1894 (Geol. Soc. Am. Bull., vol. 5, pp. 367, 382, 383). *Longwood red shales.*—Red beds, with green to buff layers, which break into sh. on exposure, overlain by about 12 ft. of light-colored thin-bedded qtzites. Thickness 150 ft. Underlie Waterlime memb. [Decker ls.] of Helderberg ls. [broad usage of Helderberg] and grade into underlying Green Pond cgl. Named for fact the most extensive exposures are along Longwood Valley E. of Milton [Morris Co.,] N. J.

According to C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 54), the Longwood sh. is in part, or perhaps wholly, the strat. equiv. of High Falls sh. and may include also the horizon of Binnewater ss.

C. K. and F. M. Swartz, 1931 (Geol. Soc. Am. Bull., vol. 42, p. 657). *Bloomsburg red sh.* of NE. Pa. is continuous with *Longwood red ss.* of N. J. and *High Falls red beds* in SE. N. Y. One name should be used for the fm., and Bloomsburg has priority.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 342). *Longwood shales* (the red sh. above the Shawangunk in Orange Co., N. Y., and in N. J.) are considered=High Falls sh. and perhaps Binnewater ss. also. Assigned to Cayugan.

Lonsdale limestone member (of McLeansboro formation).

Pennsylvanian: Central western Illinois (Peoria region).

A. H. Worthen, 1882 (Econ. Geol. Ill., vol. 3, p. 258), in description of ls. exposed at Lonsdale quarries, Peoria, in two places called the bed *Lonsdale ls.*

L. E. Young, 1916 (Ill. Geol. Surv. Coöperative Coal Min. Ser. Bull. 17, pp. 23–24). *Lonsdale ls.*—In Longwall dist. consists of (1) 15 ft. of slightly argill. and more flaggy rock in which concretionary structures can nearly always be detected; underlain by 5 ft. of firmly cemented, largely organic ls., in beds 6 in. to 1½ ft. thick. Lies 50 to 75 ft. above coal No. 7 and lower than LaSalle ls.; all included in McLeansboro fm.

G. H. Cady, 1921 (Ill. Geol. Surv. Cooperative Min. Ser. Bull. 26, p. 37 and later pages). *Lonsdale ls.* of Peoria dist. is same as Rock Creek ls. of Springfield dist. Has been traced into Fulton, Bureau, Livingston, and LaSalle Counties. Not identified S. of Sangamon Co. It is 7 to 15 ft. thick and lies 30 to 75 ft. above coal No. 7, the characteristic interval being 60 ft. It lies lower in section than coal No. 8. At Peoria it is 20 ft. thick. Named for exposures at old Lonsdale quarries, Peoria.

T. E. Savage, 1921 (Ill. Geol. Surv. Ext. from Bull. 38), placed Lonsdale ls. 50 to 60 ft. above coal No. 7.

H. R. Wanless, 1931 (Geol. Soc. Am. Bull., vol. 42, p. 804), gave thickness of *Lonsdale ls.* as 25 to 35 ft.; placed its top 85± ft. below base of Carlinville ls., and 30± ft. below coal No. 8; and placed its base 45± ft. above coal No. 7.

Lookout sandstone. (In Pottsville group.)

Pennsylvanian: Northeastern Alabama, northwestern Georgia, and southern Tennessee.

C. W. Hayes, 1892 (Ala. Geol. Surv. Bull. 4, pp. 49–51). *Lookout ss.*—Argill. sh. or fire clay, sandy sh. and ss., with 10 to 70 ft. of cgl. [Sewanee cgl.] at top. Thickness 50 to 600 ft. In thicker portions contains at least two coal seams, in places of workable thickness. Basal fm. of Coal Measures. Overlies Bangor ls. and underlies Walden ss. Is=Lower Coal Measures and Millstone grit of Smith.

Lower part of Pottsville group. Is=Sewanee cgl. above and Gizzard fm. below, of central Tenn.

Named for exposures on Lookout Mtn, NE. Ala. and NW. Ga.

Lookout schist.

Pre-Cambrian: Southeastern Wyoming (Medicine Bow Mountains).

E. Blackwelder, 1926 (Geol. Soc. Am. Bull., vol. 37, pp. 620, 623, 634). *Lookout schist.*—Chiefly finely laminated greenish-gray quartz-sericite-chlorite schist containing small amounts of biotite; interbedded with many layers of metaqtzite, a few of brown marble, and one of gray magnetite schist. Thickness 1,200 ft. Conformably underlies Sugarloaf metaqtzite and conformably overlies Medicine Peak metaqtzite. Exposed on SE. shore of Lookout Lake. Assigned to early Algonkian.

†Lookout Mountain sandstone.

Name applied by S. W. McCallie (Ga. Geol. Surv. Bull. 12, 1904) to Lookout ss.

Loomis Peak dacites.

See under *Divide Peak andesite.*

Loon Lake granite.

Mesozoic: Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 87, map). *Loon Lake granite.*—Mesozoic batholithic mass, intrusive into Stevens series. Probably underlies whole county. Essentially potash, feldspar, quartz, plagioclase, biotite, and hornblende, the relative proportions of which vary greatly in short distances. Extends S. and SW. of Loon Lake in isolated patches as far W. as junction of Spokane and Columbia Rivers.

Loon River shale.

Upper Cretaceous: Canada (Alberta and Northwest Territory).

R. G. McConnell, 1893 (Canada Geol. Surv., n. s., vol. 5, pt. 1, pp. 41D, 53D, 56D–57D).

Lopez fanglomerate.

Quaternary: Southern California (San Gabriel Mountains).

M. L. Hill, 1930 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 19, No. 6, pp. 141, 144). *Lopez fm.*—The older and topographically higher Quat. fangl., which blankets part of ridge tops on either side of Lopez Canyon. Composed of subangular and poorly sorted fragments of gneiss and granitic rocks up to 2 ft. diam. Is of browner color than the younger Kagel fm. Overlies Saugus fm. with angular uncon.

Loranger series.

Pre-Cambrian: Quebec.

F. F. Osborne, 1935 (Quebec Bur. Mines Rept. Minister Mines 1934–35, pt. E, pp. 18, 26, map).

Lorette formation.

Middle Ordovician: Eastern New York.

P. E. Raymond, 1916 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 56, p. 257). [In diagram on this page the Glens Falls [ls.] of Trenton Falls and Dolgeville sections is shown resting on *Lorette,* which overlies Leray [ls. memb. of Lowville ls.].

Loretto slate.

Pre-Cambrian (upper Huronian): Northwestern Michigan (Menominee district).

R. C. Allen, 1919 (Am. Inst. Min. Met. Engrs. Bull. 153, p. 2593). *Loretto sl.*—Slates, 0 to 500 ft. thick. Included in Hanbury sl. of Bayley, but here included in Vulcan group and in Middle Huronian. Conformably overlies Curry iron-bearing memb. and underlies (in places conformably and in other places uncon.) Hanbury sl. [restricted]. There are doubtless many places where Hanbury sl. [restricted] is in undoubted contact with Curry fm., in apparent conformity. There are doubtless also places where Loretto sl. is in apparent conformity with the Hanbury. Best developed on property of Loretto mine.

Loretto moraine.

Pleistocene (Wisconsin stage): Southern Minnesota.

F. Leverett, 1932 (U. S. G. S. P. P. 161, p. 85). Included in Crow River morainic system. Village of Loretto, Hennepin Co., stands on this moraine.

Lorrain series.

Pre-Cambrian (Huronian): Quebec and Ontario.

Robt. Harvie, Jr., 1911 (Quebec Dept. Colonization, Mines, and Fisheries, Mines Branch, pp. 9, 19).

Lorrain granite.

Pre-Cambrian: Ontario.

W. G. Miller, 1913 (Ontario Bur. Mines Rept., vol. 19, pt. 2, p. 70).

Lorrain quartzite.

Pre-Cambrian: Ontario.

W. H. Collins, 1917 (Canada Geol. Surv. Mem. 95, p. 71). Included in Cobalt series.

Lorraine group.

Upper Ordovician: New York and Ontario.

E. Emmons, 1842 (Geol. N. Y., pt. 2, div. 4, geol. 2d dist., pp. 119–123, 401, 429). [See second item under *Pulaski sh.*]

As defined by Emmons in above-cited rept, and as since applied by most geologists, *Lorraine* included Pulaski shales and Frankfort sl. of Vanuxem, and is a synonym of †Hudson River group and †Hudson River sh. But a few geologists have used the name as a synonym of Pulaski, and a few have included the Utica in †Hudson River group. Repts give thickness of Pulaski sh. as 400 ft. and of Frankfort sh. as 300–1,800 ft.

In 1908 (Sci., n. s., vol. 28, pp. 346–348) G. H. Chadwick stated that Oswego ss. constitutes merely the closing episode of Lorraine div. In 1916 (Canada Dept. Mines, Geol. Surv. Mem. 83, pp. 4–13) A. F. Foerste extended Lorraine to include at top "*Salmon River ss.* (=*Grey ss. of Oswego*)," stating that this ss. is merely the upper less fossiliferous part of the Lorraine; and he excluded Frankfort sh. at base, stating that no evidence had been found of presence of Frankfort sh. at Lorraine; that the Frankfort contains an impoverished Utica fauna with some Trenton elements, and is unknown W. of Rome. But in 1924 (Canada Dept. Mines, Geol. Surv. Mem. 138) Foerste appears to exclude Oswego ss. from Lorraine.

In 1925 (N. Y. State Mus. Bull. 258) R. Ruedemann treated the Lorraine as a group, including all beds underlying Oswego ss. and overlying Utica sh., and he introduced several new names for subdivisions of the group in different parts of the State. He included in it (descending) Pulaski sh., Moose Creek beds, Wood Creek beds, Whetstone Gulf sh., Atwater Creek sh., Deer River sh., and the in part contemp. Indian Ladder beds and Frankfort sh. He also proposed that "Lorraine gulf" be considered as type section, and he correlated the Lorraine with lower part of the Maysville group and the Eden of Ohio. Geologists generally are agreed that the Lorraine is of pre-Richmond age.

Los Angelan epoch.

Pleistocene: Southern California.

O. H. Hershey, 1902 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 3, pp. 1–29). *Los Angelan epoch* (*erosion*).—Represented by valley of Los Angeles River in city of Los Angeles. The three middle terraces of San Pedro Hill belong to this epoch, which preceded San Pedran epoch and followed Red Bluff epoch. [See under *Sierran.*]

Los Cerritos beds.

See under *Deadman Island beds.*

Losee diorite gneiss.

Pre-Cambrian: Northern New Jersey and eastern Pennsylvania.

A. C. Spencer, 1908 (U. S. G. S. Franklin Furnace folio, No. 161). The group of foliated granitoid rocks here called *Losee gneiss* includes "Losee Pond granite" of Wolff and Brooks. They consist of more or less foliated medium- to coarse-grained granular rocks, in texture closely resembling granite. They are mainly light in color and in many weathered exposures nearly white. Distinguished lithologically from the varieties of Byram gneiss in containing oligoclase (soda-lime feldspar) instead of microcline or microperthite (potash feldspars). Differ from Pochuck gneiss in that they contain much quartz and only minor amounts of dark minerals. Regarded as an intrusive igneous rock younger than Franklin ls. and Pochuck gneiss, which they intrude. Relation to Byram gneiss not known, but the Pochuck is cut by granite and by masses of pegmatite. Named for development around Losee Pond, Sussex Co.

The Losee gneiss (predominantly diorite gneiss) is now considered as probably older than Byram gneiss (predominantly granite gneiss). It is classified by E. B. Knopf and A. I. Jonas (U. S. G. S. Bull. 799, correlation chart, 1929) as post-Glenarm. Intrudes Franklin ls. and Pickering gneiss.

†Losee Pond granite.

Pre-Cambrian: Northern New Jersey.

J. E. Wolff and A. H. Brooks, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, p. 439). Lying btw. the higher crest occupied by Edison gneiss and extreme western crest is a very characteristic and well-defined band of greenish-white gneissoid binary granite, which, from its exposures around Losee Pond, Sussex Co., is named *Losee Pond granite*. Does not differ much lithologically from the other granites represented by one color on the map, but it is so isolated that it has been thought best to give it a separate name and pattern.

In U. S. G. S. Passaic folio, No. 157, 1908, W. S. Bayley stated the Losee gneiss was called *Losee Pond granite* by Wolff and Brooks. In U. S. G. S. Franklin Furnace folio, No. 161, 1908, A. C. Spencer stated that Losee gneiss includes Losee Pond granite of Wolff and Brooks.

Los Esteros formation.

Eocene: Mexico.

W. A. VerWiebe, 1924 (Am. Jour. Sci., 5th, vol. 8, p. 491).

Los Guerras sandstone member (of Fayette formation).

Eocene (upper): Northeastern Mexico (Tamaulipas, opposite Starr County, Texas).

W. G. Kane and G. B. Gierhart, 1935 (A. A. P. G. Bull., vol. 19, No. 9, pp. 1375, 1376, 1383, 1387). *Los Guerras ss. memb.*, at base of Fayette fm. in section measured on both sides of Rio Grande btw. Roma and Rio Grande City [Starr Co.], Tex. Consists of 48 ft. of soft gray ss. with chalcedony-replaced gastropods and thick bed of oysters at top; large biscuit-shaped harder ss. masses in softer sandy matrix in upper part; and lower part shows thin indurated hard brown layers as lenses in soft gray ss. making outcrop of banded appearance. *Venericardia* in some bedding planes near base. Crops out in Rio Grande at Los Guerras, Tamaulipas. Same as Salineno ss., which crops out at Salineno, Starr Co., Tex.

Losh Run shale.

Upper Devonian: Southern central Pennsylvania (Perry County).

B. Willard, 1935 (Geol. Soc. Am. Proc. 1934, p. 123). [His table of geologic fms. in Susquehanna Valley shows following subdivisions of Portage group (descending): Parkhead ss. (?), Trimmers Rock ss. (supplants Ithaca), *Losh Run sh.*, Braillier ss.-sh. [see *Braillier sh.*], Harrell sh., Burket sh. ("Genesee"), Tully ls. No further explanation of *Losh Run sh.*]

B. Willard, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 8, pp. 1195–1218). *Losh Run memb. of Fort Littleton fm.*—Chiefly dark-gray to brown sh. that weathers to rusty-brown irregular chunks. In places finely aren. Thickness 10 ft. in most exposures. Distinct faunally and lithologically. In Juniata Valley it underlies Trimmers Rock memb. and overlies Braillier memb. To W. the Braillier extends above the Losh Run as well as below, and upper part of the Braillier is offshore equiv. of Trimmers Rock ss. The Losh Run grades into both Braillier and Trimmers Rock members of Fort Littleton fm. Occurs in Lycoming, Luzerne, Perry, Huntingdon, and perhaps Fulton Counties. Named for stream in Perry Co. that enters the Juniata from the W. about 5 mi. N. of Duncannon.

Los Lamentos formation.

Cretaceous: Mexico.

W. F. Foshag, 1934 (Econ. Geol., vol. 29, No. 4, p. 334).

Los Muertos formation.

Cretaceous: Mexico.

J. E. Spurr and G. H. Garrey, 1908 (Econ. Geol., vol. 3, p. 689).

Losoya Creek conglomerate. (In Sabinetown formation.)

Eocene (lower): Southern Texas (Bexar County).

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 575, 602). Contact of Sabinetown fm. (top fm. of Wilcox group) with underlying Rockdale fm. is not exposed in Sabine River bluffs. On Losoya Creek, at the bridge on South Flores road S. of San Antonio, Bexar Co., the marine Sabinetown strata lie uncon. upon the eroded surface of massive Rockdale ss. This contact is marked by a 1-foot bed of wave-worn beach pebbles and marine shells. [On p. 575 is a section of Seguin fm. in Bexar and other counties in which the basal bed of Sabinetown fm. is called *Lasoya Creek cgl.*]

Los Pinos member (of Hinsdale formation).

Tertiary? (Pliocene?): Central southern Colorado and northern New Mexico.

W. W. Atwood and K. F. Mather, 1932 (U. S. G. S. P. P. 166). *Los Pinos gravel.*—Stream-deposited gravel, sand, and boulders with some interbedded tuff and lava flows. Thickness 500+ ft. Underlies Hinsdale volcanic series and is contemp. with Bayfield and Bridgetimber gravels. Named by E. S. Larsen, for exposures in canyon of Los Pinos Creek, near town of San Miguel, in extreme N. part of N. Mex., about 10 or 12 mi. SW. of Antonito, Conejos Co., Colo.

E. S. Larsen, 1934 (U. S. G. S. Bull. 843). *Los Pinos memb.*—Included in Hinsdale fm. because so closely related to overlying rocks as to properly constitute a memb. of that fm.

Los Puertos limestone.

Tertiary (Oligocene or Miocene): Puerto Rico.

B. Hubbard, 1920 (Sci., n. s., vol. 51, p. 396).

†Lost Cabin formation.

Eocene (lower): Northern Wyoming (Bighorn Basin).

W. J. Sinclair and W. Granger, 1911 (Am. Mus. Nat. Hist. Bull., vol. 30, pp. 104–111). Wind River group in Wind River Basin divided into 2 conformable fms., named (descending) *Lost Cabin fm.* (*Lambdotherium zone*) and *Lysite fm.* The upper fm. is named for exposures to E. of Lost Cabin (village), where fossils were collected. [Sinclair and Granger in 1912 (Am. Mus. Nat. Hist. Bull., vol. 31, pp. 60–62) gave thickness of their Lost Cabin fm. as 325+ ft. and stated: Lost Cabin fm. is conformably overlain by Tatman fm.]

This is a geographic name for *Lambdotherium* faunal zone, forming upper part of Wind River fm., or *Wind River B*, according to H. F. Osborn (U. S. G. S. Mon. 55, 1929). Geographic names are not applied to faunal zones by U. S. Geol. Survey.

†Lost City limestone.

Pennsylvanian: Northeastern Oklahoma (Tulsa County).

C. N. Gould, 1911 (Okla. Geol. Surv. Bull. 5, p. 179). A ledge of ls. which forms a prominent exposure on high hills S. of Arkansas River a few mi. SW. of Tulsa is known as Lost City ls. It is quarried at town of Lost City.

C. N. Gould, 1925 (Okla. Geol. Surv. Bull. 35, p. 73). On hills S. of Arkansas River W. of Tulsa the Hogshooter ls., which has long been known as *"Lost City" ls.*, thickens to 20 ft.

Lost Creek limestone.

Silurian: Central Pennsylvania.

J. P. Lesley, 1878 (2d Pa. Geol. Surv. Rept. F, p. xxvi). *Lost Creek ls.*—In middle of the grey sh. group forming a middle part of Clinton fm. of Juniata dist., there occur, within a thickness of 60 ft., several beds of light blue shaly ls., and near the bottom of the 60 ft., a sandy ls. with lime shales. These calc. layers are sometimes massive, even 6 or 8 ft. thick, and separated by gray shales. In Lost Creek Valley, Juniata Co., a few quarries have been opened in these beds.

Lost Creek shale member (of Admiral formation).

Permian: Central Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 421, 422). *Lost Creek bed.*—Red, bluish, or yellowish sandy clay, 25 to 50 ft. thick. Memb. of Albany div. Overlies Coleman Junction bed and underlies Hordes Creek bed.

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, pp. 192, 193, and charts). *Lost Creek sh.* of Drake is here defined as basal memb. of Admiral fm. (basal fm. of Wichita group).

Named for Lost Creek, Coleman Co.

Lost Creek granite body.

Age (?): Canada.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 302).

Lost Creek limestone.

Pennsylvanian: Eastern Kentucky (Breathitt County).

W. C. Morse, 1931 (Ky. Geol. Surv., ser. 6, vol. 36, pp. 296, 304). *Lost Creek ls.*—A thin ls. that differs markedly from all others in eastern Ky. Where exposed along crest of ridge btw. Lost Creek and Big Branch of North Fork of Ky. River (Buckhorn quad.), just N. of gap through which passes road connecting these 2 streams, the ls. is badly broken, but large blocks of it show it to be at least 3½ ft. thick. Lower two-thirds is fossiliferous dolomitic ls. and upper third a blue shelly ls. Very fossiliferous (fossils listed). Lies 175 ft. above Magoffin beds, nearly 130 ft. above Saltlick beds, and 370 ft. below Flint Ridge flint. For more reasons than one this dolomitic ls. is very appropriately named *Lost Creek ls.*, from stream of that name.

Lost Gulch monzonite.

Early Mesozoic (?): Central Arizona.

F. L. Ransome, 1903 (U. S. G. S. P. P. 12). *Lost Gulch monzonite.*—Adamellite or quartz monzonite. Intrudes Pinal schist. Occupies greater part of Lost Gulch and stretches NE. toward Horrell's ranch, on Pinal Creek, Globe quad.

F. L. Ransome, 1910 (Min. and Sci. Press, vol. 100, pp. 256–257) and 1919 (U. S. G. S. P. P. 115, p. 51) stated that this rock is probably early Mesozoic.

Lost Horse intrusives.

Age (?): British Columbia.

V. Dolmage, 1934 (Canada Dept. Mines, Geol. Surv. Mem. 171, No. 2344, p. 12).

†Lostmans River limestone.

Pleistocene and Pliocene: Southern Florida.

S. Sanford, 1909 (Fla. Geol. Surv. 2d Ann. Rept., table opp. p. 50 and pp. 222–225). *Lostmans River ls.*—The nonoolitic fossiliferous lss. which apparently underlie W. coast of southern Fla. and outcrop inland. Varies so greatly in lithology that it is impossible to give a description that contains features common to all localities. At type loc. on Lostmans River the rock is described by Dale as very hard and consisting of large masses of Polyzoa more or less completely changed into crystalline ls. The cavities are filled with crystals of calc-spar. Near Deep Lake the rock is softer and more friable. Rock from head of Hendersons Creek contained much more sand than specimens collected to S. Between Jewfish Creek and Manatee the rock is much less crystalline than on W. coast or toward entrance to White Water Bay. Thickness 30 to 40 ft. Of marine origin. Relations to Palm Beach ls. can not be determined. Miami oolite is believed to be younger than Lostmans River ls.

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept.). "Lostmans River ls." is in part Miami oolite (Pleist.) and in part Caloosahatchee marl (Plio.), and name is abandoned.

Named for exposures on Lostmans River, Monroe Co.

Lost River chert.

Mississippian: Southwestern Indiana (Orange County).

M. N. Elrod, 1899 (Ind. Acad. Sci. Proc. 1898, pp. 258–267). *Lost River chert.*—Constant stratum of chert, occasionally oolitic, 10 to 20 in. thick. Underlies Paoli ls. and overlies Mitchell ls. [as here restricted by Elrod]. [Included in St. Louis group.]

Is a thin bed included in Mitchell ls. of Siebenthal and forming top bed of St. Louis ls. of Cumings (1922).

Named for frequent occurrence on Lost River, especially near Orangeville, Orange Co.

†Lott chalk member (of Taylor marl).

Upper Cretaceous: Northeastern Texas (Falls and Bell Counties).

C. H. Dane and L. W. Stephenson, 1928 (A. A. P. G. Bull., vol. 12, p. 52). In SW. Falls Co. the southward decrease in sand constituent of Taylor marl below horizon of Marlin chalk memb. has progressed to such an extent that none of it shows an appreciable percentage of sand. In addition, there appears at a horizon several hundred ft. below position of Marlin chalk a chalky marl bed which in places can properly be called a chalk. The northernmost outcrops of this bed are in vicinity of Lott [Falls Co.], from which it is proposed to call it *Lott chalk memb. of Taylor marl.* It extends SW. through Falls Co., and good outcrops occur 1 to 3 mi. W-NW. of Rogers, Bell Co., on road to Little River. It is probably not more than 40 ft. thick at any place along its outcrop. Very fossiliferous. Has not yet been traced S. of vicinity of Rogers.

According to L. W. Stephenson (Jour. Pal., vol. 8, No. 3, p. 275, 1934), and Alva C. Ellisor and John Teagle (A. A. P. G. Bull., vol. 18, No. 11, pp. 1506–1536, 1934), the Lott chalk has proved to be the Marlin chalk repeated by faulting, and *Lott* has therefore been abandoned. The Marlin chalk has been found to be the southward continuation of Pecan Gap chalk of NE. Tex., and *Marlin* has been abandoned.

Louann sand.

See 1925 entry under *Meakin sand.*

Loudon shale.

Same as *Loudoun fm.*, the correct spelling.

Loudoun formation.

Lower Cambrian: Virginia, West Virginia, Maryland, and southern Pennsylvania.

A. Keith, 1893 (as reported by G. H. Williams and W. B. Clark, in Maryland, its resources, industries, and institutions, chap. 3, p. 68. The fm. was described, but not named, by Keith in Am. Geol., vol. 10, p. 365, 1892). *Loudon shales.*—Gray and black slaty shales, 400 ft. thick, underlying Weaverton ss.

A. Keith, 1894 (U. S. G. S. Harpers Ferry folio, No. 10). *Loudoun fm.*—Argill. sl., sandy sh., gray ss., quartz cgl., blue ls., and white marble, 0 to 800 ft. thick. Underlies Weaverton ss. and uncon. overlies Catoctin schist (Algonkian). Named for fact all of its varieties are well developed in Loudoun Co., Va.

Louis limestone.

An abbreviated form of St. Louis ls. employed by C. [R.] Keyes.

†Louise formation.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 42, p. 289). *Louise fm.*—Shales, 100 ft. thick, underlying Piran series and overlying Fairview qtzite in Alberta. Of Early Cambric age. [Apparently same as Lake Louise fm.]

Louisian.

C. [R.] Keyes, 1919 (Sci., n. s., vol. 50. p. 74). *Louisian* as a periodic title has 10 years priority over *Mississippian.* [Probably refers to early use of "*St. Louis group,*" which covered the rocks later named *Meramec group.*]

Louisiana limestone. (Of Kinderhook group.)

Mississippian: Eastern Missouri, southwestern Illinois (Jersey and Calhoun Counties), and Iowa.

C. R. Keyes, 1892 (Geol. Soc. Am. Bull., vol. 3, p. 289). *Louisiana ls.*—Ls., 60 ft. thick, usually rather thin-bedded; lower layers usually more or less aren. and highly fossiliferous. Underlies Hannibal sh. and forms basal fm. of Kinderhook group so far as known. Equiv. to Swallow's Lithographic ls.

This continued for many years to be definition of Louisiana ls.

R. C. Moore, 1928 (Mo. Bur. Geol. and Mines vol. 21, 2d ser., table opp. p. 282), showed Glen Park ls. as underlying Hannibal sh. and overlying Louisiana ls. in Jersey and Calhoun Counties, SW. Ill., and that elsewhere (Pike Co., Ill., and Pike and other counties in NE. Mo.) the Hannibal is uncon. on Louisiana ls. He also showed Louisiana ls. as underlain by Saverton and Grassy Creek shales, both of which he included in the Kinderhook. In 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 245) Moore showed Louisiana ls. as present in NE. Mo. and W. Ill. only, and absent in S. Ill. and SE. Mo., and he continued to treat Saverton and Grassy Creek shales as belonging in Kinderhook group.

Named for exposures at Louisiana, Pike Co., Mo.

Louisville limestone.

Silurian (Niagaran): North-central Kentucky and southern Indiana.

A. F. Foerste, 1897 (Ind. Dept. Geol. and Nat. Res. 21st Ann. Rept., pp. 217, 218, 232). *Louisville ls. or Utica lime rock.*—Argill. or dolomitic ls., 40 to 55 ft. thick, usually of light or medium brown color, with some white beds. Top fm. of Niagara group in southern Ind. Overlies Waldron sh. [Foerste gave further details in Denison Univ. Bull., Jour. Sci. Lab., vol. 30, 1935, pp. 166–169, 171–173, 195, and stated that the Louisville can be recognized in Macon, Sumner, and Davidson Counties, northern Tenn., but that "only place [in Tenn.] it can be identified with any degree of certainty is at Bledsoe, Tenn."]

Named for fine exposures E. of Louisville, Ky.

Louisville limestone.

Pennsylvanian: Southeastern Nebraska and eastern Kansas.

G. E. Condra and N. A. Bengston, 1915 (Nebr. Acad. Sci. Pub., vol. 9, No. 2, pp. 7, 23). *Louisville ls.* (memb. of Braddyville fm.) is exposed at base of slope W. of South Bend and in the upper slopes eastward to Louisville. Is main ledge in upper Atwood quarry in Cedar Creek Valley and in N. side of Platte Valley from State fish hatcheries to Meadow. Is main quarry ledge in abandoned Murphy and

Green quarries W. of Meadow. Thickness 10 to 12 ft. Is thin-bedded in upper part, but most of it is massive, hard, and compact. Is blue gray and weathers light. Lies 6 to 10 ft. below South Bend ls. and higher than Meadow ls.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 42, 55, 56). Although "Louisville ls." is preoccupied, it is in use for top part of Howard ls. memb. in Nebr.

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, 2d ser., pp. 11, 27). *Louisville ls.* is preoccupied, hence *Stoner ls.* is proposed for this unit, to include also Kiewitz sh. and so-called Du Bois ls. The "Louisville ls.," Kiewitz sh., Du Bois ls., Severy sh., Topeka ls., and Meadow ls. are parts of Stanton ls. memb.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 134, 252), abandoned Louisville ls. and Kiewitz sh.

†Louisville-Delphi black slate.

Upper Devonian: Indiana and Kentucky.

J. Collett, 1872 (Ind. Geol. Surv. 3rd and 4th Ann. Repts., pp. 294, 306). *Louisville-Delphi black sl.*—Dev. black sl., 62 ft. thick, overlain by "Waverly" or knob ss. and underlain locally by 0 to 15 ft. of coarse white sandrock, succeeded below by Dev. ls.

Replaced by New Albany sh., established name.

Probably named for occurrence from Louisville, Ky., to Delphi, Carroll Co., Ind.

†Loup Fork beds.

†Loup Fork group.

Miocene, Pliocene, and Pleistocene (?): Nebraska, South Dakota, eastern Colorado, and other western States.

F. B. Meek and F. V. Hayden, 1862 (Phila. Acad. Nat. Sci. Proc., vol. 13, pp. 415–435). *Loup River beds.*—Fine loose sand, with some layers of ls. Thickness 300 to 400 ft. All fresh-water fossils. Assigned to Plio. Extends from Loup Fork of Platte River N. to Niobrara River and S. to unknown distance beyond the Platte. Overlies White River group (Mio.). [No later fm. than Loup Fork mentioned. As here defined includes Ogallala and Arikaree fms., which overlie White River group (Olig.).] All fossils are fresh water.

E. D. Cope, 1880 (U. S. Geol. and Geog. Surv. Terr. Bull. 5, pp. 50–51), and 1884 (U. S. Geol. and Geog. Surv. Terr. Mon. 3, table opp. p. 43). *Loup Fork* divided into *Procamelus* beds above and *Ticholeptus* beds below. Underlies Plio. and overlies White River.

E. D. Cope, 1888 (Am. Geol., vol. 2, pp. 290–292). *Loupfork fm.* (upper Mio.) has wide extent. Overlies Whiteriver beds in Nebr., Wyo., and Colo., and extends into Kans., where it rests on Cretacic. There is a second area, in northern central N. Mex., and one perhaps in southern N. Mex., extending from Rio Grande to near Arizona border; also another tract in Washington Co., Tex., and another in Mexico, on bdy of States of Hidalgo and Vera Cruz. According to King is 2,000 ft. thick in Wyo., but thins gradually to E. and is only 250 ft. thick on White River, according to Hayden. Is same as Niobrara of Marsh.

N. H. Darton, 1899 (U. S. G. S. 19th Ann. Rept., pt. 4, pp. 732, 734, 735), divided typical *†Loup Fork beds* of Nebr. into Ogallala fm. (above) and Arikaree fm. (below), by which names these deposits are now generally known.

For history, see H. F. Osborn and W. D. Matthew, U. S. G. S. Bull. 361, 1909.

Loupian.

Name introduced by C. R. Keyes to include Ogallala (Plio. and upper Mio.) and Arikaree (Mio.) fms. (See Iowa Acad. Sci. Proc., vol. 22, 1915, p. 255.)

†Loup River beds.

A name applied by some geologists (F. B. Meek and F. V. Hayden, 1862, 1869, 1872, 1873, etc.; also W. B. Scott, History of land mammals of Western Hemisphere, 1913, p. 127) to deposits called "Loup Fork beds" by other geologists. See under *†Loup Fork beds.*

Lourian series.

A term employed by C. [R.] Keyes to cover rocks of Cordilleran region interpreted as having been formed during later part of pre-Animikie erosion interval. (See Iowa Acad. Sci. Proc., vol. 24, p. 56, 1917.)

Lovedale gypsum member (of Blaine formation).

Permian: Northwestern Oklahoma (Harper County).

N. Evans, 1931 (A. A. P. G. Bull., vol. 15, No. 4, pp. 405–432). Name proposed for next to highest gyp. memb. of Blaine fm. in NW. Okla. Consists of approx. 13 ft. of gray to white gyp. A gray dol. bed, which is ordinarily a little thicker and more prominent than the bed underlying the Shimer, underlies the Lovedale. All 3 of these dol. beds are commonly pitted and clinkerlike in appearance. Is separated from underlying Shimer gyp. memb. of Blaine by 7 ft. of red sh. and is also separated from overlying Haskew gyp. memb. by red sh. Named for exposures near Lovedale, T. 26 N., R. 20 W., Harper Co. It has been suggested that this gyp. bed may be correlated with Mangum dol. of S. side of Anadarko Basin. It seems better to give a new name until such a correlation can be proved. If it can later be shown conclusively that Lovedale is correlated with Mangum, then *Lovedale* can be dropped.

S. Buckstaff, 1931 (A. A. P. G. Bull., vol. 15, No. 4, pp. 434–437). So-called Lovedale memb. is probably Mangum memb., as Lovedale seems questionable.

Loveland loess.

Pleistocene (Sangamon): Southwestern Iowa and eastern and southern Nebraska.

B. Shimek, 1909 (Geol. Soc. Am. Bull., vol. 20, p. 405) and 1910 (Sci., n. s., vol. 31, p. 75). *Loveland joint clay.*—Bed of reddish joint clay, which frequently shows stratification and often contains sand and pebbles in lower part. Thickness 0 to 80 or more ft. Rests on Aftonian sands and underlies fossiliferous post-Kansan bluish-gray loess. Evidently bears same relation to Kansan drift as Buchanan gravels, and probably belongs to period of melting of Kansan ice.

The deposit is chiefly loess, according to W. C. Alden and F. Leverett. G. F. Kay considers it of post-Illinoian age, and F. Leverett considers it pre-Illinoian and pre-Iowan.

A. L. Lugn, 1934 (Nebr. State Mus., vol. 1, Bull. 41, pp. 326, 347–349). *Loveland fm.*—Lower or "valley phase" consists of sand, gravel, and clay filling pre-Loveland valleys, and may be of Illinoian age. This "valley phase" seems to everywhere grade upward into the loess or "upland phase," which grows less and less sandy until it is quite typical loess clay and silt. Volcanic ash or pumicite occurs at base of loess phase quite generally in Nebr. It is generally 5 to 8 ft. thick, but SW. of Eustis, Frontier Co., it is locally at least 50 ft. thick. Entire fm. is quite red. Thickness in eastern Nebr. 6 to 30 ft.; in south-central Nebr. 15 to 40 ft.; to west 100 to 150 ft. Covers about 42,000 sq. mi. of Nebr. Thickness and textural coarseness increase westward. Assigned to Sangamon stage. Rests uncon. on Upland fm. and underlies Sand Hills fm., in part of area, and Peorian loess in part of area.

Named for Loveland, Pottawattamie Co., Iowa.

Loveless sand.

A subsurface sand of Chester (Miss.) age in Ind. that has been correlated with Tar Springs ss.

Lovelockian series.

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 52, 79). *Lovelockian series* covers the early Jurassic section of NW. Nev., typically displayed in Humboldt Range, E. of Lovelock station, Humboldt Co. Includes Oreana shales above and Muttleberry lss, below.

Lovingston granite gneiss.

Pre-Cambrian: Western and northern Virginia.

A. I. Jonas, 1928 (Va. Geol. Surv. prel. ed. of geol. map of Va.). *Lovingston granite gneiss.*—Biotite-quartz monzonite, augen gneiss. Assigned to pre-Camb. Intrusive into Lynchburg gneiss. Mapped at and around Lovingston, Nelson Co. Is post-Glenarm.

Low Creek beds.

Eocene: Western Louisiana and eastern Texas.

A. C. Veatch, 1902 (La. Geol. Surv. pt. 6, Rept. for 1902, pp. 127–128, and pl. 37). *Low Creek beds.*—The peculiar beds described from Low's Creek, near Sabinetown [Sabine Co., Tex.], in 1899 and referred provisionally to the Lignitic show a much better development on the Sabine near mouth of Low's Creek, at stations 19 and 20. The beds here furnish a much more complete fauna, especially at the Negreet outcrop, and Harris is inclined to regard the material as having a decided Lower Claiborne aspect. Directly above it is a well marked Lower Claiborne fauna, and the position of these beds at or near the line of parting btw. the Lower Claiborne and Lignitic is fully proved. [Pl. 37 gives thickness of Low Creek beds as 45 ft., and places them as basal bed of Lower Claiborne.]

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, p. 635). *Low Creek beds* of Veatch carry a fauna similar to that of Weches memb., to which they are believed to belong.

Lowe granodiorite.

See *Mount Lowe granodiorite.*

Lowell limestone. (In Allegheny formation.)

Pennsylvanian: Northeastern Ohio (Mahoning County).

J. S. Newberry, 1878 (Ohio Geol. Surv. vol. 3, pp. 797–798). *Lowell ls.,* 12 to 14 ft. thick, in Coal Measures; lying 90 ft. above the ls. next below and more than 150 ft. above coal No. 3. May be either Ferriferous ls. or Freeport ls. Fully exposed near Lowell.

Lowell Mountain formation.

Paleozoic: Northeastern Vermont (Orleans County).

S. B. Keith and G. W. Bain, 1932 (Econ. Geol., vol. 27, No. 2, pp. 173, 175). *Lowell Mtn sl., phyllite, and schist.*—Fine-grained black to dark-brown slates dominate in this group and occur E. of serpentine belt. Bedding obscure; cleavage and jointed structures are characteristic; schist is rare and occurs in a few places only. Assigned to Paleozoic. Seem to correspond to Quebec group on Lake Memphremagog, Quebec. [Lowell Mtn is in Irasburg quad., Orleans Co.]

Lowell Park member (of Platteville limestone).

Middle Ordovician: Northwestern Illinois (Dixon quadrangle).

R. S. Knappen, 1926 (Ill. Geol. Surv. Bull. 49, pp. 54–61, 65). *Lowell Park memb. of Platteville ls.*—Interbedded gray and buff argill. but heavy-bedded lss. and coarse-grained, deep yellow-brown, porous dolomites, the dol. in every way typical of overlying Galena; the chalky earthy lss. are more like the impure parts of the basal or Buff ls. memb. of the Platteville. Is top memb. of Platteville ls. in Dixon quad. Overlain by Galena dol. and underlain by Blue ls. memb. of Platteville ls. Thickness 20–30 ft. Is of same age as Decorah sh. of Iowa. A local term has been used here in place of Decorah, since a ls. instead of a sh. is present in this quad., and also because original definition of Bain, and later of Calvin, who defined Decorah sh., was that the Platteville included all ls. btw. St. Peter and Galena fms. The Black River of N. Y. is correlated with Decorah sh. and with Lowell Park memb. Named for typical development in Lowell Park and along road N. of park.

Lowellville limestone. (In Pottsville formation.)

Pennsylvanian: Northeastern Ohio.

G. F. Lamb, 1910 (Ohio Nat., vol. 10, p. 129). *Lowellville ls.* lies just below horizon of Quakertown coal in Stark and Mahoning Counties.

H. Morningstar, 1922 (Ohio Geol. Surv., 4th ser., Bull. 25, p. 28). Poverty Run ls. of Stout (1918) is same as *Lowellville ls.* of Lamb (1910).

W. Stout, 1927 (Ohio Geol. Surv., 4th ser., Bull. 31, p. 97). *Lowellville ls.* is same as Poverty Run ls., and lies in interval btw. Vandusen coal [much higher in section than Quakertown coal] and Lower Mercer clay. Is well developed near Lowellville, Mahoning Co.; in Washington Twp, Coshocton Co.; and in Madison and Hopewell Twps, Muskingum Co.

Lower.

The terms *Upper* and *Lower*, connected with geographic names, have long been and still are employed in a titular sense to designate many lss., clays, and sss. of Appalachian region. A few of these, together with some in other parts of the country, are here listed. Others are mentioned under the geographic names.

†Lower quartzite.

Upper Cambrian: Leadville district, Colorado.

S. F. Emmons, 1882 (U. S. G. S. 2d Ann. Rept., pp. 215–230), 1883 (U. S. G. S. Leadville Atlas), and 1886 (U. S. G. S. Mon. 12), applied the descriptive term "Lower qtzite" to the Camb. qtzite and overlying "transition shales," in contradistinction to the younger (Ord.) "Parting qtzite." It underlies ls. called "White ls." and uncon. overlies pre-Camb. gneisses and schists. Is now known as *Sawatch qtzite*. Some mining companies exclude the "transition shales."

†Lower Archimedes limestone.

Mississippian: Southwestern Illinois and eastern Missouri.

See under †*Archimedes ls.*

†Lower Barren Coal Measures.

†Lower Barren group.

Terms applied in early repts on Appalachian region to Conemaugh fm. (Penn.), also to Conemaugh fm. exclusive of its basal Mahoning ss. memb.

†Lower Bend shale.

Miss., Tex. See 1916 entry under *Bend group*. Replaced by *Barnett sh.*

†Lower Black Band of early N. Y. repts is *Middlesex sh.*

Lower Cambrian series.

Same as *Waucoban series*. (See U. S. G. S. Bull. 769.)

†Lower Cambridge limestone member (of Conemaugh formation).

Replaced by *Brush Creek ls. memb.*

†Lower Carboniferous.

A term applied in early repts to Mississippian series of present nomenclature.

Lower Clarion clay. (In Allegheny formation.)

A clay bed, 8 ft. thick, underlying Lower Clarion coal in western Pa.

†Lower Coal Measures.

†Lower Coal Group.

Terms applied in early repts to Allegheny fm. (Penn.) of current nomenclature of Appalachian region.

Lower Connoquenessing sandstone.

See under *Connoquenessing ss. memb.* The U. S. Geol. Survey does not use *Upper* and *Lower* in a titular sense for parts of Connoquenessing ss. memb.

†Lower Cross Timbers formation.

A name applied in some early repts to *Gulf series* of Tex.

†Lower Cross Timbers sand.

A name applied in some early Tex. repts to *Woodbine sand.*

Lower Devonian series.

The generally accepted definition applies this name to Oriskany and Helderberg groups and their time equivalents.

Lower Freeman-Hampton sand.

A subsurface sand in Cisco group (Penn.) of Archer Co., Tex., which lies a short distance above Bunger ls. memb. of Graham fm. Is made up of two lenses locally about 40 ft. apart, and top lies about 160 ft. below Gose sand.

Lower Freeport clay. (In Allegheny formation.)

A clay bed, 5 ft. thick, underlying Lower Freeport coal in Appalachian region.

Lower Freeport limestone member (of Allegheny formation).

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

F. Platt, 1877 (2d Pa. Geol. Surv. Rept. H_2, p. xxviii). [See under *Freeport ls. memb.*, F. Platt, 1877.]

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q, p. 49). *Butler (Lower Freeport) ls.*—Lies 3 ft. below Lower Freeport coal and 15 ft. above Freeport (Lower Freeport) ss. in Beaver Co. Thickness 2 to 5 ft. Was called Middle Freeport ls. in Repts H_2 and H_3 (Cambria and Somerset Counties). Does not occur at Freeport, but is present at Butler [Butler Co.], in cut near R.R. Station, hence name.

I. C. White, 1879 (2d Pa. Geol. Surv. Rept. Q_2). *Lower Freeport (Butler) ls.* was called *Butler ls.* in Rept. Q, but Prof. Lesley suggests it be named *Lower Freeport ls.*

The established name for this ls. is *Lower Freeport ls. memb.*

†Lower Freeport sandstone. (In Allegheny formation.)

Pennsylvanian: Western Pennsylvania and Maryland, northern West Virginia, and eastern Ohio.

J. J. Stevenson, 1878 (2d Pa. Geol. Surv. Rept. K_3). *Lower Freeport ss.*, 50 ft. thick, underlies Lower Freeport ls. and overlies Upper Kittanning coal.

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q) and 1879 (2d Pa. Geol. Surv. Rept. Q_2). *Lower Freeport ss.* is same as *Freeport ss.* of earlier repts.

I. C. White, 1891 (U. S. G. S. Bull. 65, pp. 163–164). *Lower Freeport ss.*—Grayish white ss., sometimes double and contains a coal bed. Thickness 30 to 300 ft. Is thickest in W. Va. Underlies Lower Freeport ls. and overlies Upper Kittanning coal.

Freeport ss. memb. of Allegheny fm. is the commonly accepted name of this ss.

†Lower Helderberg group.

See under *Helderberg group.* Various limits have been assigned to this division.

†Lower Homewood sandstone. (In Pottsville formation.)

Same as *Connoquenessing ss. memb.* of Pottsville fm., q. v. See also under *Homewood ss. memb.*. The name "Lower Homewood ss." has also been applied to upper ss. of Connoquenessing ss. memb.

†Lower Kittanning limestone. (In Allegheny formation.)

Pennsylvanian: Western Pennsylvania.

J. P. Lesley, 1878 (2d Pa. Geol. Surv. Rept. Q, pp. 303–305). *Ferriferous ls. (Lower Kittanning ls.)*.—Lies lower than Lower Kittanning coal and higher than Clarion coal.

Same as *Vanport ls. memb.*

Lower Kittanning clay. (In Allegheny formation.)

A clay bed, 3 to 8 ft. thick, underlying Lower Kittanning coal in Appalachian region.

†Lower Laramie formation.

A term formerly applied in a titular sense in southern Wyo. (Hanna Basin). Replaced by *Medicine Bow fm.*, of Upper Cret. age.

†Lower Lignitic.

See under †*Lignitic.*

†Lower Little Pittsburgh limestone.

See under †*Little Pittsburgh ls.*

†Lower Magnesian limestone.

A term applied in early repts on Upper Mississippi Valley region to Shakopee dol. and Oneota dol.; later replaced by geographic name *Prairie du Chien group.*

†Lower Mahoning sandstone.

See explanation under †*Upper Mahoning ss.* and *Mahoning ss. memb.*

†Lower Medina.

Name applied in early repts to Queenston sh. of N. Y. and Juniata fm. of Pa.

Lower Mercer limestone. (In Pottsville formation.)

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

I. C. White, 1879 (2d Pa. Geol. Surv. Rept. Q_2). Rogers' name *Mercer ls.* here changed to *Lower Mercer ls.* [See quotation under *Upper Mercer ls.*]. Underlies Upper Mercer iron shales and lies 0 to 18 ft. above Lower Mercer coal in Lawrence Co., Pa. Named for Mercer, Pa.

Is a bed in Mercer sh. memb. of Pottsville fm.

Lower Mercer iron shales. (In Pottsville formation.)

Pennsylvanian: Western Pennsylvania.

I. C. White, 1879 (2d Pa. Geol. Surv. Rept. Q_2). *Lower Mercer iron shales.*—Sandy shales, 5 to 10 ft. thick. Underlie Lower Mercer coal and overlie Upper Connoquenessing ss.

Lower Mercer fire clay. (In Pottsville formation.)

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

J. P. Lesley, 1879 (2d Pa. Geol. Surv. Rept. Q_3). *Mercer Lower fire clay,* 3½ ft. thick, underlies Mercer Lower coal and overlies Mercer Lower iron shales.

Lower Narrows rhyolite.

Pre-Cambrian: South-central Wisconsin (Baraboo district).

J. T. Stark, 1932 (Jour. Geol., vol. 40, No. 2, pp. 120, 121). *Lower Narrows rhyolite.*—Rhyolite flow and breccia on N. flank of syncline on both sides of Lower Narrows of Baraboo River, secs. 20, 21, 22, and 23, T. 12 N., R. 7 E. Assigned to pre-middle Huronian.

†Lower Niagara limestone.

Name applied in some early N. Y. repts to Gasport ls. memb. of Lockport dol.

Lower Ordovician series.

The commonly accepted definition includes Chazy and Beekmantown groups (the latter group including Tribes Hill ls.) and their time equivalents.

†Lower Pentamerus limestone.

Name applied in early N. Y. repts to Coeymans ls., the names "Second Pentamerus ls." and "Upper Pentamerus ls." being applied to New Scotland ls.

Lower Pittsburgh limestone member (of Conemaugh formation).

Pennsylvanian: Western Pennsylvania and northern West Virginia.

F. and W. G. Platt, 1877 (2d Pa. Geol. Surv. Rept. H_3, p. 286). *Lower Pittsburg ls.* lies lower than Lower Pittsburg coal and higher than Morgantown ss.

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q). *Lower Pittsburg ls.*, 5 ft. thick in Allegheny Co., Pa. Lies 65 ft. below Upper Pittsburg ls. and 70 ft. above Morgantown ss. It is generally in 2 or 3 layers. Is hard, dark gray on fresh fractures but weathers dirty yellow.

See also under †Pittsburgh ls.

†Lower Productive Coal Measures.

A term applied in early repts on Appalachian region to Allegheny fm., of Penn. age.

Lowerre quartzite.

Pre-Cambrian: Southeastern New York.

F. J. H. Merrill, 1898 (N. Y. State Mus. 15th Ann. Rept., vol. 1, pp. 21–31). At base of metamorphosed Paleozoic ls. (Inwood ls.) and overlying the Fordham gneiss is a stratum of thinly bedded qtzite. It occurs in southern Westchester Co. near Lowerre station, in Yonkers at the Hastings marble quarry, and about ¼ mi. S. of Sparta on shore of Hudson River. Is well shown N. of Peekskill along E. shore of Annsville Cove and in valley of Peekskill Hollow Creek near Oregon. It does not exceed 16 ft. in thickness at Hastings. From the name of the southern locality it is called *Lowerre qtzite.* Age is probably Camb. and possibly Georgian.

F. J. H. Merrill, 1902 (U. S. G. S. New York City folio, No. 83). The qtzite overlying Fordham gneiss is here called *Poughquag qtzite,* because considered to be probable strat. equiv. to Poughquag qtzite of Dutchess Co., which carries lower Camb. fossils.

C. P. Berkey, 1907 (N. Y. State Mus. Bull. 107, pp. 361–378). *Lowerre qtzite* is pre-Cambric and may belong to Fordham gneiss, with which it is closely connected. In all essential features it is only an upper quartzitic facies of Fordham gneiss. It is 0 to perhaps over 100 ft. thick.

C. P. Berkey, 1911 (N. Y. State Mus. Bull. 146, pp. 47–57). *Lowerre qtzite* tentatively assigned to *Cambro-Ordovicic (?)*.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 22). If *Lowerre qtzite* is Postcambric [Cambrian] it is to be correlated with Poughquag qtzite [Lower Camb.].

C. P. Berkey and Marion Rice, 1921 (N. Y. State Mus. Bull. 225, 226). *Lowerre qtzite* is of uncertain age, but we are now inclined to believe it is pre-Cambric and belongs to the Grenville. [In chart on p. 140 it is classified as *later Grenville.*]

E. B. Knopf and A. I. Jonas, 1929 (U. S. G. S. Bull. 799). *Lowerre qtzite* correlates with Setters fm. of SE. Pa. and Md., the basal fm. of Glenarm series. which is classified by U. S. Geol. Survey as Algonkian.

†Lower Shaly limestone.

Name applied in early N. Y. repts to New Scotland ls.

†Lower Silurian.

A term applied in early repts to Ordovician system of present terminology, the Silurian of the present nomenclature being designated "Upper Silurian."

Lower Washington limestone member (of Washington formation).

Permian: Southwestern Pennsylvania and eastern Ohio.

J. J. Stevenson, 1876 (2d Pa. Geol. Surv. Rept. K). *Lower Washington ls.*—Thickness 20 ft. Included in Washington County group [Washington fm.]. Overlies Washington coal, from which it is in some sections separated by 6 ft. of sh. Lies about 89 ft. below Middle Washington ls.

Lower Wurtemburg limestone.

See under *Wurtemburg ls.* and under *Mercer ls.*

Lowery sand.

A subsurface sand, of Ord. age, in NE. Okla. See under *Kinter sand.*

Low Gap limestone. (In Hinton formation.)

Mississippian: Southeastern West Virginia (Summers County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 296, 344). *Low Gap ls.*—Yellow and impure calc. stratum, usually shaly or sandy; marine fossils, 1 to 5 ft. thick. Lies 0 to 3 ft. below Low Gap ss. and overlies Low Gap sh.; all members of Hinton group [fm.]. Type loc. same as Low Gap ss.

Low Gap sandstone. (In Hinton formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Tazewell County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 296, 343). *Low Gap ss.*—Greenish gray micaceous, sometimes shaly, sometimes massive; 5 to 30 ft. thick. Underlies Lower Tallery sh. and lies 0 to 3 ft. above Low Gap ls. All members of Hinton group [fm.]. Type loc. is on Wolf Creek Mtn, Summers Co., in public road slightly E. of and above Low Gap School. Also observed in Mercer and Monroe Counties, W. Va., and in Tazewell Co., Va.

Low Gap shale. (In Hinton formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 296, 345). *Low Gap sh.*—Red and variegated, 5 to 40 ft. thick. Underlies Low Gap ls. and overlies Avis ss., all members of Hinton group [fm.]. Type loc. same as Low Gap ss. Also observed in Mercer Co.

Lowhee member (of Richfield formation).

Pre-Cambrian: British Columbia (Cariboo district).

G. Hanson, 1935 (Canada Dept. Mines Geol. Surv. Bur., Econ. Geol. Mem. 181, p. 4).

Lowrie sandstone bed. (In Wellington formation.)

Permian: Central northern Oklahoma (Logan and Lincoln Counties).

J. M. Patterson, 1933 (A. A. P. G. Bull., vol. 17, No. 3, pp. 243, 251, etc.). A few mi. N. of Guthrie vertical bluffs are present on E. side of Cimarron River, in central part of T. 17 N., R. 2 W. It is here proposed that the 45-foot massive ss. bed associated with the red shales of these bluffs be named *Lowrie ss. bed,* from railroad station of Lowrie, in sec. 16. Thickness 20 to 45 ft. Is in upper part of Iconium memb. of Wellington fm., and in texture, color, and composition like rest of ss. beds in that memb. Lies higher than Evansville ss. bed. Good exposure is in bluffs E. of Lowrie.

Lowville limestone. (Of Black River group.)

Middle Ordovician: New York, Ontario, Pennsylvania, Maryland, western Virginia, Tennessee (Nashville dome).

J. M. Clarke and C. Schuchert, 1899 (Sci., n. s., vol. 10, pp. 874–878). *Lowville ls.,* instead of *Birdseye ls.* of common use. Well exposed at Lowville, Lewis Co., N. Y. Underlies Black River ls. and overlies Chazy ls. Basal fm. of Mohawkian group.

In subsequent repts up to 1910 the Lowville was treated as a fm. distinct from and underlying the *Black River ls.;* but in 1910 (N. Y. State Mus. Bull. 145) R. Ruedemann treated it as basal fm. of *Black River* *group* and divided it into (descending): (1) *Leray ls. memb.*, 10 ft., more cherty than underlying ls.; (2) *Lowville ls., s. str.*, 22 to 55 ft. of dove and blue-dove ls., both thick- and thin-bedded, and conglomeratic at base. Uncon. overlain by Watertown ls. and uncon. underlain by Pamelia ls. of Chazy group. [In subsequent repts the thickness of Lowville was stated as 0 to 85 ft.]

H. P. Cushing, 1911 (Am. Jour. Sci., 4th, vol. 31, pp. 135–144). *Leray fm.* (black cherty lss. of Watertown region) is classed provisionally as uppermost memb. of Lowville. In Watertown region it uncon. overlies *typical Lowville ls.*, but Ulrich says there is gradation elsewhere, and that the chert beds can not be separated from the Lowville. At Lowville there are 5½ ft. of cherty ls. with *Columnaria halli* and *Stromatocerium rugosum*, not seen at Watertown, and to S. this *Stromatocerium* bed is sole representative of the [Lowville?] fm. In Champlain Valley massive black ls. seems to bridge interval btw. Lowville and Leray in Watertown region. *Typical Lowville ls.* consists of thin-bedded dove lss. containing little or no chert, and is Lowville ls. as originally defined by Clarke and Schuchert in 1899, or the fm. previously called *Birdseye*. Overlain uncon. by Watertown ls. and underlain by Chazy group.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27), included Leray in Lowville.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 37), stated that "the upper cherty layers of the Lowville have been designated the Leray ls.;" but the accompanying chart placed Leray ls. above Lowville ls.

R. S. Bassler, 1915 (U. S. Nat. Mus. Bull. 92, vol. 2, pl. 1), included Leray in Lowville, but in 1919 (Md. Geol. Surv. Camb. and Ord. vol., p. 51) he excluded it, as he did in 1934 (Geol. Soc. Am. Spec. Paper No. 1). A. F. Foerste, 1924 (Canada Dept. Mines, Geol. Surv. Mem. 138, chart opp. p. 58) included Leray in Lowville, but E. O. Ulrich, 1924 (Tenn. Dept. Ed., Div. Geol. Bull. 28, p. 34, and Bull. 31, p. 16) excluded Leray from Lowville.

G. M. Kay, 1929 (Jour. Geol., vol. 37, No. 7, pp. 664–671; and A. A. P. G. Bull., vol. 13, No. 9, p. 1214), divided Black River group of N. Y. and Ont. into Chaumont fm. (above), *new*, and Lowville ls. (below); and included in his Chaumont, in descending order, Watertown ls., Glenburnie (new, 0 to 2 ft.), and Leray ls.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10), excluded Leray from Lowville in table on p. 268, but on p. 282 stated: Uppermost layers (15 to 20 ft. max.) of Lowville ls. are cherty, and separated from typical Lowville by uncon., and this portion has received name *Leray ls.*

E. O. Ulrich and R. Ruedemann, 1933 (16th Int. Geol. Cong. Guidebook 4, p. 126), used *Leray ls.* for beds btw. Watertown ls. (above) and *Lower Lowville ls.* (below).

G. M. Kay, 1935 (Geol. Soc. Am. Bull., vol. 46, pp. 227–228), divided Black River group at *type section* into Chaumont fm. (including Watertown and Leray) and Lowville.

The U. S. Geol. Survey at present treats Leray ls. as top memb. of Lowville ls.

In central Pa. the Lowville ls. is overlain by Rodman ls., a local name for post-Lowville part of Black River group. In western Va. and southern Pa. the Chambersburg ls. composes the post-Lowville part of Black River group and overlies Lowville ls. In Nashville dome, Tenn., the Lowville is divisible into 2 members, to the lower of which (consisting of massive, compact, white or light-blue cherty ls.) the name *Carters ls.* is now restricted, while the upper memb. (consisting of thin-bedded dove-colored ls. layers and yellowish gray sh.) is correlated by E. O. Ulrich and R. S. Bassler with Tyrone ls. of Miller, in central Ky.

Lowville granite.

Pleistocene: Northwestern New York (Lowville quadrangle).

A. F. Buddington, 1934 (N. Y. State Mus. Bull. 296, pp. 74, 78–79, 83, 104, and map of Lowville quad.). *Lowville type* (also *Lowville granite*).—Coarse to medium-grained equi-granular granite over wide areas, often high in quartz. Relations to Hermon and Alexandria types of granite undet. A band about 4 mi. wide strikes NE.–SW. across central part of Lowville area. Intrudes Grenville series.

Loxley ground moraine.

Pleistocene (Wisconsin stage): Northern central Michigan (Roscommon County).

W. A. Ver Wiebe, 1927 (Papers Mich. Acad. Sci., Arts, and Lett., vol. 7, p. 163). *Loxley ground moraine* is located near settlement called Loxley, in T. 22 N., R. 4 W.

Loyal Creek.

Upper Ordovician: Eastern New York (Mohawk Valley).

R. Ruedemann and G. H. Chadwick, 1935 (Sci., n. s., vol. 81, p. 400). *Loyal Creek* introduced for middle Utica or zone of *Dicranograptus nicholsoni* in Mohawk Valley.

Loyalhanna limestone (in Pennsylvania).

Loyalhanna limestone member (of Greenbrier limestone, in Maryland and West Virginia).

Mississippian: Western and central Pennsylvania, western Maryland, and northern West Virginia.

C. Butts, 1904 (U. S. G. S. Kittanning folio, No. 115, p. 5). Coarse calc. ss., strongly cross bedded, surface pitted by differential erosion. Thickness at least 40 ft. Universally known in region as "Siliceous ls.," but generally it is a rather calc. ss. In deference to general usage it is here named *Loyalhanna ls.*, because well developed along the gorge in which Loyalhanna Creek flows across Chestnut Ridge, Westmoreland Co., Pa. Underlain by Burgoon ss. Top of Loyalhanna is here taken as top of Pocono fm., as in western Pa. folios already published.

C. Butts, 1924 (Am. Jour. Sci., 5th, vol. 8, pp. 249–257). In SW. Pa. the fossils reveal a great hiatus btw. Loyalhanna ls. and Burgoon ss. memb. of Pocono fm. The Loyalhanna is therefore here separated from Pocono and treated as a distinct fm. btw. the Pocono below and the Mauch Chunk above. It is a nonfossiliferous transgressing fm., equiv. in lithology and strat. position to Ste. Genevieve ls. In western Md. it is very properly treated as a memb. of Greenbrier ls., which there replaces lower part of Mauch Chunk sh.

Loysburg formation.

Lower Ordovician: Central and central southern Pennsylvania.

R. M. Field, 1919 (Am. Jour. Sci., 4th, vol. 48, pp. 404, 410). *Loysburg fm.*—Dark and impure dolomitic ls. overlying Beekmantown ls. and underlying first intraformational zone. Only 115 ft. exposed at Bellefonte, so that base cannot be located. Appears to be not so thick at Loysburg, Bedford Co. Lowest fm. of Stones River group. Collie does not appear to have recognized the existence of this formation. Butts also does not mention the lowest div. of the Stones River group, probably because it is poorly exposed at Roaring Spring. Differs from superjacent Carlim in lithology, in paucity of fossils, and in total absence of reef-building organisms, which are so characteristic of the Carlim.

Lucas dolomite.

Lower Devonian: Ohio, southeastern Michigan, and western Ontario.

C. S. Prosser, 1903 (Jour. Geol., vol. 11, pp. 521, 540). *Lucas ls.*—To include all rocks btw. top of Sylvania ss. and base of Columbus ls. of Ohio or Dundee ls. of Mich. Is top memb. of Monroe fm.

C. R. Stauffer, 1908 (Ohio Nat., vol. 8, pp. 271–276, and Geol. Soc. Am. Bull., vol. 19, pp. 544–545, footnote). *Lucas ls.* overlies Sylvania ss. and underlies Columbus ls. Consists of (descending): (1) 63 ft. of compact drab dolomitic ls., showing banded structure, in quite massive layers but weathers into much thinner layers, and contains several fossiliferous layers near middle; (2) 36 ft. of compact drab dolomitic ls. with some drab-gray to brown sandy layers.

A. C. Lane, C. S. Prosser, W. H. Sherzer, and A. W. Grabau, 1909 (Geol. Soc. Am. Bull., vol. 19, pp. 553–556), named the "Upper Monroe" of Mich., Ohio, and western Ont. the ***Detroit River series***, and divided it into (descending): ***Lucas dol.***, 200+

ft.; Amherstburg dol., 20 ft.; Anderdon ls., 40 to 50 ft.; and Flat Rock dol., 40 to 150+ ft. This was a restriction of Lucas as originally defined.

W. H. Sherzer and A. W. Grabau, 1910 (Mich. Geol. Surv. Pub. 2, geol. ser. 1, p. 51). In Lucas Co., Ohio, the *Lucas dol.* rests on Sylvania ss. in all quarries, showing that Anderdon and Amherstburg have been cut out by overlap of the dol. on Sylvania ss.

C. R. Stauffer, 1916 (Geol. Soc. Am. Bull., vol. 27, p. 72). Amherstburg dol. certainly occurs at West Liberty, Ohio, and probably at Fremont; and Anderdon ls. outcrops in quarries at Castalia, Ohio.

J. E. Carman, 1927 (Jour. Geol., vol. 35, pp. 481–506). Flat Rock and Anderdon members have not been recognized in Ohio. They are known to be absent in Lucas Co.

In Cleveland, Ohio, region, the Lucas dol. is treated as a distinct fm. In Mich. it is treated as a memb. of Detroit River dol.

Named for Lucas Co., Ohio, which Lucas dol. crosses from N. to S.

Lucas limestone.

Middle Devonian: Central eastern Iowa.

C. [R.] Keyes, 1912 (Iowa Acad. Sci. Proc., vol. 19, p. 149) and 1913 (Iowa Acad. Sci. Proc., vol. 20, pp. 205, 206). *Lucas terrane.*—White fine-grained ls., 20 ft. thick; *Straparollus* abundant at base. Forms topmost part of Cedar Valley ls. Underlain by Coralville ls. Included in Senecan. Named for a locality [not stated] in Johnson Co.

Lucero beds.

Cretaceous: Cuba.

E. L. De Golyer, 1918 (A. A. P. G. Bull., vol. 2, p. 142).

Lucien shale member.

Permian: Central northern Oklahoma.

F. L. Aurin, H. G. Officer, and C. N. Gould, 1926 (A. A. P. G. Bull., vol. 10, pp. 786–799). *Lucien sh. memb.*—Lower 250 ft. of Garber ss., consisting largely of red, more or less fissile or laminated clay shales, with several ledges of red ss., one of which generally occurs at base of the memb. Underlies Hayward ss. memb. of Garber ss., and rests on Wellington fm. Named for exposures at Lucien, Noble Co.

Luck-Sure series.

Age (?): Southeastern Arizona (Tombstone district).

W. P. Blake, 1902 (Tombstone and its mines). *Manganiferous or Luck-Sure series.*—Series of thickly bedded massive lss., in which occur ore deposits characterized by large amounts of manganese ore. Chiefly developed in mineral claims formerly known as Lucky Cuss, Luck Sure, Wedge, Sunset, Knoxville (Stonewall), Anchor, and Grand Dipper. Underlies, uncon. (?), the Contention and Toughnut series [Mesozoic]. [Appears to be younger than his Emerald series, "which includes the heavy qtzites of Ajax Mtn."]

Lucky Cuss limestone.

Ordovician (?): Southeastern Arizona (Tombstone district).

J. A. Church, 1903 (Am. Inst. Min. Engrs. Trans., vol. 33, pp. 3–37). *Lucky Cuss ls.*—Thickness 400 ft. Is full of crinoids. Underlies Herschel qtzite [Mesozoic] and overlies Emerald ls. [Upper Camb.].

Lucky S argillite.

Upper Jurassic: Northern California (Mount Jura).

C. H. Crickmay, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 81). [See under *Combe ss.*]

C. H. Crickmay, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 5, pp. 896, 902). *Lucky S fm.*—Micaceous qtzite, with one or more fine cgls. of chert and qtzite pebbles derived from much older deposits, grading up into micaceous dark-gray siltite and black argillite. Thickness 600 ft. Very meager marine fauna in upper beds; no identifiable fossils. Of mid Upper Jurassic age. Named for Lucky S mine. Type loc., Forman Ravine, W. end of Forman Ridge. Underlies Trail tuff and cgl. and overlies Cooks Canyon aggl.

Ludlow sandstone.

Middle Devonian: Central Pennsylvania (Perry County).

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 2, pp. 1236–1237). [See under *Perry fm.*]

Ludlow lignitic member (of Lance formation).

Upper Cretaceous: Southwestern North Dakota, northwestern and northern South Dakota, and northeastern Montana.

E. R. Lloyd and C. J. Hares, 1915 (Jour. Geol., vol. 23, pp. 523–547). [See 1915 entry under *Cannonball marine memb.* The following additional details regarding the Ludlow memb. are also given in rept cited above.] *Ludlow lignitic memb. of Lance fm.* occupies large area in Harding Co., S. Dak., and has been mapped northward into Bowman and Billings Counties, N. Dak., and eastward in Perkins Co., S. Dak., where it merges with Cannonball marine memb. In vicinity of Ludlow, S. Dak., its type loc., it consists of 350 ft. of loosely consolidated buff and cream-colored calc. ss. and sh. with interbedded lignite. It contains most of lignite of S. Dak., and the presence of this lignite is one of chief criteria for considering it a distinct memb. of Lance fm. In S. Dak. its lithologic character is very like Fort Union fm. and its fossil flora so far as determined is identical with that of Fort Union; its flora is like that of lower part of Lance, but its lithology is quite different. In N. Dak. its flora has same affinities as in S. Dak., but its lithology resembles lower part of Lance except for presence of numerous lignite beds. It is this variation in color and lithology that renders its separation from overlying Fort Union so difficult. All of the *Triceratops* collected in Little Missouri country came from below the T Cross lignite bed [in lower part of the Ludlow] and the oysters from above it. Calvert, however, states that in Mont. ceratopsian bones were found just above the lowest persistent lignite bed, but there is certainly nothing in character of overlying strata to suggest that similar bones do not occur therein up through a strat. distance of perhaps 500 ft. (U. S. G. S. Bull. 471, p. 197, 1912.) The T Cross lignite bed was mapped to Mont. State line, and it is undoubtedly the same lignite as the "persistent lignite" referred to above.

See also D. E. Winchester, C. J. Hares, E. R. Lloyd, and E. M. Parks, 1916 (U. S. G. S. Bull. 627, pp. 15–26), and T. W. Stanton, 1920 (U. S. G. S. P. P. 128A).

The U. S. Geol. Survey now classifies Cannonball marine memb. of Lance fm. and the demonstrably equiv. part of the Ludlow memb. as Upper Cret.

†Ludlow conglomerate member.

Devonian or Carboniferous: Northwestern Pennsylvania.

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 202). [See 1933 entry under *Knapp fm.*]

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 61), replaced this preoccupied name with *Wetmore cgl.*

Ludlowville shale. (In Hamilton group.)

Middle Devonian: Western and central New York.

J. Hall, 1839 (N. Y. Geol. Surv. 3d Rept., p. 298). *Ludlowville shales.*—Bluish or olive sh. with different fossils from those of underlying olive sh. [later named *Skaneateles sh.*]. Underlies Encrinal ls. Named for occurrence at Ludlowville [Tompkins Co.].

Ludlowville sh. continued to be used, for many years, for beds said to overlie Skaneateles sh. and to underlie Tichenor ls., a name introduced to replace Encrinal ls. of Hall. But further studies revealed 2 encrinal lss.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 222–224). *Ludlowville fm.* in western N. Y. is composed in lower part of dark soft sh. having a "Leiorhynchus or Marcellus facies," and in upper part of soft, lighter gray shales abounding in typical Hamilton fossils. Traced eastward the beds become more aren. and "Leiorhynchus facies" of lower part is eventually lost. In western and central N. Y. the Ludlowville is divisible into several members, but in eastern central part of State the uniformity of lithology and faunas prevent any subdivision. The name Ludlowville was used first by Hall in 1839 for the sequence on Cayuga Lake btw. base of Centerfield memb. and a certain bed designated by him "Encrinal ls." The type section was not happily chosen, as only about 50 ft. of the Ludlowville is exposed there, the overlying fms. (Moscow sh. and Tully ls.) being found within the village. It is clear from above that Hall's type section is utterly inadequate, but as the name has been entrenched in the literature for 90 years writer suggests that it be retained, but that the section for reference be that sequence on Paines Creek at Aurora beginning with the Centerfield at Moonshine Falls and terminating with Portland Point beds (erroneously referred to Tichenor by N. Y. State Surv. bulletins) at Black Rock. [See also under *Centerfield ls.* and 1930 entry under *Moscow sh.*] Is here divided into (descending) Deep River memb., Tichenor memb., Wanakah memb., Ledyard memb., and Centerfield memb. In Chenango Valley the typical Centerfield fauna is absent, and base of Ludlowville is drawn at base of *Spirifer divaricatus* zone, the latter species also occurring in Centerfield ls.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369), defined *Ludlowville sh.* as underlying Menteth ls. memb. of Moscow sh., overlying Skaneateles sh., and as including Tichenor ls. in upper part and Centerfield ls. at base. This is present definition of U. S. Geol. Survey.

†Ludlowville group.

Middle Devonian: New York.

J. Hall, 1842 (Am. Jour. Sci., 1st, vol. 42, pp. 57–62). The great group of fossiliferous shales so well developed along Cayuga and Seneca Lakes, and known as Marcellus, Skaneateles, Ludlowville, and Moscow shales, I shall for the sake of brevity speak of under the name of *Ludlowville group*. [This broad use of Ludlowville did not gain currency, for Vanuxem the same year (Geol. N. Y., pt. 3) adopted *Hamilton group* to include all beds btw. Tully ls. above and Marcellus sh. below, or (descending) Moscow sh., encrinal ls., Ludlowville or Olive sh., and Skaneateles sh.; and Hall himself in 1843 and later publications ceased to use this broad definition of Ludlowville.]

Lueders limestone. (Of Wichita group.)

Permian: Central northern and central Texas.

W. E. Wrather, 1917 (SW. Ass. Pet. Geol. Bull., vol. 1, p. 94 and chart opp. p. 96). *Lueders ls.*—Top memb. of Wichita div. Has been identified by writer from a point S. of Harrold, on Fort Worth and Denver City R. R. in Wilbarger Co., past Seymour, across NW. Throckmorton and SE. Haskell Co. to Ballinger, Runnels Co. Persists to within few mi. of Red River. Thickness *20 ft.* in section from Abilene to Sweetwater. Around Abilene and perhaps southward beneath Callahan Divide, Lueders ls. is overlain by Abilene fm., which there forms top memb. of Wichita. Named for small town on Clear Fork of Brazos River, in eastern Jones Co.

J. W. Beede and V. V. Waite, 1918 (Univ. Tex. Bull. 1816, pp. 41–42). *Lueders fm.*—Over top of Paintrock fm. is a series of rocks with a larger proportion of sh. and marly impure lss., which weather easily, except in upper part, which is formed by Ballinger lss. The shales below these lss. are frequently marly and very fossiliferous; in fact they are coarse fossil cgls. made up mainly of Myalinas and other pelecypods with many gastropods and Bryozoa. The lss. at Ballinger are quite fossiliferous, and the beds are relatively thick and massive, and mostly buff. The Lueders fm. is here regarded as beginning with No. 142 and extending to top of No. 158 of general section. As thus defined it has *thickness of 194 ft.* It is uncertain how Lueders fm. as here used will check with section at Lueders, but according to Wrather they are in general equiv. The Lueders fm. as a whole naturally breaks into an upper and a lower part with rather distinct characteristics, and further study may necessitate its subdivision.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 169). *Paint Rock beds of Drake* are basal part of Lueders fm. as defined in this rept.

Lueders limestone member (of Lueders formation).

See 1930 entry under *Lake Kemp ls.*

†Lufkin beds. (In Claiborne group.)

Eocene: Eastern Texas.

W. Kennedy, 1892 (Tex. Geol. Surv. 3d Ann. Rept., pp. 45, 58). *Lufkin or Angelina County beds.*—Chiefly dark-blue gypseous clays (gray, white, and blue), sands (sometimes laminated and cross-bedded), sandy clays, and lignites, 100 or more ft. thick. Basal fm. of Mio. Underlies Fayette sands and sss. and uncon. overlies Eocene Cook's Mtn beds.

Same as Yegua fm. (Eo.), the better established name.
Named for Lufkin, Angelina Co.

Lufkin rhyolite.

Tertiary: Southwestern New Mexico (Sierra County).

C. R. Keyes, 1908 (Am. Inst. Min. Engrs. Bi-Mon. Bull. 19, pp. 7–21). *Lufkin rhyolite*, Tert., 500 ft. thick. Type loc., Lufkin Mtn, near Lake Valley [Sierra Co.].

Lufkin member (of Cook Mountain formation).

Eocene: Eastern Texas.

B. C. Renick, 1928 (A. A. P. G. Bull., vol. 12, pp. 521, 534). *Lufkin memb.*—Top memb. of Cook Mtn fm. Underlies Yegua fm. and overlies Nacogdoches memb. of Cook Mtn fm. Consists of 300 to 400 ft. of marine chocolate-brown clay, containing some fossiliferous beds, some glauconitic beds, and thin beds of sand. Upper 5 to 15 ft. generally contains macrofossils, making this memb. easily recognizable as distinct from overlying Yegua fm. Weathers reddish brown. The term Lufkin was introduced by G. M. Knebel and Miss Alva Ellisor. [The compiler has been unable to find where Mr. Knebel and Miss Ellisor published this name, and Renick does not give the reference.]

Lugert granite.

Pre-Cambrian: Southwestern Oklahoma (Kiowa and Greer Counties).

C. H. Taylor, 1915 (Okla. Geol. Surv. Bull. 20). Intrusive red granite, younger and finer-grained than Reformatory granite and older than Quanah granite. Occurs in vicinity of Lugert, Kiowa Co. Appears to be younger than Cold Springs granite.

M. G. Hoffman, 1930 (Okla. Geol. Surv. Bull. 52, pp. 33–45). *Lugert granophyre.*—Salmon-pink medium-grained granophyre, speckled with little dark-gray to black spots of ferromagnesian minerals. Was called Lugert granite by Taylor, 1915. Intrudes Meers qtzite, the basic rocks, and the Saddle Mtn, Davidson, and Carlton granophyres in Wichita Mtns, SW. Okla.

Luisian stage.

Tertiary: California.

See under *Zemorrian stage*, R. M. Kleinpell, 1934.

H. G. Schenck and R. M. Kleinpell, 1936 (A. A. P. G. Bull., vol. 20, No. 2, p. 224). *Luisian stage* includes lower Monterey fm., Claremont sh., "*Valvulineria californica* zone," etc.

Lukachukai sandstone.

Triassic (?): Northwestern New Mexico and northeastern Arizona.

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, pp. 250, 337). *Lukachukai ss.*—Application for lower ss. section of Doloresian series, as outcropping in Lukachukai Valley, at N. end of Chuska Mtns [NW. N. Mex.]. Thickness 200 ft. Younger than Holbrook sss.

Lukashukai.

See *Lukachukai*.

Luke clay. (In Allegheny formation.)

Pennsylvanian: Western Maryland (Allegany and Garrett Counties).

C. K. Swartz, W. A. Price, and H. Bassler, 1919 (Geol. Soc. Am. Bull., vol. 30, p. 572). *Luke clay* (*Middle Kittanning clay*).—Underlies Middle Kittanning (Luke) coal and overlies Ellerslie ss.; all included in Allegheny fm.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, pp. 47, 343, pl. 6). *Luke clay* (*Middle Kittanning clay*).—Impure clay, lenticular. Overlies Lower Kittanning rider coal. Exposed in cut on B. & O. R. R. opposite Luke [Allegany Co.].

Luke Hill formation.

Name applied by H. W. McGerrigle (17th Rept. Vt. State Geol., pp. 182, 185, 1931) to B_4 (160 ft. of dark bluish-gray thin-bedded lss.) of Logan's section of Philipsburg series of Quebec. McGerrigle mapped his Luke Hill fm. in St. Albans quad., NW. Vt. (See 1931 entry under *Philipsburg series.*)

Luke Hill limestone.

Name applied by T. H. Clark (Geol. Soc. Am. Bull., vol. 45, No. 1, pp. 6–7, 1934) to a ls. in Quebec.

Lulbegrud clay.

Silurian (Niagaran): East-central Kentucky.

A. F. Foerste, 1905 (Ky. Geol. Surv. Bull. 6, p. 145) and 1906 (Ky. Geol. Surv. Bull. 7, pp. 10, 50). *Lulbegrud clay.*—Clay, 10 to 13 ft. thick; forms basal memb. of Alger fm. (of Niagaran age). Overlain by Waco ls. (of Alger fm.) and underlain by Indian Fields fm. (also of Niagaran age).

In 1931 (Ky. Geol. Surv. ser. 6, vol. 36, pp. 172, 173) Foerste assigned this clay to Clinton epoch.

Named for Lulbegrud Creek, Clark and Powell Counties.

Lunasan series.

Lunasian series.

A term introduced by C. [R.] Keyes for a part of the middle Carbf. (Penn.) of N. Mex.—"the main ls. sequence in Manzano Mtns." (See his Conspectus of geol. fms. of N. Mex., 1915, pp. 3, 8.)

Lundy.

Name applied to a glacial lake, of Pleist. age, in Great Lakes region. (See U. S. G. S. Mon. 53, 1915, p. 469.)

Lundy glacial epoch.

A name applied by E. Blackwelder (Geol. Soc. am. Bull., vol. 41, pp. 91–92, 1930) to time during which the next to youngest drift was laid down on slopes of Sierra Nevada, Calif. He later (G. S. A. Bull., vol. 42, pp. 865–922, 1931) replaced this name with *Tahoe glacial stage*, which he correlated with Iowan stage

Lundy Mountain type.

Pre-Cambrian: Eastern Alabama.

W. F. Prouty, 1923 (Ala. Geol. Surv. County Rept. No. 1, pp. 18, 19). In crossing Ashland series [Ashland mica schist] from NW to SE., going from border near Clairmont Springs through Ashland, one finds from W. border past Sardis Church and nearly to Idaho, soils of grayish to pink color. In a number of exposures through here the [Ashland] mica schist has large compound flakes of green mica together with many bluish-gray scales of aluminous material. This type of mica schist has been called *Lundy Mountain type* by Dr. E. A. Smith in his field notes of 1896.

Lunenburg schist.

Upper Cambrian: Northeastern Vermont (Essex County).

C. H. Richardson, 1906 (5th Rept. Vt. State Geol., pp. 79–82). *Lunenburg schist.*—Highly metamorphic green, greasy, chlorite schist. [Pre-Camb. on pp. 79–80; probably Camb., p. 80; on p. 82 is following:] Prof. Hitchcock suggested, in "Geol. sections crossing N. H. and Vt.," term *Montalban* as=White Mtn series in N. H., whose age is upper Laurentian. In this rept I have included these with Lunenburg schist as pre-Camb., awaiting further field investigation.

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288). *Lunenburg group,* uppermost Upper Camb. of eastern Vt., consists of sericite qtzite, sericite schist, and chlorite schist.

Apparently named for village or Twp of Lunenburg, Whitefield quad., Essex Co.

Luning formation.

Upper Triassic: Southwestern Nevada (Tonopah and Hawthorne quadrangles).

S. W. Muller and H. G. Ferguson, 1936 (Geol. Soc. Am. Bull., vol. 47, pp. 241–252). *Luning fm.*—Chiefly ls. and dol., but where in contact with or close to Excelsior fm., as in Pilot Mtns, there are one or more members of siliceous slates with cgls. whose pebbles are almost wholly chert. In Gabbs Valley the fm. is chiefly dark ls. and dol. with subordinate sl.; in places there are interbedded lava flows, altered andesite, and quartz latite. Some of siliceous slates may be, at least in part, of tuffaceous origin. Fossils are Upper Triassic. Thickness 10,000 ft. Conformably underlies Gabbs fm., and uncon. overlies Excelsior fm. (Middle Triassic). Named for little settlement of Luning, in Soda Springs Valley, the best exposures being in mtns bordering this valley. Type loc. is on N. slope of Pilot Mtns, about 12 mi. SE. of Luning.

Lupton sand.

Lower Cretaceous: Central northern Montana (Cat Creek oil field).

F. Reeves, March 1921 (U. S. G. S. Press Bull. on Cat Creek anticline, Twps 13, 14, 15, Rs. 28, 29, 30, 31 E., Fergus and Garfield Counties). About 200 ft. below top of Kootenai fm. is a multiple-bedded ss., 30 to 60 ft. thick, which has yielded small quantities of oil in Franz Corp. discovery well, sec. 21, T. 15 N., R. 30 E., and in Decker-Collins well, sec. 13, T. 15 N., R. 29 E. It also yields strong artesian flow of fresh water. Is usually called second Kootenai sand, but it will be here referred to as *Lupton sand*, after the geologist who located the discovery well—a name suggested by O. W. Freeman in Eng. and Min. Jour. April 17, 1920.

Is now sometimes called Second Cat Creek sand.

Luquillo formation.

Cretaceous: Puerto Rico.

H. A. Meyerhoff, 1931 (N. Y. Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, vol. 2, pt. 3, p. 279).

Luscar formation.

Lower Cretaceous: Alberta.

B. R. MacKay, 1929 (Canada Geol. Surv. Summ. Rept. 1928, pt. B, p. 12) and 1930 (Canadian Min. and Met. Bull. 222, p. 1312).

Lusk.

A name applied by C. [R.] Keyes (Pan-Am. Geol., vol. 39, No. 4, 1923, p. 320) to 140 ft. of Miss. lss. shown as occupying interval btw. Hardinsburg and Cypress sss. of Ill. This is position of Golconda fm. (Brokaw, 1916). Derivation of name not stated, but probably named for the small village very near Golconda, Pope Co., SE. Ill.

Luta limestone. (In Sumner group.)

Permian: Central and southern Kansas and northern Oklahoma.

J. W. Beede, 1909 (Jour. Geol., vol. 17, pp. 710–729, and Kans. Acad. Sci. Trans., vol. 22, p. 251). *Luta ls.*—More or less cellular, soft gray ls., 10 to 30 ft. thick, with siliceous and other geodes scattered through it and with layers of more or less banded chert concretions. Basal memb. of Marion stage. Overlain by Enterprise shales and underlain by Winfield ls.

"Marion fm." has been abandoned by both Kans. Geol. Survey and U. S. Geol. Survey, and Luta ls. has for many years been treated as basal fm. of Sumner group. In Sept. 1936, however, R. C. Moore (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 12) transferred Luta ls. to Chase group and treated it as top memb. of Winfield ls., thus redefining Sumner group, Winfield ls., and Chase group. These redefinitions have not yet been considered by U. S. Geol. Survey for its publications.

See also under *Cresswell ls.*

Named for Luta Brook, a tributary of Antelope Creek, just N. of Marion, Marion Co., Kans.

Luthers Mills coquinite.

Upper Devonian: Northeastern Pennsylvania (Bradford County).

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 571, 580, 583, 589, 592). *Luthers Mills coquinite.*—Name here applied to type "Burlington ls" of Sherwood, 1878. Coquinites at Lemon, Lime Hill, Le Raysville, Rome, and Burlington assumed to be the same. Useful key bed to upper part of New Milford fm., or lowest recognized Canadaway. Lies near top of New Milford. [On p. 583 is a section showing Luthers Mills coquinite, 40 ft. thick, separated from overlying Damascus red sh. by a concealed interval of 25 ft.] Williams and Kindle (U. S. G. S. Bull. 244, 1905) gave name *Franklindale ls.* to a memb. which they found near Franklindale and at Towanda Narrows, which was to supplant Sherwood's preoccupied term "Burlington ls.," which at its type loc. is actually a mass of broken shells, a shell breccia, cemented by red mud. For this type of deposit writer has proposed the name coquinite. It is 40 ft. thick in central Bradford Co., near Burlington. The Franklindale ls., according to Williams and Kindle and also the writer's observations, is more nearly a true ls. or group of thin lss., and it is older than the "Burlington," being probably late Chemung. Therefore, for type "Burlington" the name *Luthers Mills coquinite* is proposed, from a crossroads E. of Burlington, Bradford Co., near which place the beds are well exposed along the highway. They lie higher than most of Mansfield iron ores.

Luyano marls.

Cretaceous: Cuba.

E. L. De Golyer, 1918 (A. A. P. G. Bull., vol. 2, p. 141).

Lyell formation.

Upper Cambrian: Alberta and British Columbia.

C. D. Walcott, 1920 (Smithsonian Misc. Coll., vol. 72, No. 1, p. 15). *Lyell fm.*, Camb., Alberta. [Walcott fully defined this fm. in Smithsonian Misc. Coll., vol. 67, No. 8, Mar. 5, 1923, pp. 460–461, when he assigned it to Upper Camb. and stated that it underlies Mons fm., overlies Sullivan fm., and is 1,270 to 1,700+ ft. thick.]

†Lykens series.

Pennsylvanian: Eastern Pennsylvania.

D. White, 1900 (U. S. G. S. 20th Ann. Rept., pt. 2, p. 755). Pottsville fm. has been locally called "Lykens series" by Second Geol. Survey (Ann. Rept. 1886, pt. III; Summ. Final Rept. 1895, vol. III, pt. 1; Atlas southern anthracite field, pls. I–VI). Contains the Lykens coals.

Lykins formation.

Triassic (?) and probably Permian: Eastern Colorado.

N. M. Fenneman, 1905 (U. S. G. S. Bull. 265). *Lykins fm.*—A series of sss. and sandy shales, with a little ls. Is clearly distinguished from underlying Lyons ss. and Fountain fm. by its softness and its showy colors, the most striking of which is a rich brick red that characterizes its sandy shales and shaly sands. At places the color is more brownish, but it is always deep and rich. At Fourmile Canyon, where the fm. is somewhat more than 800 ft. thick, the lowest 230 ft. are largely if not wholly sss. of a clear red color, a little darker than brick. These are overlain by the "crinkled" ss., here 35 ft. thick. Above this for 467 ft. there are no exposures, but soil is very red and exposures not far distant indicate that most of this thickness is red aren. shales. Above these obscured beds are 100 ft. of the familiar red ss. Any horizon of this fm. may be slightly calc., but this is not general. The "crinkled" ss. is present wherever the Lykins is found. The Lykins is the "Upper Wyoming" of Eldridge at localities farther S It is named for Lykins Gulch [about 9 mi. N. of Boulder], the scenery along which owes its strange and beautiful character to this fm.

In places is overlain uncon. by Upper Jurassic Morrison fm. and in other places by the older Entrada ss., also Upper Jurassic.

Lyman formation.

Silurian (Niagaran) and older (?): Northwestern New Hampshire (Ammonoosuc River region).

C. H. Hitchcock, 1874 (Am. Jour. Sci., 3d, vol. 7, pp. 468–476). *Lyman group*.—Chiefly drab soapy qtzite, weathering nearly white; parts of it conglomeratic; also includes a cgl. 200 ft. thick. Thickness, 2,330 ft. Underlies clay sl. and an auriferous cgl. that will be distinguished from Lyman group in my forthcoming rept. Overlies Lisbon group. Included in Huronian.

C. H. Hitchcock, 1904 (Geol. Soc. Am. Bull., vol. 15, pp. 461–482), called the Lyman of Ammonoosuc dist. *Lyman schist*, and stated that it consisted chiefly of argillitic schists, also that the Lyman, Lisbon, and Swiftwater "may be Ord."

C. H. Hitchcock, 1905 (Geol. of Littleton, N. H., p. 31, Univ. Press, Cambridge). *Lyman schists* do not represent a strat. terrane; it is a petrographical designation. At present it is not known what the original rocks were, but one of them must have been the aren. div. of sands and cgls. and another an argillite. Underlies auriferous cgl. and overlies Lisbon group, both of which are Lower Sil. [Ord.] or Camb.

F. H. Lahee, 1913 (Am. Jour. Sci., 4th, vol. 36, pp. 231–250). *Lyman schists*.—Highly metamorphosed fine-grained sss. and mudstones with few beds of fine cgl.; drab or greenish gray. Are pre-Sil.

F. H. Lahee, 1916 (Jour. Geol., vol. 24, pp. 366–381). "Lyman schists" was applied by Hitchcock to a group of schists many of which are characteristically whitish on weathered surfaces. Hitherto *Lyman series* has been regarded as a group of metamorphosed sed. rocks. Field evidence, megascopic examination of hand specimens, and microscopic examination of thin sections indicate that Lyman series contains interbedded members that appear to be of volcanic origin. These metamorphosed volcanic rocks include, among others, species related to quartz keratophyres and keratophyres and probably also tuffs and aggls. of similar composition. Structural relations and age obscure. Not younger than Dev. and may be older. [Appears to include Lyman and Lisbon fms.]

C. P. Ross, 1923 (Am. Jour. Sci., 5th, vol. 5, pp. 267–302). *Lyman fm.*—Interbedded gray, white, and buff schists and gray phyllites, parts of which are distinctly calc. Contains cgls., and sandy schists (not so coarse as those in underlying Lisbon and Swift Water fms.) are interbedded with fine-grained more or less calc. gray phyllites. Corresponds to Lyman group of Hitchcock, although there are minor differences in map boundaries. Scanty fossils, but appears fairly certain to be= nearby rocks of Niagaran age. As here defined may contain rocks of 2 ages, the older being=Lyman series of Lahee.

M. Billings in 1934 (see 1934 entry under *Swift Water fm.*) dropped Lisbon, Lyman, and Swift Water from the nomenclature of Littleton and Moosilauke quads.

Named for exposures over wide area around village of Lyman, Grafton Co.

Lyman series.

See 1916 entry under *Lyman fm.*

Lyman erosion surface.

Pleistocene: Northeastern Utah (Uinta Mountains).

W. H. Bradley, 1936 (U. S. G. S. P. P. 185). Lies 50 to 75 ft. above Tipperary surface. Named for fact that Lyman, Wyo., is built upon its northern edge.

Lyme granite gneiss.

Late Carboniferous or post-Carboniferous (?): Southeastern Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 115, 148, 152, and map). *Lyme granite gneiss*.—Massive, medium-grained, generally light red shading to gray. Essentially pink orthoclase, quartz, and albite, with a small though somewhat variable amount of biotite and occasional crystals of hornblende. Considerable pegmatite, in veins and in spots, is associated with the rock. Covers portions of towns of Lyme, Old Lyme, and East Lyme. Intrudes Mamacoke gneiss. Is intruded by Westerly granite.

Lynch dolomite.

Upper and Middle (?) Cambrian: Central northern Utah (Oquirrh Mountains region).

J. Gilluly, 1932 (U. S. G. S. P. P. 173). *Lynch dol.*—Thick-bedded light-gray dol. with some dark-gray dol. spangled with short white rods in lower part and with a few ls. beds, especially in lower half. Thickness 825 to 1,000 ft. Uncon. underlies Dev. dol. (Jefferson?). Grades into underlying Bowman ls., the bdy being arbitrarily drawn at base of lowest dol. bed. Named for exposures on Lynch Ridge, N. of Ophir.

Lynchburg gneiss.

Pre-Cambrian: Northeastern Virginia.

A. I. Jonas, 1927 (Geol. Soc. Am. Bull., vol. 38, pp. 844, 845). *Lynchburg gneiss* [also called *Lynchburg mica gneiss*].—Fine-grained biotite-quartz gneiss and schist, in part garnetiferous. Typically exposed at Lynchburg. Is intruded and injected by Precamb. hornblende gneiss, gabbro, and quartz monzonite. Widely exposed from Madison Co. southward, and is oldest known rock of the anticlinorium. May be= Carolina gneiss. Some previous workers have included this Precamb. gneiss in Loudoun fm. [Lower Camb.], but it can readily be separated from the Loudoun because of its greater degree of metamorphism and the igneous intrusions of Precamb. age which it contains.

Lynch Creek bed. (In Strawn formation.)

Pennsylvanian: Central Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, p. 375). *Lynch Creek bed.*—At base usually 50 to 75 ft. of bluish sandy clay, graduating upward into shaly to massive ss. and downward into sh. In places the ss. is 75 to 100 ft. thick. Basal memb. of Strawn div. Uncon. overlies Bend div. and underlies Burnt Branch bed.

Named for Lynch Creek, W. and NW. of Nix, Lampasas Co.

Lyndon limestone.

Middle Cambrian: Eastern Nevada (Pioche region).

L. G. Westgate and A. Knopf, 1927 (Am. Inst. Min. Met. Engrs. Trans., No. 1647, p. 5) and 1932 (U. S. G. S. P. P. 171). *Lyndon ls.*—Consists of 200 ft. of light-gray to white more crystalline ls. (than below), usually thick bedded but showing distinct partings, underlain by 200 ft. of fine-grained dark-gray, rather heavy-bedded ls. Conformably underlies Middle Camb. Chisholm sh. and conformably overlies Lower Camb. Pioche sh. So closely resembles the younger Highland Peak ls. that where intervening Chisholm sh. is absent it is difficult to separate the lss. Typically exposed in Lyndon Gulch, and is present in Highland and Ely Ranges. Fossils not abundant, but fm. is here assigned somewhat arbitrarily to Middle Camb., along with the fossiliferous Chisholm sh.

Lyndon gypsum bed.

Silurian (Cayugan): Central New York (Syracuse region).

G. H. Chadwick, 1930 (Geol. Soc. Am. Bull., vol. 41, p. 81). The full succession of *Bertie* (*Tonoloway*) *group* in central N. Y. is: Chrysler "waterlimes" ("Rondout" of this region); Akron dol.; Williamsville waterlime (cement bed); Scajaquada shaly beds; Falkirk dol.; and Oatka shaly waterlimes. Below this lies Camillus fm. The Falkirk corresponds in position with the Fiddler's Green. The massive bed taken for latter by Hopkins at mouth of Chrysler's Glen is lithologically indistinguishable from the Falkirk. *If* the covered space above it is actually occupied by *Lyndon gyp.*, then these two beds may belong to Bertie group and search should be made for the Oatka beneath them. The alternative is an uncon. Lyndon has been in use by us informally a long time, but I think not till now officially introduced. It is from the old quarries at Lyndon, a locality made typical by T. C. Hopkins' bull. on Syracuse quad.

Lynn volcanic complex.

Devonian or Carboniferous: Northeastern Massachusetts.

C. H. Clapp, 1910 (Igneous rocks of Essex Co., Mass.). *Lynn volcanics*.—Quartz keratophytes, trachytes, dacites, and andesites, with dikes of similar rocks and one bostonite dike.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, p. 200). In Essex Co. the earliest volcanic rocks rest in places on a coarse aggl. of Dedham granodiorite and are called *Lynn volcanics* by Clapp. They form the older and more felsitic part of the complex of volcanic rocks to which LaForge has given the name Mattapan volcanic complex.

C. H. Clapp, 1921 (U. S. G. S. Bull. 704, pp. 30–31, 34, 51, 58–71). *Lynn volcanics* is term applied to the so-called felsites, formerly called petrosilex, which occur N. of Boston Basin. They are chiefly effusive rocks but include some closely related dike rocks that apparently served as feeders for the lavas. The effusive types are chiefly felsic, largely quartz keratophyre, but include trachyte, dacite, and andesite. Extend westward from Lynn to Middlesex Co. Rest on eroded surface of Dedham granodiorite.

L. LaForge, 1932 (U. S. G. S. Bull. 839). *Lynn volcanic complex*.—Nearly all of volcanic origin but partly effusive and partly sedimentary. Believed to be contemp. with Mattapan volcanic complex, but tentatively treated as a distinct fm. Also believed to be of same age as Newbury volcanic complex, which has been determined to be probably Lower Dev. The norite of Nahant, which Clapp included in the Lynn, is here excluded.

Lynnfield serpentine.

Cambrian or pre-Cambrian: Northeastern Massachusetts (Essex County).

C. H. Clapp, 1910 (Igneous rocks of Essex Co., Mass.).

Named for occurrence at Lynnfield, Essex Co.

Lynx formation.

Cambrian (Upper): British Columbia and Alberta.

C. D. Walcott, 1913 (Smithsonian Misc. Coll., vol. 57, No. 12, pp. 334, 337).

Lyon Mountain granite.

Pre-Cambrian: Northern New York (Clinton County).

W. J. Miller, 1919 (Jour. Geol., vol. 27, p. 29; also see Econ. Geol., vol. 14, p. 512). *Lyon Mountain granite*.—Fine- to medium-grained rock usually pink; varies from true granite through granitic syenite to quartz syenite or even quartz diorite. Well exposed in and near village of Lyon Mountain [Clinton Co.]. Is perhaps most conspicuous memb. of Cushing's Saranac fm. There is considerable field evidence to show that Lyon Mountain granite grades into and is only a facies of the coarse-grained rock which writer proposes to name *Hawkeye granite*. Both of these granites are believed to have developed from a single body of intruding magma. Lyon Mountain granite contains great profusion of silexite and pegmatite masses, while Hawkeye granite contains relatively few. The Hawkeye contains many aplite dikes, but none was observed in typical Lyon Mountain granite.

Lyons sandstone.

Permian: Central northern Colorado (Boulder and neighboring regions).

N. M. Fenneman, 1905 (U. S. G. S. Bull. 265). The rocks of Boulder region hitherto called "Wyoming" embrace 3 fms. (descending) Lykins fm., Lyons ss., and Fountain fm. The Lykins fm. is "Upper Wyoming" of previous repts. The "Lower Wyoming" here clearly embraces two lithological units. The lower and major part consists chiefly of rather coarse, arkose sss. and cgls. of reddish color, while the upper and lesser part is a finer-grained quartzose ss. of white, "creamy", or light-reddish color. The coarse sss. were called Fountain fm. by Cross in Pikes Peak folio. The top of Fountain fm. is not exposed in Pikes Peak quad., but Darton (Geol. Soc. Am. Bull., vol. 15, p. 22) has found the character of the Fountain as described by Cross to continue [upward] to a white ss. corresponding with "creamy ss." of Eldridge occurring in Garden of the Gods, to which name *Lyons ss.* is here given. The Fountain is characterized by very thick beds throughout and cross-bedding may be found at any horizon. The Lyons ss. consists of purely quartzose ss. It is best developed at Lyons (a few mi. N. of Boulder dist. as mapped), where it is quarried in large amounts. The siliceous cement of this ss. has sufficient iron to produce shades of pink, but the popular name "creamy sss." conveys a wrong impression as to their color. While they have a fairly uniform shade they are locally almost white, and at some places red. These sands are characterized by cross-bedding of unusual dimensions, perfection, and dip, which is at a lower angle than that of the true bedding. This cross-bedded stratum reaches max. thickness of 297 ft. at Fourmile Canyon and is absent just S. of Boulder Creek. It grades into underlying Fountain of "Red Beds," and is conformably overlain by Lykins fm.

R. M. Butters, 1913 (Colo. Geol. Surv. Bull. 5, pp. 68, 75, etc.), applied *Ingleside fm.* to 100 to 125 ft. of beds underlying Lyons ss. and overlying Fountain fm. from N. line of State to a little N. of Lyons. [See under *Ingleside fm.*]

W. T. Lee, 1927 (U. S. G. S. P. P. 149). *Lyons ss. redefined.*—A hard ledge-making ss., 100 ft. thick, characterized by conspicuous cross-bedding, occurs at Lyons, Colo., from which it takes its name. It differs in general appearance from all neighboring rocks. It is of light-red or pink color, consists almost wholly of coarse sand, contains a few small pebbles in some places near the base, and is separated by an inconspicuous erosional uncon. from the older rocks. The most conspicuous peculiarity of the ss. is its cross-bedding. As originally defined by Fenneman some of the red sed. rocks here referred to Ingleside fm. were included in Lyons ss., for the Lyons was said to rest on the Fountain. However, the original description applies chiefly to the cross-bedded upper part (popularly called "Creamy" ss. because of its light color), which is the Lyons of present paper. The inclusion in the Lyons of sss. here referred to Ingleside fm. and the miscorrelation of these older sss. with beds in upper part of the Fountain farther S. have led to confusion, which is dispelled by following the fms. at outcrop to points where both Lyons ss. as here redefined and the underlying Ingleside fm. wedge out toward S. The Lyons ss. as here redefined is traceable by its strat. position and physical peculiarity southward beyond Eldorado, where it thins out. It was not found near Golden nor at Morrison. It is practically continuous northward to Boxelder Canyon, where it seems to thin out. No fossils except tracks of a reptile which C. W. Gilmore regards as Perm. The fossiliferous beds in basal part of overlying Lykins fm. are regarded as probably Perm. Hence Lyons ss. is here classified as Perm. [See also under *Ingleside fm.*]

Lyons limestone.

Pennsylvanian (?): Central Oklahoma.

A. I. Levorsen, 1928 (Okla. Geol. Surv. Bull. 40BB, pp. 17, 43). *Cromwell sand* is basal sand of the Penn. It varies in thickness from 0 to 100 ft. and extends as far W. as E. side of R. 6 E. A thin ls., which thickens to 125 ft. farther E., there known as *Lyons ls.*, is found capping it in several places in Cromwell field. The Lyons ls. is correlated by some geologists with Morrow and Wapanucka lss. of the outcrop, but according to Okla. Geol. Surv. Bull. 40Q, 1928, p. 180, it is of Miss. age.

Lyons sand.

Lyons-Quinn sand.

A subsurface limy sand, of early Penn. or late Miss. age, in Lyons-Quinn pool of Okmulgee and Okfuskee Counties, Okla., the outcrop of which has been named, by R. V. Hollingsworth, *Union Valley ss. memb. of Wapanucka fm.*, and said to compose middle memb. of Wapanucka (early Penn., Pottsville).

Lyons moraine.

Pleistocene (Wisconsin stage): Central Michigan. Shown on moraine map (pl. 32) in U. S. G. S. Mon. 53. Named for Lyons, Ionia Co.

†Lysite formation.

Eocene (lower): Northern Wyoming (Bighorn Basin).

W. J. Sinclair and W. Granger, 1911 (Am. Mus. Nat. Hist. Bull., vol. 30, pp. 104, etc.). *Lysite fm.*—Lower fm. of Wind River group in Wind River Basin; well exposed on Lysite Creek. Consists of (descending): (1) Yellowish and gray sandy shales covered with heavy mantle of pebbles from older rocks of mtns, 50 ft.; (2) alternating buff sss. (1 to 5 ft. thick) and red and blue-gray shales, 200 ft.; (3)

gray and dark brick-red sandy shales (red predominating) and gray sss., 100 ft.; (4) dull-colored, deeply disintegrated clays with feldspathic ss. and much gyp., thickness undet. [Sinclair and Granger in 1912 (Am. Mus. Nat. Hist. Bull., vol. 31, pp. 60–62) gave thickness of their Lysite fm. as 600± ft.]

This is a geographic name applied to a paleontologic zone in lower part of Wind River fm., or *Wind River A* (*Heptodon-Coryphodon-Eohippus* zone), according to H. F. Osborn (U. S. G. S. Mon. 55, 1929). Geographic names are not applied to paleontologic zones by U. S. Geol. Survey.

Lytle sandstone member (of Purgatoire formation).

Lower Cretaceous (Comanche series): Eastern Colorado (Colorado Springs region).

G. I. Finlay, 1916 (U. S. G. S. Colorado Springs folio, No. 203). *Lytle ss. memb. of Purgatoire fm.*—Consists of 145 ft. (average thickness) of ss. with intercalated beds of grit and sh. Contains pebbly beds at several horizons. Base is generally marked by 15 ft. or less of coarse massive ss., prevailingly siliceous, white, yellowish-brown, or blackish grains. Near Colorado City the base of Lytle memb. consists of 100 ft. of fine-grained white or cream-colored ss. Basal memb. of Purgatoire fm. Underlies Glencairn sh. memb. Named for Lytle.

Lytle limestone.

Permian: Central northern Texas.

A. M. Lloyd and W. C. Thompson, 1929 (A. A. P. G. Bull., vol. 13, pl. 9, pp. 948, 949). *Lytle ls.*—A thin ls., of local extent, lying 30 ft. above Rainy ls. and 125± ft. below Standpipe ls.; all members of Clear Fork fm.

Probably named for Lytle Creek, Taylor Co.

†Lytton formation.

Eocene: Central Texas.

R. T. Hill and T. W. Vaughan, 1902 (U. S. G. S. Austin folio, No. 76, p. 6). *Lytton fm.*—Laminated clay, clay and sand, and ss., the latter often cross-bedded. Thickness 300 ft. in Austin quad. Fossils correspond to those of Midway fm. of Eocene. Overlies, probably uncon., Webberville [Navarro] fm. and underlies Uvalde fm.

Same as Midway fm.

Named for Lytton Springs, Caldwell Co.

Lytton Springs sand.

Local name for a subsurface unit consisting of porous, soft green altered basic igneous rock called serpentine, which produces oil at Lytton Springs, Tex. Probably somewhat older than Thrall sand. Extends from base of Austin chalk well up into overlying Taylor marl.
